[RssDisableTrace](#)

RssFindItem Function

```
INT WINAPI RssFindItem(  
    HCHANNEL hChannel,  
    LPCTSTR lpszValue,  
    DWORD dwOptions,  
    LPRSSCHANNELITEM lpItem  
);
```

The **RssFindItem** function searches for an item in the news feed channel which matches the unique identifier (GUID) value and returns information about that item.

Parameters

hChannel

Handle to the news feed channel.

lpszValue

A pointer to a string which specifies the value of the item being searched for. This value should uniquely identify the item in the feed, and this parameter cannot be an empty string or NULL pointer.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
RSS_FIND_GUID	Search the feed for items with a matching GUID property value. This is the default option, and is the only item property that is guaranteed to be unique in the feed. The search is case-sensitive, requiring that the <i>lpszValue</i> parameter match the property value exactly.
RSS_FIND_LINK	Search the feed for items with a matching link property value. For feeds that do not specify a GUID property, this is the recommended option for searching for an item. The search is not case-sensitive.
RSS_FIND_TITLE	Search the feed for items with a matching title. This option should not be used if you must ensure that the item returned is unique in the feed because there may be multiple items with the same title in the feed. The search is not case-sensitive.
RSS_FIND_PUBDATE	Search the feed for items with a matching publishing date. This option should not be used if you must ensure that the item returned is unique in the feed because more than one item may have the same publishing date. The format of the date string must match the standard format used with the RSS protocol and the match is not case-sensitive.

lpItem

A pointer to a **RSSCHANNELITEM** structure which contains information about the specified item in the news feed. This structure is initialized by the function and the parameter can never be specified as a NULL pointer.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is `RSS_ERROR`. To get extended error information, call **RssGetLastError**.

Remarks

It is recommended that you use the `RSS_FIND_GUID` option with news feeds that are using version 2.0 or later of the RSS specification. If the feed uses an earlier version, items may not include a GUID property. It is also possible that a feed may omit the GUID property even though it is considered a requirement for the current RSS specification. For the broadest compatibility with all news feeds, an application should not depend on being able to search for a specific news feed item by its GUID.

Only the GUID property is guaranteed to be unique in the feed. If the feed does not specify GUIDs for the news items, the application must use an alternate criteria such as the item hyperlink or publishing date. If there are multiple items that match the *lpzValue* value, the first matching item will be returned.

The data referenced in the **RSSCHANNELITEM** structure should be considered read-only and never modified by the application. Not all members of the structure may contain valid values, in which case those members will either have a value of zero or will specify NULL pointers. When the feed is closed, the members of this structure will no longer be valid, and therefore should never be stored by the application. If the application needs to store or modify this information, it should create its own private copy of the data.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csrsvg10.lib`

Unicode: Implemented as Unicode and ANSI versions.

RssGetErrorString Function

```
INT WINAPI RssGetErrorString(  
    DWORD dwErrorCode,  
    LPTSTR lpszDescription,  
    INT cbDescription  
);
```

The **RssGetErrorString** function is used to return a description of a specific error code. Typically this is used in conjunction with the **RssGetLastError** function for use with warning dialogs or as diagnostic messages.

Parameters

dwErrorCode

The last-error code for which a description is returned.

lpszDescription

A pointer to the buffer that will contain a description of the specified error code. This buffer should be at least 128 characters in length.

cbDescription

The maximum number of characters that may be copied into the description buffer.

Return Value

If the function succeeds, the return value is the length of the description string. If the function fails, the return value is zero, meaning that no description exists for the specified error code. Typically this indicates that the error code passed to the function is invalid.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csrsv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

RssGetFirstItem Function

```
BOOL WINAPI RssGetFirstItem(  
    HCHANNEL hChannel,  
    LPRSSCHANNELITEM lpItem  
);
```

The **RssGetFirstItem** function returns information about the first item in the specified news feed channel.

Parameters

hChannel

Handle to the news feed channel.

lpItem

A pointer to a **RSSCHANNELITEM** structure which contains information about the first item in the news feed. This structure is initialized by the function and the parameter can never be specified as a NULL pointer.

Return Value

If the function succeeds, it returns a non-zero value. If the function fails, the return value is zero. To get extended error information, call **RssGetLastError**.

Remarks

The **RssGetFirstItem** function is used in conjunction with the **RssGetNextItem** function to enumerate the available items in the specified news feed channel. If this function fails, it typically indicates that the channel does not contain any valid news items or that the format of the news feed is invalid.

The data referenced in the **RSSCHANNELITEM** structure should be considered read-only and never modified by the application. Not all members of the structure may contain valid values, in which case those members will either have a value of zero or will specify NULL pointers. When the feed is closed, the members of this structure will no longer be valid, and therefore should never be stored by the application. If the application needs to store or modify this information, it should create its own private copy of the data.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csrsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

RssGetItem Function

```
BOOL WINAPI RssGetItem(  
    HCHANNEL hChannel,  
    UINT nItemId,  
    LPRSSCHANNELITEM lpItem  
);
```

The **RssGetItem** function returns information about the specified item in the news feed channel.

Parameters

hChannel

Handle to the news feed channel.

nItemId

An integer value which identifies the news feed item. The first item identifier in the news feed has a value of one, and that value is incremented for each additional item in the feed. If this parameter is zero or specifies a value larger than the number of items in the feed, this function will fail.

lpItem

A pointer to a **RSSCHANNELITEM** structure which contains information about the specified item in the news feed. This structure is initialized by the function and the parameter can never be specified as a NULL pointer.

Return Value

If the function succeeds, it returns a value of zero. If the function fails, the return value is **RSS_ERROR**. To get extended error information, call **RssGetLastError**.

Remarks

The **RssGetItem** function is used to return information about a specific item in the news feed. If this function fails, it typically indicates that the item ID is invalid or that the feed does not contain any valid news items. The **RssGetItemCount** function can be used to determine the number of items contained in the feed channel.

The data referenced in the **RSSCHANNELITEM** structure should be considered read-only and never modified by the application. Not all members of the structure may contain valid values, in which case those members will either have a value of zero or will specify NULL pointers. When the feed is closed, the members of this structure will no longer be valid, and therefore should never be stored by the application. If the application needs to store or modify this information, it should create its own private copy of the data.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csrsv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

See Also

[RssFindItem](#), [RssGetFirstItem](#), [RssGetItemCount](#), [RssGetItemProperty](#), [RssGetItemText](#), [RssGetNextItem](#), [RSSCHANNELITEM](#)

RssGetItemCount Function

```
INT WINAPI RssGetItemCount(  
    HCHANNEL hChannel  
);
```

The **RssGetItemCount** function returns the number of items in the news feed channel.

Parameters

hChannel

Handle to the news feed channel.

Return Value

If the function succeeds, the return value is the number of items in the news feed. A value of zero indicates that the feed channel is empty. If the function fails, the return value is `RSS_ERROR`. To get extended error information, call **RssGetLastError**.

Remarks

The **RssGetItemCount** function is used to determine the number of items that are contained in the news feed channel, and therefore determine the maximum value of the item identifier which can be used to reference a specific item in the feed. This value is the same as the value specified by the *nItemCount* member of the **RSSCHANNEL** structure.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csrsvg10.lib`

See Also

[RssFindItem](#), [RssGetItem](#), [RssGetItemProperty](#), [RssGetItemText](#), [RSSCHANNEL](#)

RssGetItemProperty Function

```
INT WINAPI RssGetItemProperty(  
    HCHANNEL hChannel,  
    UINT nItemId,  
    DWORD dwReserved,  
    LPCTSTR lpszProperty,  
    LPCTSTR lpszAttribute,  
    LPTSTR lpszValue,  
    INT nMaxLength  
);
```

The **RssGetItemProperty** function is used to return the value of a property for the specified item in the news feed channel.

Parameters

hChannel

Handle to the news feed channel.

nItemId

An integer value which identifies the news feed item. The first item identifier in the news feed has a value of one, and that value is incremented for each additional item in the feed. If this parameter is zero or specifies a value larger than the number of items in the feed, this function will fail.

dwReserved

A parameter reserved for future use. This value should always be zero.

lpszProperty

A pointer to a string which specifies the name of the item property. This parameter cannot point to an empty string or specify a NULL pointer.

lpszAttribute

A pointer to a string which specifies the name of an attribute for the property. If this parameter is an empty string or NULL pointer, the function will return the value of the property, rather than an attribute of the specified property.

lpszValue

A pointer to a string buffer which will contain the value of the specified item property or attribute. This string should be large enough to contain the property value. If this parameter is a NULL pointer, it will be ignored and the function will only return the length of value for the specified property.

nMaxLength

The maximum number of characters that may be copied into the property value buffer. If the value of this parameter is zero, then the *lpszValue* parameter is ignored and the function will only return the length of the value for the specified property.

Return Value

If the function succeeds, the return value is the length of the property value string. A return value of zero indicates that the property does not contain any value. If the function fails, the return value is `RSS_ERROR`. To get extended error information, call **RssGetLastError**.

Remarks

The **RssGetItemProperty** function is primarily used with custom item properties that may be used with extensions to the news feed. The standard properties for an item such as the title, link and description can be obtained using **RssGetItem** and related functions. However, if items in the feed contain custom properties that are not part of the standard RSS format, this function can be used to obtain those values.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csrssv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[RssFindItem](#), [RssGetItem](#), [RssGetItemText](#), [RSSCHANNELITEM](#)

RssGetItemText Function

```
INT WINAPI RssGetItemText(  
    HCHANNEL hChannel,  
    UINT nItemId,  
    LPTSTR lpszBuffer,  
    INT nMaxLength  
);
```

The **RssGetItemText** function is used to return a copy of an item's description.

Parameters

hChannel

Handle to the news feed channel.

nItemId

An integer value which identifies the news feed item. The first item identifier in the news feed has a value of one, and that value is incremented for each additional item in the feed. If this parameter is zero or specifies a value larger than the number of items in the feed, this function will fail.

lpszBuffer

A pointer to a string buffer which will contain the value of the item description. If this parameter is a NULL pointer, it will be ignored and the function will only return the length of the item description.

nMaxLength

The maximum number of characters that may be copied into the description buffer. If the value of this parameter is zero, then the *lpszValue* parameter is ignored and the function will only return the length of the item description.

Return Value

If the function succeeds, the return value is the length of the item description. A return value of zero indicates that the item does not have a description. If the function fails, the return value is `RSS_ERROR`. To get extended error information, call **RssGetLastError**.

Remarks

The **RssGetItemText** function is used to obtain a copy of the string that describes the specified item. Typically this is text that provides a summary of the news feed item and is used in conjunction with the item's title and hyperlink to additional content.

The content of an item description is typically either plain text or HTML formatted text. It is the responsibility of the application to display the content in a format is appropriate for the end-user.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csrsv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

See Also

[RssFindItem](#), [RssGetItem](#), [RssGetItemProperty](#), [RSSCHANNELITEM](#)

RssGetLastError Function

DWORD WINAPI RssGetLastError();

Parameters

None.

Return Value

The return value is the last error code value for the current thread. Functions set this value by calling the **RssSetLastError** function. The Return Value section of each reference page notes the conditions under which the function sets the last error code.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. You should call the **RssGetLastError** function immediately when a function's return value indicates that an error has occurred. That is because some functions call **RssSetLastError(0)** when they succeed, clearing the error code set by the most recently failed function.

Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CHANNEL or RSS_ERROR. Those functions which call **RssSetLastError** when they succeed are noted on the function reference page.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csrssv10.lib

See Also

[RssGetErrorString](#), [RssSetLastError](#)

RssGetNextItem Function

```
BOOL WINAPI RssGetNextItem(  
    HCHANNEL hChannel,  
    LPRSSCHANNELITEM lpItem  
);
```

The **RssGetNextItem** function returns information about the next item in the specified news feed channel.

Parameters

hChannel

Handle to the news feed channel.

lpItem

A pointer to a **RSSCHANNELITEM** structure which contains information about the next item in the news feed. This structure is initialized by the function and the parameter can never be specified as a NULL pointer.

Return Value

If the function succeeds, it returns a non-zero value. If the function fails, the return value is zero. To get extended error information, call **RssGetLastError**.

Remarks

The **RssGetNextItem** function is used in conjunction with the **RssGetFirstItem** function to enumerate the available items in the specified news feed channel. If this function fails, it typically indicates that there are no more items in the news feed channel.

The data referenced in the **RSSCHANNELITEM** structure should be considered read-only and never modified by the application. Not all members of the structure may contain valid values, in which case those members will either have a value of zero or will specify NULL pointers. When the feed is closed, the members of this structure will no longer be valid, and therefore should never be stored by the application. If the application needs to store or modify this information, it should create its own private copy of the data.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csrssv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[RssFindItem](#), [RssGetFirstItem](#), [RssGetItem](#), [RssGetItemProperty](#), [RssGetItemText](#), [RSSCHANNELITEM](#)

RssInitialize Function

```
BOOL WINAPI RssInitialize(  
    LPCTSTR lpszLicenseKey,  
    LPINITDATA lpData  
);
```

The **RssInitialize** function initializes the library and validates the specified license key at runtime.

Parameters

lpszLicenseKey

Pointer to a string that specifies the runtime license key to be validated. If this parameter is NULL, the library will validate the development license installed on the local system.

lpData

Pointer to an INITDATA data structure. This parameter may be NULL if the initialization data for the library is not required.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **RssGetLastError**. All other client functions will fail until a license key has been successfully validated.

Remarks

This must be the first function that an application calls before using any of the other functions in the library. When a NULL license key is specified, the library will only function on the development system. Before redistributing the application to an end-user, you must insure that this function is called with a valid license key.

If the *lpData* argument is specified, it must point to an INITDATA structure which has been initialized by setting the *dwSize* member to the size of the structure. All other structure members should be set to zero. If the function is successful, then the INITDATA structure will be filled with identifying information about the library.

Although it is only required that **RssInitialize** be called once for the current process, it may be called multiple times; however, each call must be matched by a corresponding call to **RssUninitialize**.

This function dynamically loads other system libraries and allocates thread local storage. If you are calling the functions in this library from within another DLL, it is important that you do not call the **RssInitialize** or **RssUninitialize** functions from the **DllMain** function because it can result in deadlocks or access violation errors. If the DLL is linked with the C runtime library (CRT), it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csrsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

Copyright © 2023 Catalyst Development Corporation. All rights reserved.

RssOpenFeed Function

```
HCHANNEL WINAPI RssOpenFeed(  
    LPCTSTR lpszFeedUrl,  
    UINT nTimeout,  
    DWORD dwOptions,  
    LPRSSCHANNEL lpChannel  
);
```

The **RssOpenFeed** function is used to open a news feed and return a handle which can be used to access the individual news items in the feed.

Parameters

lpszFeedUrl

A pointer to a string which specifies the URL for the news feed. To access a news feed on a web server, a standard http or https URL may be specified. To access a file on the local system or network share, a file name or file URL may be specified.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation. This parameter is ignored if the *lpszFeedUrl* parameter specifies a local file name or URL.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
RSS_OPTION_NONE	No additional options are specified and the news feed is processed using relaxed rules when checking the validity of the feed. The library will attempt to automatically compensate for a feed that is malformed or does not strictly conform to the RSS standard.
RSS_OPTION_STRICT	The news feed content should be processed using strict rules to ensure that the feed meets the appropriate RSS standard specification and all feed property values are case-sensitive. By default, relaxed rules are used which allows the application to open a feed that may not strictly conform to the standard specification.

lpChannel

A pointer to an **RSSCHANNEL** structure which contains information about the news feed channel such as the feed title, hyperlink and description. If the parameter is not NULL, the structure is initialized by the function. If the parameter is NULL, it is ignored and no information is returned.

Return Value

If the function succeeds, the return value is a handle to the news feed channel. If the function fails, the return value is INVALID_CHANNEL. To get extended error information, call **RssGetLastError**.

Remarks

A news feed may be local or remote, depending on the URL that is specified. If a local file name or file URL is specified for the feed, then it is opened locally and no network access is required. If an http or https URL is specified, then **RssOpenFeed** will attempt to download the feed from the server and store it temporarily on the local system. Accessing a remote feed requires that the application has permission to establish a connection with the server and will cause the application to block until the feed has been downloaded, the operation times out or an error occurs.

Although the **RssOpenFeed** function will meet the needs of most applications, if you require more complex functionality such as retrieving the feed asynchronously in the background or event notifications for large transfers, you can use the SocketTools [Hypertext Transfer Protocol](#) API to download the news feed and then use the **RssParseFeed** function to parse the contents.

The data referenced in the **RSSCHANNEL** structure should be considered read-only and never modified by the application. Not all members of the structure may contain valid values, in which case those members will either have a value of zero or will specify NULL pointers. When the feed is closed, the members of this structure will no longer be valid, and therefore should never be stored by the application. If the application needs to store or modify this information, it should create its own private copy of the data.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csrssv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[RssCloseFeed](#), [RssInitialize](#), [RssParseFeed](#), [RssRefreshFeed](#), [RssStoreFeed](#), [RssUninitialize](#), [RssValidateFeed](#), [RSSCHANNEL](#)

RssParseFeed Function

```
HCHANNEL WINAPI RssParseFeed(  
    LPCTSTR lpszFeedXml,  
    DWORD dwOptions,  
    LPRSSCHANNEL lpChannel  
);
```

The **RssParseFeed** function is used to parse the contents of a news feed, returning a handle which can be used to access the individual news items in the feed.

Parameters

lpszFeedXml

A pointer to a string which contains the contents of the news feed. The string must contain XML formatted data that conforms to the RSS standard specification. This parameter cannot specify an empty string or a NULL pointer.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
RSS_OPTION_NONE	No additional options are specified.
RSS_OPTION_STRICT	The news feed content should be processed using strict rules to ensure that the feed meets the appropriate RSS standard specification and all feed property values are case-sensitive. By default, relaxed rules are used which allows the application to open a feed that may not strictly conform to the standard specification.

lpChannel

A pointer to an **RSSCHANNEL** structure which contains information about the news feed channel such as the feed title, hyperlink and description. If the parameter is not NULL, the structure is initialized by the function. If the parameter is NULL, it is ignored and no information is returned.

Return Value

If the function succeeds, the return value is a handle to the news feed channel. If the function fails, the return value is **INVALID_CHANNEL**. To get extended error information, call **RssGetLastError**.

Remarks

The **RssParseFeed** function is an alternative to the **RssOpenFeed** function, enabling the application to process a news feed from alternative sources such as a database or compressed file. It is important to note that the string which contains the news feed XML must be properly formatted and conform to the RSS standard specification.

The data referenced in the **RSSCHANNEL** structure should be considered read-only and never modified by the application. Not all members of the structure may contain valid values, in which case those members will either have a value of zero or will specify NULL pointers. When the feed is closed, the members of this structure will no longer be valid, and therefore should never be stored by the application. If the application needs to store or modify this information, it should

create its own private copy of the data.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csrssv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[RssCloseFeed](#), [RssInitialize](#), [RssOpenFeed](#), [RssRefreshFeed](#), [RssStoreFeed](#), [RssUninitialize](#), [RSSCHANNEL](#)

RssRefreshFeed Function

```
INT WINAPI RssRefreshFeed(  
    HCHANNEL hChannel,  
    LPRSSCHANNEL lpChannel  
);
```

The **RssRefreshFeed** function reloads the news feed and updates the items in the channel.

Parameters

hChannel

Handle to the news feed channel.

lpChannel

A pointer to an **RSSCHANNEL** structure which contains information about the news feed channel such as the feed title, hyperlink and description. If the parameter is not NULL, the structure is initialized by the function. If the parameter is NULL, it is ignored and no information is returned.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is **RSS_ERROR**. To get extended error information, call **RssGetLastError**.

Remarks

When the **RssRefreshFeed** function is called, the news feed is reloaded from the original source and the items in the channel are updated. For news feeds that are frequently updated, the *nTimeToLive* member of the **RSSCHANNEL** structure can provide a hint to the application as to how frequently the feed should be refreshed.

If the news feed was originally opened using an http or https URL, this function will download the updated feed from the server and store it temporarily on the local system. Accessing a remote feed requires that the application has permission to establish a connection with the server and will cause the application to block until the feed has been downloaded, the operation times out or an error occurs. The same timeout period and options will be used as when the feed was originally opened.

The **RssRefreshFeed** function should only be used if the feed was opened using the **RssOpenFeed** function, otherwise the function will fail with an error indicating that the operation is not supported.

The data referenced in the **RSSCHANNEL** structure should be considered read-only and never modified by the application. The members of this structure returned by previous calls to either the **RssOpenFeed** or **RssRefreshFeed** functions will no longer be valid and should not be referenced. Likewise, the members of an **RSSCHANNELITEM** structure will no longer be valid after this function returns.

It is important that the application does not make any assumptions about the number of news items in the channel, or the content associated with those items after the **RssRefreshFeed** function has been called. For example, never assume that the number of items in the channel remains the same, or that the item IDs for each item remains the same. If you need to find a specific item in the news feed, use the **RssFindItem** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csrssv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[RssCloseFeed](#), [RssFindItem](#), [RssGetItem](#), [RssOpenFeed](#), [RssStoreFeed](#), [RSSCHANNEL](#)

RssSetLastError Function

```
VOID WINAPI RssSetLastError(  
    DWORD dwErrorCode  
);
```

The **RssSetLastError** function sets the error code for the current thread. This function is typically used to clear the last error by passing a value of zero as the parameter.

Parameters

dwErrorCode

Specifies the error code for the current thread.

Return Value

None.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or RSS_ERROR. Those functions which call **RssSetLastError** when they succeed are noted on the function reference page.

Applications can retrieve the value saved by this function by using the **RssGetLastError** function. The use of **RssGetLastError** is optional; an application can call the function to determine the specific reason for a function failure.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csrsv10.lib

RssStoreFeed Function

```
INT WINAPI RssStoreFeed(  
    HCHANNEL hChannel,  
    LPCTSTR lpszFileName,  
    DWORD dwReserved  
);
```

The **RssStoreFeed** function stores the contents of the news feed in an XML formatted text file.

Parameters

hChannel

Handle to the news feed channel.

lpszFileName

A pointer to a string which specifies the name of the file on the local system. The contents of the news feed will be stored in this file. If the file does not exist, it will be created; otherwise it will overwrite the contents of the file.

dwReserved

A reserved parameter for future use. This value should always be zero.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is **RSS_ERROR**. To get extended error information, call **RssGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csrsv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

See Also

[RssOpenFeed](#), [RssParseFeed](#)

RssUninitialize Function

```
VOID WINAPI RssUninitialize();
```

The **RssUninitialize** function terminates the use of the library.

Parameters

There are no parameters.

Return Value

None.

Remarks

An application is required to perform a successful **RssInitialize** call before it can call any of the other the library functions. When it has completed the use of library, the application must call **RssUninitialize** to allow the library to free any resources allocated on behalf of the process. Any pending blocking or asynchronous calls in this process are canceled without posting any notification messages, and all sockets that were opened by the process are closed.

There must be a call to **RssUninitialize** for every successful call to **RssInitialize** made by a process. In a multithreaded environment, operations for all threads in the client are terminated.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csrssv10.lib

RssValidateFeed Function

```
INT WINAPI RssValidateFeed(  
    LPCTSTR lpszFeedUrl,  
    UINT nTimeout,  
    DWORD dwOptions,  
    LPSYSTEMTIME lpstModified  
);
```

The **RssValidateFeed** function is used to validate a news feed, returning the number of items in the feed and the date it was last modified.

Parameters

lpszFeedUrl

A pointer to a string which specifies the URL for the news feed. To access a news feed on a web server, a standard http or https URL may be specified. To access a file on the local system or network share, a file name or file URL may be specified.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation. This parameter is ignored if the *lpszFeedUrl* parameter specifies a local file name or URL.

dwOptions

An unsigned integer that specifies one or more options. This parameter is reserved for future use and should always have a value of zero.

lpstModified

A pointer to a **SYSTEMTIME** structure which will specify the date that the feed was last modified when the function returns. If the parameter is NULL, it is ignored and no information is returned.

Return Value

If the function succeeds, the return value is the number of items in the news feed channel. If the function fails, the return value is `RSS_ERROR`. To get extended error information, call **RssGetLastError**.

Remarks

The **RssValidateFeed** function can be used to check that a news feed exists and is properly formatted. If the contents of the feed are valid, the function will return the number of items in the feed and the date that it was last modified. This can be useful for applications that want to periodically check a news feed and determine if the contents have changed.

The **SYSTEMTIME** structure that is populated by the function specifies the date when the feed was last modified. The function first checks the value of the `lastBuildDate` property of the feed channel. If that property is not defined, then it will use the value of the `pubDate` property. If neither are defined, then the structure members will have a value of zero.

The validation process imposes strict checks on the structure of the news feed and requires that it conform to the RSS specification. For example, the feed must have a title, link and description. Each item in the feed must have either a title or description, and the hyperlinks specified in the feed must be valid. If the feed XML is malformed, or a required property of the feed is invalid or missing, this function will fail.

If a news feed cannot be validated, it still may be possible to open the feed using the

RssOpenFeed function. By default, relaxed rules are used when parsing the contents of the feed and it does not check to ensure all required properties are defined and have valid values.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csrsv10.lib

INITDATA Structure

This structure contains information about the SocketTools library when the initialization function returns.

```
typedef struct _INITDATA
{
    DWORD        dwSize;
    DWORD        dwVersionMajor;
    DWORD        dwVersionMinor;
    DWORD        dwVersionBuild;
    DWORD        dwOptions;
    DWORD_PTR    dwReserved1;
    DWORD_PTR    dwReserved2;
    TCHAR        szDescription[128];
} INITDATA, *LPINITDATA;
```

Members

dwSize

Size of this structure. This structure member must be set to the size of the structure prior to calling the initialization function. Failure to do so will cause the function to fail.

dwVersionMajor

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the major version number for the library.

dwVersionMinor

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the minor version number for the library.

dwVersionBuild

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the build number for the library.

dwOptions

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

dwReserved1

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

dwReserved2

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

szDescription

A null terminated string which describes the library.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Unicode: Implemented as Unicode and ANSI versions.

RSSCHANNEL Structure

This structure contains information about the properties of the news feed channel.

```
typedef struct _RSSCHANNEL
{
    UINT        nItemCount;
    UINT        nTimeToLive;
    WORD        wVersionMajor;
    WORD        wVersionMinor;
    DWORD       dwFlags;
    DWORD       dwReserved;
    LPCTSTR     lpszTitle;
    LPCTSTR     lpszLink;
    LPCTSTR     lpszDescription;
    LPCTSTR     lpszCategory;
    LPCTSTR     lpszLanguage;
    LPCTSTR     lpszCopyright;
    LPCTSTR     lpszEditor;
    LPCTSTR     lpszWebmaster;
    LPCTSTR     lpszGenerator;
    LPCTSTR     lpszImageLink;
    LPCTSTR     lpszImageTitle;
    LPCTSTR     lpszImageUrl;
    SYSTEMTIME  stPublished;
    SYSTEMTIME  stLastBuild;
} RSSCHANNEL, *LPRSSCHANNEL;
```

Members

nItemCount

An integer value which specifies number of news items in the channel.

nTimeToLive

An integer value which specifies the frequency in seconds at which the feed should be refreshed to obtain updated information. Not all feeds specify a time-to-live, in which case this member will have a value of zero.

wVersionMajor

A word value which specifies the major version number for the news feed.

wVersionMinor

A word value which specifies the minor version number for the news feed.

dwFlags

A value which specifies one or more option flags for the news feed channel. Currently there are no option flags defined and this member is reserved for future expansion.

dwReserved

A value reserved for future expansion.

lpszTitle

A pointer to a string which specifies the name of the channel. If the content of the news feed corresponds to a website, this is typically the same as the title of the website. If a title has not been specified, this member will be NULL. Note that a strictly conforming news feed requires a title.

lpszLink

A pointer to a string which specifies a URL to the website corresponding to the channel. Note that this is not the URL of the news feed itself. Typically it is a link to the home page of the site which owns the news feed. If a link has not been specified, this member will be NULL. Note that a strictly conforming news feed requires a valid link URL.

lpszDescription

A pointer to a string which describes the channel. This provides an overview of the news feed and the type of information that is provided. If a description of the feed has not been specified, this member will be NULL. Note that a strictly conforming news feed requires a description.

lpszCategory

A pointer to a string which defines the category or categories that the channel belongs to. This property is optional and the category names themselves are user-defined. If a category has not been specified, this member will be NULL.

lpszLanguage

A pointer to a string which defines the language the channel is written in, using the standard language codes. This property is optional and if this member is NULL, the English language is typically presumed to be the default.

lpszCopyright

A pointer to a string which specifies a copyright notice for the content. If a copyright has not been specified, this member will be NULL.

lpszEditor

A pointer to a string which identifies the person responsible for managing the content of the news feed. If this property is defined, it is typically the name and email address of the feed editor. If an editor has not been specified, this member will be NULL.

lpszWebmaster

A pointer to a string which identifies the person responsible for technical issues related to the news feed. If this property is defined, it is typically the name and email address of a system administrator. If a webmaster has not been specified, this member will be NULL.

lpszGenerator

A pointer to a string which identifies the application that was used to create the news feed. If the application that generated the feed has not been specified, this member will be NULL.

lpszImageLink

A pointer to a string which specifies a URL to the website corresponding to the channel. In most cases, this is the same URL that is specified by the *lpszLink* member. If an image link has not been specified, this member will be NULL.

lpszImageTitle

A pointer to a string which identifies the image associated with the channel. This is usually a brief description of the image, and may be the same as the value specified by the *lpszTitle* member. If an image title has not been specified, this member will be NULL.

lpszImageUrl

A pointer to a string which specifies a URL for the image associated with the channel. An application can download this image and display it with the contents of the news feed. If an image URL has not been specified, this member will be NULL.

stPublished

The date that the news feed was published. For example, a feed that is associated with a weekly print publication may update this value once per week. Note that this is not necessarily the date

that the feed was last modified. If the channel does not specify the publish date, this structure will contain all zeroes.

stLastBuild

The date that the content of the channel was last modified. If the channel does not specify the build date, this structure will contain all zeroes.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Unicode: Implemented as Unicode and ANSI versions.

RSSCHANNELITEM Structure

This structure contains information about the properties of an item in a news feed channel.

```
typedef struct _RSSCHANNELITEM
{
    UINT            nItemId;
    DWORD           dwFlags;
    DWORD           dwReserved;
    LPCTSTR         lpszTitle;
    LPCTSTR         lpszLink;
    LPCTSTR         lpszText;
    LPCTSTR         lpszGuid;
    LPCTSTR         lpszAuthor;
    LPCTSTR         lpszSource;
    LPCTSTR         lpszComments;
    LPCTSTR         lpszEnclosure;
    SYSTEMTIME      stPublished;
} RSSCHANNELITEM, *LPRSSCHANNELITEM;
```

Members

nItemId

An integer which identifies this item in the channel.

dwFlags

A value which specifies one or more option flags for the item. Currently there are no option flags defined and this member is reserved for future expansion.

dwReserved

A value reserved for future expansion.

lpszTitle

A pointer to a string which specifies the title of the item. If a title for the item has not been specified, this member will be NULL.

lpszLink

A pointer to a string which specifies a URL that typically links to additional information related to the item. If a link for the item has not been specified, this member will be NULL.

lpszText

A pointer to a string which specifies a summary or description of the item. This may contain either plain text or HTML formatted text, and there is no fixed limit to the length of the text. If no text has been specified for the item, this member will be NULL.

lpszGuid

A pointer to a string which uniquely identifies the item in the channel. If this property is defined, it is guaranteed to be a unique, persistent value. It is important to note that this string does not have to be a standard GUID reference number, it can be any unique string. In many cases it is the same value as the item hyperlink specified by the *lpszLink* member, although an application should never depend on this behavior. If there is no unique identifier associated with the item, this member will be NULL.

lpszAuthor

A pointer to a string which identifies the author of the item. If this property is defined, it is typically the name and email address of the person who created the content that the item links to. If the author is not specified, this member will be NULL.

lpszSource

A pointer to a string which identifies the source of the item, specified as a URL for the original news feed that contained it. This typically used to propagate credit for items that are aggregated by a third-party and re-published in their own channel. If the source is not specified, this member will be NULL.

lpszComments

A pointer to a string which specifies a URL that links to further discussion about the item. Typically this is a link to the comment area of a weblog or a forum topic specific to the item. If a comment link is not specified, this member will be NULL.

lpszEnclosure

A pointer to a string which specifies a URL that links to a file related to the item. This is similar to an attachment in an email message, however instead of the item containing the contents of the attached file, it only specifies a link to the file. Enclosures are most commonly used with podcasting where an item is linked to an audio or video file, however the link may reference any type of file. If there is no enclosure specified for the item, this member will be NULL.

stPublished

The date that the item was published. If the item does not specify the publish date, this structure will contain all zeroes.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Unicode: Implemented as Unicode and ANSI versions.

SYSTEMTIME Structure

The **SYSTEMTIME** structure represents a date and time using individual members for the month, day, year, weekday, hour, minute, second, and millisecond.

```
typedef struct _SYSTEMTIME
{
    WORD wYear;
    WORD wMonth;
    WORD wDayOfWeek;
    WORD wDay;
    WORD wHour;
    WORD wMinute;
    WORD wSecond;
    WORD wMilliseconds;
} SYSTEMTIME, *LPSYSTEMTIME;
```

Members

wYear

Specifies the current year. The year value must be greater than 1601.

wMonth

Specifies the current month. January is 1, February is 2 and so on.

wDayOfWeek

Specifies the current day of the week. Sunday is 0, Monday is 1 and so on.

wDay

Specifies the current day of the month

wHour

Specifies the current hour.

wMinute

Specifies the current minute

wSecond

Specifies the current second.

wMilliseconds

Specifies the current millisecond.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include windows.h.

Post Office Protocol Library

List and retrieve email messages from a mail server.

Reference

- [Functions](#)
- [Data Structures](#)
- [Error Codes](#)

Library Information

File Name	CSPOPV10.DLL
Version	10.0.1468.2518
LibID	E4B30E06-4091-4A79-8A4C-17547C76A995
Import Library	CSPOPV10.LIB
Dependencies	None
Standards	RFC 1939

Overview

The Post Office Protocol (POP3) provides access to a user's new email messages on a mail server. Functions are provided for listing available messages and then retrieving those messages, storing them either in files or in memory. Once a user's messages have been downloaded to the local system, they are typically removed from the server. This is the most popular email protocol used by Internet Service Providers (ISPs) and the library provides a complete interface for managing a user's mailbox. This library is typically used in conjunction with the Mail Message library, which is used to process the messages that are retrieved from the server.

This library supports secure connections using the standard SSL and TLS protocols. Both implicit and explicit SSL connections can be established, enabling the library to work with a wide variety of servers.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). If you are using Visual C++ 6.0 it is required that you have Service Pack 6 (SP6) installed. You should install all updates for your development tools and have the current Windows SDK installed. The minimum recommended version of Visual Studio is Visual Studio 2010.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are using Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. It is recommended that you install the current service pack and all critical updates available for your version of the operating system.

This product includes both 32-bit and 64-bit libraries. Native 64-bit CPU support requires the 64-bit version of Windows 7 or later versions of the Windows operating system.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location

on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

Post Office Protocol Functions

Function	Description
PopAsyncConnect	Connect asynchronously to the specified server
PopAttachThread	Attach the specified client handle to another thread
PopCancel	Cancel the current blocking operation
PopChangePassword	Change the specified mail account password
PopCommand	Send a command to the server
PopConnect	Connect to the specified server
PopCreateSecurityCredentials	Allocate a structure to establish client security credentials
PopDeleteMessage	Delete the specified message from the mailbox
PopDeleteSecurityCredentials	Delete the specified client security credentials
PopDisableEvents	Disable the event notification mechanism
PopDisableTrace	Disable logging of socket function calls to the trace log
PopDisconnect	Disconnect from the current server
PopEnableEvents	Enable the client event notification mechanism
PopEnableTrace	Enable logging of socket function calls to a file
PopEventProc	Callback function that processes events generated by the client
PopFreezeEvents	Suspend and resume event handling by the client
PopGetErrorString	Return a description for the specified error code
PopGetHeaderValue	Return the value of the specified header field
PopGetLastError	Return the last error code
PopGetMessage	Retrieve the specified message from the server
PopGetMessageCount	Return the number of messages available in the mailbox
PopGetMessageCountEx	Return the number of messages available in the mailbox
PopGetMessageHeaders	Retrieve the specified message header from the server
PopGetMessageId	Return the message ID string for the specified message
PopGetMessageSender	Return the address of the message sender
PopGetMessageSize	Return the size of the specified message
PopGetMessageUid	Return the unique identifier for the specified message
PopGetMultiLine	Return the client multi-line output flag
PopGetResultCode	Return the result code from the previous command
PopGetResultString	Return the result string from the previous command
PopGetSecurityInformation	Return security information about the current client connection

PopGetStatus	Return the current status of the client
PopGetTimeout	Return the number of seconds until an operation times out
PopGetTransferStatus	Return data transfer statistics
PopInitialize	Initialize the library and validate the specified license key at runtime
PopIsBlocking	Determine if the client is blocked, waiting for information
PopIsConnected	Determine if the client is connected to the server
PopIsReadable	Determine if data can be read from the server
PopIsWritable	Determine if data can be written to the server
PopLogin	Login to the server
PopOpenMessage	Open the specified message for reading on the server
PopRead	Read data returned by the server
PopRegisterEvent	Register an event handler for the specified event
PopReset	Reset the client and return to a command state
PopSendMessage	Send a message through the mail server
PopSetLastError	Set the last error code
PopSetMultiLine	Set the client multi-line output flag
PopSetTimeout	Set the number of seconds until an operation times out
PopStoreMessage	Store the contents of a message in the specified file
PopUninitialize	Terminate use of the library by the application
PopWrite	Write data to the server

PopAsyncConnect Function

```
HCLIENT WINAPI PopAsyncConnect(  
    LPCTSTR lpszRemoteHost,  
    UINT nRemotePort,  
    UINT nTimeout,  
    DWORD dwOptions,  
    LPSECURITYCREDENTIALS LpCredentials,  
    HWND hEventWnd,  
    UINT uEventMsg  
);
```

The **PopAsyncConnect** function is used to establish a connection with the server.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

The application should create a background worker thread and establish a connection by calling **PopConnect** within that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each client session.

Parameters

lpszRemoteHost

A pointer to the name of the server to connect to; this may be a fully-qualified domain name or an IP address.

nRemotePort

The port number the server is listening on. A value of zero specifies that the default port number should be used. For standard connections, the default port number is 110. For secure connections, the default port number is 995. If the secure port number is specified, an implicit SSL/TLS connection will be established by default.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
POP_OPTION_NONE	No connection options specified. A standard connection to the server will be established using the specified host name and port number.
POP_OPTION_LINEBREAK	Message data that is received from the server is read as individual lines of text terminated by a carriage return and linefeed control sequence. This option can be useful for applications that need to use the lower level network I/O functions and must process the message text on a line-by-line basis. This option is not recommended for most

	<p>applications because it can have a negative impact on performance when retrieving large messages from the server.</p>
POP_OPTION_TUNNEL	<p>This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established.</p>
POP_OPTION_TRUSTEDSITE	<p>This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using either the SSL or TLS protocols.</p>
POP_OPTION_SECURE	<p>This option specifies that a secure connection should be established with the server and requires that the server support either the SSL or TLS protocol. This option is the same as specifying POP_OPTION_SECURE_EXPLICIT, which initiates the secure session using the STLS command.</p>
POP_OPTION_SECURE_EXPLICIT	<p>This option specifies the client should attempt to establish a secure connection with the server. The server must support secure connections using either the SSL or TLS protocol and the STLS command.</p>
POP_OPTION_SECURE_IMPLICIT	<p>This option specifies the client should attempt to establish a secure connection with the server. It should only be used when the server expects an implicit SSL connection or does not implement RFC 2595 where the STLS command is used to negotiate a secure connection with the server.</p>
POP_OPTION_SECURE_FALLBACK	<p>This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.</p>
POP_OPTION_PREFER_IPV6	<p>This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.</p>

POP_OPTION_FREETHREAD

This option specifies the handle returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the handle is synchronized across multiple threads.

lpCredentials

A pointer to a [SECURITYCREDENTIALS](#) structure which is used to establish the client credentials for a secure connection to the server. The function **PopCreateSecurityCredentials** can be used to create this structure if necessary. If a standard non-secure connection is being established, or client credentials are not required by the server, this parameter can be NULL.

hEventWnd

The handle to the event notification window. This window receives messages which notify the client of various asynchronous socket events that occur. If this parameter is NULL, a blocking connection is established with the server.

uEventMsg

The message identifier that is used when an asynchronous socket event occurs. This value should be greater than WM_USER as defined in the Windows header files. If the *hEventWnd* parameter is NULL, this parameter must be specified as WM_NULL.

Return Value

If the function succeeds, the return value is a handle to a client session. If the function fails, the return value is INVALID_CLIENT. To get extended error information, call **PopGetLastError**.

Remarks

When a message is posted to the notification window, the low word of the *lParam* parameter contains the event identifier. The high word of *lParam* contains the low word of the error code, if an error has occurred. The *wParam* parameter contains the client handle. One or more of the following event identifiers may be sent:

Constant	Description
POP_EVENT_CONNECT	The connection to the server has completed. The high word of the <i>lParam</i> parameter should be checked, since this notification message will be posted if an error has occurred.
POP_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
POP_EVENT_READ	Data is available to read by the client. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the calling process is in asynchronous mode.
POP_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
POP_EVENT_TIMEOUT	The client has timed out while waiting for a response from the server. Note that under some circumstances this event can be

	generated for a non-blocking connection, such as when the client is establishing a secure connection.
POP_EVENT_CANCEL	The client has canceled the current operation.
POP_EVENT_COMMAND	The client has processed a command that was sent to the server. The result code and result string can be used to determine if the response to the command. The high word of the IParam parameter should be checked, since this notification message will also be posed if the command cannot be executed.
POP_EVENT_PROGRESS	This event notification is sent periodically during lengthy blocking operations, such as retrieving a complete message from the server.

To cancel asynchronous notification and return the client to a blocking mode, use the **PopDisableEvents** function.

It is recommended that you only establish an asynchronous connection if you understand the implications of doing so. In most cases, it is preferable to create a synchronous connection and create threads for each additional session if more than one active client session is required.

The *dwOptions* argument can be used to specify the threading model that is used by the library when a connection is established. By default, the handle is initially attached to the thread that created it. From that point on, until the it is released, only the owner may call functions using that handle. The ownership of the handle may be transferred from one thread to another using the **PopAttachThread** function.

Specifying the POP_OPTION_FREETHREAD option enables any thread to call any function using the handle, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the handle is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same handle.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cspopv10.lib

Unicode: Implemented as Unicode and ANSI versions.

PopAttachThread Function

```
DWORD WINAPI PopAttachThread(  
    HCLIENT hClient  
    DWORD dwThreadId  
);
```

The **PopAttachThread** function attaches the specified client handle to another thread.

Parameters

hClient

Handle to the client session.

dwThreadId

The ID of the thread that will become the new owner of the handle. A value of zero specifies that the current thread should become the owner of the client handle.

Return Value

If the function succeeds, the return value is the thread ID of the previous owner. If the function fails, the return value is POP_ERROR. To get extended error information, call **PopGetLastError**.

Remarks

When a client handle is created, it is associated with the current thread that created it. Normally, if another thread attempts to perform an operation using that handle, an error is returned since it does not own the handle. This is used to ensure that other threads cannot interfere with an operation being performed by the owner thread. In some cases, it may be desirable for one thread in a client application to create the client handle, and then pass that handle to another worker thread. The **PopAttachThread** function can be used to change the ownership of the handle to the new worker thread. By preserving the return value from the function, the original owner of the handle can be restored before the worker thread terminates.

This function should be called by the new thread immediately after it has been created, and if the new thread does not release the handle itself, the ownership of the handle should be restored to the parent thread before it terminates. Under no circumstances should **PopAttachThread** be used to forcibly release a handle allocated by another thread while a blocking operation is in progress. To cancel an operation, use the **PopCancel** function and then release the handle after the blocking function exits and control is returned to the current thread.

Note that the *dwThreadId* parameter is presumed to be a valid thread ID and no checks are performed to ensure that the thread actually exists. Specifying an invalid thread ID will orphan the handle until the **PopUninitialize** function is called.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstoools10.h

Import Library: cspopv10.lib

See Also

[PopCancel](#), [PopAsyncConnect](#), [PopConnect](#), [PopDisconnect](#), [PopUninitialize](#)

PopCancel Function

```
INT WINAPI PopCancel(  
    HCLIENT hClient  
);
```

The **PopCancel** function cancels any outstanding blocking operation in the client, causing the blocking function to fail. The application may then retry the operation or terminate the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is POP_ERROR. To get extended error information, call **PopGetLastError**.

Remarks

When the **PopCancel** function is called, the blocking function will not immediately fail. An internal flag is set which causes the blocking operation to exit with an error. This means that the application cannot cancel an operation and immediately perform some other operation. Instead it must allow the calling stack to unwind, returning back to the blocking operation before making any further function calls.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cspopv10.lib

See Also

[PopIsBlocking](#), [PopReset](#)

PopChangePassword Function

```
BOOL WINAPI PopChangePassword(  
    HCLIENT hClient,  
    LPCTSTR lpszUserName,  
    LPCTSTR lpszOldPassword,  
    LPCTSTR lpszNewPassword  
);
```

The **PopChangePassword** function changes the account password for the specified user.

Parameters

hClient

Handle to the client session.

lpszUserName

Pointer to a string which specifies the user name of the account who's password will be changed. It is not required that this be the same user name that was used to login to the mail server.

lpszOldPassword

Pointer to a string which specifies the current account password.

lpszNewPassword

Pointer to a string which specifies the new account password. When the function returns, the user's mailbox password will be set to this value.

Return Value

If the function succeeds, it will return a non-zero value. If the function fails, it will return zero. To get extended error information, call **PopGetLastError**.

Remarks

The **PopChangePassword** function is used to change the password associated with the specified account on the server. The function establishes a connection to a separate service running on the server, and does not use the POP3 protocol. For this function to succeed, the server must be configured to allow password changes using the "poppass" service, running on port 106.

Because passwords are sent over the network as clear text, this service is considered to be insecure.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cspopv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[PopConnect](#), [PopLogin](#)

PopCloseMessage Function

```
INT WINAPI PopCloseMessage(  
    HCLIENT hClient  
);
```

The **PopCloseMessage** function closes the current message that has been opened or created.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is POP_ERROR. To get extended error information, call **PopGetLastError**.

Remarks

If an message is being created, this function actually submits the message to the server. Note that the client application is responsible for generating the message headers as well as the body of the message. News messages conform to the same general characteristics of an email message.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cspopv10.lib

See Also

[PopOpenMessage](#), [PopRead](#)

PopCommand Function

```
BOOL WINAPI PopCommand(  
    HCLIENT hClient,  
    LPCTSTR lpszCommand,  
    LPCTSTR lpszParameter  
);
```

The **PopCommand** function sends a command to the server and returns the result code back to the caller. This function is typically used for site-specific commands not directly supported by the API.

Parameters

hClient

Handle to the client session.

lpszCommand

The command which will be executed by the server.

lpszParameter

An optional command parameter. If the command requires more than one parameter, then they should be combined into a single string, with a space separating each parameter. If the command does not accept any parameters, this value may be NULL.

Return Value

If the command was successful, the function returns a non-zero value. If the command failed, the function returns zero. To get extended error information, call **PopGetLastError**.

Remarks

A list of valid commands can be found in the technical specification for the protocol. Many servers will list supported commands when the HELP command is used.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cspopv10.lib

Unicode: Implemented as Unicode and ANSI versions.

PopConnect Function

```
HCLIENT WINAPI PopConnect(  
    LPCTSTR lpszRemoteHost,  
    UINT nRemotePort,  
    UINT nTimeout,  
    DWORD dwOptions,  
    LPSECURITYCREDENTIALS LpCredentials  
);
```

The **PopConnect** function is used to establish a connection with the server.

Parameters

lpszRemoteHost

A pointer to the name of the server to connect to; this may be a fully-qualified domain name or an IP address.

nRemotePort

The port number the server is listening on. A value of zero specifies that the default port number should be used. For standard connections, the default port number is 110. For secure connections, the default port number is 995. If the secure port number is specified, an implicit SSL/TLS connection will be established by default.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
POP_OPTION_NONE	No connection options specified. A standard connection to the server will be established using the specified host name and port number.
POP_OPTION_LINEBREAK	Message data that is received from the server is read as individual lines of text terminated by a carriage return and linefeed control sequence. This option can be useful for applications that need to use the lower level network I/O functions and must process the message text on a line-by-line basis. This option is not recommended for most applications because it can have a negative impact on performance when retrieving large messages from the server.
POP_OPTION_TUNNEL	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection

	and how the connection is established.
POP_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using either the SSL or TLS protocols.
POP_OPTION_SECURE	This option specifies that a secure connection should be established with the server and requires that the server support either the SSL or TLS protocol. This option is the same as specifying POP_OPTION_SECURE_EXPLICIT, which initiates the secure session using the STLS command.
POP_OPTION_SECURE_EXPLICIT	This option specifies the client should attempt to establish a secure connection with the server. The server must support secure connections using either the SSL or TLS protocol and the STLS command.
POP_OPTION_SECURE_IMPLICIT	This option specifies the client should attempt to establish a secure connection with the server. It should only be used when the server expects an implicit SSL connection or does not implement RFC 2595 where the STLS command is used to negotiate a secure connection with the server.
POP_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
POP_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
POP_OPTION_FREETHREAD	This option specifies the handle returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the handle is synchronized across multiple threads.

lpCredentials

A pointer to a [SECURITYCREDENTIALS](#) structure which is used to establish the client credentials for a secure connection to the server. The **PopCreateSecurityCredentials** function can be used

to create this structure if necessary. If a standard connection is being established, or client credentials are not required by the server, this parameter can be NULL.

Return Value

If the function succeeds, the return value is a handle to a client session. If the function fails, the return value is `INVALID_CLIENT`. To get extended error information, call **PopGetLastError**.

Remarks

To prevent this function from blocking the main user interface thread, the application should create a background worker thread and establish a connection by calling **PopConnect** in that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each client session.

The *dwOptions* argument can be used to specify the threading model that is used by the library when a connection is established. By default, the handle is initially attached to the thread that created it. From that point on, until the it is released, only the owner may call functions using that handle. The ownership of the handle may be transferred from one thread to another using the **PopAttachThread** function.

Specifying the `POP_OPTION_FREETHREAD` option enables any thread to call any function using the handle, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the handle is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same handle.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `cspopv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

See Also

PopCreateSecurityCredentials Function

```
BOOL WINAPI PopCreateSecurityCredentials(  
    DWORD dwProtocol,  
    DWORD dwOptions,  
    LPCTSTR lpszUserName,  
    LPCTSTR lpszPassword,  
    LPCTSTR lpszCertStore,  
    LPCTSTR lpszCertName,  
    LPVOID lpvReserved,  
    LPSECURITYCREDENTIALS* lppCredentials  
);
```

The **PopCreateSecurityCredentials** function creates a **SECURITYCREDENTIALS** structure.

Parameters

dwProtocol

A bitmask of supported security protocols. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_SSL	Either SSL 2.0 or SSL 3.0 should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, TLS will be excluded from the list of supported protocols. Both SSL 2.0 and 3.0 have been deprecated and will never be used unless explicitly specified. It is not recommended that you enable either of these protocols for secure connections because it will cause most servers to reject your connection request, even if a version of TLS is also specified.
SECURITY_PROTOCOL_TLS	Either the TLS 1.0, 1.1 or 1.2 protocol should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers that reject any attempt to use the older SSL protocol and require that only TLS be used.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol should be used when establishing a secure connection. This version is

	supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This is the recommended version of TLS to use with secure connections.

dwOptions

A value which specifies one or options. This member is constructed by using a bitwise operator with any of the following values:

Constant	Description
CREDENTIAL_STORE_CURRENT_USER	The library will attempt to open a store for the current user using the certificate store name provided in this structure. If no options are specified, then this is the default behavior.
CREDENTIAL_STORE_LOCAL_MACHINE	The library will attempt to open a local machine store using the certificate store name provided in this structure. If this option is specified, the library will always search for a local machine store before searching for the store by that name for the current user.
CREDENTIAL_STORE_FILENAME	The certificate store name is a file that contains the certificate and private key that will be used.

lpszUserName

A pointer to a string which specifies the certificate owner's username. A value of NULL specifies that no username is required. Currently this parameter is not used and any value specified will be ignored.

lpszPassword

A pointer to a string which specifies the certificate owner's password. A value of NULL specifies

that no password is required. This parameter is only used if a PKCS12 (PFX) certificate file is specified and that certificate has been secured with a password. This value will be ignored the current user or local machine certificate store is specified.

lpszCertStore

A pointer to a string which specifies the name of the certificate store to open. A certificate store is a collection of certificates and their private keys, typically organized by how they are used. If this value is NULL or points to an empty string, the default certificate store "MY" will be used.

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as VeriSign and Thawte act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. This corresponds to the "Personal" store that is displayed by the certificate manager utility and is the default store used by the library.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as VeriSign and Thawte are installed as part of the operating system and periodically updated by Microsoft.

lpszCertName

A pointer to a null terminated string which specifies the name of the certificate to use. The function will first search the certificate store for a certificate with a matching "friendly name"; this is a name for the certificate that is assigned by the user. Note that the name must match completely, but the comparison is not case sensitive. If no matching certificate is found, the function will then attempt to find a certificate that has a matching common name (also called the certificate subject). This comparison is less stringent, and the first partial match will be returned. If this second search fails, the function will return an error indicating that the certificate could not be found.

lpvReserved

Pointer reserved for future use. Set it to NULL when using this function.

lppCredentials

Pointer to an [LPSECURITYCREDENTIALS](#) pointer. The memory for the credentials structure will be allocated by this function and must be released by calling the **PopDeleteSecurityCredentials** function when it is no longer needed. The pointer value must be set to NULL before the function is called. It is important to note that this is a pointer to a pointer variable, not a pointer to the SECURITYCREDENTIALS structure itself.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **PopGetLastError**.

Remarks

The structure that is created by this function may be used as client credentials when establishing a secure connection. This is particularly useful for programming languages other than C/C++ which may not support C structures or pointers. The pointer to the SECURITYCREDENTIALS structure can

be declared as an unsigned integer variable which is passed by reference to this function, and then passed by value to the **PopAsyncConnect** or **PopConnect** functions.

Example

```
LPSECURITYCREDENTIALS lpSecCred = NULL;
PopCreateSecurityCredentials(SEcurity_PROTOCOL_DEFAULT,
                            0,
                            NULL,
                            NULL,
                            lpzCertStore,
                            lpzCertName,
                            NULL,
                            &lpSecCred);

hClient = PopConnect(lpzHostName,
                    POP_PORT_SECURE,
                    POP_TIMEOUT,
                    POP_OPTION_SECURE,
                    lpSecCred);
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cspopv10.lib

Unicode: Implemented as Unicode and ANSI versions.

PopDeleteMessage Function

```
INT WINAPI PopDeleteMessage(  
    HCLIENT hClient,  
    UINT nMessage  
);
```

The **PopDeleteMessage** function marks the specified message for deletion from the mailbox.

Parameters

hClient

Handle to the client session.

nMessage

Number of message to delete from the server. This value must be greater than zero. The first message in the mailbox is message number one.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is POP_ERROR. To get extended error information, call **PopGetLastError**.

Remarks

This function only marks the message for deletion. The message is not actually deleted until the user disconnects from the server. To prevent one or more marked messages from actually being deleted from the mailbox, call the **PopReset** function to reset the client session.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cspopv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

PopDeleteSecurityCredentials Function

```
VOID WINAPI PopDeleteSecurityCredentials(  
    LPSECURITYCREDENTIALS* lppCredentials  
);
```

The **PopDeleteSecurityCredentials** function deletes an existing **SECURITYCREDENTIALS** structure.

Parameters

lppCredentials

Pointer to an **LPSECURITYCREDENTIALS** pointer. On exit from the function, the pointer will be NULL.

Return Value

None.

Example

```
if (lpSecCred)  
    PopDeleteSecurityCredentials(&lpSecCred);  
  
PopUninitialize();
```

Remarks

This function can be used to release the memory allocated to the client or server credentials after a secure connection has been terminated.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cspopv10.lib

Unicode: Implemented as Unicode and ANSI versions.

PopDisableEvents Function

```
INT WINAPI PopDisableEvents(  
    HCLIENT hClient  
);
```

The **PopDisableEvents** function disables the event notification mechanism, preventing subsequent event notification messages from being posted to the application's message queue.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is POP_ERROR. To get extended error information, call **PopGetLastError**.

Remarks

This function affects both event notification and event callbacks. Any outstanding events in the message queue should be ignored by the client application.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstoools10.h

Import Library: cspopv10.lib

See Also

[PopEnableEvents](#), [PopFreezeEvents](#), [PopRegisterEvent](#)

PopDisableTrace Function

```
BOOL WINAPI PopDisableTrace();
```

The **PopDisableTrace** function disables the logging of socket function calls to the trace log.

Parameters

None.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cspopv10.lib

See Also

[PopEnableTrace](#)

PopDisconnect Function

```
INT WINAPI PopDisconnect(  
    HCLIENT hClient  
);
```

The **PopDisconnect** function terminates the connection with the server, closing the socket and releasing the memory allocated for the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is POP_ERROR. To get extended error information, call **PopGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cspopv10.lib

See Also

[PopAsyncConnect](#), [PopConnect](#), [PopUninitialize](#)

PopEnableEvents Function

```
INT WINAPI PopEnableEvents(  
    HCLIENT hClient,  
    HWND hEventWnd,  
    UINT uEventMsg  
);
```

The **PopEnableEvents** function enables event notifications using Windows messages.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Applications should use the **PopRegisterEvent** function to register an event handler which is invoked when an event occurs.

Parameters

hClient

Handle to the client session.

hEventWnd

Handle to the event notification window. This window receives a user-defined message which specifies the event that has occurred. If this value is NULL, event notification is disabled.

uEventMsg

An unsigned integer which specifies the user-defined message that is sent when an event occurs. This parameter's value must be greater than the value of WM_USER. If the *hEventWnd* parameter is NULL, this value must be specified as WM_NULL.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is POP_ERROR. To get extended error information, call **PopGetLastError**.

Remarks

When a message is posted to the notification window, the low word of the *lParam* parameter contains the event identifier. The high word of *lParam* contains the low word of the error code, if an error has occurred. The *wParam* parameter contains the client handle. One or more of the following event identifiers may be sent:

Constant	Description
POP_EVENT_CONNECT	The connection to the server has completed. The high word of the <i>lParam</i> parameter should be checked, since this notification message will be posted if an error has occurred.
POP_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
POP_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.

POP_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
POP_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
POP_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.
POP_EVENT_COMMAND	A command has been issued by the client and the server response has been received and processed. This event can be used to log the result codes and messages returned by the server in response to actions taken by the client.
POP_EVENT_PROGRESS	The client is in the process of sending or receiving data from the server. This event is called periodically during a transfer so that the client can update any user interface components such as a status control or progress bar.

As noted, some events are only generated when the client is asynchronous mode. These events depend on the Windows Sockets asynchronous notification mechanism.

If event notification is disabled by specifying a NULL window handle, there may still be outstanding events in the message queue that must be processed. Since event handling has been disabled, these events should be ignored by the client application.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cspopv10.lib

See Also

PopEnableTrace Function

```
BOOL WINAPI PopEnableTrace(  
    LPCTSTR lpszTraceFile,  
    DWORD dwTraceFlags  
);
```

The **PopEnableTrace** function enables the logging of Windows Sockets function calls to a file.

Parameters

lpszTraceFile

A pointer to a string which specifies the name of the trace log file. If this parameter is NULL or an empty string, the default file name **cstrace.log** is used. The file is stored in the directory specified by the TEMP environment variable, if it is defined; otherwise, the current working directory is used.

dwTraceFlags

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
TRACE_INFO	All function calls are written to the trace file. This is the default value.
TRACE_ERROR	Only those function calls which fail are recorded in the trace file.
TRACE_WARNING	Only those function calls which fail or return values which indicate a warning are recorded in the trace file.
TRACE_HEXDUMP	All functions calls are written to the trace file, plus all the data that is sent or received is displayed, in both ASCII and hexadecimal format.
TRACE_PROCESS	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for multithreaded applications that are using worker threads.

Return Value

If the function succeeds, the return value is non-zero. A return value of zero indicates an error. Failure typically indicates that the tracing library **cstrcv10.dll** cannot be loaded on the local system.

Remarks

When trace logging is enabled, the file is opened, appended to and closed for each socket function call. This makes it possible for an application to append its own logging information, however care should be taken to ensure that the file is closed before the next network operation is performed. To limit the size of the log files, enable and disable logging only around those sections of code that you wish to trace.

Note that the TRACE_HEXDUMP trace level generates very large log files since it includes all of the data exchanged between your application and the server.

Trace function logging is managed on a per-thread basis, not for each client handle. This means that all SocketTools libraries and components share the same settings in the current thread. If you

are using multiple SocketTools libraries or components in your application, you only need to enable logging once.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cspopv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[PopDisableTrace](#)

PopEventProc Function

```
VOID CALLBACK PopEventProc(  
    HCLIENT hClient,  
    UINT nEvent,  
    DWORD dwError,  
    DWORD_PTR dwParam  
);
```

The **PopEventProc** function is an application-defined callback function that processes events generated by the client.

Parameters

hClient

Handle to the client session.

nEvent

An unsigned integer which specifies which event occurred. For a complete list of events, refer to the **PopRegisterEvent** function.

dwError

An unsigned integer which specifies any error that occurred. If no error occurred, then this parameter will be zero.

dwParam

A user-defined integer value which was specified when the event callback was registered.

Return Value

None.

Remarks

An application must register this callback function by passing its address to the **PopRegisterEvent** function. The **PopEventProc** function is a placeholder for the application-defined function name.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `cspopv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

See Also

[PopDisableEvents](#), [PopEnableEvents](#), [PopFreezeEvents](#), [PopRegisterEvent](#)

PopFreezeEvents Function

```
INT WINAPI PopFreezeEvents(  
    HCLIENT hClient,  
    BOOL bFreeze  
);
```

The **PopFreezeEvents** function is used to suspend and resume event handling by the client.

Parameters

hClient

Handle to the client session.

bFreeze

A non-zero value specifies that event handling should be suspended by the client. A zero value specifies that event handling should be resumed.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is POP_ERROR. To get extended error information, call **PopGetLastError**.

Remarks

This function should be used when the application does not want to process events, such as when a modal dialog is being displayed. When events are suspended, all client events are queued. If events are re-enabled at a later point, those queued events will be sent to the application for processing. Note that only one of each event will be generated. For example, if the client has suspended event handling, and four read events occur, once event handling is resumed only one of those read events will be posted to the client. This prevents the application from being flooded by a potentially large number of queued events.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cspopv10.lib

See Also

[PopDisableEvents](#), [PopEnableEvents](#), [PopRegisterEvent](#)

PopGetErrorString Function

```
INT WINAPI PopGetErrorString(  
    DWORD dwErrorCode,  
    LPTSTR lpszDescription,  
    INT cbDescription  
);
```

The **PopGetErrorString** function is used to return a description of a specific error code. Typically this is used in conjunction with the **PopGetLastError** function for use with warning dialogs or as diagnostic messages.

Parameters

dwErrorCode

The error code for which a description is returned.

lpszDescription

A pointer to the buffer that will contain a description of the specified error code. This buffer should be at least 128 characters in length.

cbDescription

The maximum number of characters that may be copied into the description buffer.

Return Value

If the function succeeds, the return value is the length of the description string. If the function fails, the return value is zero, meaning that no description exists for the specified error code. Typically this indicates that the error code passed to the function is invalid.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cspopv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[PopGetLastError](#), [PopSetLastError](#)

PopGetHeaderValue Function

```
INT WINAPI PopGetHeaderValue(  
    HCLIENT hClient,  
    UINT nMessageId,  
    LPCTSTR LpszHeader,  
    LPTSTR LpszValue,  
    INT nMaxLength  
);
```

The **PopGetHeaderValue** function returns the value of a header field in the specified message.

Parameters

hClient

Handle to the client session.

nMessageId

Number of message to retrieve header value from. This value must be greater than zero. The first message in the mailbox is message number one.

lpszHeader

Pointer to a string which specifies the message header to retrieve. The colon should not be included in this string.

lpszValue

Pointer to a string buffer that will contain the value of the specified message header.

nMaxLength

The maximum number of characters that may be copied into the buffer, including the terminating null character.

Return Value

If the function succeeds, the function returns the length of the header field value. If the header field is not present in the message, the function will return a value of zero. If the function fails, the return value is POP_ERROR. To get extended error information, call **PopGetLastError**.

Remarks

The **PopGetHeaderValue** function returns the value of a header field from the specified message. This allows an application to be able to easily determine the value of a header (such as the sender, or the subject of the message) without downloading the entire header block or contents of the message.

This function uses the XTND XLST command, which is an extension to the POP3 protocol. Not all servers support the use of this command. If this command is not supported by the server, the function will attempt to retrieve the entire message header and return the value for the specified header field. This enables an application to use this function even if the server does not support command extensions.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib.h

Import Library: cspopv10.lib

Unicode: Implemented as Unicode and ANSI versions.

Copyright © 2023 Catalyst Development Corporation. All rights reserved.

PopGetLastError Function

```
DWORD WINAPI PopGetLastError();
```

Parameters

None.

Return Value

The return value is the last error code value for the current thread. Functions set this value by calling the **PopSetLastError** function. The Return Value section of each reference page notes the conditions under which the function sets the last error code.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. You should call the **PopGetLastError** function immediately when a function's return value indicates that an error has occurred. That is because some functions call **PopSetLastError(0)** when they succeed, clearing the error code set by the most recently failed function.

Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or POP_ERROR. Those functions which call **PopSetLastError** when they succeed are noted on the function reference page.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cspopv10.lib

See Also

[PopGetErrorString](#), [PopSetLastError](#)

PopGetMessage Function

```
INT WINAPI PopGetMessage(  
    HCLIENT hClient,  
    LONG nMessageId,  
    LPVOID lpvBuffer,  
    LPDWORD lpdwLength,  
    DWORD dwReserved  
);
```

The **PopGetMessage** function retrieves the specified message and copies the contents to a local buffer.

Parameters

hClient

Handle to the client session.

nMessageId

Number of message to retrieve from the server. This value must be greater than zero.

lpvBuffer

A pointer to a byte buffer which will contain the data transferred from the server, or a pointer to a global memory handle which will reference the data when the function returns.

lpdwLength

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the *lpvBuffer* parameter. If the *lpvBuffer* parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the actual length of the file that was downloaded.

dwReserved

A reserved parameter. This value should always be zero.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is POP_ERROR. To get extended error information, call **PopGetLastError**.

Remarks

The **PopGetMessage** function is used to retrieve an message from the server and copy it into a local buffer. The function may be used in one of two ways, depending on the needs of the application. The first method is to pre-allocate a buffer large enough to store the contents of the message. In this case, the *lpvBuffer* parameter will point to the buffer that was allocated, the value that the *lpdwLength* parameter points to should be initialized to the size of that buffer.

The second method that can be used is have the *lpvBuffer* parameter point to a global memory handle which will contain the message data when the function returns. In this case, the value that the *lpdwLength* parameter points to must be initialized to zero. It is important to note that the memory handle returned by the function must be freed by the application, otherwise a memory leak will occur. See the example code below.

This function will cause the current thread to block until the complete message has been retrieved, a timeout occurs or the operation is canceled. During the transfer, the POP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls.

Event notification must be enabled, either by calling **PopEnableEvents**, or by registering a callback function using the **PopRegisterEvent** function.

To determine the current status of a transfer while it is in progress, use the **PopGetTransferStatus** function.

Example

```
HGLOBAL hgblBuffer = (HGLOBAL)NULL;
LPBYTE lpBuffer = (LPBYTE)NULL;
DWORD cbBuffer = 0;

// Return the message into block of global memory allocated by
// the GlobalAlloc function; the handle to this memory will be
// returned in the hgblBuffer parameter
nResult = PopGetMessage(hClient,
                       nMessageId,
                       &hgblBuffer,
                       &cbBuffer,
                       0);

if (nResult != POP_ERROR)
{
    // Lock the global memory handle, returning a pointer to the
    // message text
    lpBuffer = (LPBYTE)GlobalLock(hgblBuffer);

    // After the data has been used, the handle must be unlocked
    // and freed, otherwise a memory leak will occur
    GlobalUnlock(hgblBuffer);
    GlobalFree(hgblBuffer);
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

PopGetMessageCount Function

```
INT WINAPI PopGetMessageCount(  
    HCLIENT hClient  
);
```

The **PopGetMessageCount** function returns the number of mail messages that are currently available in the mailbox.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, it returns the number of messages that are currently available. If no messages are available, either because the mailbox is empty or all of the messages have been deleted, this function will return zero. If the function fails, the return value is POP_ERROR. To get extended error information, call **PopGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cspopv10.lib

PopGetMessageCountEx Function

```
INT WINAPI PopGetMessageCountEx(  
    HCLIENT hClient,  
    UINT *LpnLastMessage,  
    DWORD *LpdwMailboxSize  
);
```

The **PopGetMessageCountEx** function returns the number of mail messages that are currently available in the mailbox.

Parameters

hClient

Handle to the client session.

lpnLastMessage

Address of a variable that receives the number of the last valid message in the mailbox. If a NULL value is specified, this argument is ignored.

lpdwMailboxSize

Address of a variable that receives the current size of the mailbox. This value will decrease as messages are deleted. If a NULL value is specified, this argument is ignored.

Return Value

If the function succeeds, it returns the number of messages that are currently available. If no messages are available, either because the mailbox is empty or all of the messages have been deleted, this function will return zero. If the function fails, the return value is POP_ERROR. To get extended error information, call **PopGetLastError**.

Remarks

The **PopGetMessageCountEx** function returns the number of messages available in the mailbox, the last valid message number in the mailbox and the current size of the mailbox in bytes.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

PopGetMessageHeaders Function

```
INT WINAPI PopGetMessageHeaders(  
    HCLIENT hClient,  
    LONG nMessageId,  
    LPVOID lpvHeaders,  
    LPDWORD lpdwLength  
);
```

The **PopGetMessageHeaders** function retrieves the headers for the specified message from the server.

Parameters

hClient

Handle to the client session.

nMessageId

Number of message to retrieve from the server. This value must be greater than zero.

lpvHeaders

A pointer to a byte buffer which will contain the data transferred from the server, or a pointer to a global memory handle which will reference the data when the function returns.

lpdwLength

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the *lpvHeaders* parameter. If the *lpvHeaders* parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the actual length of the message that was downloaded.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is POP_ERROR. To get extended error information, call **PopGetLastError**.

Remarks

The **PopGetMessageHeaders** function is used to retrieve an message header block from the server and copy it into a local buffer. The function may be used in one of two ways, depending on the needs of the application. The first method is to pre-allocate a buffer large enough to store the contents of the file. In this case, the *lpvHeaders* parameter will point to the buffer that was allocated, the value that the *lpdwLength* parameter points to should be initialized to the size of that buffer.

The second method that can be used is have the *lpvHeaders* parameter point to a global memory handle which will contain the message headers when the function returns. In this case, the value that the *lpdwLength* parameter points to must be initialized to zero. It is important to note that the memory handle returned by the function must be freed by the application, otherwise a memory leak will occur.

This function will cause the current thread to block until the transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the POP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **PopEnableEvents**, or by registering a callback function using the **PopRegisterEvent** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cspopv10.lib

See Also

[PopGetHeaderValue](#), [PopGetMessage](#), [PopGetMessageId](#), [PopOpenMessage](#)

PopGetMessageId Function

```
INT WINAPI PopGetMessageId(  
    HCLIENT hClient,  
    UINT nMessageId,  
    LPTSTR lpszMessageId,  
    INT nMaxLength  
);
```

The **PopGetMessageId** function returns the message identifier for the specified message.

Parameters

hClient

Handle to the client session.

nMessageId

Number of message to retrieve the unique identifier for. This value must be greater than zero. The first message in the mailbox is message number one.

lpszMessageId

Address of a string buffer to receive the message identifier. This should be at least 64 bytes in length.

nMaxLength

The maximum length of the string buffer.

Return Value

If the function succeeds, the return value is the length of the unique identifier string. If the function fails, the return value is POP_ERROR. To get extended error information, call **PopGetLastError**.

Remarks

The **PopGetMessageId** function returns the message identifier from the Message-ID header of the specified message. The returned value is typically a string which specifies the domain, date and timestamp for the message that is created when the message is submitted to the mail server for delivery. To obtain a unique identifier for the message in the mailbox, it is recommended that you use the **PopGetMessageUid** function instead.

This function uses the XTND XLST command to obtain the value of the "Message-ID" header field. If this command is not supported by the server, the function will attempt to retrieve the entire message header and return the value for the specified header field. This enables an application to use this function even if the server does not support command extensions.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cspopv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[PopGetHeaderValue](#), [PopGetMessage](#), [PopGetMessageHeaders](#), [PopGetMessageSender](#), [PopGetMessageUid](#)

PopGetMessageSender Function

```
INT WINAPI PopGetMessageSender(  
    HCLIENT hClient,  
    UINT nMessageId,  
    LPTSTR lpszAddress,  
    INT nMaxLength  
);
```

The **PopGetMessageSender** function returns the sender's address for the specified message.

Parameters

hClient

Handle to the client session.

nMessageId

Number of message to retrieve header value from. This value must be greater than zero. The first message in the mailbox is message number one.

lpszAddress

Pointer to a string buffer that will contain the address of the message sender.

nMaxLength

The maximum number of characters that may be copied into the buffer, including the terminating null character.

Return Value

If the function succeeds, the function returns the length of the address. If the sender cannot be determined, the function will return a value of zero. If the function fails, the return value is POP_ERROR. To get extended error information, call **PopGetLastError**.

Remarks

The **PopGetMessageSender** function returns the email address of the user who sent the specified message. This allows an application to be able to easily determine the sender, without downloading the entire header block or contents of the message.

This function uses the XSENDER command, which is an extension to the POP3 protocol, to determine the address of the authenticated sender of the message. If the command is not supported, or the server was unable to authenticate the sender, the function will use the XTND XLST command to obtain the value of the "From" header field. If this command is not supported by the server, the function will attempt to retrieve the entire message header and return the value for the specified header field. This enables an application to use this function even if the server does not support command extensions.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cspopv10.lib

Unicode: Implemented as Unicode and ANSI versions.

PopGetMessageSize Function

```
DWORD WINAPI PopGetMessageSize(  
    HCLIENT hClient,  
    UINT nMessageId  
);
```

The **PopGetMessageSize** function returns the size of the specified message.

Parameters

hClient

Handle to the client session.

nMessageId

Number of message to retrieve size of. This value must be greater than zero. The first message in the mailbox is message number one.

Return Value

If the function succeeds, the return value is the size of the specified message in bytes. If the function fails, the return value is POP_ERROR. To get extended error information, call

PopGetLastError.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cspopv10.lib

PopGetMessageUid Function

```
INT WINAPI PopGetMessageUid(  
    HCLIENT hClient,  
    UINT nMessageId,  
    LPTSTR lpszMessageUID,  
    INT nMaxLength  
);
```

The **PopGetMessageUid** function returns the unique identifier (UID) for the specified message in the current mailbox.

Parameters

hClient

Handle to the client session.

nMessageId

Number of message to retrieve the unique identifier for. This value must be greater than zero. The first message in the mailbox is message number one.

lpszMessageUID

Address of a string buffer to receive the unique identifier for the specified message. This should be at least 64 bytes in length.

nMaxLength

The maximum length of the string buffer for the message UID.

Return Value

If the function succeeds, it returns a non-zero value. If no unique identifier is assigned to the message, the function will return zero. If an error occurs, the function returns POP_ERROR. To get extended error information, call **PopGetLastError**.

Remarks

The **PopGetMessageUid** function returns the unique message identifier for the specified message. The returned value is a string which can be used to uniquely identify a specific message in the mailbox across multiple client sessions. This is commonly used by mail clients to determine if they have already retrieved a message from the server in a previous session. The UID can also be used as a key or component of the file name to reference the message after it has been stored on the local system.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cspopv10.lib

See Also

[PopGetHeaderValue](#), [PopGetMessage](#), [PopGetMessageHeaders](#), [PopGetMessageId](#), [PopGetMessageSender](#)

PopGetMultiLine Function

```
INT WINAPI PopGetMultiLine(  
    HCLIENT hClient,  
    LPBOOL lpbMultiLine  
);
```

The **PopGetMultiLine** function returns the value of the client multi-line flag in the specified boolean parameter.

Parameters

hClient

Handle to the client session.

lpbMultiLine

A pointer to a boolean variable. This variable will be set to the current value of the client's internal multi-line flag.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is POP_ERROR. To get extended error information, call **PopGetLastError**.

Remarks

The multi-line flag is used by the library to determine if multiple lines of data will be returned by the server as the result of a command. Unlike a single line response, which consists of a result code and result string, a multi-line response consists of one or more lines of text, terminated by a special end-of-data marker.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cspopv10.lib

See Also

[PopCommand](#), [PopGetResultCode](#), [PopGetResultString](#), [PopSetMultiLine](#)

PopGetResultCode Function

```
BOOL WINAPI PopGetResultCode(  
    HCLIENT hClient  
);
```

The **PopGetResultCode** function reads the result code returned by the server in response to a command. The result code is a Boolean value, and indicates if the operation succeeded or failed.

Parameters

hClient

Handle to the client session.

Return Value

If the previous command was successful, the function returns a non-zero value. If the previous command failed, the function returns zero. To get extended error information, call **PopGetLastError**.

Remarks

Unlike most other Internet application protocols, the Post Office Protocol does not return numeric result codes to indicate success or failure. If a command is successful, the server will respond with the string "+OK" and this is indicated by the **PopGetResultCode** function returning a non-zero value. If the command fails, the server will respond with the string "-ERR" along with a description of the error, and this is indicated by the function returning a value of zero. The description of the error returned by the server can be obtained by calling the **PopGetResultString** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cspopv10.lib

See Also

[PopCommand](#), [PopGetResultString](#)

PopGetResultString Function

```
INT WINAPI PopGetResultString(  
    HCLIENT hClient,  
    LPTSTR lpszResult,  
    INT nMaxLength  
);
```

The **PopGetResultString** function returns the last message sent by the server along with the result code.

Parameters

hClient

Handle to the client session.

lpszResult

A pointer to the buffer that will contain the result string returned by the server.

nMaxLength

The maximum number of characters that may be copied into the result string buffer, including the terminating null character.

Return Value

If the function succeeds, the return value is the length of the result string. If a value of zero is returned, this means that no result string was sent by the server. If the function fails, the return value is POP_ERROR. To get extended error information, call **PopGetLastError**.

Remarks

The **PopGetResultString** function is most useful when an error occurs because the server will typically include a brief description of the cause of the error. This can then be parsed by the application or displayed to the user. The result string is updated each time the client sends a command to the server and then calls **PopGetResultCode** to obtain the result code for the operation.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cspopv10.lib

Unicode: Implemented as Unicode and ANSI versions.

PopGetSecurityInformation Function

```
BOOL WINAPI PopGetSecurityInformation(  
    HCLIENT hClient,  
    LPSECURITYINFO lpSecurityInfo  
);
```

The **PopGetSecurityInformation** function returns security protocol, encryption and certificate information about the current client connection.

Parameters

hClient

Handle to the client session.

lpSecurityInfo

A pointer to a [SECURITYINFO](#) structure which contains information about the current client connection. The *dwSize* member of this structure must be initialized to the size of the structure before passing the address of the structure to this function.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **PopGetLastError**.

Remarks

This function is used to obtain security related information about the current client connection to the server. It can be used to determine if a secure connection has been established, what security protocol was selected, and information about the server certificate. Note that a secure connection has not been established, the *dwProtocol* structure member will contain the value `SECURITY_PROTOCOL_NONE`.

Example

The following example notifies the user if the connection is secure or not:

```
SECURITYINFO securityInfo;  
  
securityInfo.dwSize = sizeof(SECURITYINFO);  
if (PopGetSecurityInformation(hClient, &securityInfo))  
{  
    if (securityInfo.dwProtocol == SECURITY_PROTOCOL_NONE)  
    {  
        MessageBox(NULL, _T("The connection is not secure"),  
                    _T("Connection"), MB_OK);  
    }  
    else  
    {  
        if (securityInfo.dwCertStatus == SECURITY_CERTIFICATE_VALID)  
        {  
            MessageBox(NULL, _T("The connection is secure"),  
                        _T("Connection"), MB_OK);  
        }  
        else  
        {  
            MessageBox(NULL, _T("The server certificate not valid"),  
                        _T("Connection"), MB_OK);  
        }  
    }  
}
```

```
}  
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cspopv10.lib

Unicode: Implemented as Unicode and ANSI versions.

PopGetStatus Function

```
INT WINAPI PopGetStatus(  
    HCLIENT hClient  
);
```

The **PopGetStatus** function returns the current status of the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the client status code. If the function fails, the return value is POP_ERROR. To get extended error information, call **PopGetLastError**.

Remarks

The **PopGetStatus** function returns a numeric code which identifies the current state of the client session. The following values may be returned:

Value	Constant	Description
1	POP_STATUS_IDLE	The client is current idle and not sending or receiving data.
2	POP_STATUS_CONNECT	The client is establishing a connection with the server.
3	POP_STATUS_READ	The client is reading data from the server.
4	POP_STATUS_WRITE	The client is writing data to the server.
5	POP_STATUS_DISCONNECT	The client is disconnecting from the server.

In a multithreaded application, any thread in the current process may call this function to obtain status information for the specified client session.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cspopv10.lib

See Also

[PopIsBlocking](#), [PopIsConnected](#), [PopIsReadable](#), [PopIsWritable](#)

PopGetTimeout Function

```
INT WINAPI PopGetTimeout(  
    HCLIENT hClient  
);
```

The **PopGetTimeout** function returns the number of seconds the client will wait for a response from the server. Once the specified number of seconds has elapsed, the function will fail and return to the caller.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the timeout period in seconds. If the function fails, the return value is POP_ERROR. To get extended error information, call **PopGetLastError**.

Remarks

The timeout value is only used with blocking client connections. A value of zero indicates that the default timeout period of 20 seconds should be used.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cspopv10.lib

See Also

[PopConnect](#), [PopIsReadable](#), [PopIsWritable](#), [PopRead](#), [PopSetTimeout](#)

PopGetTransferStatus Function

```
INT WINAPI PopGetTransferStatus(  
    HCLIENT hClient,  
    LPPOPTRANSFERSTATUS lpStatus  
);
```

The **PopGetTransferStatus** function returns information about the current file transfer in progress.

Parameters

hClient

Handle to the client session.

lpStatus

A pointer to an [POPTRANSFERSTATUS](#) structure which contains information about the status of the current file transfer.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is POP_ERROR. To get extended error information, call **PopGetLastError**.

Remarks

The **PopGetTransferStatus** function returns information about the current file transfer, including the average number of bytes transferred per second and the estimated amount of time until the transfer completes. If there is no file currently being transferred, this function will return the status of the last successful transfer made by the client.

In a multithreaded application, any thread in the current process may call this function to obtain status information for the specified client session.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cspopv10.lib

See Also

[PopEnableEvents](#), [PopGetStatus](#), [PopRegisterEvent](#)

PopInitialize Function

```
BOOL WINAPI PopInitialize(  
    LPCTSTR lpszLicenseKey,  
    LPINITDATA lpData  
);
```

The **PopInitialize** function initializes the library and validates the specified license key at runtime.

Parameters

lpszLicenseKey

Pointer to a string that specifies the runtime license key to be validated. If this parameter is NULL, the library will validate the development license installed on the local system.

lpData

Pointer to an INITDATA data structure. This parameter may be NULL if the initialization data for the library is not required.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **PopGetLastError**. All other client functions will fail until a license key has been successfully validated.

Remarks

This must be the first function that an application calls before using any of the other functions in the library. When a NULL license key is specified, the library will only function on the development system. Before redistributing the application to an end-user, you must insure that this function is called with a valid license key.

If the *lpData* argument is specified, it must point to an INITDATA structure which has been initialized by setting the *dwSize* member to the size of the structure. All other structure members should be set to zero. If the function is successful, then the INITDATA structure will be filled with identifying information about the library.

Although it is only required that **PopInitialize** be called once for the current process, it may be called multiple times; however, each call must be matched by a corresponding call to **PopUninitialize**.

This function dynamically loads other system libraries and allocates thread local storage. If you are calling the functions in this library from within another DLL, it is important that you do not call the **PopInitialize** or **PopUninitialize** functions from the **DllMain** function because it can result in deadlocks or access violation errors. If the DLL is linked with the C runtime library (CRT), it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cspopv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

PopIsBlocking Function

```
BOOL WINAPI PopIsBlocking(  
    HCLIENT hClient  
);
```

The **PopIsBlocking** function is used to determine if the client is currently performing a blocking operation.

Parameters

hClient

Handle to the client session.

Return Value

If the client is performing a blocking operation, the function returns a non-zero value. If the client is not performing a blocking operation, or the client handle is invalid, the function returns zero.

Remarks

Because a blocking operation can allow the application to be re-entered (for example, by pressing a button while the operation is being performed), it is possible that another blocking function may be called while it is in progress. Since only one thread of execution may perform a blocking operation at any one time, an error would occur. The **PopIsBlocking** function can be used to determine if the client is already blocked, and if so, take some other action (such as warning the user that they must wait for the operation to complete).

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `cspopv10.lib`

See Also

[PopCancel](#)

PopIsConnected Function

```
BOOL WINAPI PopIsConnected(  
    HCLIENT hClient  
);
```

The **PopIsConnected** function is used to determine if the client is currently connected to a server.

Parameters

hClient

Handle to the client session.

Return Value

If the client is connected to a server, the function returns a non-zero value. If the client is not connected, or the client handle is invalid, the function returns zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cspopv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[PopIsBlocking](#), [PopIsReadable](#), [PopIsWritable](#)

PopIsReadable Function

```
BOOL WINAPI PopIsReadable(  
    HCLIENT hClient,  
    INT nTimeout,  
    LPDWORD lpdwAvail  
);
```

The **PopIsReadable** function is used to determine if data is available to be read from the server.

Parameters

hClient

Handle to the client session.

nTimeout

Timeout for server response, in seconds. A value of zero specifies that the connection should be polled without blocking the current thread.

lpdwAvail

A pointer to an unsigned integer which will contain the number of bytes available to read. This parameter may be NULL if this information is not required.

Return Value

If the client can read data from the server within the specified timeout period, the function returns a non-zero value. If the client cannot read any data, the function returns zero.

Remarks

On some platforms, this value will not exceed the size of the receive buffer (typically 64K bytes). Because of differences between TCP/IP stack implementations, it is not recommended that your application exclusively depend on this value to determine the exact number of bytes available. Instead, it should be used as a general indicator that there is data available to be read.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cspopv10.lib

See Also

[PopGetStatus](#), [PopIsBlocking](#), [PopIsConnected](#), [PopIsWritable](#), [PopRead](#)

PopIsWritable Function

```
BOOL WINAPI PopIsWritable(  
    HCLIENT hClient,  
    INT nTimeout  
);
```

The **PopIsWritable** function is used to determine if data can be written to the server.

Parameters

hClient

Handle to the client session.

nTimeout

Timeout for server response, in seconds. A value of zero specifies that the connection should be polled without blocking the current thread.

Return Value

If the client can write data to the server within the specified timeout period, the function returns a non-zero value. If the client cannot write any data, the function returns zero.

Remarks

Although this function can be used to determine if some amount of data can be sent to the remote process it does not indicate the amount of data that can be written without blocking the client. In most cases, it is recommended that large amounts of data be broken into smaller logical blocks, typically some multiple of 512 bytes in length.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `cspopv10.lib`

See Also

PopLogin Function

```
INT WINAPI PopLogin(  
    HCLIENT hClient,  
    UINT nAuthType,  
    LPCTSTR LpszUserName,  
    LPCTSTR LpszPassword  
);
```

The **PopLogin** function authenticates the specified user in on the server. This function must be called after the connection has been established, and before attempting to retrieve messages or perform any other function on the server.

Parameters

hClient

Handle to the client session.

nAuthType

Identifies the type of authentication that should be used when the client logs in to the mail server. The following authentication methods are supported:

Constant	Description
POP_AUTH_DEFAULT	The default authentication scheme which sends the username and password as cleartext to the server. Because the user credentials are not encrypted, this method should only be used over a secure connection. This is the same as specifying POP_AUTH_PASS as the authentication method.
POP_AUTH_PASS	The username and password is sent to the server using the USER and PASS commands. This authentication method is supported by most servers and is the default authentication type. The credentials are not encrypted and this method should only be used over secure connections.
POP_AUTH_APOP	The APOP authentication method which uses an MD5 digest of the password. This method has been deprecated is not supported by all servers. It should only be used if required by legacy mail servers which do not support the SASL authentication methods.
POP_AUTH_LOGIN	This authentication type will use the LOGIN method to authenticate the client session. This encodes the username and password in a specific format, but the credentials are not encrypted and should only be used over a secure connection. The server must support the Simple Authentication and Security Layer (SASL) mechanism as defined in RFC 4422.
POP_AUTH_PLAIN	This authentication type will use the PLAIN method to authenticate the client session. This encodes the username and password in a specific format, but the credentials are not encrypted and should only be used over a secure connection. The server must support the PLAIN Simple Authentication and Security Layer (SASL) mechanism as defined in RFC 4616.

POP_AUTH_XOAUTH2	This authentication type will use the XOAUTH2 method to authenticate the client session. This authentication method does not require the user password, instead the <i>lpszPassword</i> parameter must specify the OAuth 2.0 bearer token issued by the service provider. The application must provide a valid access token which has not expired, or this function will fail.
POP_AUTH_BEARER	This authentication type will use the OAUTHBEARER method to authenticate the client session as defined in RFC 7628. This authentication method does not require the user password, instead the <i>lpszPassword</i> parameter must specify the OAuth 2.0 bearer token issued by the service provider. The application must provide a valid access token which has not expired, or this function will fail.

lpszUserName

A null terminated string which specifies the user name to be used to authenticate the current client session. For many service providers, the user name is the full email address of the user which owns the mailbox. In some cases, this may only be the portion of their email address before the domain name.

lpszPassword

A null terminated string which specifies the password to be used when authenticating the current client session. If you are using the POP_AUTH_XOAUTH2 or POP_AUTH_BEARER authentication methods, this parameter is not a password, instead it specifies the OAuth 2.0 bearer token provided by the mail service.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is POP_ERROR. To get extended error information, call **PopGetLastError**.

Remarks

The POP_AUTH_LOGIN and POP_AUTH_PLAIN authentication methods require the mail server support the Simple Authentication and Security Layer (SASL) AUTH command as defined in RFC 5034. Most modern mail servers do support one or both of these methods, and they are generally preferred over the POP_AUTH_PASS method when possible. However, for backwards compatibility with legacy servers, the API will default to using POP_AUTH_PASS for client authentication.

You should only use an OAuth 2.0 authentication method if you understand the process of how to request the access token. Obtaining an access token requires registering your application with the mail service provider (e.g.: Microsoft or Google), getting a unique client ID associated with your application and then requesting the access token using the appropriate scope for the service. Obtaining the initial token will typically involve interactive confirmation on the part of the user, requiring they grant permission to your application to access their mail account.

The POP_AUTH_XOAUTH2 and POP_AUTH_BEARER authentication methods are similar, but they are not interchangeable. Both use an OAuth 2.0 bearer token to authenticate the client session, but they differ in how the token is presented to the server. It is currently preferable to use the XOAUTH2 method because it is more widely available and some service providers do not yet support the OAUTHBEARER method.

Your application should not store an OAuth 2.0 bearer token for later use. They have a relatively short lifespan, typically about an hour, and are designed to be used with that session. You should

specify offline access as part of the OAuth 2.0 scope if necessary and store the refresh token provided by the service. The refresh token has a much longer validity period and can be used to obtain a new bearer token when needed.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cspopv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[PopAsyncConnect](#), [PopConnect](#), [PopGetMessage](#), [PopGetMessageCountEx](#), [PopInitialize](#)

PopOpenMessage Function

```
INT WINAPI PopOpenMessage(  
    HCLIENT hClient,  
    UINT nMessageId,  
    DWORD dwReserved  
);
```

The **PopOpenMessage** function opens the specified message for reading.

Parameters

hClient

Handle to the client session.

nMessageId

Number that specifies which message to open. This value must be greater than zero. The first message in the mailbox is message one.

dwReserved

A reserved parameter. This value must be zero.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is POP_ERROR. To get extended error information, call **PopGetLastError**.

Remarks

The **PopOpenMessage** function is used to begin the process of reading the contents of a message from the server. Similar to how a file is opened and read, this method is followed by one or more calls to the **PopRead** method. When the entire contents of the message has been read, the **PopCloseMessage** method is used to close the message, completing the transaction on the server.

This is a lower-level function which enables the application to process the message as the contents are being returned by the server. In general, it is recommended that most applications use the **PopGetMessage** method instead, which provides a simpler method for retrieving the contents of a message.

It is important to note that you cannot use this function to read the partial contents of a message. Opening a message on the server begins a process where the entire message contents must be read and the message closed before the next command can be issued to the server. If you only want to obtain the headers for a message, use the **PopGetMessageHeaders** function instead.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cspopv10.lib

See Also

PopRead Function

```
INT WINAPI PopRead(  
    HCLIENT hClient,  
    LPBYTE lpBuffer,  
    INT cbBuffer  
);
```

The **PopRead** function reads the specified number of bytes from the client socket and copies them into the buffer. The data may be of any type, and is not terminated with a null character.

Parameters

hClient

Handle to the client session.

lpBuffer

Pointer to the buffer in which the data will be copied.

cbBuffer

The maximum number of bytes to read and copy into the specified buffer. This value must be greater than zero.

Return Value

If the function succeeds, the return value is the number of bytes actually read. A return value of zero indicates that there is no more data available to be read. If the function fails, the return value is POP_ERROR. To get extended error information, call **PopGetLastError**.

Remarks

When **PopRead** is called and the client is in non-blocking mode, it is possible that the function will fail because there is no available data to read at that time. This should not be considered a fatal error. Instead, the application should simply wait to receive the next asynchronous notification that data is available.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cspopv10.lib

See Also

PopRegisterEvent Function

```
INT WINAPI PopRegisterEvent(  
    HCLIENT hClient,  
    UINT nEvent,  
    POPEVENTPROC LpEventProc,  
    DWORD_PTR dwParam  
);
```

The **PopRegisterEvent** function registers an event handler for the specified event.

Parameters

hClient

Handle to the client session.

nEvent

An unsigned integer which specifies which event should be registered with the specified callback function. One of the following values may be used:

Constant	Description
POP_EVENT_CONNECT	The connection to the server has completed.
POP_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
POP_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
POP_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
POP_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
POP_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.
POP_EVENT_COMMAND	A command has been issued by the client and the server response has been received and processed. This event can be used to log the result codes and messages returned by the server in response to actions taken by the client.
POP_EVENT_PROGRESS	The client is in the process of sending or receiving data from the server. This event is called periodically during a

	transfer so that the client can update any user interface components such as a status control or progress bar.
--	--

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **PopEventProc** callback function. If this parameter is NULL, the callback for the specified event is disabled.

dwParam

A user-defined integer value that is passed to the callback function. If the application targets the x86 (32-bit) platform, this parameter must be a 32-bit unsigned integer. If the application targets the x64 (64-bit) platform, this parameter must be a 64-bit unsigned integer.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is POP_ERROR. To get extended error information, call **PopGetLastError**.

Remarks

The **PopRegisterEvent** function associates a callback function with a specific event. The event handler is an **PopEventProc** function that is invoked when the event occurs. Arguments are passed to the function to identify the client session, the event type and the user-defined value specified when the event handler is registered. If the event occurs because of an error condition, the error code will be provided to the handler.

This function is typically used to register an event handler that is invoked while a message is being retrieved. The POP_EVENT_PROGRESS event will only be generated periodically during the transfer to ensure the application is not flooded with event notifications. It is guaranteed that at least one POP_EVENT_PROGRESS notification will occur at the beginning of the transfer, and one at the end of the transfer when it has completed.

The callback function specified by the *lpEventProc* parameter must be declared using the **__stdcall** calling convention. This ensures the arguments passed to the event handler are pushed on to the stack in the correct order. Failure to use the correct calling convention will corrupt the stack and cause the application to terminate abnormally.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cspopv10.lib

See Also

[PopDisableEvents](#), [PopEnableEvents](#), [PopEventProc](#), [PopFreezeEvents](#)

PopReset Function

```
BOOL WINAPI PopReset(  
    HCLIENT hClient  
);
```

The **PopReset** function resets the client state and resynchronizes with the server. This function is typically called after an unexpected error has occurred, or an operation has been canceled.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **PopGetLastError**.

Remarks

This function will prevent any messages marked for deletion from actually being deleted from the mailbox. The client cannot be reset while the client is in a blocked state.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cspopv10.lib

See Also

PopSendMessage Function

```
INT WINAPI PopSendMessage(  
    HCLIENT hClient,  
    LPVOID lpMessage,  
    DWORD dwMessageSize,  
    DWORD dwReserved  
);
```

The **PopSendMessage** function sends a message to the specified recipients.

Parameters

hClient

Handle to the client session.

lpMessage

Pointer to a buffer which contains the message to be submitted to the mail server for delivery.

dwMessageSize

The length of the buffer in bytes. This specifies the number of bytes to be written to the mail server. This value must be greater than zero.

dwReserved

A reserved parameter. This value must be zero.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is POP_ERROR. To get extended error information, call **PopGetLastError**.

Remarks

The **PopSendMessage** function sends a message through the POP3 server using the XTND XMIT command. The specified file must be in the standard format as described in RFC 822, with the recipient addresses specified in the To: and Cc: header fields. Some servers may support blind carbon copies by using addresses specified in a Bcc: header field, and then removing those addresses from the header before delivering the message.

Note that not all POP3 servers support this command, and it is recommended that you use the Simple Mail Transfer Protocol (SMTP) for general mail delivery purposes.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cspopv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[PopGetMessage](#), [PopStoreMessage](#)

PopSetLastError Function

```
VOID WINAPI PopSetLastError(  
    DWORD dwErrorCode  
);
```

The **PopSetLastError** function sets the last error code for the current thread. This function is typically used to clear the last error by specifying a value of zero as the parameter.

Parameters

dwErrorCode

Specifies the last error code for the current thread.

Return Value

None.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or POP_ERROR. Those functions which call **PopSetLastError** when they succeed are noted on the function reference page.

Applications can retrieve the value saved by this function by using the **PopGetLastError** function. The use of **PopGetLastError** is optional; an application can call the function to determine the specific reason for a function failure.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cspopv10.lib

[PopGetErrorString](#), [PopGetLastError](#)

PopSetMultiLine Function

```
INT WINAPI PopSetMultiLine(  
    HCLIENT hClient,  
    BOOL bMultiLine  
);
```

The **PopSetMultiLine** function sets the client multi-line flag into the specified value.

Parameters

hClient

Handle to the client session.

bMultiLine

A boolean flag which determines if the client is processing multiple lines of data as the result of a command.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is POP_ERROR. To get extended error information, call **PopGetLastError**.

Remarks

The multi-line flag is used by the library to determine if multiple lines of data will be returned by the server as the result of a command. Unlike a single line response, which consists of a result code and result string, a multi-line response consists of one or more lines of text, terminated by a special end-of-data marker.

The **PopSetMultiLine** function should only be used in conjunction with the **PopCommand** function. If a command is issued which would result in multiple lines of output, the multi-line flag must be set TRUE. The multi-line flag must be set after each command, since it is reset to FALSE with each command that is sent to the server.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cspopv10.lib

PopSetTimeout Function

```
INT WINAPI PopSetTimeout(  
    HCLIENT hClient,  
    INT nTimeout  
);
```

The **PopSetTimeout** function sets the number of seconds the client will wait for a response from the server. Once the specified number of seconds has elapsed, the function will fail and return to the caller.

Parameters

hClient

Handle to the client session.

nTimeout

The number of seconds to wait for a blocking operation to complete.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is POP_ERROR. To get extended error information, call **PopGetLastError**.

Remarks

The timeout value is only used with blocking client connections.

Requirements

PopStoreMessage Function

```
INT WINAPI PopStoreMessage(  
    HCLIENT hClient,  
    UINT nMessageId,  
    LPCTSTR lpszFileName  
);
```

The **PopStoreMessage** function stores a message in the specified file.

Parameters

hClient

Handle to the client session.

nMessageId

Number of the message to retrieve. This value must be greater than zero. The first message in the mailbox is message number one.

lpszFileName

Pointer to a string which specifies the file that the message will be stored in. If an empty string or NULL pointer is passed as an argument, the message is copied to the system clipboard.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is POP_ERROR. To get extended error information, call **PopGetLastError**.

Remarks

The **PopStoreMessage** function provides a method of retrieving and storing a message on the local system. The contents of the message is stored as a text file, using the specified file name. This function always causes the caller to block until the entire message has been retrieved, even if the client has been put in asynchronous mode.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cspopv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[PopGetMessage](#), [PopGetMessageHeaders](#), [PopGetTransferStatus](#), [PopSendMessage](#)

PopUninitialize Function

```
VOID WINAPI PopUninitialize();
```

The **PopUninitialize** function terminates the use of the library.

Parameters

There are no parameters.

Return Value

None.

Remarks

An application is required to perform a successful **PopInitialize** call before it can call any of the other library functions. When it has completed the use of library, the application must call **PopUninitialize** to allow the library to free any resources allocated on behalf of the process. Any pending blocking or asynchronous calls in this process are canceled without posting any notification messages, and all sockets that were opened by the process are closed.

There must be a call to **PopUninitialize** for every successful call to **PopInitialize** made by a process. In a multithreaded environment, operations for all threads in the client are terminated.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cspopv10.lib

[PopDisconnect](#), [PopInitialize](#)

PopWrite Function

```
INT WINAPI PopWrite(  
    HCLIENT hClient,  
    LPBYTE lpBuffer,  
    INT cbBuffer  
);
```

The **PopWrite** function sends the specified number of bytes to the server.

Parameters

hClient

Handle to the client session.

lpBuffer

The pointer to the buffer which contains the data that is to be sent to the server.

cbBuffer

The number of bytes to send from the specified buffer.

Return Value

If the function succeeds, the return value is the number of bytes actually written. If the function fails, the return value is POP_ERROR. To get extended error information, call **PopGetLastError**.

Remarks

The return value may be less than the number of bytes specified by the *cbBuffer* parameter. In this case, the data has been partially written and it is the responsibility of the client application to send the remaining data at some later point. For non-blocking clients, the client must wait for the POP_EVENT_WRITE asynchronous notification message before it resumes sending data.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cspopv10.lib

Unicode: Implemented as Unicode and ANSI versions.

Post Office Protocol Data Structures

- INITDATA
- POPTRANSFERSTATUS
- SECURITYCREDENTIALS
- SECURITYINFO
- SYSTEMTIME

INITDATA Structure

This structure contains information about the SocketTools library when the initialization function returns.

```
typedef struct _INITDATA
{
    DWORD      dwSize;
    DWORD      dwVersionMajor;
    DWORD      dwVersionMinor;
    DWORD      dwVersionBuild;
    DWORD      dwOptions;
    DWORD_PTR  dwReserved1;
    DWORD_PTR  dwReserved2;
    TCHAR      szDescription[128];
} INITDATA, *LPINITDATA;
```

Members

dwSize

Size of this structure. This structure member must be set to the size of the structure prior to calling the initialization function. Failure to do so will cause the function to fail.

dwVersionMajor

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the major version number for the library.

dwVersionMinor

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the minor version number for the library.

dwVersionBuild

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the build number for the library.

dwOptions

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

dwReserved1

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

dwReserved2

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

szDescription

A null terminated string which describes the library.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Unicode: Implemented as Unicode and ANSI versions.

POPTRANSFERSTATUS Structure

This structure is used by the [PopGetTransferStatus](#) function to return information about a message transfer in progress.

```
typedef struct _POPTRANSFERSTATUS
{
    UINT    nMessageId;
    DWORD   dwBytesTotal;
    DWORD   dwBytesCopied;
    DWORD   dwBytesPerSecond;
    DWORD   dwTimeElapsed;
    DWORD   dwTimeEstimated;
} POPTRANSFERSTATUS, *LPPOPTRANSFERSTATUS;
```

Members

nMessageId

The message ID of the current message that is being transferred.

dwBytesTotal

The total number of bytes that will be transferred. If the message is being copied from the server to the local host, this is the size of the message on the server. If the message is being posted to the server, it is the size of message on the local system. If the message size cannot be determined, this value will be zero.

dwBytesCopied

The total number of bytes that have been copied.

dwBytesPerSecond

The average number of bytes that have been copied per second.

dwTimeElapsed

The number of seconds that have elapsed since the transfer started.

dwTimeEstimated

The estimated number of seconds until the transfer is completed. This is based on the average number of bytes transferred per second.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

SECURITYCREDENTIALS Structure

The **SECURITYCREDENTIALS** structure specifies the information needed by the library to specify additional security credentials, such as a client certificate or private key, when establishing a secure connection.

```
typedef struct _SECURITYCREDENTIALS
{
    DWORD    dwSize;
    DWORD    dwProtocol;
    DWORD    dwOptions;
    DWORD    dwReserved;
    LPCTSTR  lpszHostName;
    LPCTSTR  lpszUserName;
    LPCTSTR  lpszPassword;
    LPCTSTR  lpszCertStore;
    LPCTSTR  lpszCertName;
    LPCTSTR  lpszKeyFile;
} SECURITYCREDENTIALS, *LPSECURITYCREDENTIALS;
```

Members

dwSize

Size of this structure. If the structure is being allocated dynamically, this member must be set to the size of the structure and all other unused structure members must be initialized to a value of zero or NULL.

dwProtocol

A bitmask of supported security protocols. The value of this structure member is constructed by using a bitwise operator with any of the following values:

Constant	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_SSL	Either SSL 2.0 or SSL 3.0 should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, TLS will be excluded from the list of supported protocols. Both SSL 2.0 and 3.0 have been deprecated and will never be used unless explicitly specified. It is not recommended that you enable either of these protocols for secure connections because it will cause most servers to reject your connection request, even if a version of TLS is also specified.
SECURITY_PROTOCOL_TLS	Either the TLS 1.0, 1.1 or 1.2 protocol should be used when establishing a secure connection. The correct protocol is automatically selected, based on

	what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers that reject any attempt to use the older SSL protocol and require that only TLS be used.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This is the recommended version of TLS to use with secure connections.

dwOptions

A value which specifies one or options. This member is constructed by using a bitwise operator with any of the following values:

Constant	Description
CREDENTIAL_STORE_CURRENT_USER	The library will attempt to open a store for the current user using the certificate store name provided in this structure. If no options are specified, then this is the default behavior.
CREDENTIAL_STORE_LOCAL_MACHINE	The library will attempt to open a local machine store using the certificate store name provided in this structure. If this option is specified, the library will always search for a local machine store before searching for the store by that name for the current user.
CREDENTIAL_STORE_FILENAME	The certificate store name is a file that contains the certificate and private key that

will be used.

dwReserved

This structure member is reserved for future use and should always be initialized to zero.

lpszHostName

A pointer to a null terminated string which specifies the hostname that will be used when validating the server certificate. If this member is NULL, then the server certificate will be validated against the hostname used to establish the connection.

lpszUserName

A pointer to a null terminated string which identifies the owner of client certificate. Currently this member is not used by the library and should always be initialized as a NULL pointer.

lpszPassword

A pointer to a null terminated string which specifies the password needed to access the certificate. Currently this member is only used if the CREDENTIAL_STORE_FILENAME option has been specified. If there is no password associated with the certificate, then this member should be initialized as a NULL pointer.

lpszCertStore

A pointer to a null terminated string which specifies the name of the certificate store to open. A certificate store is a collection of certificates and their private keys, typically organized by how they are used. If this value is NULL or points to an empty string, the default certificate store "MY" will be used.

Store Name	Description
------------	-------------

CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as VeriSign and Thawte act as certification authorities.
----	---

MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. This corresponds to the "Personal" store that is displayed by the certificate manager utility and is the default store used by the library.
----	--

ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as VeriSign and Thawte are installed as part of the operating system and periodically updated by Microsoft.
------	--

lpszCertName

A pointer to a null terminated string which specifies the name of the certificate to use. The library will first search the certificate store for a certificate with a matching "friendly name"; this is a name for the certificate that is assigned by the user. Note that the name must match completely, but the comparison is not case sensitive. If no matching certificate is found, the library will then attempt to find a certificate that has a matching common name (also called the certificate subject). This comparison is less stringent, and the first partial match will be returned. If this second search fails, the library will return an error indicating that the certificate could not be found. If the SECURITY_PROTOCOL_SSH protocol has been specified, this member should be NULL.

lpszKeyFile

A pointer to a null terminated string which specifies the name of the file which contains the private key required to establish the connection. This member is only used for SSH connections

and should always be NULL when establishing a secure connection using SSL or TLS.

Remarks

A client application only needs to create this structure if the server requires that the client provide a certificate as part of the process of negotiating the secure session. If a certificate is required, note that it must have a private key associated with it. Attempting to use a certificate that does not have a private key will result in an error during the connection process indicating that the client credentials could not be established.

If you are using a local certificate store, with the certificate and private key stored in the registry, you can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU:" for the current user, or "HKLM:" for the local machine. For example, a certificate store name of "HKLM:MY" would specify the personal certificate store for the local machine, rather than the current user. If neither prefix is specified, then it will default to the certificate store for the current user. You can manage these certificates using the CertMgr.msc Microsoft Management Console (MMC) snap-in.

It is possible to load the certificate from a file rather than from current user's certificate store. The *dwOptions* member should be set to CREDENTIAL_STORE_FILENAME and the *lpzCertStore* member should specify the name of the file that contains the certificate and its private key. The file must be in Private Information Exchange (PFX) format, also known as PKCS#12. These certificate files typically have an extension of .pfx or .p12. Note that if a password was specified when the certificate file was created, it must be provided in the *lpzPassword* member or the library will be unable to access the certificate.

Note that the *lpzUserName* and *lpzPassword* members are values which are used to access the certificate store or private key file. They are not the credentials which are used when establishing the connection with the remote host or authenticating the client session.

The TLS 1.1 and TLS 1.2 protocols are only supported on Windows 7, Windows Server 2008 R2 and later versions of the platform. If these options are specified and the application is running on Windows XP or Windows Vista, the protocol version will be downgraded to TLS 1.0 for backwards compatibility with those platforms.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include ctools10.h

Unicode: Implemented as Unicode and ANSI versions.

SECURITYINFO Structure

This structure contains information about a secure connection that has been established.

```
typedef struct _SECURITYINFO
{
    DWORD        dwSize;
    DWORD        dwProtocol;
    DWORD        dwCipher;
    DWORD        dwCipherStrength;
    DWORD        dwHash;
    DWORD        dwHashStrength;
    DWORD        dwKeyExchange;
    DWORD        dwCertStatus;
    SYSTEMTIME   stCertIssued;
    SYSTEMTIME   stCertExpires;
    LPCTSTR      lpszCertIssuer;
    LPCTSTR      lpszCertSubject;
    LPCTSTR      lpszFingerprint;
} SECURITYINFO, *LPSECURITYINFO;
```

Members

dwSize

Specifies the size of the data structure. This member must always be initialized to **sizeof(SECURITYINFO)** prior to passing the address of this structure to the function. Note that if this member is not initialized, an error will be returned indicating that an invalid parameter has been passed to the function.

dwProtocol

A numeric value which specifies the protocol that was selected to establish the secure connection. One of the following values will be returned:

Constant	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_SSL	Either SSL 2.0 or SSL 3.0 should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, TLS will be excluded from the list of supported protocols. Both SSL 2.0 and 3.0 have been deprecated and will never be used unless explicitly specified. It is not recommended that you enable either of these protocols for secure connections because it will cause most servers to reject your connection request, even if a version of TLS is also specified.
SECURITY_PROTOCOL_TLS	Either the TLS 1.0, 1.1 or 1.2 protocol should be used when establishing a secure connection. The

	<p>correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers that reject any attempt to use the older SSL protocol and require that only TLS be used.</p>
SECURITY_PROTOCOL_TLS10	<p>The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.</p>
SECURITY_PROTOCOL_TLS11	<p>The TLS 1.1 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.</p>
SECURITY_PROTOCOL_TLS12	<p>The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This is the recommended version of TLS to use with secure connections.</p>

dwCipher

A numeric value which specifies the cipher that was selected when establishing the secure connection. One of the following values will be returned:

Constant	Description
SECURITY_CIPHER_RC2	The RC2 block cipher was selected. This is a variable key length cipher which supports keys between 40 and 128 bits, in 8-bit increments.
SECURITY_CIPHER_RC4	The RC4 stream cipher was selected. This is a variable key length cipher which supports keys between 40 and 128 bits, in 8-bit increments.
SECURITY_CIPHER_RC5	The RC5 block cipher was selected. This is a variable key length cipher which supports keys up to 2040 bits, in 8-bit increments.
SECURITY_CIPHER_DES	The DES (Data Encryption Standard) block cipher was selected. This is a fixed key length cipher, using 56-bit

	keys.
SECURITY_CIPHER_DES3	The Triple DES block cipher was selected. This cipher encrypts the data three times using different keys, effectively providing a 168-bit length key.
SECURITY_CIPHER_DESX	A variant of the DES block cipher which XORs an extra 64-bits of the key before and after the plaintext has been encrypted, increasing the key size to 184 bits.
SECURITY_CIPHER_AES	The Advanced Encryption Standard cipher (also known as the Rijndael cipher) is a fixed block size cipher which use a key size of 128, 192 or 256 bits. This cipher is supported on Windows XP SP3 and later versions of the operating system.
SECURITY_CIPHER_SKIPJACK	The Skipjack block cipher was selected. This is a fixed key length cipher, using 80-bit keys.
SECURITY_CIPHER_BLOWFISH	The Blowfish block cipher was selected. This is a variable key length cipher up to 448 bits, using a 64-bit block size.

dwCipherStrength

A numeric value which specifies the strength (the length of the cipher key in bits) of the cipher that was selected. Typically this value will be 128 or 256. 40-bit and 56-bit key lengths are considered weak encryption, and subject to brute force attacks. 128-bit and 256-bit key lengths are considered to be secure, and are the recommended key length for secure communications.

dwHash

A numeric value which specifies the hash algorithm which was selected. One of the following values will be returned:

Constant	Description
SECURITY_HASH_MD5	The MD5 algorithm was selected. Its use has been deprecated and is no longer considered to be cryptographically secure.
SECURITY_HASH_SHA1	The SHA-1 algorithm was selected. Its use has been deprecated and is no longer considered to be cryptographically secure.
SECURITY_HASH_SHA256	The SHA-256 algorithm was selected.
SECURITY_HASH_SHA384	The SHA-384 algorithm was selected.
SECURITY_HASH_SHA512	The SHA-512 algorithm was selected.

dwHashStrength

A numeric value which specifies the strength (the length in bits) of the message digest that was selected.

dwKeyExchange

A numeric value which specifies the key exchange algorithm which was selected. One of the following values will be returned:

--	--

Constant	Description
SECURITY_KEYEX_RSA	The RSA public key algorithm was selected.
SECURITY_KEYEX_KEA	The Key Exchange Algorithm (KEA) was selected. This is an improved version of the Diffie-Hellman public key algorithm.
SECURITY_KEYEX_DH	The Diffie-Hellman key exchange algorithm was selected.
SECURITY_KEYEX_ECDH	The Elliptic Curve Diffie-Hellman key exchange algorithm was selected. This is a variant of the Diffie-Hellman algorithm which uses elliptic curve cryptography. This key exchange algorithm is only supported on Windows XP SP3 and later versions of the operating system.

dwCertStatus

A numeric value which specifies the status of the certificate returned by the secure server. This member only has meaning for connections using the SSL or TLS protocols. One of the following values will be returned:

Constant	Description
SECURITY_CERTIFICATE_VALID	The certificate is valid.
SECURITY_CERTIFICATE_NOMATCH	The certificate is valid, but the domain name does not match the common name in the certificate.
SECURITY_CERTIFICATE_EXPIRED	The certificate is valid, but has expired.
SECURITY_CERTIFICATE_REVOKED	The certificate has been revoked and is no longer valid.
SECURITY_CERTIFICATE_UNTRUSTED	The certificate or certificate authority is not trusted on the local system.
SECURITY_CERTIFICATE_INVALID	The certificate is invalid. This typically indicates that the internal structure of the certificate has been damaged.

stCertIssued

A structure which contains the date and time that the certificate was issued by the certificate authority. If the issue date cannot be determined for the certificate, the SYSTEMTIME structure members will have zero values. This member only has meaning for connections using the SSL or TLS protocols.

stCertExpires

A structure which contains the date and time that the certificate expires. If the expiration date cannot be determined for the certificate, the SYSTEMTIME structure members will have zero values. This member only has meaning for connections using the SSL or TLS protocols.

lpszCertIssuer

A pointer to a string which contains information about the organization that issued the certificate. This string consists of one or more comma-separated tokens. Each token consists of an identifier, followed by an equal sign and a value. If the certificate issuer could not be determined, this member may be NULL. This member only has meaning for connections using the SSL or TLS protocols.

lpszCertSubject

A pointer to a string which contains information about the organization that the certificate was issued to. This string consists of one or more comma-separated tokens. Each token consists of an identifier, followed by an equal sign and a value. If the certificate subject could not be determined, this member may be NULL. This member only has meaning for connections using the SSL or TLS protocols.

lpszFingerprint

A pointer to a string which contains a sequence of hexadecimal values that uniquely identify the server. This member is only used when a connection has been established using the Secure Shell (SSH) protocol.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Unicode: Implemented as Unicode and ANSI versions.

SYSTEMTIME Structure

The **SYSTEMTIME** structure represents a date and time using individual members for the month, day, year, weekday, hour, minute, second, and millisecond.

```
typedef struct _SYSTEMTIME
{
    WORD wYear;
    WORD wMonth;
    WORD wDayOfWeek;
    WORD wDay;
    WORD wHour;
    WORD wMinute;
    WORD wSecond;
    WORD wMilliseconds;
} SYSTEMTIME, *LPSYSTEMTIME;
```

Members

wYear

Specifies the current year. The year value must be greater than 1601.

wMonth

Specifies the current month. January is 1, February is 2 and so on.

wDayOfWeek

Specifies the current day of the week. Sunday is 0, Monday is 1 and so on.

wDay

Specifies the current day of the month

wHour

Specifies the current hour.

wMinute

Specifies the current minute

wSecond

Specifies the current second.

wMilliseconds

Specifies the current millisecond.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include windows.h.

Remote Command Protocol Library

Execute commands on a server or establish an interactive terminal session.

Reference

- [Functions](#)
- [Data Structures](#)
- [Error Codes](#)

Library Information

File Name	CSRSHV10.DLL
Version	10.0.1468.2518
LibID	4893754D-AF7A-4892-9320-D829EEC98DD6
Import Library	CSRSHV10.LIB
Dependencies	None
Standards	RFC 1282

Overview

The Remote Command protocol is used to execute a command on a server and return the output of that command to the client. This is most commonly used with UNIX based servers, although there are implementations of remote command servers for the Windows operating system. The library supports both the rcmd and rshell remote execution protocols and provides methods which can be used to search the data stream for specific sequences of characters. This makes it extremely easy to write Windows applications which serve as light-weight client interfaces to commands being executed on a UNIX server or another Windows system. The library can also be used to establish a remote terminal session using the rlogin protocol, which is similar to the Telnet protocol.

This library should not be used when connecting to a server over the Internet because the user credentials are sent as unencrypted text. For secure remote command execution and interactive terminal sessions, it is recommended that you use the SocketTools Secure Shell (SSH) library instead.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). If you are using Visual C++ 6.0 it is required that you have Service Pack 6 (SP6) installed. You should install all updates for your development tools and have the current Windows SDK installed. The minimum recommended version of Visual Studio is Visual Studio 2010.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are using Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. It is recommended that you install the current service pack and all critical updates available for your version of the operating system.

This product includes both 32-bit and 64-bit libraries. Native 64-bit CPU support requires the 64-bit version of Windows 7 or later versions of the Windows operating system.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

Remote Command Protocol Functions

Function	Description
RshAsyncExecute	Execute a command on the specified server
RshAsyncLogin	Establish an asynchronous login session with the specified server
RshAttachThread	Attach the specified client handle to another thread
RshCancel	Cancel the current blocking operation
RshDisableEvents	Disable asynchronous event notification
RshDisableTrace	Disable logging of socket function calls to the trace log
RshDisconnect	Disconnect from the current server
RshEnableEvents	Enable asynchronous event notification
RshEnableTrace	Enable logging of socket function calls to a file
RshEventProc	Callback function that processes events generated by the client
RshExecute	Execute a command on the server
RshFreezeEvents	Suspend asynchronous event processing
RshGetErrorString	Return a description for the specified error code
RshGetLastError	Return the last error code
RshGetStatus	Return the current client status
RshGetTimeout	Return the number of seconds until an operation times out
RshInitialize	Initialize the library and validate the specified license key at runtime
RshIsBlocking	Determine if the client is blocked, waiting for information
RshIsConnected	Determine if the client is connected to the server
RshIsReadable	Determine if data can be read from the server
RshIsWritable	Determine if data can be written to the server
RshLogin	Establish a login session with the specified server
RshRead	Read data returned by the server
RshRegisterEvent	Register an event callback function
RshSearch	Search for a specific character sequence in the data stream
RshSetLastError	Set the last error code
RshSetTimeout	Set the number of seconds until an operation times out
RshUninitialize	Terminate use of the library by the application
RshWrite	Write data to the server

RshAsyncExecute Function

```
HCLIENT WINAPI RshAsyncExecute(  
    LPCTSTR lpszRemoteHost,  
    UINT nRemotePort,  
    UINT nTimeout,  
    DWORD dwOptions,  
    LPCTSTR lpszUserName,  
    LPCTSTR lpszPassword,  
    LPCTSTR lpszCommand,  
    HWND hEventWnd,  
    UINT uEventMsg  
);
```

The **RshAsyncExecute** function is used to establish a connection with the server and execute the specified command.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

The application should create a background worker thread and establish a connection by calling **RshExecute** within that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each client session.

Parameters

lpszRemoteHost

A pointer to the name of the server to connect to; this may be a fully-qualified domain name or an IP address.

nRemotePort

The port number the server is listening on. One of the following values should be used:

Constant	Description
RSH_PORT_REXEC	A connection is established with the server using port 512, the rexec service. This service requires that the client provide a username and password to execute the specified command.
RSH_PORT_RSHELL	A connection is established with the server using port 514, the rshell service. This service uses host equivalence to authenticate the user. With host equivalence, the server considers the client to be equivalent to itself, and as long as the specified user exists on the server, the client is permitted to execute commands on behalf of the user without requiring a password. Host equivalence is configured by the server administrator.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
RSH_OPTION_RESERVEDPORT	This option specifies that a reserved port should be used to establish the connection. Reserved ports are those port numbers which are less than 1024. This option should be specified when connecting on the RSH_PORT_RSHELL port.
RSH_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
RSH_OPTION_FREETHREAD	This option specifies the handle returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the handle is synchronized across multiple threads.

lpszUserName

A pointer to a string which specifies the username used to authenticate the client session.

lpszPassword

A pointer to a string which specifies the password used to authenticate the client session. This parameter is only used when connecting to the RSH_PORT_REXEC port. If the password is not required, this parameter may be NULL.

lpszCommand

A pointer to a string which specifies the command to execute on the server.

hEventWnd

The handle to the event notification window. This window receives messages which notify the client of various asynchronous network events that occur. If this parameter is NULL, then a synchronous (blocking) connection will be established with the server.

uEventMsg

The message identifier that is used when an asynchronous network event occurs. This value should be greater than WM_USER as defined in the Windows header files. If the *hEventWnd* parameter is NULL, this parameter should be specified as WM_NULL.

Return Value

If the function succeeds, the return value is a handle to a client session. If the function fails, the return value is INVALID_CLIENT. To get extended error information, call **RshGetLastError**.

Remarks

When a message is posted to the notification window, the low word of the *lParam* parameter contains the event identifier. The high word of *lParam* contains the low word of the error code, if an error has occurred. The *wParam* parameter contains the client handle. One or more of the

following event identifiers may be sent:

Constant	Description
RSH_EVENT_CONNECT	The connection to the server has completed. The high word of the <i>lParam</i> parameter should be checked, since this notification message will be posted if an error has occurred.
RSH_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
RSH_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
RSH_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
RSH_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
RSH_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and reconnect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.

To cancel asynchronous notification and return the client to a blocking mode, use the **RshDisableEvents** function.

It is recommended that you only establish an asynchronous connection if you understand the implications of doing so. In most cases, it is preferable to create a synchronous connection and create threads for each additional session if more than one active client session is required.

The *dwOptions* argument can be used to specify the threading model that is used by the library when a connection is established. By default, the handle is initially attached to the thread that created it. From that point on, until the it is released, only the owner may call functions using that handle. The ownership of the handle may be transferred from one thread to another using the **RshAttachThread** function.

Specifying the RSH_OPTION_FREETHREAD option enables any thread to call any function using the handle, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the handle is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same handle.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csrshv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[RshAsyncLogin](#), [RshDisconnect](#), [RshExecute](#), [RshInitialize](#), [RshLogin](#), [RshUninitialize](#)

RshAsyncLogin Function

```
HCLIENT WINAPI RshAsyncLogin(  
    LPCTSTR lpszRemoteHost,  
    UINT nRemotePort,  
    UINT nTimeout,  
    DWORD dwReserved,  
    LPCTSTR lpszUserName,  
    LPCTSTR lpszTerminal,  
    HWND hEventWnd,  
    UINT uEventMsg  
);
```

The **RshAsyncLogin** function is used to establish a terminal session with the server.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

The application should create a background worker thread and establish a connection by calling **RshLogin** within that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each client session.

Parameters

lpszRemoteHost

A pointer to the name of the server to connect to; this may be a fully-qualified domain name or an IP address.

nRemotePort

The port number the server is listening on. A value of zero specifies that the default port should be used.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwReserved

A reserved parameter. This value should always be zero.

lpszUserName

A pointer to a string which specifies the username used to authenticate the client session.

lpszTerminal

A pointer to a string which specifies the terminal type which the client will be identified as using during the session. If no particular terminal emulation is required, this parameter may be NULL.

hEventWnd

The handle to the event notification window. This window receives messages which notify the client of various asynchronous network events that occur. If this parameter is NULL, then a synchronous (blocking) connection will be established with the server.

uEventMsg

The message identifier that is used when an asynchronous network event occurs. This value should be greater than WM_USER as defined in the Windows header files. If the *hEventWnd*

parameter is NULL, this parameter should be specified as WM_NULL.

Return Value

If the function succeeds, the return value is a handle to a client session. If the function fails, the return value is INVALID_CLIENT. To get extended error information, call **RshGetLastError**.

Remarks

The **RshAsyncLogin** function uses host equivalence, where the client is permitted to login without requiring a password. Host equivalence must be configured by the server administrator and it is typically restricted to specific users. Note that if configured improperly, host equivalence can introduce a significant security loophole. Refer to your UNIX system documentation for more information about host equivalence and the various remote command services.

On UNIX based systems, the terminal name specified by the *lpszTerminal* parameter corresponds to a termcap or terminfo entry as set in the TERM environment variable. On Windows based systems which implement the rlogin service, this parameter may be ignored and the server will assume that the client is capable of displaying ANSI escape sequences. On VMS systems, the terminal name should correspond to the terminal type used with the SET TERMINAL/DEVICE command.

If this parameter is passed as NULL pointer or an empty string, a default terminal type named "unknown" will be used. On most UNIX and VMS systems this defines a terminal which is not capable of cursor positioning using control or escape sequences. This terminal type may not be recognized and an error may be displayed when the user logs in indicating that the terminal type is invalid.

Refer to the documentation for the server system to determine what terminal type names are available to you. Remember that on UNIX systems, the terminal type is case-sensitive. Some of the more common terminal types are:

Terminal Type	Description
ansi	This terminal type is usually available on UNIX based servers. This specifies that the client is capable of displaying standard ANSI escape sequences for cursor control.
dumb	This terminal type typically specifies a terminal display which does not support control or escape sequences for cursor positioning. If you do not want escape sequences embedded in the data stream and the server returns an error if the terminal type is not specified, try using this terminal type.
pcansi	This terminal type is usually available on UNIX based servers. This specifies that the client is using a PC terminal emulator that supports basic ANSI escape sequences for cursor control. This may also enable escape sequences which can set the display colors.
vt100	This terminal type is usually available on UNIX and VMS based servers. On some VMS systems this string may need to be specified as DEC-VT100. This specifies that the client is capable of emulating a DEC VT100 terminal. The VT100 supports many of the same cursor control sequences as an ANSI terminal.
vt220	This terminal type is usually available on UNIX and VMS based servers. On some VMS systems this string may need to be specified as DEC-

	VT220. This specifies that the client is capable of emulating a DEC VT220 terminal, which is a later version of the VT100.
vt320	This terminal type is usually available on UNIX and VMS based servers. On some VMS systems this string may need to be specified as DEC-VT320. This specifies that the client is capable of emulating a DEC VT320 terminal, which is similar to the VT100 and VT220 and provides advanced features such as the ability to set display colors.
xterm	This terminal type is may be available on UNIX based servers which have X Windows installed. This specifies that the client is a using the X Windows xterm emulator which supports standard ANSI escape sequences for cursor control.

When a message is posted to the notification window, the low word of the *lParam* parameter contains the event identifier. The high word of *lParam* contains the low word of the error code, if an error has occurred. The *wParam* parameter contains the client handle. One or more of the following event identifiers may be sent:

Constant	Description
RSH_EVENT_CONNECT	The connection to the server has completed. The high word of the <i>lParam</i> parameter should be checked, since this notification message will be posted if an error has occurred.
RSH_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
RSH_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
RSH_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
RSH_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
RSH_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.

To cancel asynchronous notification and return the client to a blocking mode, use the **RshDisableEvents** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csrshv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[RshAsyncExecute](#), [RshDisconnect](#), [RshExecute](#), [RshInitialize](#), [RshLogin](#), [RshUninitialize](#)

RshAttachThread Function

```
DWORD WINAPI RshAttachThread(  
    HCLIENT hClient  
    DWORD dwThreadId  
);
```

The **RshAttachThread** function attaches the specified client handle to another thread.

Parameters

hClient

Handle to the client session.

dwThreadId

The ID of the thread that will become the new owner of the handle. A value of zero specifies that the current thread should become the owner of the client handle.

Return Value

If the function succeeds, the return value is the thread ID of the previous owner. If the function fails, the return value is RSH_ERROR. To get extended error information, call **RshGetLastError**.

Remarks

When a client handle is created, it is associated with the current thread that created it. Normally, if another thread attempts to perform an operation using that handle, an error is returned since it does not own the handle. This is used to ensure that other threads cannot interfere with an operation being performed by the owner thread. In some cases, it may be desirable for one thread in a client application to create the client handle, and then pass that handle to another worker thread. The **RshAttachThread** function can be used to change the ownership of the handle to the new worker thread. By preserving the return value from the function, the original owner of the handle can be restored before the worker thread terminates.

This function should be called by the new thread immediately after it has been created, and if the new thread does not release the handle itself, the ownership of the handle should be restored to the parent thread before it terminates. Under no circumstances should **RshAttachThread** be used to forcibly release a handle allocated by another thread while a blocking operation is in progress. To cancel an operation, use the **RshCancel** function and then release the handle after the blocking function exits and control is returned to the current thread.

Note that the *dwThreadId* parameter is presumed to be a valid thread ID and no checks are performed to ensure that the thread actually exists. Specifying an invalid thread ID will orphan the handle until the **RshUninitialize** function is called.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csrshv10.lib

RshCancel Function

```
INT WINAPI RshCancel(  
    HCLIENT hClient  
);
```

The **RshCancel** function cancels any outstanding blocking operation in the client, causing the blocking function to fail. The application may then retry the operation or terminate the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero.

If the function fails, the return value is RSH_ERROR. To get extended error information, call **RshGetLastError**.

Remarks

When the **RshCancel** function is called, the blocking function will not immediately fail. An internal flag is set which causes the blocking operation to exit with an error. This means that the application cannot cancel an operation and immediately perform some other operation. Instead it must allow the calling stack to unwind, returning back to the blocking operation before making any further function calls.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csrshv10.lib

Unicode: Implemented as Unicode and ANSI versions.

RshDisableEvents Function

```
INT WINAPI RshDisableEvents(  
    HCLIENT hClient  
);
```

The **RshDisableEvents** function disables the event notification mechanism, preventing subsequent event notification messages from being posted to the application's message queue.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is RSH_ERROR. To get extended error information, call **RshGetLastError**.

Remarks

This function affects both event notification and event callbacks. Any outstanding events in the message queue should be ignored by the client application.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

RshDisableTrace Function

```
BOOL WINAPI RshDisableTrace();
```

The **RshDisableTrace** function disables the logging of socket function calls to the trace log file.

Parameters

None.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csrshv10.lib

See Also

[RshEnableTrace](#)

RshDisconnect Function

```
INT WINAPI RshDisconnect(  
    HCLIENT hClient  
);
```

The **RshDisconnect** function terminates the connection with the server, closing the socket and releasing the memory allocated for the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is RSH_ERROR. To get extended error information, call **RshGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csrshv10.lib

[RshAsyncExecute](#), [RshAsyncLogin](#), [RshExecute](#), [RshInitialize](#), [RshLogin](#), [RshUninitialize](#)

RshEnableEvents Function

```
INT WINAPI RshEnableEvents(  
    HCLIENT hClient,  
    HWND hEventWnd,  
    UINT uEventMsg  
);
```

The **RshEnableEvents** function enables event notifications using Windows messages.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Applications should use the **RshRegisterEvent** function to register an event handler which is invoked when an event occurs.

Parameters

hClient

Handle to the client session.

hEventWnd

Handle to the event notification window. This window receives a user-defined message which specifies the event that has occurred. If this value is NULL, event notification is disabled.

uEventMsg

An unsigned integer which specifies the user-defined message that is sent when an event occurs. This parameter's value must be greater than the value of WM_USER.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is RSH_ERROR. To get extended error information, call **RshGetLastError**.

Remarks

When a message is posted to the notification window, the low word of the *lParam* parameter contains the event identifier. The high word of *lParam* contains the low word of the error code, if an error has occurred. The *wParam* parameter contains the client handle. One or more of the following event identifiers may be sent:

Constant	Description
RSH_EVENT_CONNECT	The connection to the server has completed. The high word of the <i>lParam</i> parameter should be checked, since this notification message will be posted if an error has occurred.
RSH_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
RSH_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
RSH_EVENT_WRITE	The client can now write data. This notification is sent after a

	connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
RSH_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
RSH_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and reconnect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.

To cancel asynchronous notification and return the client to a blocking mode, use the **RshDisableEvents** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csrshv10.lib

See Also

[RshDisableEvents](#), [RshFreezeEvents](#), [RshRegisterEvent](#)

RshEnableTrace Function

```
BOOL WINAPI RshEnableTrace(  
    LPCTSTR lpszTraceFile,  
    DWORD dwTraceFlags  
);
```

The **RshEnableTrace** function enables the logging of socket function calls to a file.

Parameters

lpszTraceFile

A pointer to a string which specifies the name of the trace log file. If this parameter is NULL or an empty string, the default file name **cstrace.log** is used. The file is stored in the directory specified by the TEMP environment variable, if it is defined; otherwise, the current working directory is used.

dwTraceFlags

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
TRACE_INFO	All function calls are written to the trace file. This is the default value.
TRACE_ERROR	Only those function calls which fail are recorded in the trace file.
TRACE_WARNING	Only those function calls which fail or return values which indicate a warning are recorded in the trace file.
TRACE_HEXDUMP	All functions calls are written to the trace file, plus all the data that is sent or received is displayed, in both ASCII and hexadecimal format.
TRACE_PROCESS	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for multithreaded applications that are using worker threads.

Return Value

If the function succeeds, the return value is non-zero. A return value of zero indicates an error. Failure typically indicates that the tracing library **cstrcv10.dll** cannot be loaded on the local system.

Remarks

When trace logging is enabled, the file is opened, appended to and closed for each socket function call. This makes it possible for an application to append its own logging information, however care should be taken to ensure that the file is closed before the next network operation is performed. To limit the size of the log files, enable and disable logging only around those sections of code that you wish to trace.

Note that the TRACE_HEXDUMP trace level generates very large log files since it includes all of the data exchanged between your application and the server.

Trace function logging is managed on a per-thread basis, not for each client handle. This means that all SocketTools libraries and components share the same settings in the current thread. If you

are using multiple SocketTools libraries or components in your application, you only need to enable logging once.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csrshv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[RshDisableTrace](#)

RshEventProc Function

```
VOID CALLBACK RshEventProc(  
    HCLIENT hClient,  
    UINT nEventId,  
    DWORD dwError,  
    DWORD_PTR dwParam  
);
```

The **RshEventProc** function is an application-defined callback function that processes events generated by the calling process.

Parameters

hClient

The handle to the client session.

nEvent

An unsigned integer which specifies which event occurred. For a complete list of events, refer to the **RshRegisterEvent** function.

dwError

An unsigned integer which specifies any error that occurred. If no error occurred, then this parameter will be zero.

dwParam

A user-defined integer value which was specified when the event callback was registered.

Return Value

None.

Remarks

An application must register this callback function by passing its address to the **RshRegisterEvent** function. The **RshEventProc** function is a placeholder for the application-defined function name.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csrshv10.lib

See Also

[RshDisableEvents](#), [RshEnableEvents](#), [RshFreezeEvents](#), [RshRegisterEvent](#)

RshExecute Function

```
HCLIENT WINAPI RshExecute(  
    LPCTSTR lpszRemoteHost,  
    UINT nRemotePort,  
    UINT nTimeout,  
    DWORD dwOptions,  
    LPCTSTR lpszUserName,  
    LPCTSTR lpszPassword,  
    LPCTSTR lpszCommand  
);
```

The **RshExecute** function is used to establish a connection with the server and execute the specified command.

Parameters

lpszRemoteHost

A pointer to the name of the server to connect to; this may be a fully-qualified domain name or an IP address.

nRemotePort

The port number the server is listening on. One of the following values should be used:

Constant	Description
RSH_PORT_REXEC	A connection is established with the server using port 512, the rexec service. This service requires that the client provide a username and password to execute the specified command.
RSH_PORT_RSHELL	A connection is established with the server using port 514, the rshell service. This service uses host equivalence to authenticate the user. With host equivalence, the server considers the client to be equivalent to itself, and as long as the specified user exists on the server, the client is permitted to execute commands on behalf of the user without requiring a password. Host equivalence is configured by the server administrator.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
RSH_OPTION_RESERVEDPORT	This option specifies that a reserved port should be used to establish the connection. Reserved ports are those port numbers which are less than 1024. This option should be specified when connecting on the RSH_PORT_RSHELL port.
RSH_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both

	an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
RSH_OPTION_FREETHREAD	This option specifies the handle returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the handle is synchronized across multiple threads.

lpszUserName

A pointer to a string which specifies the username used to authenticate the client session.

lpszPassword

A pointer to a string which specifies the password used to authenticate the client session. This parameter is only used when connecting to the RSH_PORT_REXEC port. If the password is not required, this parameter may be NULL.

lpszCommand

A pointer to a string which specifies the command to execute on the server.

Return Value

If the function succeeds, the return value is a handle to a client session. If the function fails, the return value is INVALID_CLIENT. To get extended error information, call **RshGetLastError**.

Remarks

To prevent this function from blocking the main user interface thread, the application should create a background worker thread and establish a connection by calling **RshExecute** in that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each client session.

The *dwOptions* argument can be used to specify the threading model that is used by the library when a connection is established. By default, the handle is initially attached to the thread that created it. From that point on, until the it is released, only the owner may call functions using that handle. The ownership of the handle may be transferred from one thread to another using the **RshAttachThread** function.

Specifying the RSH_OPTION_FREETHREAD option enables any thread to call any function using the handle, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the handle is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same handle.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csrshv10.lib

Unicode: Implemented as Unicode and ANSI versions.

RshFreezeEvents Function

```
INT WINAPI RshFreezeEvents(  
    HCLIENT hClient,  
    BOOL bFreeze  
);
```

The **RshFreezeEvents** function is used to suspend and resume event handling by the client.

Parameters

hClient

Handle to the client session.

bFreeze

A non-zero value specifies that event handling should be suspended by the client. A zero value specifies that event handling should be resumed.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is RSH_ERROR. To get extended error information, call **RshGetLastError**.

Remarks

This function should be used when the application does not want to process events, such as when a modal dialog is being displayed. When events are suspended, all client events are queued. If events are re-enabled at a later point, those queued events will be sent to the application for processing. Note that only one of each event will be generated. For example, if the client has suspended event handling, and four read events occur, once event handling is resumed only one of those read events will be posted to the client. This prevents the application from being flooded by a potentially large number of queued events.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csrshv10.lib

See Also

RshGetErrorString Function

```
INT WINAPI RshGetErrorString(  
    DWORD dwErrorCode,  
    LPTSTR lpszDescription,  
    INT cbDescription  
);
```

The **RshGetErrorString** function is used to return a description of a specific error code. Typically this is used in conjunction with the **RshGetLastError** function for use with warning dialogs or as diagnostic messages.

Parameters

dwErrorCode

The last-error code for which a description is returned.

lpszDescription

A pointer to the buffer that will contain a description of the specified error code. This buffer should be at least 128 characters in length.

cbDescription

The maximum number of characters that may be copied into the description buffer.

Return Value

If the function succeeds, the return value is the length of the description string. If the function fails, the return value is zero, meaning that no description exists for the specified error code. Typically this indicates that the error code passed to the function is invalid.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csrshv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

See Also

[RshGetLastError](#), [RshSetLastError](#)

RshGetLastError Function

```
DWORD WINAPI RshGetLastError();
```

Parameters

None.

Return Value

The return value is the last error code value for the current thread. Functions set this value by calling the **RshSetLastError** function. The Return Value section of each reference page notes the conditions under which the function sets the last error code.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. You should call the **RshGetLastError** function immediately when a function's return value indicates that an error has occurred. That is because some functions call **RshSetLastError(0)** when they succeed, clearing the error code set by the most recently failed function.

Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or RSH_ERROR. Those functions which call **RshSetLastError** when they succeed are noted on the function reference page.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csrshv10.lib

See Also

[RshGetErrorString](#), [RshSetLastError](#)

RshGetStatus Function

```
INT WINAPI RshGetStatus(  
    HCLIENT hClient  
);
```

The **RshGetStatus** function returns the current status of the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the client status code. If the function fails, the return value is RSH_ERROR. To get extended error information, call **RshGetLastError**.

Remarks

The **RshGetStatus** function returns a numeric code which identifies the current state of the client session. The following values may be returned:

Value	Constant	Description
1	RSH_STATUS_IDLE	The client is current idle and not sending or receiving data.
2	RSH_STATUS_CONNECT	The client is establishing a connection with the server.
3	RSH_STATUS_READ	The client is reading data from the server.
4	RSH_STATUS_WRITE	The client is writing data to the server.
5	RSH_STATUS_DISCONNECT	The client is disconnecting from the server.

In a multithreaded application, any thread in the current process may call this function to obtain status information for the specified client session.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csrshv10.lib

See Also

[RshIsBlocking](#), [RshIsConnected](#), [RshIsReadable](#)

RshGetTimeout Function

```
INT WINAPI RshGetTimeout(  
    HCLIENT hClient  
);
```

The **RshGetTimeout** function returns the number of seconds the client will wait for a response from the server. Once the specified number of seconds has elapsed, the function will fail and return to the caller.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the timeout period in seconds. If the function fails, the return value is RSH_ERROR. To get extended error information, call **RshGetLastError**.

Remarks

The timeout value is only used with blocking client connections. A value of zero indicates that the default timeout period of 20 seconds should be used.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csrshv10.lib

See Also

[RshSetTimeout](#)

RshInitialize Function

```
BOOL WINAPI RshInitialize(  
    LPCTSTR lpszLicenseKey,  
    LPINITDATA lpData  
);
```

The **RshInitialize** function initializes the library and validates the specified license key at runtime.

Parameters

lpszLicenseKey

Pointer to a string that specifies the runtime license key to be validated. If this parameter is NULL, the library will validate the development license installed on the local system.

lpData

Pointer to an INITDATA data structure. This parameter may be NULL if the initialization data for the library is not required.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **RshGetLastError**. All other client functions will fail until a license key has been successfully validated.

Remarks

This must be the first function that an application calls before using any of the other functions in the library. When a NULL license key is specified, the library will only function on the development system. Before redistributing the application to an end-user, you must insure that this function is called with a valid license key.

If the *lpData* argument is specified, it must point to an INITDATA structure which has been initialized by setting the *dwSize* member to the size of the structure. All other structure members should be set to zero. If the function is successful, then the INITDATA structure will be filled with identifying information about the library.

Although it is only required that **RshInitialize** be called once for the current process, it may be called multiple times; however, each call must be matched by a corresponding call to **RshUninitialize**.

This function dynamically loads other system libraries and allocates thread local storage. If you are calling the functions in this library from within another DLL, it is important that you do not call the **RshInitialize** or **RshUninitialize** functions from the **DllMain** function because it can result in deadlocks or access violation errors. If the DLL is linked with the C runtime library (CRT), it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csrshv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

RshIsBlocking Function

```
BOOL WINAPI RshIsBlocking(  
    HCLIENT hClient  
);
```

The **RshIsBlocking** function is used to determine if the client is currently performing a blocking operation.

Parameters

hClient

Handle to the client session.

Return Value

If the client is performing a blocking operation, the function returns TRUE. If the client is not performing a blocking operation, or the client handle is invalid, the function returns FALSE.

Remarks

Because a blocking operation can allow the application to be re-entered (for example, by pressing a button while the operation is being performed), it is possible that another blocking function may be called while it is in progress. Since only one thread of execution may perform a blocking operation at any one time, an error would occur. The **RshIsBlocking** function can be used to determine if the client is already blocked, and if so, take some other action (such as warning the user that they must wait for the operation to complete).

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csrshv10.lib

See Also

[RshCancel](#), [RshGetStatus](#), [RshIsConnected](#), [RshIsReadable](#)

RshIsConnected Function

```
BOOL WINAPI RshIsConnected(  
    HCLIENT hClient  
);
```

The **RshIsConnected** function is used to determine if the client is currently connected to a server.

Parameters

hClient

Handle to the client session.

Return Value

If the client is connected to a server, the function returns a non-zero value. If the client is not connected, or the client handle is invalid, the function returns zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csrshv10.lib

See Also

[RshGetStatus](#), [RshIsBlocking](#), [RshIsReadable](#), [RshIsWritable](#)

RshIsReadable Function

```
BOOL WINAPI RshIsReadable(  
    HCLIENT hClient,  
    INT nTimeout,  
    LPDWORD lpdwAvail  
);
```

The **RshIsReadable** function is used to determine if data is available to be read from the server.

Parameters

hClient

Handle to the client session.

nTimeout

Timeout for server response, in seconds. A value of zero specifies that the connection should be polled without blocking the current thread.

lpdwAvail

A pointer to an unsigned integer which will contain the number of bytes available to read. This parameter may be NULL if this information is not required.

Return Value

If the client can read data from the server within the timeout period, the function returns a non-zero value. If the client cannot read any data, the function returns zero.

Remarks

On some platforms, this value will not exceed the size of the receive buffer (typically 64K bytes). Because of differences between TCP/IP stack implementations, it is not recommended that your application exclusively depend on this value to determine the exact number of bytes available. Instead, it should be used as a general indicator that there is data available to be read.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csrshv10.lib

See Also

[RshGetStatus](#), [RshIsBlocking](#), [RshIsConnected](#), [RshIsWritable](#), [RshRead](#)

RshIsWritable Function

```
BOOL WINAPI RshIsWritable(  
    HCLIENT hClient,  
    INT nTimeout  
);
```

The **RshIsWritable** function is used to determine if data can be written to the server.

Parameters

hClient

Handle to the client session.

nTimeout

Timeout for server response, in seconds. A value of zero specifies that the connection should be polled without blocking the current thread.

Return Value

If the client can write data to the server within the specified timeout period, the function returns a non-zero value. If the client cannot write any data, the function returns zero.

Remarks

Although this function can be used to determine if some amount of data can be sent to the remote process it does not indicate the amount of data that can be written without blocking the client. In most cases, it is recommended that large amounts of data be broken into smaller logical blocks, typically some multiple of 512 bytes in length.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csrshv10.lib

See Also

[RshGetStatus](#), [RshIsBlocking](#), [RshIsConnected](#), [RshIsReadable](#), [RshWrite](#)

RshLogin Function

```
HCLIENT WINAPI RshLogin(  
    LPCTSTR lpszRemoteHost,  
    UINT nRemotePort,  
    UINT nTimeout,  
    DWORD dwReserved,  
    LPCTSTR lpszUserName,  
    LPCTSTR lpszTerminal  
);
```

The **RshLogin** function is used to establish a terminal session with the server.

Parameters

lpszRemoteHost

A pointer to the name of the server to connect to; this may be a fully-qualified domain name or an IP address.

nRemotePort

The port number the server is listening on. A value of zero specifies that the default port should be used.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwReserved

A reserved parameter. This value should always be zero.

lpszUserName

A pointer to a string which specifies the username used to authenticate the client session.

lpszTerminal

A pointer to a string which specifies the terminal type which the client will be identified as using during the session. If no particular terminal emulation is required, this parameter may be NULL.

Return Value

If the function succeeds, the return value is a handle to a client session. If the function fails, the return value is `INVALID_CLIENT`. To get extended error information, call **RshGetLastError**.

Remarks

To prevent this function from blocking the main user interface thread, the application should create a background worker thread and establish a connection by calling **RshLogin** in that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each client session.

The **RshLogin** function uses host equivalence, where the client is permitted to login without requiring a password. Host equivalence must be configured by the server administrator and it is typically restricted to specific users. Note that if configured improperly, host equivalence can introduce a significant security loophole. Refer to your UNIX system documentation for more information about host equivalence and the various remote command services. Note that if there is no host equivalence for the local host and the user account requires a password, the system will prompt for a password.

On UNIX based systems, the terminal name specified by the *lpszTerminal* parameter corresponds

to a termcap or terminfo entry as set in the TERM environment variable. On Windows based systems which implement the rlogin service, this parameter may be ignored and the server will assume that the client is capable of displaying ANSI escape sequences. On VMS systems, the terminal name should correspond to the terminal type used with the SET TERMINAL/DEVICE command.

If this parameter is passed as NULL pointer or an empty string, a default terminal type named "unknown" will be used. On most UNIX and VMS systems this defines a terminal which is not capable of cursor positioning using control or escape sequences. This terminal type may not be recognized and an error may be displayed when the user logs in indicating that the terminal type is invalid.

Refer to the documentation for the server system to determine what terminal type names are available to you. Remember that on UNIX systems, the terminal type is case-sensitive. Some of the more common terminal types are:

Terminal Type	Description
ansi	This terminal type is usually available on UNIX based servers. This specifies that the client is capable of displaying standard ANSI escape sequences for cursor control.
dumb	This terminal type typically specifies a terminal display which does not support control or escape sequences for cursor positioning. If you do not want escape sequences embedded in the data stream and the server returns an error if the terminal type is not specified, try using this terminal type.
pcansi	This terminal type is usually available on UNIX based servers. This specifies that the client is using a PC terminal emulator that supports basic ANSI escape sequences for cursor control. This may also enable escape sequences which can set the display colors.
vt100	This terminal type is usually available on UNIX and VMS based servers. On some VMS systems this string may need to be specified as DEC-VT100. This specifies that the client is capable of emulating a DEC VT100 terminal. The VT100 supports many of the same cursor control sequences as an ANSI terminal.
vt220	This terminal type is usually available on UNIX and VMS based servers. On some VMS systems this string may need to be specified as DEC-VT220. This specifies that the client is capable of emulating a DEC VT220 terminal, which is a later version of the VT100.
vt320	This terminal type is usually available on UNIX and VMS based servers. On some VMS systems this string may need to be specified as DEC-VT320. This specifies that the client is capable of emulating a DEC VT320 terminal, which is similar to the VT100 and VT220 and provides advanced features such as the ability to set display colors.
xterm	This terminal type is may be available on UNIX based servers which have X Windows installed. This specifies that the client is using the X Windows xterm emulator which supports standard ANSI escape sequences for cursor control.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csrshv10.lib

Unicode: Implemented as Unicode and ANSI versions.

RshRead Function

```
INT WINAPI RshRead(  
    HCLIENT hClient,  
    LPBYTE lpBuffer,  
    INT cbBuffer  
);
```

The **RshRead** function reads the specified number of bytes from the client socket and copies them into the buffer. The data may be of any type, and is not terminated with a null character.

Parameters

hClient

Handle to the client session.

lpBuffer

Pointer to the buffer in which the data will be copied.

cbBuffer

The maximum number of bytes to read and copy into the specified buffer. This value must be greater than zero.

Return Value

If the function succeeds, the return value is the number of bytes actually read. A return value of zero indicates that the server has closed the connection and there is no more data available to be read. If the function fails, the return value is RSH_ERROR. To get extended error information, call **RshGetLastError**.

Remarks

When **RshRead** is called and the client is in non-blocking mode, it is possible that the function will fail because there is no available data to read at that time. This should not be considered a fatal error. Instead, the application should simply wait to receive the next asynchronous notification that data is available.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csrshv10.lib

See Also

[RshIsBlocking](#), [RshIsReadable](#), [RshSearch](#), [RshWrite](#)

RshRegisterEvent Function

```
INT WINAPI RshRegisterEvent(  
    HCLIENT hClient,  
    UINT nEventId,  
    INETEVENTPROC LpfnEvent,  
    DWORD_PTR dwParam  
);
```

The **RshRegisterEvent** function registers an event handler for the specified event.

Parameters

hClient

Handle to client session.

nEventId

An unsigned integer which specifies which event should be registered with the specified callback function. One or more of the following values may be used:

Constant	Description
RSH_EVENT_CONNECT	The connection to the server has completed.
RSH_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
RSH_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
RSH_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
RSH_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
RSH_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.

lpfnEvent

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **RshEventProc** callback function. If this parameter is NULL, the callback for the specified event is disabled.

dwParam

A user-defined integer value that is passed to the callback function. If the application targets the

x86 (32-bit) platform, this parameter must be a 32-bit unsigned integer. If the application targets the x64 (64-bit) platform, this parameter must be a 64-bit unsigned integer.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is RSH_ERROR. To get extended error information, call **RshGetLastError**.

Remarks

The **RshRegisterEvent** function associates a callback function with a specific event. The event handler is an **RshEventProc** function that is invoked when the event occurs. Arguments are passed to the function to identify the client session, the event type and the user-defined value specified when the event handler is registered. If the event occurs because of an error condition, the error code will be provided to the handler.

The callback function specified by the *lpEventProc* parameter must be declared using the **__stdcall** calling convention. This ensures the arguments passed to the event handler are pushed on to the stack in the correct order. Failure to use the correct calling convention will corrupt the stack and cause the application to terminate abnormally.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csrshv10.lib

See Also

RshSearch Function

```
BOOL WINAPI RshSearch(  
    HCLIENT hClient,  
    LPCTSTR lpszString,  
    LPVOID lpvBuffer,  
    LPDWORD lpdwLength,  
    DWORD dwReserved  
);
```

The **RshSearch** function searches for a specific character sequence in the data stream and stops reading if the sequence is encountered.

Parameters

hClient

Handle to the client session.

lpszString

A pointer to a string which specifies the sequence of characters to search for in the data stream. This parameter cannot be NULL or point to an empty string.

lpvBuffer

A pointer to a byte buffer which will contain the output from the server, or a pointer to a global memory handle which will reference the output when the function returns. If the output from the server is not required, this parameter may be NULL.

lpdwLength

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the *lpvBuffer* parameter. If the *lpvBuffer* parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the actual number of bytes of output stored in the buffer. If the *lpvBuffer* parameter is NULL, this parameter should also be NULL.

dwReserved

A reserved parameter. This value must be zero.

Return Value

If the function succeeds and the character sequences was found in the data stream, the return value is non-zero. If the function fails or a timeout occurs before the sequence is found, the return value is zero. To get extended error information, call **RshGetLastError**.

Remarks

The **RshSearch** function searches for a character sequence in the data stream and stops reading when it is found. This is useful when the client wants to automate responses to the server, such as executing a command and processing the output. The function collects the output from the server and stores it in the buffer specified by the *lpvBuffer* parameter. When the function returns, the buffer will contain everything sent by the server up to and including the search string.

The *lpvBuffer* parameter may be specified in one of two ways, depending on the needs of the application. The first method is to pre-allocate a buffer large enough to store the a fixed amount of output. In this case, the *lpvBuffer* parameter will point to the buffer that was allocated, the value that the *lpdwLength* parameter points to should be initialized to the size of that buffer. If the server sends more output than can be stored in the buffer, the remaining output will be discarded.

The second method that can be used is have the *lpvBuffer* parameter point to a global memory handle which will contain the output when the function returns. In this case, the value that the *lpdwLength* parameter points to must be initialized to zero. It is important to note that the memory handle returned by the function must be freed by the application, otherwise a memory leak will occur. This method is preferred if the client application does not have a general idea of how much output will be generated until the search string is found.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csrshv10.lib

Unicode: Implemented as Unicode and ANSI versions.

RshSetLastError Function

```
VOID WINAPI RshSetLastError(  
    DWORD dwErrorCode  
);
```

The **RshSetLastError** function sets the error code for the current thread. This function is typically used to clear the last error by passing a value of zero as the parameter.

Parameters

dwErrorCode

Specifies the error code for the current thread.

Return Value

None.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or RSH_ERROR. Those functions which call **RshSetLastError** when they succeed are noted on the function reference page.

Applications can retrieve the value saved by this function by using the **RshGetLastError** function. The use of **RshGetLastError** is optional; an application can call the function to determine the specific reason for a function failure.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csrshv10.lib

RshSetTimeout Function

```
INT WINAPI RshSetTimeout(  
    HCLIENT hClient,  
    INT nTimeout  
);
```

The **RshSetTimeout** function sets the number of seconds the client will wait for a response from the server. Once the specified number of seconds has elapsed, the function will fail and return to the caller.

Parameters

hClient

Handle to the client session.

nTimeout

The number of seconds to wait for a blocking operation to complete.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is RSH_ERROR. To get extended error information, call **RshGetLastError**.

Remarks

The timeout value is only used with blocking client connections.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csrshv10.lib

See Also

[RshGetTimeout](#)

RshUninitialize Function

```
VOID WINAPI RshUninitialize();
```

The **RshUninitialize** function terminates the use of the library.

Parameters

There are no parameters.

Return Value

None.

Remarks

An application is required to perform a successful **RshInitialize** call before it can call any of the other the library functions. When it has completed the use of library, the application must call **RshUninitialize** to allow the library to free any resources allocated on behalf of the process. Any pending blocking or asynchronous calls in this process are canceled without posting any notification messages, and all sockets that were opened by the process are closed.

There must be a call to **RshUninitialize** for every successful call to **RshInitialize** made by a process. In a multithreaded environment, operations for all threads in the client are terminated.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csrshv10.lib

See Also

[RshDisconnect](#), [RshInitialize](#)

RshWrite Function

```
INT WINAPI RshWrite(  
    HCLIENT hClient,  
    LPBYTE lpBuffer,  
    INT cbBuffer  
);
```

The **RshWrite** function sends the specified number of bytes to the server.

Parameters

hClient

Handle to the client session.

lpBuffer

The pointer to the buffer which contains the data that is to be sent to the server.

cbBuffer

The number of bytes to send from the specified buffer.

Return Value

If the function succeeds, the return value is the number of bytes actually written. If the function fails, the return value is RSH_ERROR. To get extended error information, call **RshGetLastError**.

Remarks

The return value may be less than the number of bytes specified by the *cbBuffer* parameter. In this case, the data has been partially written and it is the responsibility of the client application to send the remaining data at some later point. For non-blocking clients, the client must wait for the RSH_EVENT_WRITE asynchronous notification message before it resumes sending data.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

- INITDATA

INITDATA Structure

This structure contains information about the SocketTools library when the initialization function returns.

```
typedef struct _INITDATA
{
    DWORD      dwSize;
    DWORD      dwVersionMajor;
    DWORD      dwVersionMinor;
    DWORD      dwVersionBuild;
    DWORD      dwOptions;
    DWORD_PTR  dwReserved1;
    DWORD_PTR  dwReserved2;
    TCHAR      szDescription[128];
} INITDATA, *LPINITDATA;
```

Members

dwSize

Size of this structure. This structure member must be set to the size of the structure prior to calling the initialization function. Failure to do so will cause the function to fail.

dwVersionMajor

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the major version number for the library.

dwVersionMinor

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the minor version number for the library.

dwVersionBuild

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the build number for the library.

dwOptions

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

dwReserved1

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

dwReserved2

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

szDescription

A null terminated string which describes the library.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Unicode: Implemented as Unicode and ANSI versions.

Secure Shell Protocol Library

Establish an interactive terminal session with an SSH server and execute remote commands.

Reference

- [Functions](#)
- [Data Structures](#)
- [Error Codes](#)

Library Information

File Name	CSTSHV10.DLL
Version	10.0.1468.2518
LibID	4C76F231-8ED9-4850-B882-01B77485F43A
Import Library	CSTSHV10.LIB
Dependencies	None
Standards	RFC 4251

Remarks

The Secure Shell (SSH) protocol API is used to establish a secure connection with a server which provides a virtual terminal session for a user. Its functionality is similar to how character based consoles and serial terminals work, enabling a user to login to the server, execute commands and interact with applications running on the server. The library provides an interface for establishing the connection and handling the standard I/O functions needed by the program. It also provides functions that enable a program to easily scan the data stream for specific sequences of characters, making it very simple to write light-weight client interfaces to applications running on the server. This library can be combined with the Terminal Emulation library to provide complete terminal emulation services for a standard ANSI or DEC-VT220 terminal.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). If you are using Visual C++ 6.0 it is required that you have Service Pack 6 (SP6) installed. You should install all updates for your development tools and have the current Windows SDK installed. The minimum recommended version of Visual Studio is Visual Studio 2010.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are using Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. It is recommended that you install the current service pack and all critical updates available for your version of the operating system.

This product includes both 32-bit and 64-bit libraries. Native 64-bit CPU support requires the 64-bit version of Windows 7 or later versions of the Windows operating system.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it

should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

Secure Shell Protocol Functions

Function	Description
SshAsyncConnect	Connect asynchronously to the specified server
SshAttachThread	Attach the specified client handle to another thread
SshCancel	Cancel the current blocking operation
SshConnect	Connect to the specified server
SshControl	Send a control sequence to the server
SshCreateSecurityCredentials	Create a new security credentials structure
SshDeleteSecurityCredentials	Delete a previously created security credentials structure
SshDisableEvents	Disable asynchronous event notification
SshDisableTrace	Disable logging of socket function calls to the trace log
SshDisconnect	Disconnect from the current server
SshEnableEvents	Enable asynchronous event notification
SshEnableTrace	Enable logging of socket function calls to a file
SshEventProc	Callback function that processes events generated by the client
SshExecute	Execute a command on a server and return the output in the specified buffer
SshFreezeEvents	Suspend asynchronous event processing
SshGetErrorString	Return a description for the specified error code
SshGetExitCode	Return the exit code from the remote program
SshGetLastError	Return the last error code
SshGetLineMode	Return the current mode used to send end-of-line character sequences
SshGetSecurityInformation	Return security information about the current client connection
SshGetStatus	Return the current client status
SshGetTimeout	Return the number of seconds until an operation times out
SshInitialize	Initialize the library and validate the specified license key at runtime
SshIsBlocking	Determine if the client is blocked, waiting for information
SshIsConnected	Determine if the client is connected to the server
SshIsReadable	Determine if data can be read from the server
SshIsWritable	Determine if data can be written to the server
SshPeek	Read data returned by the server, but do not remove it from the receive buffer
SshRead	Read data returned by the server
SshReadLine	Read a line of text from the server and return it in a string buffer

SshRegisterEvent	Register an event callback function
SshSearch	Search for a specific character sequence in the data stream
SshSetLastError	Set the last error code
SshSetLineMode	Change how end-of-line character sequences are sent to the server
SshSetTimeout	Set the number of seconds until an operation times out
SshUninitialize	Terminate use of the library by the application
SshWrite	Write data to the server
SshWriteLine	Write a line of text to the server

SshAsyncConnect Function

```
HCLIENT WINAPI SshAsyncConnect(  
    LPCTSTR lpszRemoteHost,  
    UINT nRemotePort,  
    LPCTSTR lpszUserName,  
    LPCTSTR lpszPassword,  
    UINT nTimeout,  
    DWORD dwOptions,  
    LPSSHOPTIONDATA lpOptions,  
    LPSECURITYCREDENTIALS lpCredentials,  
    HWND hEventWnd,  
    UINT uEventMsg  
);
```

The **SshAsyncConnect** function is used to establish a connection with the server.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Parameters

lpszRemoteHost

A pointer to a string which specifies the name of the server to connect to. This may either be a fully-qualified domain name or an IP address. This parameter cannot be NULL.

nRemotePort

The port number the server is listening on. A value of zero specifies that the default port number 22 should be used.

lpszUserName

A pointer to a string which specifies the user name which will be used to authenticate the client session. This parameter must specify a valid user name and cannot be NULL or an empty string.

lpszPassword

A pointer to a string which specifies the password which will be used to authenticate the client session. If the user does not have a password, this parameter can be NULL or an empty string.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
SSH_OPTION_NONE	No options specified. A standard terminal session will be established with the default terminal type.
SSH_OPTION_KEEPALIVE	This option specifies the library should attempt to maintain an idle client session for long periods of time. This option is only necessary if you expect that the

	connection will be held open for more than two hours.
SSH_OPTION_NOPTY	This option specifies that a pseudoterminal (PTY) should not be created for the client session. This option is automatically set if the SSH_OPTION_COMMAND option has been specified.
SSH_OPTION_NOSHELL	This option specifies that a command shell should not be used when executing a command on the server.
SSH_OPTION_NOAUTHRSA	This option specifies that RSA authentication should not be used with SSH-1 connections. This option is ignored with SSH-2 connections and should only be specified if required by the server.
SSH_OPTION_NOPWDNULL	This option specifies the user password cannot be terminated with a null character. This option is ignored with SSH-2 connections and should only be specified if required by the server.
SSH_OPTION_NOREKEY	This option specifies the client should never attempt a repeat key exchange with the server. Some SSH servers do not support rekeying the session, and this can cause the client to become non-responsive or abort the connection after being connected for an hour.
SSH_OPTION_COMPATSID	This compatibility option changes how the session ID is handled during public key authentication with older SSH servers. This option should only be specified when connecting to servers that use OpenSSH 2.2.0 or earlier versions.
SSH_OPTION_COMPATHMAC	This compatibility option changes how the HMAC authentication codes are generated. This option should only be specified when connecting to servers that use OpenSSH 2.2.0 or earlier versions.
SSH_OPTION_TERMINAL	This option specifies the client session will use terminal emulation and the SSHOPTIONDATA structure specifies the characteristics of the virtual terminal. This enables the caller to specify the dimensions of the virtual display (in columns and rows) and the type of terminal that will be emulated. If this option is omitted, the session will default to a virtual display that is 80 columns, 25 rows.
SSH_OPTION_COMMAND	This option specifies the client session will be used to issue a command that is executed on the server, and the output will be returned to the caller. If this option is specified, the session will not be interactive and no pseudoterminal is created for the client. The szCommandLine member of the SSHOPTIONDATA structure specifies the command string that will be sent to the server.

SSH_OPTION_PROXYSERVER	This option specifies the client should establish a connection through a proxy server. The two protocols that are supported are SSH_PROXY_HTTP and SSH_PROXY_TELNET, which specifies the protocol that the proxy connection is created through. The proxy-related members of the SSHOPTIONDATA structure should be set to the appropriate values.
SSH_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
SSH_OPTION_FREETHREAD	This option specifies the handle returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the handle is synchronized across multiple threads.

lpOptions

A pointer to a [SSHOPTIONDATA](#) structure which specifies additional information for one or more options. If no optional data is required, a NULL pointer may be specified.

lpCredentials

A pointer to a [SECURITYCREDENTIALS](#) structure which specifies additional security-related information required to establish the connection. This parameter may be NULL, in which case default values will be used. Note that the *dwSize* member must be initialized to the size of the **SECURITYCREDENTIALS** structure that is being passed to the function.

hEventWnd

The handle to the event notification window. This window receives messages which notify the client of various asynchronous socket events that occur.

uEventMsg

The message identifier that is used when an asynchronous socket event occurs. This value should be greater than WM_USER as defined in the Windows header files.

Return Value

If the function succeeds, the return value is a handle to a client session. If the function fails, the return value is INVALID_CLIENT. To get extended error information, call **SshGetLastError**.

Remarks

When a message is posted to the notification window, the low word of the *lParam* parameter contains the event identifier. The high word of *lParam* contains the low word of the error code, if an error has occurred. The *wParam* parameter contains the client handle. One or more of the following event identifiers may be sent:

Constant	Description

SSH_EVENT_CONNECT	The connection to the server has completed. The high word of the <i>lParam</i> parameter should be checked, since this notification message will be posted if an error has occurred.
SSH_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
SSH_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
SSH_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
SSH_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
SSH_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and reconnect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.

To cancel asynchronous notification and return the client to a blocking mode, use the **SshDisableEvents** function.

It is recommended that you only establish an asynchronous connection if you understand the implications of doing so. In most cases, it is preferable to create a synchronous connection and create worker threads for each additional session if more than one active client session is required.

The *dwOptions* argument can be used to specify the threading model that is used by the library when a connection is established. By default, the handle is initially attached to the thread that created it. From that point on, until the it is released, only the owner may call functions using that handle. The ownership of the handle may be transferred from one thread to another using the **SshAttachThread** function.

Specifying the SSH_OPTION_FREETHREAD option enables any thread to call any function using the handle, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the handle is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same handle.

Example

```
// Define the asynchronous event notification message ID
#define WM_CLIENT_EVENTS (WM_APP + 1)

HCLIENT hClient;
SSHOPTIONDATA sshOptions;

// Initialize the SSHOPTIONDATA structure and specify the
```

```

// command that should be executed on the server
ZeroMemory(&sshOptions, sizeof(sshOptions));
lstrcpyn(sshOptions.szCommandLine, lpszCommand, SSH_MAXCOMMANDLEN);

// Establish a connection with the SSH server

hClient = SshAsyncConnect(lpszHostName,
                        SSH_PORT_DEFAULT,
                        lpszUserName,
                        lpszPassword,
                        SSH_TIMEOUT,
                        SSH_OPTION_COMMAND,
                        &sshOptions,
                        NULL,
                        hAppWnd,
                        WM_CLIENT_EVENTS);

// If the connection attempt fails, then get a description of
// the error and display it in a message box

if (hClient == INVALID_CLIENT)
{
    DWORD dwError;
    TCHAR szError[128];

    dwError = SshGetLastError();
    if (dwError > 0)
    {
        SshGetErrorString(dwError, szError, 128);
        MessageBox(NULL, szError, _T("Error"), MB_ICONEXCLAMATION);
    }

    return;
}

```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstshv10.lib

Unicode: Implemented as Unicode and ANSI versions.

SshAttachThread Function

```
DWORD WINAPI SshAttachThread(  
    HCLIENT hClient  
    DWORD dwThreadId  
);
```

The **SshAttachThread** function attaches the specified client handle to another thread.

Parameters

hClient

Handle to the client session.

dwThreadId

The ID of the thread that will become the new owner of the handle. A value of zero specifies that the current thread should become the owner of the client handle.

Return Value

If the function succeeds, the return value is the thread ID of the previous owner. If the function fails, the return value is SSH_ERROR. To get extended error information, call **SshGetLastError**.

Remarks

When a client handle is created, it is associated with the current thread that created it. Normally, if another thread attempts to perform an operation using that handle, an error is returned since it does not own the handle. This is used to ensure that other threads cannot interfere with an operation being performed by the owner thread. In some cases, it may be desirable for one thread in a client application to create the client handle, and then pass that handle to another worker thread. The **SshAttachThread** function can be used to change the ownership of the handle to the new worker thread. By preserving the return value from the function, the original owner of the handle can be restored before the worker thread terminates.

This function should be called by the new thread immediately after it has been created, and if the new thread does not release the handle itself, the ownership of the handle should be restored to the parent thread before it terminates. Under no circumstances should **SshAttachThread** be used to forcibly release a handle allocated by another thread while a blocking operation is in progress. To cancel an operation, use the **SshCancel** function and then release the handle after the blocking function exits and control is returned to the current thread.

Note that the *dwThreadId* parameter is presumed to be a valid thread ID and no checks are performed to ensure that the thread actually exists. Specifying an invalid thread ID will orphan the handle until the **SshUninitialize** function is called.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstshv10.lib

See Also

[SshCancel](#), [SshAsyncConnect](#), [SshConnect](#), [SshDisconnect](#), [SshUninitialize](#)

SshCancel Function

```
INT WINAPI SshCancel(  
    HCLIENT hClient  
);
```

The **SshCancel** function cancels any outstanding blocking operation in the client, causing the blocking function to fail. The application may then retry the operation or terminate the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is SSH_ERROR. To get extended error information, call **SshGetLastError**.

Remarks

When the **SshCancel** function is called, the blocking function will not immediately fail. An internal flag is set which causes the blocking operation to exit with an error. This means that the application cannot cancel an operation and immediately perform some other operation. Instead it must allow the calling stack to unwind, returning back to the blocking operation before making any further function calls.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstshv10.lib

SshConnect Function

```
HCLIENT WINAPI SshConnect(  
    LPCTSTR lpszRemoteHost,  
    UINT nRemotePort,  
    LPCTSTR lpszUserName,  
    LPCTSTR lpszPassword,  
    UINT nTimeout,  
    DWORD dwOptions,  
    LPSSHOPTIONDATA lpOptions,  
    LPSECURITYCREDENTIALS lpCredentials  
);
```

The **SshConnect** function is used to establish a connection with the server.

Parameters

lpszRemoteHost

A pointer to a string which specifies the name of the server to connect to. This may either be a fully-qualified domain name or an IP address. This parameter cannot be NULL.

nRemotePort

The port number the server is listening on. A value of zero specifies that the default port number 22 should be used.

lpszUserName

A pointer to a string which specifies the user name which will be used to authenticate the client session. This parameter must specify a valid user name and cannot be NULL or an empty string.

lpszPassword

A pointer to a string which specifies the password which will be used to authenticate the client session. If the user does not have a password, this parameter can be NULL or an empty string.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
SSH_OPTION_NONE	No options specified. A standard terminal session will be established with the default terminal type.
SSH_OPTION_KEEPAIVE	This option specifies the library should attempt to maintain an idle client session for long periods of time. This option is only necessary if you expect that the connection will be held open for more than two hours.
SSH_OPTION_NOPTY	This option specifies that a pseudoterminal (PTY) should not be created for the client session. This option is automatically set if the SSH_OPTION_COMMAND option has been specified.
SSH_OPTION_NOSHELL	This option specifies that a command shell should not

	be used when executing a command on the server.
SSH_OPTION_NOAUTHRSA	This option specifies that RSA authentication should not be used with SSH-1 connections. This option is ignored with SSH-2 connections and should only be specified if required by the server.
SSH_OPTION_NOPWDNULL	This option specifies the user password cannot be terminated with a null character. This option is ignored with SSH-2 connections and should only be specified if required by the server.
SSH_OPTION_NOREKEY	This option specifies the client should never attempt a repeat key exchange with the server. Some SSH servers do not support rekeying the session, and this can cause the client to become non-responsive or abort the connection after being connected for an hour.
SSH_OPTION_COMPATSID	This compatibility option changes how the session ID is handled during public key authentication with older SSH servers. This option should only be specified when connecting to servers that use OpenSSH 2.2.0 or earlier versions.
SSH_OPTION_COMPATHMAC	This compatibility option changes how the HMAC authentication codes are generated. This option should only be specified when connecting to servers that use OpenSSH 2.2.0 or earlier versions.
SSH_OPTION_TERMINAL	This option specifies the client session will use terminal emulation and the SSHOPTIONDATA structure specifies the characteristics of the virtual terminal. This enables the caller to specify the dimensions of the virtual display (in columns and rows) and the type of terminal that will be emulated. If this option is omitted, the session will default to a virtual display that is 80 columns, 25 rows.
SSH_OPTION_COMMAND	This option specifies the client session will be used to issue a command that is executed on the server, and the output will be returned to the caller. If this option is specified, the session will not be interactive and no pseudoterminal is created for the client. The szCommandLine member of the SSHOPTIONDATA structure specifies the command string that will be sent to the server.
SSH_OPTION_PROXYSERVER	This option specifies the client should establish a connection through a proxy server. The two protocols that are supported are SSH_PROXY_HTTP and SSH_PROXY_TELNET, which specifies the protocol that the proxy connection is created through. The proxy-related members of the SSHOPTIONDATA structure

	should be set to the appropriate values.
SSH_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
SSH_OPTION_FREETHREAD	This option specifies the handle returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the handle is synchronized across multiple threads.

lpOptions

A pointer to a [SSH_OPTIONDATA](#) structure which specifies additional information for one or more options. If no optional data is required, a NULL pointer may be specified.

lpCredentials

A pointer to a [SECURITY_CREDENTIALS](#) structure which specifies additional security-related information required to establish the connection. This parameter may be NULL, in which case default values will be used. Note that the *dwSize* member must be initialized to the size of the **SECURITY_CREDENTIALS** structure that is being passed to the function.

Return Value

If the function succeeds, the return value is a handle to a client session. If the function fails, the return value is **INVALID_CLIENT**. To get extended error information, call **SshGetLastError**.

Remarks

To prevent this function from blocking the main user interface thread, the application should create a background worker thread and establish a connection by calling **SshConnect** in that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each client session.

The *dwOptions* argument can be used to specify the threading model that is used by the library when a connection is established. By default, the handle is initially attached to the thread that created it. From that point on, until the it is released, only the owner may call functions using that handle. The ownership of the handle may be transferred from one thread to another using the **SshAttachThread** function.

Specifying the **SSH_OPTION_FREETHREAD** option enables any thread to call any function using the handle, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the handle is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same handle.

Example

```
HCLIENT hClient;
SSH_OPTIONDATA sshOptions;
```

```

// Initialize the SSHOPTIONDATA structure and specify the
// command that should be executed on the server
ZeroMemory(&sshOptions, sizeof(sshOptions));
lstrcpyn(sshOptions.szCommandLine, lpszCommand, SSH_MAXCOMMANDLEN);

// Establish a connection with the SSH server

hClient = SshConnect(lpszHostName,
                    SSH_PORT_DEFAULT,
                    lpszUserName,
                    lpszPassword,
                    SSH_TIMEOUT,
                    SSH_OPTION_COMMAND,
                    &sshOptions,
                    NULL);

// If the connection attempt fails, then get a description of
// the error and display it in a message box

if (hClient == INVALID_CLIENT)
{
    DWORD dwError;
    TCHAR szError[128];

    dwError = SshGetLastError();
    if (dwError > 0)
    {
        SshGetErrorString(dwError, szError, 128);
        MessageBox(NULL, szError, _T("Error"), MB_ICONEXCLAMATION);
    }

    return;
}

```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstshv10.lib

Unicode: Implemented as Unicode and ANSI versions.

SshControl Function

```
INT WINAPI SshControl(  
    HCLIENT hClient  
    DWORD dwControlCode,  
    LPVOID lpvReserved,  
    DWORD dwReserved  
);
```

The **SshControl** function sends a control message to the server.

Parameters

hClient

Handle to the client session.

dwControlCode

A numeric control code which specifies the control message which should be sent to the server. This may be one of the following values:

Constant	Description
SSH_CONTROL_BREAK	Sends a control message to the server which simulates a break signal on a physical terminal. This is used by some operating systems as an instruction to enter a privileged configuration mode. Note that this is not the same as sending an interrupt character such as Ctrl+C to the server. This control code is ignored for SSH 1.0 sessions.
SSH_CONTROL_NOOP	Sends a control message to the server, but it does not perform any operation. This is typically used by clients to prevent the server from automatically closing a session that has been idle for a long period of time.
SSH_CONTROL_EOF	Sends a control message to the server indicating that the client has finished sending data. Note that this option is normally not used with interactive terminal sessions, and should only be used when required by the server.
SSH_CONTROL_PING	Sends a control message to the server which is used to test whether or not the server is responsive to the client. This is typically used by clients to attempt to detect if the connection to the server is still active.
SSH_CONTROL_REKEY	Sends a control message to the server requesting that the key exchange be performed again. This control code is ignored for SSH 1.0 sessions.

lpvReserved

A reserved parameter which should always be specified as NULL.

dwReserved

A reserved parameter which should always be specified as a value of 0.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is

SSH_ERROR. To get extended error information, call **SshGetLastError**.

Remarks

The **SshControl** function enables an application to send control messages to the server, which can cause it to take specific actions such as simulate a terminal break or request that the key exchanged be performed again. Some control messages are not supported by the SSH 1.0 protocol, in which case the control message is ignored.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstshv10.lib

See Also

[SshCancel](#), [SshIsBlocking](#)

SshCreateSecurityCredentials Function

```
BOOL WINAPI SshCreateSecurityCredentials(  
    DWORD dwProtocol,  
    DWORD dwOptions,  
    LPCTSTR lpszKeyFile,  
    LPCTSTR lpszPassword,  
    LPVOID lpvReserved,  
    LPSECURITYCREDENTIALS* lppCredentials  
);
```

The **SshCreateSecurityCredentials** function creates a **SECURITYCREDENTIALS** structure.

Parameters

dwProtocol

A bitmask of supported security protocols. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
SECURITY_PROTOCOL_SSH	Select either version 1.0 or 2.0 of the Secure Shell protocol. The actual protocol version that is selected is determined automatically. This is the recommended value.
SECURITY_PROTOCOL_SSH1	Version 1.0 of the Secure Shell protocol. This protocol has been deprecated and its use is not recommended.
SECURITY_PROTOCOL_SSH2	Version 2.0 of the Secure Shell protocol. This is currently the most commonly used version of the protocol, and most servers will require this version when establishing a connection.

dwOptions

Credentials options. This argument is reserved for future use. Set it to a value of zero when using this function.

lpszKeyFile

A pointer to a string which specifies the name of a private key file that used when authenticating the client connection. If a private key is not required, value of NULL should be specified.

lpszPassword

A pointer to a string which specifies the password for the private key file. A value of NULL specifies that no password is required.

lppCredentials

Pointer to an [LPSECURITYCREDENTIALS](#) pointer. The memory for the credentials structure will be allocated by this function and must be released by calling the **SshDeleteSecurityCredentials** function when it is no longer needed. The pointer value must be set to NULL before the function is called.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **SshGetLastError**.

Remarks

The structure that is created by this function may be used as client credentials when establishing a secure connection. This is particularly useful for programming languages other than C/C++ which may not support C structures or pointers. The pointer to the SECURITYCREDENTIALS structure can be declared as an unsigned integer variable which is passed by reference to this function, and then passed by value to the **SshAsyncConnect** or **SshConnect** functions.

Example

```
LPSECURITYCREDENTIALS lpSecCred = NULL;
SshCreateSecurityCredentials(SEcurity_PROTOCOL_SSH2,
                            0,
                            lpzKeyFile,
                            lpzPassword,
                            NULL,
                            &lpSecCred);

hClient = SshConnect(lpzHostName,
                    SSH_PORT_DEFAULT,
                    lpzUserName,
                    lpzPassword,
                    SSH_TIMEOUT,
                    SSH_OPTION_DEFAULT,
                    NULL,
                    lpSecCred);
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstshv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

SshDeleteSecurityCredentials Function

```
VOID WINAPI SshDeleteSecurityCredentials(  
    LPSECURITYCREDENTIALS* lppCredentials  
);
```

The **SshDeleteSecurityCredentials** function deletes an existing **SECURITYCREDENTIALS** structure.

Parameters

lppCredentials

Pointer to an **LPSECURITYCREDENTIALS** pointer. On exit from the function, the pointer will be NULL.

Return Value

None.

Example

```
if (lpSecCred)  
    SshDeleteSecurityCredentials(&lpSecCred);  
  
SshUninitialize();
```

Remarks

This function can be used to release the memory allocated to the client or server credentials after a secure connection has been terminated.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cstshv10.lib

Unicode: Implemented as Unicode and ANSI versions.

SshDisableEvents Function

```
INT WINAPI SshDisableEvents(  
    HCLIENT hClient  
);
```

The **SshDisableEvents** function disables the event notification mechanism, preventing subsequent event notification messages from being posted to the application's message queue.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Applications should use the **SshRegisterEvent** function to register an event handler which is invoked when an event occurs.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is SSH_ERROR. To get extended error information, call **SshGetLastError**.

Remarks

This function affects both event notification and event callbacks. Any outstanding events in the message queue should be ignored by the client application.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstshv10.lib

[SshEnableEvents](#), [SshFreezeEvents](#), [SshRegisterEvent](#)

SshDisableTrace Function

```
BOOL WINAPI SshDisableTrace();
```

The **SshDisableTrace** function disables the logging of socket function calls to the trace log.

Parameters

None.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstshv10.lib

See Also

[SshEnableTrace](#)

SshDisconnect Function

```
INT WINAPI SshDisconnect(  
    HCLIENT hClient  
);
```

The **SshDisconnect** function terminates the connection with the server, closing the socket and releasing the memory allocated for the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is SSH_ERROR. To get extended error information, call **SshGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstshv10.lib

Unicode: Implemented as Unicode and ANSI versions.

SshEnableEvents Function

```
INT WINAPI SshEnableEvents(  
    HCLIENT hClient,  
    HWND hEventWnd,  
    UINT uEventMsg  
);
```

The **SshEnableEvents** function enables event notifications using Windows messages.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Parameters

hClient

Handle to the client session.

hEventWnd

Handle to the event notification window. This window receives a user-defined message which specifies the event that has occurred. If this value is NULL, event notification is disabled.

uEventMsg

An unsigned integer which specifies the user-defined message that is sent when an event occurs. This parameter's value must be greater than the value of WM_USER. If the *hEventWnd* parameter is NULL, this value must be specified as WM_NULL.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is SSH_ERROR. To get extended error information, call **SshGetLastError**.

Remarks

When a message is posted to the notification window, the low word of the *lParam* parameter contains the event identifier. The high word of *lParam* contains the low word of the error code, if an error has occurred. The *wParam* parameter contains the client handle. One or more of the following event identifiers may be sent:

Constant	Description
SSH_EVENT_CONNECT	The connection to the server has completed. The high word of the <i>lParam</i> parameter should be checked, since this notification message will be posted if an error has occurred.
SSH_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
SSH_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
SSH_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking

	operation. This event is only generated if the client is in asynchronous mode.
SSH_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
SSH_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and reconnect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.

As noted, some events are only generated when the client is asynchronous mode. These events depend on the Windows Sockets asynchronous notification mechanism.

If event notification is disabled by specifying a NULL window handle, there may still be outstanding events in the message queue that must be processed. Since event handling has been disabled, these events should be ignored by the client application.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstshv10.lib

See Also

[SshDisableEvents](#), [SshFreezeEvents](#), [SshRegisterEvent](#)

SshEnableTrace Function

```
BOOL WINAPI SshEnableTrace(  
    LPCTSTR lpszTraceFile,  
    DWORD dwTraceFlags  
);
```

The **SshEnableTrace** function enables the logging of Windows Sockets function calls to a file.

Parameters

lpszTraceFile

A pointer to a string which specifies the name of the trace log file. If this parameter is NULL or an empty string, the default file name **cstrace.log** is used. The file is stored in the directory specified by the TEMP environment variable, if it is defined; otherwise, the current working directory is used.

dwTraceFlags

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
TRACE_INFO	All function calls are written to the trace file. This is the default value.
TRACE_ERROR	Only those function calls which fail are recorded in the trace file.
TRACE_WARNING	Only those function calls which fail or return values which indicate a warning are recorded in the trace file.
TRACE_HEXDUMP	All functions calls are written to the trace file, plus all the data that is sent or received is displayed, in both ASCII and hexadecimal format.
TRACE_PROCESS	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for multithreaded applications that are using worker threads.

Return Value

If the function succeeds, the return value is non-zero. A return value of zero indicates an error. Failure typically indicates that the tracing library **cstrcv10.dll** cannot be loaded on the local system.

Remarks

When trace logging is enabled, the file is opened, appended to and closed for each socket function call. This makes it possible for an application to append its own logging information, however care should be taken to ensure that the file is closed before the next network operation is performed. To limit the size of the log files, enable and disable logging only around those sections of code that you wish to trace.

Note that the TRACE_HEXDUMP trace level generates very large log files since it includes all of the data exchanged between your application and the server.

Trace function logging is managed on a per-thread basis, not for each client handle. This means that all SocketTools libraries and components share the same settings in the current thread. If you

are using multiple SocketTools libraries or components in your application, you only need to enable logging once.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstshv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[SshDisableTrace](#)

SshEventProc Function

```
VOID CALLBACK SshEventProc(  
    HCLIENT hClient,  
    UINT nEvent,  
    DWORD dwError,  
    DWORD_PTR dwParam  
);
```

The **SshEventProc** function is an application-defined callback function that processes events generated by the client.

Parameters

hClient

Handle to the client session.

nEvent

An unsigned integer which specifies which event occurred. For a complete list of events, refer to the **SshRegisterEvent** function.

dwError

An unsigned integer which specifies any error that occurred. If no error occurred, then this parameter will be zero.

dwParam

A user-defined integer value which was specified when the event callback was registered.

Return Value

None.

Remarks

An application must register this callback function by passing its address to the **SshRegisterEvent** function. The **SshEventProc** function is a placeholder for the application-defined function name.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstshv10.lib

Unicode: Implemented as Unicode and ANSI versions.

SshExecute Function

```
INT WINAPI SshExecute(  
    LPCTSTR lpszRemoteHost,  
    UINT nRemotePort,  
    LPCTSTR lpszUserName,  
    LPCTSTR lpszPassword,  
    LPCTSTR lpszCommandLine,  
    UINT nTimeout,  
    DWORD dwOptions,  
    LPVOID lpvBuffer,  
    LPDWORD lpdwLength,  
    LPSECURITYCREDENTIALS lpCredentials  
);
```

The **SshExecute** function executes a command on the server and returns the output in the specified buffer.

Parameters

lpszRemoteHost

A pointer to a string which specifies the name of the server. This may either be a fully-qualified domain name, or an IP address. This parameter cannot be NULL.

nRemotePort

The port number the server is listening on. A value of zero specifies that the default port number 22 should be used.

lpszUserName

A pointer to a string which specifies the user name which will be used to authenticate the client session.

lpszPassword

A pointer to a string which specifies the password which will be used to authenticate the client session.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
SSH_OPTION_NONE	No options specified. A standard terminal session will be established with the default terminal type.
SSH_OPTION_KEEPAIVE	This option specifies the library should attempt to maintain an idle client session for long periods of time. This option is only necessary if you expect that the connection will be held open for more than two hours.
SSH_OPTION_NOPTY	This option specifies that a pseudoterminal (PTY) should not be created for the client session. This

	option is automatically set if the SSH_OPTION_COMMAND option has been specified.
SSH_OPTION_NOSHELL	This option specifies that a command shell should not be used when executing a command on the server.
SSH_OPTION_NOAUTHRSA	This option specifies that RSA authentication should not be used with SSH-1 connections. This option is ignored with SSH-2 connections and should only be specified if required by the server.
SSH_OPTION_NOPWDNULL	This option specifies the user password cannot be terminated with a null character. This option is ignored with SSH-2 connections and should only be specified if required by the server.
SSH_OPTION_NOREKEY	This option specifies the client should never attempt a repeat key exchange with the server. Some SSH servers do not support rekeying the session, and this can cause the client to become non-responsive or abort the connection after being connected for an hour.
SSH_OPTION_COMPATSID	This compatibility option changes how the session ID is handled during public key authentication with older SSH servers. This option should only be specified when connecting to servers that use OpenSSH 2.2.0 or earlier versions.
SSH_OPTION_COMPATHMAC	This compatibility option changes how the HMAC authentication codes are generated. This option should only be specified when connecting to servers that use OpenSSH 2.2.0 or earlier versions.

lpvBuffer

A pointer to a byte buffer which will contain the data transferred from the server, or a pointer to a global memory handle which will reference the data when the function returns.

lpdwLength

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the *lpvBuffer* parameter. If the *lpvBuffer* parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the actual length of the file that was downloaded.

lpCredentials

A pointer to a [SECURITYCREDENTIALS](#) structure which specifies additional security-related information required to establish the connection. This parameter may be NULL, in which case default values will be used. Note that the *dwSize* member must be initialized to the size of the **SECURITYCREDENTIALS** structure that is being passed to the function.

Return Value

If the function succeeds, the return value is the exit code from the program that was executed on the server. If the function fails, the return value is SSH_ERROR. To get extended error information, call **SshGetLastError**.

Remarks

The **SshExecute** function is used to execute a command on a server, read the output from that command and copy it into a local buffer. This function cannot be used if the connection to the server must be established through a proxy server; if a proxy server must be used, then you should use the **SshConnect** function to establish the connection, and then use either the **SshRead** or **SshReadLine** functions to read the output.

This function may be used in one of two ways, depending on the needs of the application. The first method is to pre-allocate a buffer large enough to store the command output. In this case, the *lpvBuffer* parameter will point to the buffer that was allocated, the value that the *lpdwLength* parameter points to should be initialized to the size of that buffer.

The second method that can be used is have the *lpvBuffer* parameter point to a global memory handle which will contain the output when the function returns. In this case, the value that the *lpdwLength* parameter points to must be initialized to zero. It is important to note that the memory handle returned by the function must be freed by the application, otherwise a memory leak will occur. See the example code below.

When the command output is being read from the server, this function will automatically convert the data to match the end-of-line convention used on the Windows platform. This is useful when executing a command on a UNIX based system where the end-of-line is indicated by a single linefeed, while on Windows it is a carriage-return and linefeed pair. If the output contains embedded nulls or escape sequences, then this conversion will not be performed.

This function will cause the current thread to block until the command completes or a timeout occurs.

Example

```
HGLOBAL hgblBuffer = (HGLOBAL)NULL;
LPBYTE lpBuffer = (LPBYTE)NULL;
DWORD cbBuffer = 0;

// Execute a command on the server and return the data into block
// of global memory allocated by the GlobalAlloc function; the handle
// to this memory will be returned in the hgblBuffer parameter
nResult = SshExecute(lpszHostName,
                    SSH_PORT_DEFAULT,
                    lpszUserName,
                    lpszPassword,
                    lpszCommandLine,
                    SSH_TIMEOUT,
                    SSH_OPTION_NONE,
                    &hgblBuffer,
                    &cbBuffer,
                    NULL);

if (nResult != SSH_ERROR)
{
    // Lock the global memory handle, returning a pointer to the
    // resource data
    lpBuffer = (LPBYTE)GlobalLock(hgblBuffer);

    // After the data has been used, the handle must be unlocked
    // and freed, otherwise a memory leak will occur
    GlobalUnlock(hgblBuffer);
    GlobalFree(hgblBuffer);
}
```

```
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstshv10.lib

Unicode: Implemented as Unicode and ANSI versions.

SshFreezeEvents Function

```
INT WINAPI SshFreezeEvents(  
    HCLIENT hClient,  
    BOOL bFreeze  
);
```

The **SshFreezeEvents** function is used to suspend and resume event handling by the client.

Parameters

hClient

Handle to the client session.

bFreeze

A non-zero value specifies that event handling should be suspended by the client. A zero value specifies that event handling should be resumed.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is SSH_ERROR. To get extended error information, call **SshGetLastError**.

Remarks

This function should be used when the application does not want to process events, such as when a modal dialog is being displayed. When events are suspended, all client events are queued. If events are re-enabled at a later point, those queued events will be sent to the application for processing. Note that only one of each event will be generated. For example, if the client has suspended event handling, and four read events occur, once event handling is resumed only one of those read events will be posted to the client. This prevents the application from being flooded by a potentially large number of queued events.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstshv10.lib

See Also

[SshDisableEvents](#), [SshEnableEvents](#), [SshRegisterEvent](#)

SshGetErrorString Function

```
INT WINAPI SshGetErrorString(  
    DWORD dwErrorCode,  
    LPTSTR lpszDescription,  
    INT cbDescription  
);
```

The **SshGetErrorString** function is used to return a description of a specific error code. Typically this is used in conjunction with the **SshGetLastError** function for use with warning dialogs or as diagnostic messages.

Parameters

dwErrorCode

The error code for which a description is returned.

lpszDescription

A pointer to the buffer that will contain a description of the specified error code. This buffer should be at least 128 characters in length.

cbDescription

The maximum number of characters that may be copied into the description buffer.

Return Value

If the function succeeds, the return value is the length of the description string. If the function fails, the return value is zero, meaning that no description exists for the specified error code. Typically this indicates that the error code passed to the function is invalid.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `cstshv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

See Also

[SshGetLastError](#), [SshSetLastError](#)

SshGetExitCode Function

```
INT WINAPI SshGetExitCode(  
    HCLIENT hClient  
);
```

The **SshGetExitCode** function returns the exit code for the remote session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the numeric exit code. If the function fails, the return value is SSH_ERROR. To get extended error information, call **SshGetLastError**.

Remarks

This function should only be called after the command has completed and the **SshRead** function has returned a value of zero. In most cases, an exit code value of zero indicates success, while any other value indicates an error condition.

Note that the actual value is application dependent and is only meaningful in the context of that particular program. A program may choose or use exit codes in a non-standard way, such as having certain non-zero values indicate success.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstshv10.lib

See Also

[SshGetStatus](#)

SshGetLastError Function

DWORD WINAPI SshGetLastError();

Parameters

None.

Return Value

The return value is the last error code value for the current thread. Functions set this value by calling the **SshSetLastError** function. The Return Value section of each reference page notes the conditions under which the function sets the last error code.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. You should call the **SshGetLastError** function immediately when a function's return value indicates that an error has occurred. That is because some functions call **SshSetLastError(0)** when they succeed, clearing the error code set by the most recently failed function.

Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or SSH_ERROR. Those functions which call **SshSetLastError** when they succeed are noted on the function reference page.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstshv10.lib

See Also

[SshGetErrorString](#), [SshSetLastError](#)

SshGetLineMode Function

```
INT WINAPI SshGetLineMode(  
    HCLIENT hClient  
);
```

The **SshGetLineMode** function returns the current line mode.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the current line mode. If the function fails, the return value is SSH_ERROR. To get extended error information, call **SshGetLastError**.

Remarks

The **SshGetLineMode** function returns an integer value that specifies how end-of-line character sequences are sent to the server. For more information about how newlines are processed by the library and the available options, refer to the **SshSetLineMode** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstshv10.lib

See Also

[SshSetLineMode](#), [SshWrite](#), [SshWriteLine](#)

SshGetSecurityInformation Function

```
BOOL WINAPI SshGetSecurityInformation(  
    HCLIENT hClient,  
    LPSECURITYINFO lpSecurityInfo  
);
```

The **SshGetSecurityInformation** function returns security protocol, encryption and certificate information about the current client connection.

Parameters

hClient

Handle to the client session.

lpSecurityInfo

A pointer to a [SECURITYINFO](#) structure which contains information about the current client connection. The *dwSize* member of this structure must be initialized to the size of the structure before passing the address of the structure to this function.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **SshGetLastError**.

Remarks

This function is used to obtain security related information about the current client connection to the server. It can be used to determine if a secure connection has been established, what security protocol was selected, and information about the server certificate. Note that a secure connection has not been established, the *dwProtocol* structure member will contain the value SECURITY_PROTOCOL_NONE.

Example

The following example demonstrates how to obtain the fingerprint for the server:

```
SECURITYINFO securityInfo;  
  
securityInfo.dwSize = sizeof(SECURITYINFO);  
if (SshGetSecurityInformation(hClient, &securityInfo))  
{  
    if (securityInfo.lpszFingerprint != NULL)  
    {  
        TCHAR szMessage[256];  
        wsprintf(szMessage, _T("The fingerprint is %s",  
securityInfo.lpszFingerprint);  
        MessageBox(NULL, szMessage, "Connection", MB_OK);  
    }  
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

SshGetStatus Function

```
INT WINAPI SshGetStatus(  
    HCLIENT hClient  
);
```

The **SshGetStatus** function returns the current status of the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the client status code. If the function fails, the return value is SSH_ERROR. To get extended error information, call **SshGetLastError**.

Remarks

The **SshGetStatus** function returns a numeric code which identifies the current state of the client session. The following values may be returned:

Value	Constant	Description
1	SSH_STATUS_IDLE	The client is current idle and not sending or receiving data.
2	SSH_STATUS_CONNECT	The client is establishing a connection with the server.
3	SSH_STATUS_AUTHENTICATE	The client is authenticating the session with the server.
4	SSH_STATUS_READ	The client is reading data from the server.
5	SSH_STATUS_WRITE	The client is writing data to the server.
6	SSH_STATUS_DISCONNECT	The client is disconnecting from the server.

In a multithreaded application, any thread in the current process may call this function to obtain status information for the specified client session.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cstshv10.lib

See Also

[SshGetExitCode](#), [SshIsBlocking](#), [SshIsConnected](#), [SshIsReadable](#), [SshIsWritable](#)

SshGetTimeout Function

```
INT WINAPI SshGetTimeout(  
    HCLIENT hClient  
);
```

The **SshGetTimeout** function returns the number of seconds the client will wait for a response from the server. Once the specified number of seconds has elapsed, the function will fail and return to the caller.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the timeout period in seconds. If the function fails, the return value is SSH_ERROR. To get extended error information, call **SshGetLastError**.

Remarks

The timeout value is only used with blocking client connections. A value of zero indicates that the default timeout period of 20 seconds should be used.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstshv10.lib

See Also

[SshSetTimeout](#)

SshInitialize Function

```
BOOL WINAPI SshInitialize(  
    LPCTSTR lpszLicenseKey,  
    LPINITDATA lpData  
);
```

The **SshInitialize** function initializes the library and validates the specified license key at runtime.

Parameters

lpszLicenseKey

Pointer to a string that specifies the runtime license key to be validated. If this parameter is NULL, the library will validate the development license installed on the local system.

lpData

Pointer to an INITDATA data structure. This parameter may be NULL if the initialization data for the library is not required.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **SshGetLastError**. All other client functions will fail until a license key has been successfully validated.

Remarks

This must be the first function that an application calls before using any of the other functions in the library. When a NULL license key is specified, the library will only function on the development system. Before redistributing the application to an end-user, you must insure that this function is called with a valid license key.

If the *lpData* argument is specified, it must point to an INITDATA structure which has been initialized by setting the *dwSize* member to the size of the structure. All other structure members should be set to zero. If the function is successful, then the INITDATA structure will be filled with identifying information about the library.

Although it is only required that **SshInitialize** be called once for the current process, it may be called multiple times; however, each call must be matched by a corresponding call to **SshUninitialize**.

This function dynamically loads other system libraries and allocates thread local storage. If you are calling the functions in this library from within another DLL, it is important that you do not call the **SshInitialize** or **SshUninitialize** functions from the **DllMain** function because it can result in deadlocks or access violation errors. If the DLL is linked with the C runtime library (CRT), it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstshv10.lib

Unicode: Implemented as Unicode and ANSI versions.

SshIsBlocking Function

```
BOOL WINAPI SshIsBlocking(  
    HCLIENT hClient  
);
```

The **SshIsBlocking** function is used to determine if the client is currently performing a blocking operation.

Parameters

hClient

Handle to the client session.

Return Value

If the client is performing a blocking operation, the function returns a non-zero value. If the client is not performing a blocking operation, or the client handle is invalid, the function returns zero.

Remarks

Because a blocking operation can allow the application to be re-entered (for example, by pressing a button while the operation is being performed), it is possible that another blocking function may be called while it is in progress. Since only one thread of execution may perform a blocking operation at any one time, an error would occur. The **SshIsBlocking** function can be used to determine if the client is already blocked, and if so, take some other action such as warning the user that they must wait for the operation to complete.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstshv10.lib

See Also

[SshCancel](#)

SshIsConnected Function

```
BOOL WINAPI SshIsConnected(  
    HCLIENT hClient  
);
```

The **SshIsConnected** function is used to determine if the client is currently connected to a server.

Parameters

hClient

Handle to the client session.

Return Value

If the client is connected to a server, the function returns a non-zero value. If the client is not connected, or the client handle is invalid, the function returns zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstshv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[SshIsBlocking](#), [SshIsReadable](#), [SshIsWritable](#)

SshIsReadable Function

```
BOOL WINAPI SshIsReadable(  
    HCLIENT hClient,  
    INT nTimeout,  
    LPDWORD lpdwAvail  
);
```

The **SshIsReadable** function is used to determine if data is available to be read from the server.

Parameters

hClient

Handle to the client session.

nTimeout

Timeout for server response, in seconds. A value of zero specifies that the connection should be polled without blocking the current thread.

lpdwAvail

A pointer to an unsigned integer which will contain the number of bytes available to read. This parameter may be NULL if this information is not required.

Return Value

If the client can read data from the server within the specified timeout period, the function returns a non-zero value. If the client cannot read any data, the function returns zero.

Remarks

On some platforms, this value will not exceed the size of the receive buffer (typically 64K bytes). Because of differences between TCP/IP stack implementations on different versions of Windows, it is not recommended that your application exclusively depend on this value to determine the exact number of bytes available. Instead, it should be used as a general indicator that there is data available to be read.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstshv10.lib

See Also

[SshGetStatus](#), [SshIsBlocking](#), [SshIsConnected](#), [SshIsWritable](#), [SshRead](#)

SshIsWritable Function

```
BOOL WINAPI SshIsWritable(  
    HCLIENT hClient,  
    INT nTimeout  
);
```

The **SshIsWritable** function is used to determine if data can be written to the server.

Parameters

hClient

Handle to the client session.

nTimeout

Timeout for server response, in seconds. A value of zero specifies that the connection should be polled without blocking the current thread.

Return Value

If the client can write data to the server within the specified timeout period, the function returns a non-zero value. If the client cannot write any data, the function returns zero.

Remarks

Although this function can be used to determine if some amount of data can be sent to the remote process it does not indicate the amount of data that can be written without blocking the client. In most cases, it is recommended that large amounts of data be broken into smaller logical blocks, typically some multiple of 512 bytes in length.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cstshv10.lib

SshPeek Function

```
INT WINAPI SshPeek(  
    HCLIENT hClient,  
    LPBYTE lpBuffer,  
    INT cbBuffer  
);
```

The **SshPeek** function reads the specified number of bytes from the server and copies them into the buffer, but it does not remove the data from the internal receive buffer. The data may be of any type, and is not terminated with a null character.

Parameters

hClient

Handle to the client session.

lpBuffer

Pointer to the buffer in which the data will be copied.

cbBuffer

The maximum number of bytes to read and copy into the specified buffer. This value must be greater than zero.

Return Value

If the function succeeds, the return value is the number of bytes actually read. A return value of zero indicates that there is no data available to be read at that time. If the function fails, the return value is SSH_ERROR. To get extended error information, call **SshGetLastError**.

Remarks

The **SshPeek** function can be used to examine the data that is available to be read from the internal receive buffer. If there is no data in the receive buffer at that time, a value of zero is returned. It should be noted that this differs from the **SshRead** function, where a return value of zero indicates that there is no more data available to be read and the connection has been closed. The **SshPeek** function will never cause the client to block, and so may be safely used with asynchronous connections.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstshv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[SshIsReadable](#), [SshRead](#), [SshSearch](#), [SshWrite](#)

SshRead Function

```
INT WINAPI SshRead(  
    HCLIENT hClient,  
    LPBYTE lpBuffer,  
    INT cbBuffer  
);
```

The **SshRead** function reads the specified number of bytes from the client socket and copies them into the buffer. The data may be of any type, and is not terminated with a null character.

Parameters

hClient

Handle to the client session.

lpBuffer

Pointer to the buffer in which the data will be copied.

cbBuffer

The maximum number of bytes to read and copy into the specified buffer. This value must be greater than zero.

Return Value

If the function succeeds, the return value is the number of bytes actually read. A return value of zero indicates that the server has closed the connection and there is no more data available to be read. If the function fails, the return value is SSH_ERROR. To get extended error information, call **SshGetLastError**.

Remarks

When **SshRead** is called and the client is in non-blocking mode, it is possible that the function will fail because there is no available data to read at that time. This should not be considered a fatal error. Instead, the application should simply wait to receive the next asynchronous notification that data is available.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cstshv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[SshIsReadable](#), [SshPeek](#), [SshReadLine](#), [SshSearch](#), [SshWrite](#), [SshWriteLine](#)

SshReadLine Function

```
BOOL WINAPI SshReadLine(  
    HCLIENT hClient,  
    LPTSTR lpszBuffer,  
    LPINT lpnLength  
);
```

The **SshReadLine** function reads up to a line of data and returns it in a string buffer.

Parameters

hSocket

Handle to the client session.

lpszBuffer

Pointer to the string buffer that will contain the data when the function returns. The string will be terminated with a null byte, and will not contain the end-of-line characters.

lpnLength

A pointer to an integer value which specifies the length of the buffer. The value should be initialized to the maximum number of characters that can be copied into the string buffer, including the terminating null character. When the function returns, its value will updated with the actual length of the string.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **SshGetLastError**.

Remarks

The **SshReadLine** function reads data sent by the server and copies it into a specified string buffer. Unlike the **SshRead** function which reads arbitrary bytes of data, this function is specifically designed to return a single line of text data in a string. When an end-of-line character sequence is encountered, the function will stop and return the data up to that point. The string buffer is guaranteed to be null-terminated and will not contain the end-of-line characters.

There are some limitations when using **SshReadLine**. The function should only be used to read text, never binary data. In particular, the function will discard nulls, linefeed and carriage return control characters. The Unicode version of this function will return a Unicode string, however this function does not support reading raw Unicode data from the server. The data is internally buffered as octets (eight-bit bytes) and converted to Unicode using the **MultiByteToWideChar** function.

This function will force the thread to block until an end-of-line character sequence is processed, the read operation times out or the server closes its end of the connection. If this function is called with asynchronous events enabled, it will automatically switch the client into a blocking mode, read the data and then restore the client to asynchronous operation. If another client operation is attempted while **SshReadLine** is blocked waiting for data from the server, an error will occur. It is recommended that this function only be used with blocking (synchronous) client connections; if the application needs to establish multiple simultaneous connections, it should create worker threads to manage each connection.

The **SshRead** and **SshReadLine** function calls can be intermixed, however be aware that **SshRead** will consume any data that has already been buffered by the **SshReadLine** function and this may

have unexpected results.

Unlike the **SshRead** function, it is possible for data to be returned in the buffer even if the return value is zero. Applications should also check the value of the *lpnLength* argument to determine if any data was copied into the buffer. For example, if a timeout occurs while the function is waiting for more data to arrive, it will return zero; however, data may have already been copied into the string buffer prior to the error condition. It is the responsibility of the application to process that data, regardless of the function return value.

Example

```
TCHAR szBuffer[MAXBUFLEN];
INT nLength;
BOOL bResult;

do
{
    nLength = sizeof(szBuffer);
    bResult = SshReadLine(hSocket, szBuffer, &nLength);

    if (nLength > 0)
    {
        // Process the line of data returned in the string
        // buffer; the string is always null-terminated
    }
} while (bResult);

DWORD dwError = SshGetLastError();
if (dwError == ST_ERROR_CONNECTION_CLOSED)
{
    // The server has closed its side of the connection and
    // there is no more data available to be read
}
else if (dwError != 0)
{
    // An error has occurred while reading a line of data
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstshv10.lib

Unicode: Implemented as Unicode and ANSI versions.

SshRegisterEvent Function

```
INT WINAPI SshRegisterEvent(  
    HCLIENT hClient,  
    UINT nEvent,  
    SSHEVENTPROC lpEventProc,  
    DWORD_PTR dwParam  
);
```

The **SshRegisterEvent** function registers an event handler for the specified event.

Parameters

hClient

Handle to the client session.

nEvent

An unsigned integer which specifies which event should be registered with the specified callback function. One of the following values may be used:

Constant	Description
SSH_EVENT_CONNECT	The connection to the server has completed.
SSH_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
SSH_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
SSH_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
SSH_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
SSH_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **SshEventProc** callback function. If this parameter is NULL, the callback for the specified event is disabled.

dwParam

A user-defined integer value that is passed to the callback function. If the application targets the

x86 (32-bit) platform, this parameter must be a 32-bit unsigned integer. If the application targets the x64 (64-bit) platform, this parameter must be a 64-bit unsigned integer.

Remarks

The **SshRegisterEvent** function associates a callback function with a specific event. The event handler is an **SshEventProc** function that is invoked when the event occurs. Arguments are passed to the function to identify the client session, the event type and the user-defined value specified when the event handler is registered. If the event occurs because of an error condition, the error code will be provided to the handler.

The callback function specified by the *lpEventProc* parameter must be declared using the **__stdcall** calling convention. This ensures the arguments passed to the event handler are pushed on to the stack in the correct order. Failure to use the correct calling convention will corrupt the stack and cause the application to terminate abnormally.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is `SSH_ERROR`. To get extended error information, call **SshGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `cstshv10.lib`

See Also

SshSearch Function

```
BOOL WINAPI SshSearch(  
    HCLIENT hClient,  
    LPCTSTR lpszString,  
    LPVOID lpvBuffer,  
    LPDWORD lpdwLength,  
    DWORD dwReserved  
);
```

The **SshSearch** function searches for a specific character sequence in the data stream and stops reading if the sequence is encountered.

Parameters

hClient

Handle to the client session.

lpszString

A pointer to a string which specifies the sequence of characters to search for in the data stream. This parameter cannot be NULL or point to an empty string.

lpvBuffer

A pointer to a byte buffer which will contain the output from the server, or a pointer to a global memory handle which will reference the output when the function returns. If the output from the server is not required, this parameter may be NULL.

lpdwLength

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the *lpvBuffer* parameter. If the *lpvBuffer* parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the actual number of bytes of output stored in the buffer. If the *lpvBuffer* parameter is NULL, this parameter should also be NULL.

dwReserved

A reserved parameter. This value must be zero.

Return Value

If the function succeeds and the character sequences was found in the data stream, the return value is non-zero. If the function fails or a timeout occurs before the sequence is found, the return value is zero. To get extended error information, call **SshGetLastError**.

Remarks

The **SshSearch** function searches for a character sequence in the data stream and stops reading when it is found. This is useful when the client wants to automate responses to the server. The function collects the output from the server and stores it in the buffer specified by the *lpvBuffer* parameter. When the function returns, the buffer will contain everything sent by the server up to and including the matching string.

The *lpvBuffer* parameter may be specified in one of two ways, depending on the needs of the application. The first method is to pre-allocate a buffer large enough to store the a fixed amount of output. In this case, the *lpvBuffer* parameter will point to the buffer that was allocated, the value that the *lpdwLength* parameter points to should be initialized to the size of that buffer. If the server sends more output than can be stored in the buffer, the remaining output will be discarded.

The second method that can be used is have the *lpvBuffer* parameter point to a global memory handle which will contain the output when the function returns. In this case, the value that the *lpdwLength* parameter points to must be initialized to zero. It is important to note that the memory handle returned by the function must be freed by the application, otherwise a memory leak will occur. This method is preferred if the client application does not have a general idea of how much output will be generated until the search string is found.

Example

```
LPCTSTR lpszCommand = _T("/bin/ls -l\r\n");
LPCTSTR lpszPrompt = _T("$ ");
HGLOBAL hgblOutput = NULL;
DWORD cbOutput = 0;
BOOL bResult;

// Search for a command prompt issued by the server

bResult = SshSearch(hClient,
                   lpszPrompt,
                   NULL,
                   NULL,
                   0);

// If the shell prompt was found, issue the command
// and capture the output into the hgblBuffer global
// memory buffer; the cbBuffer variable will contain
// the actual number of bytes in the buffer when the
// function returns

if (bResult)
{
    SshWrite(hClient,
            (LPBYTE)lpszCommand,
            lstrlen(lpszCommand));

    bResult = SshSearch(hClient,
                       lpszPrompt,
                       &hgblOutput,
                       &cbOutput,
                       0);
}

// Write the contents of the output buffer to the
// standard output stream

if (bResult)
{
    LPBYTE lpBuffer = (LPBYTE)GlobalLock(hgblBuffer);

    if (lpBuffer)
        fwrite(lpBuffer, 1, cbOutput, stdout);

    GlobalUnlock(hgblBuffer);
    GlobalFree(hgblBuffer);
}
```

Requirements

SshSetLastError Function

```
VOID WINAPI SshSetLastError(  
    DWORD dwErrorCode  
);
```

The **SshSetLastError** function sets the last error code for the current thread. This function is typically used to clear the last error by specifying a value of zero as the parameter.

Parameters

dwErrorCode

Specifies the last error code for the current thread.

Return Value

None.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or SSH_ERROR. Those functions which call **SshSetLastError** when they succeed are noted on the function reference page.

Applications can retrieve the value saved by this function by using the **SshGetLastError** function. The use of **SshGetLastError** is optional; an application can call the function to determine the specific reason for a function failure.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cstshv10.lib

[SshGetErrorString](#), [SshGetLastError](#)

SshSetLineMode Function

```
INT WINAPI SshSetLineMode(  
    HCLIENT hClient,  
    INT nLineMode  
);
```

The **SshSetLineMode** function changes the current line mode for the client session.

Parameters

hClient

Handle to the client session.

nLineMode

An integer value which specifies how the newlines are sent by the library. It must be one of the following values:

Value	Constant	Description
0	SSH_NEWLINE_DEFAULT	There are no changes to how data is sent to the server. Any carriage return or linefeed characters that are sent using the SshWrite function will be sent as-is. The SshWriteLine function will terminate each line of text with a carriage return and linefeed (CRLF) sequence. This is the default line mode that is set when a new connection is established.
1	SSH_NEWLINE_CR	A carriage return is used as the end-of-line character. Any data sent using the SshWrite function that contains only a linefeed (LF) character or a carriage return and linefeed (CRLF) sequence to indicate the end-of-line will be replaced by a carriage return (CR) character. The SshWriteLine function will terminate each line of text with a single carriage return character.
2	SSH_NEWLINE_LF	A linefeed is used as the end-of-line character. Any data sent using the SshWrite function that contains only a carriage return (CR) character or a carriage return and linefeed (CRLF) sequence to indicate the end-of-line will be replaced by a linefeed (LF) character. The SshWriteLine function will terminate each line of text with a single linefeed character.
3	SSH_NEWLINE_CRLF	A carriage return and linefeed (CRLF) character sequence is used to indicate the end-of-line. Any data sent using the SshWrite function that contains only a carriage return (CR) or linefeed (LF) will be replaced by a carriage return and linefeed. The SshWriteLine function will terminate each line of text with a carriage return and linefeed sequence.

Return Value

If the function succeeds, the return value is the previous line mode for the client session. If the function fails, the return value is `SSH_ERROR`. To get extended error information, call **SshGetLastError**.

Remarks

When a connection is initially established with the server, it determines what characters are used to indicate the end-of-line and how they are displayed. On UNIX based systems, this is controlled by the settings for the pseudo-terminal that is allocated for the client session, and can be changed using the **stty** command. In most cases, the client line mode can be left at the default. However, in some cases you may need to change the line mode, particularly if you intend to send data from a Windows text file or copied from the clipboard.

Windows uses a carriage return and linefeed (CRLF) sequence to indicate the end-of-line and a UNIX based server may interpret that as multiple newlines. To prevent this, use the **SshSetLineMode** function to change the current line mode to **SSH_NEWLINE_CR** and the CRLF sequence in the text will be replaced by a single carriage return.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `cstshv10.lib`

See Also

[SshGetLineMode](#), [SshWrite](#), [SshWriteLine](#)

SshSetTimeout Function

```
INT WINAPI SshSetTimeout(  
    HCLIENT hClient,  
    INT nTimeout  
);
```

The **SshSetTimeout** function sets the number of seconds the client will wait for a response from the server. Once the specified number of seconds has elapsed, the function will fail and return to the caller.

Parameters

hClient

Handle to the client session.

nTimeout

The number of seconds to wait for a blocking operation to complete.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is SSH_ERROR. To get extended error information, call **SshGetLastError**.

Remarks

The timeout value is only used with blocking client connections.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstshv10.lib

See Also

[SshGetTimeout](#)

SshUninitialize Function

```
VOID WINAPI SshUninitialize();
```

The **SshUninitialize** function terminates the use of the library.

Parameters

There are no parameters.

Return Value

None.

Remarks

An application is required to perform a successful **SshInitialize** call before it can call any of the other library functions. When it has completed the use of library, the application must call **SshUninitialize** to allow the library to free any resources allocated on behalf of the process. Any pending blocking or asynchronous calls in this process are canceled without posting any notification messages, and all sockets that were opened by the process are closed.

There must be a call to **SshUninitialize** for every successful call to **SshInitialize** made by a process. In a multithreaded environment, operations for all threads in the client are terminated.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstshv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[SshDisconnect](#), [SshInitialize](#)

SshWrite Function

```
INT WINAPI SshWrite(  
    HCLIENT hClient,  
    LPBYTE lpBuffer,  
    INT cbBuffer  
);
```

The **SshWrite** function sends the specified number of bytes to the server.

Parameters

hClient

Handle to the client session.

lpBuffer

The pointer to the buffer which contains the data that is to be sent to the server.

cbBuffer

The number of bytes to send from the specified buffer.

Return Value

If the function succeeds, the return value is the number of bytes actually written. If the function fails, the return value is SSH_ERROR. To get extended error information, call **SshGetLastError**.

Remarks

The return value may be less than the number of bytes specified by the *cbBuffer* parameter. In this case, the data has been partially written and it is the responsibility of the client application to send the remaining data at some later point. For non-blocking clients, the client must wait for the SSH_EVENT_WRITE asynchronous notification message before it resumes sending data.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstshv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

SshWriteLine Function

```
BOOL WINAPI SshWriteLine(  
    HCLIENT hClient,  
    LPCTSTR lpszBuffer,  
    LPINT lpnLength  
);
```

The **SshWriteLine** function sends a line of text to the server, terminated by a carriage-return and linefeed.

Parameters

hClient

Handle to the client session.

lpszBuffer

The pointer to a string buffer which contains the data that will be sent to the server. All characters up to, but not including, the terminating null character will be written to the server. The data will always be terminated with a carriage-return and linefeed control character sequence. If this parameter points to an empty string or NULL pointer, then a only a carriage-return and linefeed are written to the server.

lpnLength

A pointer to an integer value which will contain the number of characters written to the server, including the carriage-return and linefeed sequence. If this information is not required, a NULL pointer may be specified.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **SshGetLastError**.

Remarks

The **SshWriteLine** function writes a line of text to the server and terminates the line with a carriage-return and linefeed control character sequence. Unlike the **SshWrite** function which writes arbitrary bytes of data to the server, this function is specifically designed to write a single line of text data from a string.

If the *lpszBuffer* string is terminated with a linefeed (LF) or carriage return (CR) character, it will be automatically converted to a standard CRLF end-of-line sequence. Because the string will be sent with a terminating CRLF sequence, the value returned in the *lpnLength* parameter will typically be larger than the original string length (reflecting the additional CR and LF characters), unless the string was already terminated with CRLF.

There are some limitations when using **SshWriteLine**. The function should only be used to send text, never binary data. In particular, the function will discard nulls and append linefeed and carriage return control characters to the data stream. The Unicode version of this function will accept a Unicode string, however this function does not support sending raw Unicode data to the server. Unicode strings will be automatically converted to UTF-8 encoding using the **WideCharToMultiByte** function and then written as a stream of bytes.

This function will force the thread to block until the complete line of text has been written, the write operation times out or the server aborts the connection. If this function is called with asynchronous events enabled, it will automatically switch the client into a blocking mode, send the

data and then restore the client to asynchronous operation. If another network operation is attempted while **SshWriteLine** is blocked sending data to the server, an error will occur. It is recommended that this function only be used with blocking (synchronous) connections; if the application needs to establish multiple simultaneous connections, it should create worker threads to manage each connection.

The **SshWrite** and **SshWriteLine** function calls can be safely intermixed.

Unlike the **SshWrite** function, it is possible for data to have been written to the server if the return value is zero. For example, if a timeout occurs while the function is waiting to send more data to the server, it will return zero; however, some data may have already been written prior to the error condition. If this is the case, the *lpnLength* argument will specify the number of characters actually written up to that point.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstshv10.lib

Unicode: Implemented as Unicode and ANSI versions.

SSH Protocol Data Structures

- INITDATA
- SECURITYCREDENTIALS
- SECURITYINFO
- SSOPTIONDATA

INITDATA Structure

This structure contains information about the SocketTools library when the initialization function returns.

```
typedef struct _INITDATA
{
    DWORD      dwSize;
    DWORD      dwVersionMajor;
    DWORD      dwVersionMinor;
    DWORD      dwVersionBuild;
    DWORD      dwOptions;
    DWORD_PTR  dwReserved1;
    DWORD_PTR  dwReserved2;
    TCHAR      szDescription[128];
} INITDATA, *LPINITDATA;
```

Members

dwSize

Size of this structure. This structure member must be set to the size of the structure prior to calling the initialization function. Failure to do so will cause the function to fail.

dwVersionMajor

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the major version number for the library.

dwVersionMinor

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the minor version number for the library.

dwVersionBuild

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the build number for the library.

dwOptions

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

dwReserved1

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

dwReserved2

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

szDescription

A null terminated string which describes the library.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Unicode: Implemented as Unicode and ANSI versions.

SECURITYINFO Structure

This structure contains information about a secure connection that has been established with a server.

```
typedef struct _SECURITYINFO
{
    DWORD        dwSize;
    DWORD        dwProtocol;
    DWORD        dwCipher;
    DWORD        dwCipherStrength;
    DWORD        dwHash;
    DWORD        dwHashStrength;
    DWORD        dwKeyExchange;
    DWORD        dwCertStatus;
    SYSTEMTIME   stCertIssued;
    SYSTEMTIME   stCertExpires;
    LPCTSTR      lpszCertIssuer;
    LPCTSTR      lpszCertSubject;
    LPCTSTR      lpszFingerprint;
} SECURITYINFO, *LPSECURITYINFO;
```

Members

dwSize

Specifies the size of the data structure. This member must always be initialized to **sizeof(SECURITYINFO)** prior to passing the address of this structure to the function. Note that if this member is not initialized, an error will be returned indicating that an invalid parameter has been passed to the function.

dwProtocol

A numeric value which specifies the protocol that was selected to establish the secure connection. One of the following values will be returned:

Constant	Description
SECURITY_PROTOCOL_NONE	No security protocol has been selected. A secure connection has not been established with the server. The remaining member values in this structure are not valid and should be ignored.
SECURITY_PROTOCOL_SSH1	The Secure Shell 1.0 protocol has been selected. This protocol has been deprecated and is no longer widely used. It is not recommended that this protocol be used when establishing secure connections. This protocol can only be specified when connecting to an SSH server and is not supported with any other application protocol.
SECURITY_PROTOCOL_SSH2	The Secure Shell 2.0 protocol has been selected. This is the most commonly used version of the protocol. It is recommended that this version of the protocol be used unless the server explicitly requires the client to use an earlier version. This protocol can only be specified when connecting to an SSH server and is not supported with any other application protocol.

dwCipher

A numeric value which specifies the cipher that was selected when establishing the secure connection. One of the following values will be returned:

Constant	Description
SECURITY_CIPHER_RC5	The RC5 block cipher was selected. This is a variable key length cipher which supports keys up to 2040 bits, in 8-bit increments.
SECURITY_CIPHER_DES	The DES (Data Encryption Standard) block cipher was selected. This is a fixed key length cipher, using 56-bit keys.
SECURITY_CIPHER_DES3	The Triple DES block cipher was selected. This cipher encrypts the data three times using different keys, effectively providing a 168-bit length key.
SECURITY_CIPHER_AES	The Advanced Encryption Standard cipher (also known as the Rijndael cipher) is a fixed block size cipher which use a key size of 128, 192 or 256 bits. This cipher is supported on Windows XP SP3 and later versions of the operating system.

dwCipherStrength

A numeric value which specifies the strength (the length of the cipher key in bits) of the cipher that was selected. Typically this value will be 128 or 256. 40-bit and 56-bit key lengths are considered weak encryption, and subject to brute force attacks. 128-bit and 256-bit key lengths are considered to be secure and are the recommended key length for secure communications.

dwHash

A numeric value which specifies the hash algorithm which was selected. One of the following values will be returned:

Constant	Description
SECURITY_HASH_MD5	The MD5 algorithm was selected. Its use has been deprecated and is no longer considered to be cryptographically secure.
SECURITY_HASH_SHA1	The SHA-1 algorithm was selected. Its use has been deprecated and is no longer considered to be cryptographically secure.
SECURITY_HASH_SHA256	The SHA-256 algorithm was selected.

dwHashStrength

A numeric value which specifies the strength (the length in bits) of the message digest that was selected.

dwKeyExchange

A numeric value which specifies the key exchange algorithm which was selected. One of the following values will be returned:

Constant	Description
SECURITY_KEYEX_RSA	The RSA public key algorithm was selected.

SECURITY_KEYEX_KEA	The Key Exchange Algorithm (KEA) was selected. This is an improved version of the Diffie-Hellman public key algorithm.
SECURITY_KEYEX_DH	The Diffie-Hellman key exchange algorithm was selected.
SECURITY_KEYEX_ECDH	The Elliptic Curve Diffie-Hellman key exchange algorithm was selected. This is a variant of the Diffie-Hellman algorithm which uses elliptic curve cryptography. This key exchange algorithm is only supported on Windows XP SP3 and later versions of the operating system.

dwCertStatus

A numeric value which specifies the status of the certificate returned by the secure server. This member only has meaning for connections using the SSL or TLS protocols.

stCertIssued

A structure which contains the date and time that the certificate was issued by the certificate authority. If the issue date cannot be determined for the certificate, the SYSTEMTIME structure members will have zero values. This member only has meaning for connections using the SSL or TLS protocols.

stCertExpires

A structure which contains the date and time that the certificate expires. If the expiration date cannot be determined for the certificate, the SYSTEMTIME structure members will have zero values. This member only has meaning for connections using the SSL or TLS protocols.

lpszCertIssuer

A pointer to a string which contains information about the organization that issued the certificate. This string consists of one or more comma-separated tokens. Each token consists of an identifier, followed by an equal sign and a value. If the certificate issuer could not be determined, this member may be NULL. This member only has meaning for connections using the SSL or TLS protocols.

lpszCertSubject

A pointer to a string which contains information about the organization that the certificate was issued to. This string consists of one or more comma-separated tokens. Each token consists of an identifier, followed by an equal sign and a value. If the certificate subject could not be determined, this member may be NULL. This member only has meaning for connections using the SSL or TLS protocols.

lpszFingerprint

A pointer to a string which contains a sequence of hexadecimal values that uniquely identify the server. This member is only used when a connection has been established using the Secure Shell (SSH) protocol.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Unicode: Implemented as Unicode and ANSI versions.

SECURITYCREDENTIALS Structure

The **SECURITYCREDENTIALS** structure specifies the information needed by the library to specify additional security credentials, such as a client certificate or private key, when establishing a secure connection.

```
typedef struct _SECURITYCREDENTIALS
{
    DWORD    dwSize;
    DWORD    dwProtocol;
    DWORD    dwOptions;
    DWORD    dwReserved;
    LPCTSTR  lpszHostName;
    LPCTSTR  lpszUserName;
    LPCTSTR  lpszPassword;
    LPCTSTR  lpszCertStore;
    LPCTSTR  lpszCertName;
    LPCTSTR  lpszKeyFile;
} SECURITYCREDENTIALS, *LPSECURITYCREDENTIALS;
```

Members

dwSize

Size of this structure. If the structure is being allocated dynamically, this member must be set to the size of the structure and all other unused structure members must be initialized to a value of zero or NULL.

dwProtocol

A value which specifies which security protocols are supported:

Constant	Description
SECURITY_PROTOCOL_SSH	Either version 1.0 or 2.0 of the Secure Shell protocol should be used when establishing the connection. The correct protocol is automatically selected based on the version of the protocol that is supported by the server.
SECURITY_PROTOCOL_SSH1	The Secure Shell 1.0 protocol should be used when establishing the connection. This is an older version of the protocol which should not be used unless explicitly required by the server. Most modern SSH server support version 2.0 of the protocol.
SECURITY_PROTOCOL_SSH2	The Secure Shell 2.0 protocol should be used when establishing the connection. This is the default version of the protocol that is supported by most SSH servers.

dwOptions

This structure member is reserved for use with SSL and TLS connections and should always be initialized to zero.

dwReserved

This structure member is reserved for future use and should always be initialized to zero.

lpszHostName

A pointer to a null terminated string which specifies the hostname that will be used when

validating a server certificate. This member should always be initialized as a NULL pointer for connections using the SSH protocol.

lpszUserName

A pointer to a null terminated string which identifies the owner of client certificate. Currently this member is not used by the library and should always be initialized as a NULL pointer.

lpszPassword

A pointer to a null terminated string which specifies the password needed to access the certificate. Currently this member is only used if a private key file has been specified. If there is no password associated with the certificate, then this member should be initialized as a NULL pointer.

lpszCertStore

A pointer to a null terminated string which specifies the name of the certificate store to open. This member should always be initialized as a NULL pointer for connections using the SSH protocol.

lpszCertName

A pointer to a null terminated string which specifies the name of the certificate to use. This member should always be initialized as a NULL pointer for connections using the SSH protocol.

lpszKeyFile

A pointer to a null terminated string which specifies the name of the file which contains the private key required to establish the connection. This member is only used with the SSH protocol. If the member is NULL, then no private key is used.

Remarks

A client application typically only needs to create this structure if the server requires that the client provide a private key as part of the process of negotiating the secure session.

Note that the *lpszUserName* and *lpszPassword* members are values which are used to access the private key file. They are not the credentials which are used when establishing the connection with the server or authenticating the client session.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Unicode: Implemented as Unicode and ANSI versions.

SSHOPTIONDATA Structure

This structure specifies additional option information for the client session. A pointer to this structure can be passed to the [SshAsyncConnect](#) or [SshConnect](#) functions.

```
#define SSH_MAXTERMNAMELEN 32
#define SSH_MAXHOSTNAMELEN 128
#define SSH_MAXUSERNAMELEN 128
#define SSH_MAXPASSWORDLEN 128
#define SSH_MAXCOMMANDLEN 512

typedef struct _SSHOPTIONDATA
{
    DWORD dwSize;
    DWORD dwReserved;
    UINT nProxyType;
    UINT nProxyPort;
    TCHAR szProxyHost[SSH_MAXHOSTNAMELEN];
    TCHAR szProxyUser[SSH_MAXUSERNAMELEN];
    TCHAR szProxyPassword[SSH_MAXPASSWORDLEN];
    UINT nTermCols;
    UINT nTermRows;
    TCHAR szTermName[SSH_MAXTERMNAMELEN];
    TCHAR szCommandLine[SSH_MAXCOMMANDLEN];
} SSHOPTIONDATA, *LPSSHOPTIONDATA;
```

Members

dwSize

An unsigned integer value which specifies the size of the SSHOPTIONDATA structure. This member must be initialized prior to passing the structure to the **SshAsyncConnect** or **SshConnect** functions.

dwReserved

An unsigned integer value that is reserved for internal use, and should always be initialized to a value of zero.

nProxyType

An unsigned integer value that specifies the type of proxy that the client should connect through. This structure member is only used if the option SSH_OPTION_PROXYSERVER has been specified. Possible values are:

Constant	Description
SSH_PROXY_NONE	No proxy server should be used when establishing the connection.
SSH_PROXY_HTTP	The connection should be established on port 80 using HTTP. An alternate port number can be specified by setting the <i>nProxyPort</i> structure member to the desired value.
SSH_PROXY_TELNET	The connection should be established on port 23 using TELNET. An alternate port number can be specified by setting the <i>nProxyPort</i> structure member to the desired value.

nProxyPort

An unsigned integer value that specifies the port number which should be used to establish the

proxy connection. A value of zero specifies that the default port number appropriate for the selected protocol should be used. This structure member is only used if the option SSH_OPTION_PROXYSERVER has been specified.

szProxyHost

A null terminated string which specifies the host name or IP address of the proxy server. This structure member is only used if the option SSH_OPTION_PROXYSERVER has been specified.

szProxyUser

A null terminated string which specifies the user name which is used to authenticate the connection through the proxy server. This structure member is only used if the option SSH_OPTION_PROXYSERVER has been specified.

szProxyPassword

A null terminated string which specifies the password which is used to authenticate the connection through the proxy server. This structure member is only used if the option SSH_OPTION_PROXYSERVER has been specified.

nTermCols

An unsigned integer value which specifies the number of columns for the virtual terminal allocated for the client session. The default number of columns is 80. This structure member is only used if the option SSH_OPTION_TERMINAL has been specified.

nTermRows

An unsigned integer value which specifies the number of rows for the virtual terminal allocated for the client session. The default number of rows is 25. This structure member is only used if the option SSH_OPTION_TERMINAL has been specified.

szTermName

A null terminated string which specifies the name of the terminal emulation type. On UNIX based systems, this name typically corresponds to an entry in the terminal capability database (either termcap or terminfo). If the name is not specified, then the default name terminal name of "unknown" will be used. This structure member is only used if the option SSH_OPTION_TERMINAL has been specified.

szCommandLine

A null terminated string which specifies the command that should be executed on the server. The output from the command is returned to the client, and the session is terminated. This structure member is only used if the option SSH_OPTION_COMMAND has been specified.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Simple Mail Transfer Protocol Library

Submit email messages for delivery to one or more recipients.

Reference

- [Functions](#)
- [Data Structures](#)
- [Error Codes](#)

Library Information

File Name	CSMTPV10.DLL
Version	10.0.1468.2518
LibID	D74CB488-F2C1-4F78-858A-201AEA7483FE
Import Library	CSMTPV10.LIB
Dependencies	None
Standards	RFC 821, RFC 1425, RFC 1869, RFC 2821

Overview

The Simple Mail Transfer Protocol (SMTP) enables applications to deliver email messages to one or more recipients. The library provides an API for addressing and delivering messages, and extended features such as user authentication and delivery status notification. Unlike Microsoft's Messaging API (MAPI) or Collaboration Data Objects (CDO), there is no requirement to have certain third-party email applications installed or specific types of servers installed on the local system. The library can be used to deliver mail through a wide variety of systems, from standard UNIX based mail servers to Windows systems running Microsoft Exchange.

Using this library, messages can be delivered directly to the recipient, or they can be routed through a relay server, such as an Internet service provider's mail system. The SocketTools Mail Message API can be integrated with this library in order to provide an extremely simple, yet flexible interface for composing and delivering messages.

This library supports secure connections using the standard SSL and TLS protocols. Both implicit and explicit SSL connections are supported, as well as client certificates used for authentication.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). If you are using Visual C++ 6.0 it is required that you have Service Pack 6 (SP6) installed. You should install all updates for your development tools and have the current Windows SDK installed. The minimum recommended version of Visual Studio is Visual Studio 2010.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are using Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. It is recommended that you install the current service pack and all critical updates available for your version of the operating system.

This product includes both 32-bit and 64-bit libraries. Native 64-bit CPU support requires the 64-bit version of Windows 7 or later versions of the Windows operating system.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

Simple Mail Transfer Protocol Functions

Function	Description
SmtpAddRecipient	Add an address to the recipient list
SmtpAppendMessage	Append contents of specified file to the current message
SmtpAsyncConnect	Establish an asynchronous connection with a server
SmtpAsyncSendMessage	Send message to the specified recipient
SmtpAsyncSubmitMessage	Compose and submit a message for delivery to the specified mail server
SmtpAttachThread	Attach the specified client handle to another thread
SmtpAuthenticate	Authenticate the client session with a user name and password
SmtpCancel	Cancel the current blocking operation
SmtpCloseMessage	Close the message being composed and submit for delivery
SmtpCommand	Send a command to the server
SmtpConnect	Establish a connection with a server
SmtpCreateMessage	Create a new message
SmtpCreateSecurityCredentials	Allocate a structure to establish client security credentials
SmtpDeleteSecurityCredentials	Delete the specified client security credentials
SmtpDisableEvents	Disable all event notification, including event callbacks
SmtpDisableTrace	Disable logging of socket function calls to the trace log
SmtpDisconnect	Disconnect from the current server
SmtpEnableEvents	Enable event handling by the library
SmtpEnableTrace	Enable logging of socket function calls to a file
SmtpEnumTasks	Return a list of asynchronous tasks
SmtpEventProc	Process events generated by the client
SmtpExpandAddress	Expand the specified address
SmtpFreezeEvents	Suspend and resume event handling by the client
SmtpGetCurrentDate	Return the current date and time
SmtpGetDeliveryOptions	Return the delivery options for the current session
SmtpGetErrorString	Return a description for the specified error code
SmtpGetExtendedOptions	Return the extended options supported by the server
SmtpGetLastError	Return the last error code
SmtpGetResultCode	Return the result code from the previous command
SmtpGetResultString	Return the result string from the previous command
SmtpGetSecurityInformation	Return security information about the current client connection
SmtpGetStatus	Return the current status of the client

SmtpGetTaskError	Return the last error code for the specified asynchronous task
SmtpGetTaskId	Return the unique task identifier associated with the specified client session
SmtpGetTimeout	Return the number of seconds until an operation times out
SmtpGetTransferStatus	Return data transfer statistics
SmtpInitialize	Initialize the library and validate the specified license key at runtime
SmtpIsBlocking	Determine if the client is blocked, waiting for information
SmtpIsConnected	Determine if the client is connected to the server
SmtpIsReadable	Determine if data can be read from the server
SmtpIsWritable	Determine if data can be written to the server
SmtpRegisterEvent	Register an event handler for the specified event
SmtpReset	Reset the client and return to a command state
SmtpSendMessage	Send message to the specified recipient
SmtpSetDeliveryOptions	Set the delivery options for the current session
SmtpSetLastError	Set the last error code
SmtpSetTimeout	Set the number of seconds until an operation times out
SmtpSubmitMessage	Compose and submit a message for delivery to the specified mail server
SmtpSubmitMessageEx	Compose and submit a message for delivery with additional options
SmtpTaskAbort	Abort the specified asynchronous task
SmtpTaskDone	Determine if an asynchronous task has completed
SmtpTaskResume	Resume execution of an asynchronous task
SmtpTaskSuspend	Suspend execution of an asynchronous task
SmtpTaskWait	Wait for an asynchronous task to complete
SmtpUninitialize	Terminate use of the library by the application
SmtpVerifyAddress	Verify that the specified address is valid
SmtpWrite	Write data to the server

SmtpAddRecipient Function

```
INT WINAPI SmtpAddRecipient(  
    HCLIENT hClient,  
    LPCTSTR lpszAddress  
);
```

The **SmtpAddRecipient** function adds the specified address to the recipient list for the current message. This function should be called once for each recipient.

Parameters

hClient

Handle to the client session.

lpszAddress

Points to a string which specifies the address to be added to the recipient list.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is SMTP_ERROR. To get extended error information, call **SmtpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmtpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

SmtpAppendMessage Function

```
INT WINAPI SmtpAppendMessage(  
    HCLIENT hClient,  
    LPVOID lpvMessage,  
    DWORD dwMessageSize,  
    DWORD dwOptions  
);
```

The **SmtpAppendMessage** function writes the contents of a specified file or buffer to the data stream, appending it to the current message contents.

Parameters

hClient

Handle to the client session.

lpvMessage

Pointer to a buffer which contains the message data to be appended, or a pointer to the name of the file which contains the data to be written to the data stream. The use of this parameter depends on the value of the *dwOptions* parameter.

dwMessageSize

An unsigned integer which specifies the length of the message in bytes.

dwOptions

Specifies the source of the message data that will be written to the data stream; it may be one of the following values:

Constant	Description
SMTP_MESSAGE_MEMORY	The <i>lpvMessage</i> parameter specifies a pointer to an array of characters. If the value of <i>dwMessageSize</i> is zero, then it is assumed to be a pointer to a string.
SMTP_MESSAGE_HGLOBAL	The <i>lpvMessage</i> parameter specifies an HGLOBAL which contains the data to be written to the data stream. If the value of the <i>dwMessageSize</i> parameter is zero, then the data is assumed to be null-terminated.
SMTP_MESSAGE_FILE	The <i>lpvMessage</i> parameter specifies a pointer to a string which contains the name of a file. The file is opened and the contents of the file are written to the data stream. The value of the <i>dwMessageSize</i> parameter is ignored when this option is specified.
SMTP_MESSAGE_CLIPBOARD	The <i>lpvMessage</i> and <i>dwMessageSize</i> parameters are ignored. The current contents of the clipboard are written to the data stream.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is SMTP_ERROR. To get extended error information, call **SmtpGetLastError**.

Remarks

The **SmtpAppendMessage** function is used to append the contents of a memory buffer, file or

the system clipboard to the current message that is being composed for delivery. To send a complete RFC 822 formatted message, refer to the **SmtpSendMessage** function.

This function will cause the current thread to block until the complete message has been written, a timeout occurs or the operation is canceled. During the transfer, the SMTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **SmtpEnableEvents**, or by registering a callback function using the **SmtpRegisterEvent** function.

To determine the current status of a transfer while it is in progress, use the **SmtpGetTransferStatus** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmtpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

SmtpAsyncConnect Function

```
HCLIENT WINAPI SmtpAsyncConnect(  
    LPCTSTR lpszRemoteHost,  
    UINT nRemotePort,  
    UINT nTimeout,  
    DWORD dwOptions,  
    LPCTSTR lpszLocalName,  
    LPSECURITYCREDENTIALS lpCredentials,  
    HWND hEventWnd,  
    UINT uEventMsg  
);
```

The **SmtpAsyncConnect** function is used to establish a connection with the server.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

The application should create a background worker thread and establish a connection by calling **SmtpConnect** within that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each client session.

Parameters

lpszRemoteHost

A pointer to the name of the server to connect to; this may be a fully-qualified domain name or an IP address.

nRemotePort

The port number the server is listening on. A value of zero specifies that the default port number should be used. For standard connections, the default port number is 25. An alternative port is 587, which is commonly used by authenticated clients to submit messages for delivery. For secure connections, the default port number is 465. If the secure port number is specified, an implicit SSL/TLS connection will be established by default.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
SMTP_OPTION_NONE	No additional options are specified when establishing a connection with the server. A standard, non-secure connection will be used and the client will not attempt to use extended (ESMTP) features of the protocol. Note that if the mail server requires authentication, the SMTP_OPTION_EXTENDED option must be specified.

SMTP_OPTION_EXTENDED	Extended SMTP commands should be used if possible. This option enables features such as authentication and delivery status notification. If this option is not specified, the library will not attempt to use any extended features. This option is automatically enabled if the connection is established on port 587 because submitting messages for delivery using this port typically requires client authentication.
SMTP_OPTION_TUNNEL	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established.
SMTP_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using either the SSL or TLS protocols.
SMTP_OPTION_SECURE	This option specifies that a secure connection should be established with the server and requires that the server support either the SSL or TLS protocol. This option is the same as specifying SMTP_OPTION_SECURE_EXPLICIT, which initiates the secure session using the STARTTLS command.
SMTP_OPTION_SECURE_EXPLICIT	This option specifies the client should attempt to establish a secure connection with the server using the STARTTLS command. Note that the server must support secure connections using either the SSL or TLS protocol.
SMTP_OPTION_SECURE_IMPLICIT	This option specifies the client should attempt to establish a secure connection with the server. The server must support secure connections using either the SSL or TLS protocol, and the secure session must be negotiated immediately after the connection has been established.
SMTP_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
SMTP_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This

	option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
SMTP_OPTION_FREETHREAD	This option specifies the handle returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the handle is synchronized across multiple threads.

lpzLocalName

A pointer to a string which specifies the domain name of the local host. This parameter can be NULL or point to an empty string, in which case the local domain name is determined automatically from the system configuration. This parameter should be used if the mail server only accepts messages from a client that identifies itself using a specific domain name.

lpCredentials

A pointer to a [SECURITYCREDENTIALS](#) structure which is used to establish the client credentials for a secure connection to the server. The function **SmtplibCreateSecurityCredentials** can be used to create this structure if necessary. If a standard non-secure connection is being established, or client credentials are not required by the server, this parameter can be NULL.

hEventWnd

The handle to the event notification window. This window receives messages which notify the client of various asynchronous socket events that occur. If this parameter is NULL, a blocking connection is established with the server.

uEventMsg

The message identifier that is used when an asynchronous socket event occurs. This value should be greater than WM_USER as defined in the Windows header files. If the *hEventWnd* parameter is NULL, this parameter must be specified as WM_NULL.

Return Value

If the function succeeds, the return value is a handle to a client session. If the function fails, the return value is INVALID_CLIENT. To get extended error information, call **SmtplibGetLastError**.

Remarks

The *lpzLocalName* argument should only specify a domain name if it is absolutely necessary. In most cases, it is preferable to pass this parameter as NULL or an empty string and allow the library to automatically determine the correct domain name to use. Providing an invalid domain name may cause the mail server to reject the connection.

When a message is posted to the notification window, the low word of the *lParam* parameter contains the event identifier. The high word of *lParam* contains the low word of the error code, if an error has occurred. The *wParam* parameter contains the client handle. One or more of the following event identifiers may be sent:

Constant	Description

SMTP_EVENT_CONNECT	The connection to the server has completed. The high word of the IParam parameter should be checked, since this notification message will be posted if an error has occurred.
SMTP_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
SMTP_EVENT_READ	Data is available to read by the client. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the calling process is in asynchronous mode.
SMTP_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
SMTP_EVENT_TIMEOUT	The client has timed out while waiting for a response from the server. Note that under some circumstances this event can be generated for a non-blocking connection, such as when the client is establishing a secure connection.
SMTP_EVENT_CANCEL	The client has canceled the current operation.
SMTP_EVENT_COMMAND	The client has processed a command that was sent to the server. The result code and result string can be used to determine if the response to the command. The high word of the IParam parameter should be checked, since this notification message will also be posed if the command cannot be executed.
SMTP_EVENT_PROGRESS	This event notification is sent periodically during lengthy blocking operations, such as retrieving a complete message from the server.

To cancel asynchronous notification and return the client to a blocking mode, use the **SmtplibDisableEvents** function.

It is recommended that you only establish an asynchronous connection if you understand the implications of doing so. In most cases, it is preferable to create a synchronous connection and create threads for each additional session if more than one active client session is required.

The *dwOptions* argument can be used to specify the threading model that is used by the library when a connection is established. By default, the handle is initially attached to the thread that created it. From that point on, until the it is released, only the owner may call functions using that handle. The ownership of the handle may be transferred from one thread to another using the **SmtplibAttachThread** function.

Specifying the SMTP_OPTION_FREETHREAD option enables any thread to call any function using the handle, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the handle is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same handle.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmtpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

SmtpAsyncSendMessage Function

```
UINT WINAPI SmtpAsyncSendMessage(  
    HCLIENT hClient,  
    LPCTSTR lpszFrom,  
    LPCTSTR lpszRecipient,  
    LPVOID lpvMessage,  
    DWORD dwMessageSize,  
    DWORD dwOptions,  
    SMTPEVENTPROC lpEventProc,  
    DWORD_PTR dwParam  
);
```

Send the contents of a file or memory buffer to the specified recipients.

Parameters

hClient

Handle to the client session.

lpszFrom

Pointer to a string which specifies the email address of the sender.

lpszRecipient

Pointer to a string which specifies the recipient of the message. Multiple recipients may be specified by separating each address with a comma.

lpvMessage

Pointer to a buffer which contains the message to be delivered, or a pointer to the name of the file which contains the data to be written to the data stream. The use of this parameter depends on the value of the *dwOptions* parameter.

dwMessageSize

An unsigned integer which specifies the length of the message in bytes.

dwOptions

Specifies the source of the message data that will be written to the data stream; it may be one of the following values:

Constant	Description
SMTP_MESSAGE_MEMORY	The <i>lpvMessage</i> parameter specifies a pointer to an array of characters. If the value of <i>dwMessageSize</i> is zero, then it is assumed to be a pointer to a string.
SMTP_MESSAGE_HGLOBAL	The <i>lpvMessage</i> parameter specifies an HGLOBAL which contains the data to be written to the data stream. If the value of the <i>dwMessageSize</i> parameter is zero, then the data is assumed to be null-terminated.
SMTP_MESSAGE_FILE	The <i>lpvMessage</i> parameter specifies a pointer to a string which contains the name of a file. The file is opened and the contents of the file are written to the data stream. The value of the <i>dwMessageSize</i> parameter is ignored when this option is specified.
SMTP_MESSAGE_CLIPBOARD	The <i>lpvMessage</i> and <i>dwMessageSize</i> parameters are

ignored. The current contents of the clipboard are written to the data stream.
--

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **SmtplibEventProc** callback function. This parameter may be NULL if you do not wish to implement an event handler.

dwParam

A user-defined integer value that is passed to the callback function. This parameter is ignored if the *lpEventProc* parameter is NULL.

Return Value

If the function succeeds, the return value is non-zero integer value that specifies a unique asynchronous task identifier. If the function fails, the return value is zero. To get extended error information, call the **SmtplibGetLastError** function.

Remarks

The **SmtplibAsyncSendMessage** function is used to send the contents of a memory buffer, file or the system clipboard to the specified recipients. This function is similar to the **SmtplibSendMessage** function, however it uses a background worker thread and does not block the current working thread. This enables the application to continue to perform other operations while the message is being submitted to mail server for delivery.

Because this function works asynchronously, it is important that the memory allocated for the message is not released before the asynchronous task completes. If you provide a buffer that is allocated on the stack, ensure that your code does not return from the function while the message is being submitted. This can be achieved by calling the **SmtplibTaskWait** function or periodically calling the **SmtplibTaskDone** function to determine if the background task has completed. If you wish to return from the calling function immediately, then you must dynamically allocate memory for the *lpvMessage* parameter on the heap and free that memory after the task has completed.

If the address of an event handler is provided to this function, it is guaranteed that the handler will be invoked with the SMTP_EVENT_CONNECT event after the connection has been established, and the SMTP_EVENT_DISCONNECT event after the message has been submitted. This enables your application to know when the message is being submitted to the mail server, and immediately before the worker thread is terminated. The worker thread creates a secondary connection to the server with its own session handle. This ensures that the asynchronous operation will not interfere with the current client session. Your application can interact with this background worker thread using the client handle that is passed to the event handler.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmtplib10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[SmtplibAsyncSubmitMessage](#), [SmtplibSendMessage](#), [SmtplibSubmitMessage](#), [SmtplibTaskWait](#)

SmtpAsyncSubmitMessage Function

```
UINT WINAPI SmtpAsyncSubmitMessage(  
    LPSMTPSERVER lpServer,  
    LPSMTPMESSAGE lpMessage,  
    SMTPEVENTPROC lpEventProc,  
    DWORD_PTR dwParam  
);
```

The **SmtpSubmitMessage** function composes and submits a message for delivery to the specified mail server.

Parameters

lpServer

A pointer to an **SMTPSERVER** structure that contains information about the mail server that the message will be submitted to for delivery. This parameter cannot be NULL and the structure members must be properly initialized prior to calling this function.

lpMessage

A pointer to an **SMTPMESSAGE** structure that contains information about the message, including the sender, recipients and the body of the message. This parameter cannot be NULL and the structure members must be property initialized prior to calling this function.

lpEventProc

A pointer to the procedure-instance address of an application defined callback function. For more information about event handling and the callback function, see the description of the **SmtpEventProc** callback function. If this parameter is NULL, event notification is disabled.

dwParam

A user-defined integer value that is passed to the callback function. If the *lpEventProc* parameter is NULL, this value should be zero.

Return Value

If the function succeeds, the return value is non-zero integer value that specifies a unique asynchronous task identifier. If the function fails, the return value is zero. To get extended error information, call the **SmtpGetLastError** function.

Remarks

The **SmtpAsyncSubmitMessage** function provides a high-level interface that enables an application to send an email message with a single function call. This function is similar to the **SmtpSubmitMessage** function; however, it uses a background worker thread and does not block the current working thread. This enables the application to continue to perform other operations while the message is being submitted to the mail server.

The **SMTPSERVER** and **SMTPMESSAGE** structures are used to provide the function with information about the mail server that will accept the message and the contents of the message itself. Note that this function does not require a client session handle, and therefore it is not required that you call the **SmtpConnect** function prior to calling this function.

If the address of an event handler is provided to this function, it is guaranteed that the handler will be invoked with the SMTP_EVENT_CONNECT event after the connection has been established, and the SMTP_EVENT_DISCONNECT event after the message has been submitted. This enables your application to know when the message is being submitted to the mail server, and

immediately before the worker thread is terminated. The worker thread creates a secondary connection to the server with its own session handle. This ensures that the asynchronous operation will not interfere with the current client session. Your application can interact with this background worker thread using the client handle that is passed to the event handler.

Example

```
SMTPSERVER mailServer;
ZeroMemory(&mailServer, sizeof(mailServer));
mailServer.lpszHostName = _T("smtp.gmail.com");
mailServer.nHostPort = SMTP_PORT_SUBMIT;
mailServer.lpszUserName = m_strSender;
mailServer.lpszPassword = m_strPassword;
mailServer.dwOptions = SMTP_OPTION_SECURE;

SMTPMESSAGE mailMessage;
ZeroMemory(&mailMessage, sizeof(mailMessage));
mailMessage.lpszFrom = m_strSender;
mailMessage.lpszTo = m_strRecipients;
mailMessage.lpszSubject = m_strSubject;
mailMessage.lpszText = m_strMessage;

UINT nTaskId = SmtAsyncSubmitMessage(&mailServer, &mailMessage, NULL, 0);

if (nTaskId != 0)
{
    DWORD dwError = NO_ERROR;
    DWORD dwElapsed = 0;

    // Wait for the message to be submitted
    SmtTaskWait(nTaskId, INFINITE, &dwElapsed, &dwError);

    if (dwError == NO_ERROR)
        _tprintf(_T("SmtAsyncSubmitMessage was successful\n"));
}
else
{
    DWORD dwError = SmtGetLastError();
    _tprintf(_T("SmtSubmitMessage failed with error 0x%08lx\n"), dwError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmtpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

SmtpAttachThread Function

```
DWORD WINAPI SmtpAttachThread(  
    HCLIENT hClient  
    DWORD dwThreadId  
);
```

The **SmtpAttachThread** function attaches the specified client handle to another thread.

Parameters

hClient

Handle to the client session.

dwThreadId

The ID of the thread that will become the new owner of the handle. A value of zero specifies that the current thread should become the owner of the client handle.

Return Value

If the function succeeds, the return value is the thread ID of the previous owner. If the function fails, the return value is SMTP_ERROR. To get extended error information, call **SmtpGetLastError**.

Remarks

When a client handle is created, it is associated with the current thread that created it. Normally, if another thread attempts to perform an operation using that handle, an error is returned since it does not own the handle. This is used to ensure that other threads cannot interfere with an operation being performed by the owner thread. In some cases, it may be desirable for one thread in a client application to create the client handle, and then pass that handle to another worker thread. The **SmtpAttachThread** function can be used to change the ownership of the handle to the new worker thread. By preserving the return value from the function, the original owner of the handle can be restored before the worker thread terminates.

This function should be called by the new thread immediately after it has been created, and if the new thread does not release the handle itself, the ownership of the handle should be restored to the parent thread before it terminates. Under no circumstances should **SmtpAttachThread** be used to forcibly release a handle allocated by another thread while a blocking operation is in progress. To cancel an operation, use the **SmtpCancel** function and then release the handle after the blocking function exits and control is returned to the current thread.

Note that the *dwThreadId* parameter is presumed to be a valid thread ID and no checks are performed to ensure that the thread actually exists. Specifying an invalid thread ID will orphan the handle until the **SmtpUninitialize** function is called.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmtpv10.lib

See Also

SmtpAuthenticate Function

```
INT WINAPI SmtpAuthenticate(  
    HCLIENT hClient,  
    UINT nAuthType,  
    LPCTSTR lpszUserName,  
    LPCTSTR lpszPassword  
);
```

The **SmtpAuthenticate** function provides client authentication information to the server.

Parameters

hClient

The handle to the client session.

nAuthType

An integer value which specifies which method the library should use to authenticate the client session. This parameter should be set to one of the following values:

Constant	Description
SMTP_AUTH_LOGIN	The client will authenticate using the AUTH LOGIN command. This encodes the username and password, however the credentials are not encrypted and it is recommended you use a secure connection. This is the default method accepted by most mail servers and is the preferred authentication type for most clients.
SMTP_AUTH_PLAIN	The client will authenticate using the AUTH PLAIN command. This encodes the username and password, however the credentials are not encrypted and it is recommended you use a secure connection. The server must support the PLAIN Simple Authentication and Security Layer (SASL) mechanism as defined in RFC 4616.
SMTP_AUTH_XOAUTH2	The client will authenticate using the AUTH XOAUTH2 command. This authentication method does not require the user password, instead the <i>lpszPassword</i> parameter must specify the OAuth 2.0 bearer token issued by the service provider. The application must provide a valid access token which has not expired, or this function will fail.
SMTP_AUTH_BEARER	The client will authenticate using the AUTH OAUTHBEARER command as defined in RFC 7628. This authentication method does not require the user password, instead the <i>lpszPassword</i> parameter must specify the OAuth 2.0 bearer token issued by the service provider. The application must provide a valid access token which has not expired, or this function will fail.

lpszUserName

A null terminated string which specifies the account name for the user authorized to send mail through the server.

lpszPassword

A null terminated string which specifies the password to be used when authenticating the current client session. If you are using the SMTP_AUTH_XOAUTH2 or SMTP_AUTH_BEARER authentication methods, this parameter is not a password, instead it specifies the OAuth 2.0 access token provided by the mail service.

Return Value

If the function succeeds, the return value is the command result code. If the function fails, the return value is SMTP_ERROR. To get extended error information, call **SmtplibGetLastError**.

Remarks

To submit a mail message for delivery, virtually all public mail servers require clients to authenticate and will only accept messages from authorized users. In some cases, they may also require the sender email address match the account being used to authenticate the session. It is also typical for most public mail servers to reject authentication attempts over a standard (non-secure) connection. You should always use a secure connection whenever possible.

All authentication methods require the mail server to support the standard service extensions for authentication as specified in the RFC 4954. The server must support the ESMTP protocol extensions and the AUTH command. A user name and password are required for authentication. If you wish to authenticate without a user password, you must use one of the OAuth 2.0 authentication methods.

The default authentication method is SMTP_AUTH_LOGIN and this is accepted by most mail servers. It is common for mail servers to allow the SMTP_AUTH_PLAIN method as well, however it is recommended you explicitly check whether the server supports the desired authentication method by calling the **SmtplibGetExtendedOptions** function. If you attempt to use an authentication method which is not supported by the server, this function will fail and the last error code will be set to ST_ERROR_INVALID_AUTHENTICATION_TYPE.

You should only use an OAuth 2.0 authentication method if you understand the process of how to request the access token. Obtaining an access token requires registering your application with the mail service provider (e.g.: Microsoft or Google), getting a unique client ID associated with your application and then requesting the access token using the appropriate scope for the service. Obtaining the initial token will typically involve interactive confirmation on the part of the user, requiring they grant permission to your application to access their mail account.

The SMTP_AUTH_XOAUTH2 and SMTP_AUTH_BEARER authentication methods are similar, but they are not interchangeable. Both use an OAuth 2.0 bearer token to authenticate the client session, but they differ in how the token is presented to the server. It is currently preferable to use the XOAUTH2 method because it is more widely available and some service providers do not yet support the OAUTHBEARER method.

Your application should not store an OAuth 2.0 bearer token for later use. They have a relatively short lifespan, typically about an hour, and are designed to be used with that session. You should specify offline access as part of the OAuth 2.0 scope if necessary and store the refresh token provided by the service. The refresh token has a much longer validity period and can be used to obtain a new bearer token when needed.

Example

```
BOOL bExtended = FALSE;  
DWORD dwOptions = 0;
```

```
// Determine which extended options and authentication methods
```

```

// are supported by this server

bExtended = SntpGetExtendedOptions(hClient, &dwOptions);

if (bUseBearerToken)
{
    if (bExtended && (dwOptions & SMTP_EXTOPT_XOAUTH2))
    {
        INT nResult = SntpAuthenticate(hClient, SMTP_AUTH_XOAUTH2, lpszUserName,
lpszBearerToken);

        if (nResult == SMTP_ERROR)
        {
            // An error occurred during authentication; when using an
            // OAuth 2.0 bearer token, this typically means that the token
            // has expired and must be refreshed
            return;
        }
    }
    else
    {
        // The server does not support XOAUTH2
        return;
    }
}
else
{
    if (bExtended && (dwOptions & SMTP_EXTOPT_AUTHLOGIN))
    {
        INT nResult = SntpAuthenticate(hClient, SMTP_AUTH_LOGIN, lpszUserName,
lpszPassword);

        if (nResult == SMTP_ERROR)
        {
            // An error occurred during authentication
            return;
        }
    }
    else
    {
        // The server does not support AUTH LOGIN
        return;
    }
}
}

```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmtpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[SntpConnect](#), [SntpGetExtendedOptions](#)

SmtpCancel Function

```
INT WINAPI SmtpCancel(  
    HCLIENT hClient  
);
```

The **SmtpCancel** function cancels any outstanding blocking operation in the client, causing the blocking function to fail. The application may then retry the operation or terminate the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is SMTP_ERROR. To get extended error information, call **SmtpGetLastError**.

Remarks

When the **SmtpCancel** function is called, the blocking function will not immediately fail. An internal flag is set which causes the blocking operation to exit with an error. This means that the application cannot cancel an operation and immediately perform some other operation. Instead it must allow the calling stack to unwind, returning back to the blocking operation before making any further function calls.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmtpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[SmtpIsBlocking](#)

SmtpCloseMessage Function

```
INT WINAPI SmtpCloseMessage(  
    HCLIENT hClient  
);
```

The **SmtpCloseMessage** function ends the composition of the current message. The server then queues the message for delivery to each recipient specified by the client.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is SMTP_ERROR. To get extended error information, call **SmtpGetLastError**.

Remarks

The **SmtpCloseMessage** function should be called after all of the message data has been written to the data stream.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmtpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

SmtpCommand Function

```
INT WINAPI SmtpCommand(  
    HCLIENT hClient,  
    LPCTSTR lpszCommand,  
    LPCTSTR lpszParameter  
);
```

The **SmtpCommand** function sends a command to the server and returns the result code back to the caller. This function is typically used for site-specific commands not directly supported by the API.

Parameters

hClient

Handle to the client session.

lpszCommand

The command which will be executed by the server.

lpszParameter

An optional command parameter. If the command requires more than one parameter, then they should be combined into a single string, with a space separating each parameter. If the command does not accept any parameters, this value may be NULL.

Return Value

If the command was successful, the function returns the result code. If the command failed, the function returns SMTP_ERROR. To get extended error information, call **SmtpGetLastError**.

Remarks

A list of valid commands can be found in the technical specification for the protocol. Many servers will list supported commands when the HELP command is used.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmtpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

SmtpConnect Function

```
HCLIENT WINAPI SmtpConnect(  
    LPCTSTR lpszRemoteHost,  
    UINT nRemotePort,  
    UINT nTimeout,  
    DWORD dwOptions,  
    LPCTSTR lpszLocalName,  
    LPSECURITYCREDENTIALS lpCredentials  
);
```

The **SmtpConnect** function is used to establish a connection with the server.

Parameters

lpszRemoteHost

A pointer to the name of the server to connect to; this may be a fully-qualified domain name or an IP address.

nRemotePort

The port number the server is listening on. A value of zero specifies that the default port number should be used. For standard connections, the default port number is 25. An alternative port is 587, which is commonly used by authenticated clients to submit messages for delivery. For implicit SSL connections, the default port number is 465.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
SMTP_OPTION_NONE	No additional options are specified when establishing a connection with the server. A standard, non-secure connection will be used and the client will not attempt to use extended (ESMTP) features of the protocol. Note that if the mail server requires authentication, the SMTP_OPTION_EXTENDED option must be specified.
SMTP_OPTION_EXTENDED	Extended SMTP commands should be used if possible. This option enables features such as authentication and delivery status notification. If this option is not specified, the library will not attempt to use any extended features. This option is automatically enabled if the connection is established on port 587 because submitting messages for delivery using this port typically requires client authentication.
SMTP_OPTION_TUNNEL	This option specifies that a tunneled TCP

	connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established.
SMTP_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using either the SSL or TLS protocols.
SMTP_OPTION_SECURE	This option specifies that a secure connection should be established with the server and requires that the server support either the SSL or TLS protocol. The client will initiate the secure session using the STARTTLS command.
SMTP_OPTION_SECURE_IMPLICIT	This option specifies the client should attempt to establish a secure connection with the server. The server must support secure connections using either the SSL or TLS protocol, and the secure session must be negotiated immediately after the connection has been established.
SMTP_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
SMTP_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
SMTP_OPTION_FREETHREAD	This option specifies the handle returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the handle is synchronized across multiple threads.

lpzLocalName

A pointer to a string which specifies the domain name of the local host. This parameter can be NULL or point to an empty string, in which case the local domain name is determined

automatically from the system configuration. This parameter should be used if the mail server only accepts messages from a client that identifies itself using a specific domain name.

lpCredentials

A pointer to a [SECURITYCREDENTIALS](#) structure which is used to establish the client credentials for a secure connection to the server. The function **SsmtpCreateSecurityCredentials** can be used to create this structure if necessary. If a standard non-secure connection is being established, or client credentials are not required by the server, this parameter can be NULL.

Return Value

If the function succeeds, the return value is a handle to a client session. If the function fails, the return value is INVALID_CLIENT. To get extended error information, call **SsmtpGetLastError**.

Remarks

To prevent this function from blocking the main user interface thread, the application should create a background worker thread and establish a connection by calling **SsmtpConnect** in that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each client session.

The *lpzLocalName* argument should only point to a specific domain name if it is absolutely necessary. In most cases, it is preferable to pass this parameter as NULL or an empty string and allow the library to automatically determine the correct domain name to use. Providing an invalid domain name may cause the mail server to reject the connection.

The *dwOptions* argument can be used to specify the threading model that is used by the library when a connection is established. By default, the handle is initially attached to the thread that created it. From that point on, until the it is released, only the owner may call functions using that handle. The ownership of the handle may be transferred from one thread to another using the **SsmtpAttachThread** function.

Specifying the SMTP_OPTION_FREETHREAD option enables any thread to call any function using the handle, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the handle is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same handle.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstoools10.h

Import Library: csmtpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

SmtpCreateMessage Function

```
INT WINAPI SmtpCreateMessage(  
    HCLIENT hClient  
    LPCTSTR lpszSender,  
    DWORD dwMessageSize,  
    DWORD dwReserved  
);
```

The **SmtpCreateMessage** function creates a new message for delivery.

Parameters

hClient

Handle to the client session.

lpszSender

A pointer to a string which specifies the email address of the user sending the message. This typically corresponds to the address in the From header of the message, but it is not required that they be the same.

dwMessageSize

An unsigned integer which specifies the size of the message in bytes. If the size of the message is unknown, this value should be zero. This parameter is ignored if the server does not support extended features. If the message size is larger than what the server will accept, this function will fail. Most Internet Service Providers impose a limit on the size of an email message, typically between 5 and 10 megabytes.

dwReserved

A reserved parameter. This value should be zero.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is SMTP_ERROR. To get extended error information, call **SmtpGetLastError**.

Remarks

The **SmtpCreateMessage** function begins the composition of a new message to be submitted to the mail server for delivery. There are several steps that must be followed when dynamically composing a message for delivery:

1. Call the **SmtpCreateMessage** function to begin the message composition. The sender email address should generally be the same address as the one used in the "From" header field in the message.
2. Call the **SmtpAddRecipient** function for each recipient of the message. These addresses are typically specified in the "To" and "Cc" header fields in the message. Additional addresses may also be provided which are not specified in the email message itself. This is how one or more blind carbon copies of a message is delivered. Most servers have a limit on the total number of recipients that may be specified for a single message. This limit is usually around 100 addresses.
3. Call the **SmtpWrite** function to write the contents of the message to the data stream. The application may also choose to use the **SmtpAppendMessage** function to write out a large amount of message data, or write the contents of a file to the data stream.

4. Call the **SmtplibCloseMessage** function to close the message and submit it to the mail server for delivery.

For applications that do not need to dynamically compose the message and already have the message contents stored in a file or memory buffer, the **SmtplibSendMessage** function is the preferred method of submitting a message for delivery.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmtplib10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[SmtplibAddRecipient](#), [SmtplibAppendMessage](#), [SmtplibCloseMessage](#), [SmtplibSendMessage](#), [SmtplibWrite](#)

SmtpCreateSecurityCredentials Function

```
BOOL WINAPI SmtpCreateSecurityCredentials(  
    DWORD dwProtocol,  
    DWORD dwOptions,  
    LPCTSTR lpszUserName,  
    LPCTSTR lpszPassword,  
    LPCTSTR lpszCertStore,  
    LPCTSTR lpszCertName,  
    LPVOID lpvReserved,  
    LPSECURITYCREDENTIALS* lppCredentials  
);
```

The **SmtpCreateSecurityCredentials** function creates a **SECURITYCREDENTIALS** structure.

Parameters

dwProtocol

A bitmask of supported security protocols. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_SSL	Either SSL 2.0 or SSL 3.0 should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, TLS will be excluded from the list of supported protocols. Both SSL 2.0 and 3.0 have been deprecated and will never be used unless explicitly specified. It is not recommended that you enable either of these protocols for secure connections because it will cause most servers to reject your connection request, even if a version of TLS is also specified.
SECURITY_PROTOCOL_TLS	Either the TLS 1.0, 1.1 or 1.2 protocol should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers that reject any attempt to use the older SSL protocol and require that only TLS be used.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol should be used when establishing a secure connection. This version is

	supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This is the recommended version of TLS to use with secure connections.

dwOptions

A value which specifies one or options. This member is constructed by using a bitwise operator with any of the following values:

Constant	Description
CREDENTIAL_STORE_CURRENT_USER	The library will attempt to open a store for the current user using the certificate store name provided in this structure. If no options are specified, then this is the default behavior.
CREDENTIAL_STORE_LOCAL_MACHINE	The library will attempt to open a local machine store using the certificate store name provided in this structure. If this option is specified, the library will always search for a local machine store before searching for the store by that name for the current user.
CREDENTIAL_STORE_FILENAME	The certificate store name is a file that contains the certificate and private key that will be used.

lpszUserName

A pointer to a string which specifies the certificate owner's username. A value of NULL specifies that no username is required. Currently this parameter is not used and any value specified will be ignored.

lpszPassword

A pointer to a string which specifies the certificate owner's password. A value of NULL specifies

that no password is required. This parameter is only used if a PKCS12 (PFX) certificate file is specified and that certificate has been secured with a password. This value will be ignored the current user or local machine certificate store is specified.

lpszCertStore

A pointer to a string which specifies the name of the certificate store to open. A certificate store is a collection of certificates and their private keys, typically organized by how they are used. If this value is NULL or points to an empty string, the default certificate store "MY" will be used.

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as VeriSign and Thawte act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. This corresponds to the "Personal" store that is displayed by the certificate manager utility and is the default store used by the library.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as VeriSign and Thawte are installed as part of the operating system and periodically updated by Microsoft.

lpszCertName

A pointer to a null terminated string which specifies the name of the certificate to use. The function will first search the certificate store for a certificate with a matching "friendly name"; this is a name for the certificate that is assigned by the user. Note that the name must match completely, but the comparison is not case sensitive. If no matching certificate is found, the function will then attempt to find a certificate that has a matching common name (also called the certificate subject). This comparison is less stringent, and the first partial match will be returned. If this second search fails, the function will return an error indicating that the certificate could not be found.

lpvReserved

Pointer reserved for future use. Set it to NULL when using this function.

lppCredentials

Pointer to an [LPSECURITYCREDENTIALS](#) pointer. The memory for the credentials structure will be allocated by this function and must be released by calling the **SsmtpDeleteSecurityCredentials** function when it is no longer needed. The pointer value must be set to NULL before the function is called. It is important to note that this is a pointer to a pointer variable, not a pointer to the SECURITYCREDENTIALS structure itself.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **SsmtpGetLastError**.

Remarks

The structure that is created by this function may be used as client credentials when establishing a secure connection. This is particularly useful for programming languages other than C/C++ which may not support C structures or pointers. The pointer to the SECURITYCREDENTIALS structure can

be declared as an unsigned integer variable which is passed by reference to this function, and then passed by value to the **SmtAsyncConnect** or **SmtConnect** functions.

Example

```
LPSECURITYCREDENTIALS lpSecCred = NULL;
SmtCreateSecurityCredentials(SEcurity_PROTOCOL_DEFAULT,
    0,
    NULL,
    NULL,
    lpszCertStore,
    lpszCertName,
    NULL,
    &lpSecCred);

hClient = SmtConnect(lpszHostName,
    SMTP_PORT_SECURE,
    SMTP_TIMEOUT,
    SMTP_OPTION_EXTENDED | SMTP_OPTION_SECURE,
    lpSecCred);
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmtpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[SmtAsyncConnect](#), [SmtConnect](#), [SmtDeleteSecurityCredentials](#), [SmtGetSecurityInformation](#), [SECURITYCREDENTIALS](#)

SmtDeleteSecurityCredentials Function

```
VOID WINAPI SmtDeleteSecurityCredentials(  
    LPSECURITYCREDENTIALS* lppCredentials  
);
```

The **SmtDeleteSecurityCredentials** function deletes an existing **SECURITYCREDENTIALS** structure.

Parameters

lppCredentials

Pointer to an **LPSECURITYCREDENTIALS** pointer. On exit from the function, the pointer will be NULL.

Return Value

None.

Example

```
if (lpSecCred)  
    SmtDeleteSecurityCredentials(&lpSecCred);  
  
SmtUninitialize();
```

Remarks

This function can be used to release the memory allocated to the client or server credentials after a secure connection has been terminated.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmtpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[SmtCreateSecurityCredentials](#), [SmtUninitialize](#)

SmtplibDisableEvents Function

```
INT WINAPI SmtplibDisableEvents(  
    HCLIENT hClient  
);
```

The **SmtplibDisableEvents** function disables the event notification mechanism, preventing subsequent event notification messages from being posted to the application's message queue.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is SMTP_ERROR. To get extended error information, call **SmtplibGetLastError**.

Remarks

The **SmtplibDisableEvents** function is used to disable event message posting for the specified client session. Although this will immediately prevent any new events from being generated, it is possible that messages could be waiting in the message queue. Therefore, an application must be prepared to handle client event messages after this function has been called.

This function is automatically called if the client has event notification enabled, and the **SmtplibDisconnect** function is called. The same issues regarding outstanding event messages also applies in this situation, requiring that the application handle event messages that may reference a client handle that is no longer valid.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmtplib10.lib

See Also

[SmtplibEnableEvents](#), [SmtplibRegisterEvent](#)

SmtplibDisableTrace Function

```
BOOL WINAPI SmtplibDisableTrace();
```

The **SmtplibDisableTrace** function disables the logging of socket function calls to the trace log.

Parameters

None.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero.

To get extended error information, call **SmtplibGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmtplib10.lib

See Also

[SmtplibEnableTrace](#)

SmtpDisconnect Function

```
INT WINAPI SmtpDisconnect(  
    HCLIENT hClient  
);
```

The **SmtpDisconnect** function terminates the connection with the server, closing the socket and releasing the memory allocated for the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is SMTP_ERROR. To get extended error information, call **SmtpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmtpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[SmtpAsyncConnect](#), [SmtpConnect](#), [SmtpUninitialize](#)

Smtplib.EnableEvents Function

```
INT WINAPI Smtplib.EnableEvents(  
    HCLIENT hClient,  
    HWND hEventWnd,  
    UINT uEventMsg  
);
```

The **Smtplib.EnableEvents** function enables event notifications using Windows messages.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Applications should use the **Smtplib.RegisterEvent** function to register an event handler which is invoked when an event occurs.

Parameters

hClient

Handle to the client session.

hEventWnd

Handle to the window which will receive the client notification messages. This parameter must specify a valid window handle. If a NULL handle is specified, event notification will be disabled.

uEventMsg

The message that is received when a client event occurs. To avoid conflict with standard Windows messages, this value must be greater than WM_USER (1024) or an error will be returned. If the *hEventWnd* parameter is NULL, this value should be WM_NULL.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is SMTP_ERROR. To get extended error information, call **Smtplib.GetLastError**.

Remarks

The **Smtplib.EnableEvents** function is used to request that notification messages be posted to the specified window whenever a client event occurs. This allows an application to monitor the status of different client operations, such as a file transfer. The client must create a window message handler, which processes the various events. The *wParam* argument will contain the client handle, the low word of the *lParam* argument will contain the event identifier, and the high word will contain any error code. If no error has occurred, the high word will have a value of zero. The following events may be generated:

Constant	Description
SMTP_EVENT_CONNECT	The connection to the server has completed. The high word of the lParam parameter should be checked, since this notification message will be posted if an error has occurred.
SMTP_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
SMTP_EVENT_READ	Data is available to read by the client. No additional messages will be posted until the client has read at least some of the data.

	This event is only generated if the calling process is in asynchronous mode.
SMTP_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
SMTP_EVENT_TIMEOUT	The client has timed out while waiting for a response from the server. Note that under some circumstances this event can be generated for a non-blocking connection, such as when the client is establishing a secure connection.
SMTP_EVENT_CANCEL	The client has canceled the current operation.
SMTP_EVENT_COMMAND	The client has processed a command that was sent to the server. The result code and result string can be used to determine if the response to the command. The high word of the IParam parameter should be checked, since this notification message will also be posed if the command cannot be executed.
SMTP_EVENT_PROGRESS	This event notification is sent periodically during lengthy blocking operations, such as retrieving a complete message from the server.

It is not required that the client be placed in asynchronous (non-blocking) mode in order to receive event notifications, except for the connect, disconnect, read and write events. To disable event notification, call the **SmtplibDisableEvents** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmtplib10.lib

See Also

[SmtplibDisableEvents](#), [SmtplibRegisterEvent](#)

SntpEnableTrace Function

```
BOOL WINAPI SntpEnableTrace(  
    LPCTSTR lpszTraceFile,  
    DWORD dwTraceFlags  
);
```

The **SntpEnableTrace** function enables the logging of socket function calls to a file.

Parameters

lpszTraceFile

Name of the trace log file. If this parameter is NULL or empty, the file CSTRACE.LOG is used. The directory for CSTRACE.LOG is given by the TEMP environment variable, if it is defined; otherwise, the directory given by the TMP environment variable is used, if it is defined; otherwise, the current working directory is used.

dwTraceFlags

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Constant	Description
0	TRACE_DEFAULT	All function calls and return values are written to the trace file. The actual data being sent or received will not be logged. This is the default value.
1	TRACE_ERROR	Only those function calls which fail are recorded in the trace file. Those errors which are not fatal and only indicate a warning will not be logged.
2	TRACE_WARNING	Only those function calls which fail, or return values which indicate a warning, are recorded in the trace file.
4	TRACE_HEXDUMP	All functions calls are written to the trace file, plus all the data that is sent or received is displayed, in both ASCII and hexadecimal format.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **SntpGetLastError**.

Remarks

When trace logging is enabled, the logfile is opened, appended to and closed for each socket function call. Using the same logfile name, you can do the same in your application to add additional information to the logfile if needed. This can provide an application-level context for the entries made by the library. Make sure that the logfile is closed after the data has been written.

The TRACE_HEXDUMP option can produce very large logfiles, since all data that is being sent and received by the application is logged. To reduce the size of the file, you can enable and disable logging around limited sections of code that you wish to analyze.

All of the SocketTools networking components that use the Windows Sockets API support logging. If you are using multiple components, you only need to enable tracing once in your application or once per thread in a multithreaded application.

To redistribute an application that includes logging functionality, the **cstrcv10.dll** library must be included as part of the installation package. This library provides the trace logging features, and if it is not available the **SmtpEnableTrace** function will fail. Note that the trace logging library is a standard Windows DLL and does not need to be registered, it only needs to be redistributed with your application.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmtpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[SmtpDisableTrace](#)

SmtpEnumTasks Function

```
INT WINAPI SmtpEnumTasks(  
    UINT * lpTasks,  
    INT nMaxTasks,  
    DWORD dwOptions  
);
```

Return a list of active, suspended or finished asynchronous tasks.

Parameters

lpTasks

A pointer to an array of unsigned integer values that will contain unique task identifiers when the function returns. If this parameter is NULL, the function will return the number of tasks.

nMaxTasks

An integer value that specifies the maximum number of task identifiers that may be copied into the *lpTasks* array. If the *lpTasks* parameter is NULL, this value must be zero.

dwOptions

An unsigned integer that specifies the type of asynchronous tasks that may be returned by this function. It may be a combination of the following values:

Constant	Description
SMTP_TASK_DEFAULT	The list of asynchronous task IDs should include both active and suspended tasks. This option is the same as specifying both the SMTP_TASK_ACTIVE and SMTP_TASK_SUSPENDED options.
SMTP_TASK_ACTIVE	The list of asynchronous task IDs should include those tasks which are currently active. An active task represents a background connection to a server that is in the process of performing the requested action, such as uploading or downloading a file.
SMTP_TASK_SUSPENDED	The list of asynchronous task IDs should include those tasks which have been suspended. A suspended task represents a background connection that has been established, but the worker thread is not scheduled for execution.
SMTP_TASK_FINISHED	The list of asynchronous task IDs should include those tasks which have completed recently.

Return Value

If the function is successful, the return value is the number of task identifiers copied into the provided array. If there are no tasks which match the requested criteria, the return value is zero. A return value of SMTP_ERROR indicates an error has occurred. To get extended error information, call the **SmtpGetLastError** function.

Remarks

The **SmtpEnumTasks** function can be used to obtain a list of numeric identifiers that represent the asynchronous tasks that have been started or those that have completed. These task IDs are used by other functions to reference the background worker thread that has been created and

obtain status information for the task. For example, the **SntpTaskDone** function can be used to determine if a particular task has completed, and the **SntpTaskWait** function can be used to wait for a task to complete and return an error status code if the background operation failed.

There is an internal limit of 128 asynchronous tasks per process that may be active at any one time. When a task completes, the status information about that task is maintained for period of time after the task has completed.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmtpv10.lib

See Also

SmtpEventProc Function

```
VOID CALLBACK SmtpEventProc(  
    HCLIENT hClient,  
    UINT nEvent,  
    DWORD dwError,  
    DWORD_PTR dwParam  
);
```

The **SmtpEventProc** function is an application-defined callback function that processes events generated by the client.

Parameters

hClient

Handle to the client session.

nEvent

An unsigned integer which specifies which event occurred. For a complete list of events, refer to the **SmtpRegisterEvent** function.

dwError

An unsigned integer which specifies any error that occurred. If no error occurred, then this parameter will be zero.

dwParam

A user-defined integer value which was specified when the event callback was registered.

Return Value

None.

Remarks

An application must register this callback function by passing its address to the **SmtpRegisterEvent** function. This callback function is also used by asynchronous tasks to notify the application when the task has started and completed. The **SmtpEventProc** function is a placeholder for the application-defined function name.

If the callback function is invoked by an asynchronous task, it will execute in the context of the worker thread that is managing the client session. You must ensure that any access to global or static variables are synchronized, otherwise the results may be unpredictable. It is recommended that you do not declare any static variables within the callback function itself.

If the application has a graphical user interface, you should never attempt to directly modify a UI control from within the callback function for an asynchronous task. Controls should only be modified by the same UI thread that created their window. One common approach to resolve this issue is to post a user-defined message to the main window to signal that the user interface needs to be updated. The message handler would then process the user-defined message and update the user interface as needed.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmtpv10.lib

See Also

[SmtpDisableEvents](#), [SmtpEnableEvents](#), [SmtpFreezeEvents](#), [SmtpRegisterEvent](#)

SmtpExpandAddress Function

```
INT WINAPI SmtpExpandAddress(  
    HCLIENT hClient,  
    LPCTSTR lpszMailingList,  
    LPTSTR lpszAddresses,  
    INT nMaxLength  
);
```

The **SmtpExpandAddress** function expands the specified mailing list, returning the membership of that list.

Parameters

hClient

Handle to the client session.

lpszMailingList

Points to a string which specifies the mailing list that the server should expand into full addresses.

lpszAddresses

Points to a buffer that the expanded addresses will be copied into.

nMaxLength

Maximum number of characters that may be copied into the buffer, including the terminating null character.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is SMTP_ERROR. To get extended error information, call **SmtpGetLastError**.

Remarks

The **SmtpExpandAddress** function requests that the server expand the specified email address. Typically this is used to expand aliases which refer to a mailing list, returning all of the members of that list. A server may not support this command, or may restrict its usage. An application should not depend on the ability to expand addresses.

This function cannot be called while a mail message is being composed.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmtpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[SmtpAddRecipient](#), [SmtpVerifyAddress](#)

SmtplibFreezeEvents Function

```
INT WINAPI SmtplibFreezeEvents(  
    HCLIENT hClient,  
    BOOL bFreeze  
);
```

The **SmtplibFreezeEvents** function is used to suspend and resume event handling by the client.

Parameters

hClient

Handle to the client session.

bFreeze

A non-zero value specifies that event handling should be suspended by the client. A zero value specifies that event handling should be resumed.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is SMTP_ERROR. To get extended error information, call **SmtplibGetLastError**.

Remarks

This function should be used when the application does not want to process events, such as when a modal dialog is being displayed. When events are suspended, all client events are queued. If events are re-enabled at a later point, those queued events will be sent to the application for processing. Note that only one of each event will be generated. For example, if the client has suspended event handling, and four events of the same type occur, once event handling is resumed only one of those events will be posted to the client. This prevents the application from being flooded by a potentially large number of queued events.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmtplib10.lib

See Also

SmtpGetCurrentDate Function

```
INT WINAPI SmtpGetCurrentDate(  
    LPTSTR lpszDateString,  
    INT nMaxLength  
);
```

The **SmtpGetCurrentDate** function copies the current date and time to the specified buffer in a format that is commonly used in mail messages. This date format should be used in all date-related fields in the message header.

Parameters

lpszDateString

Pointer to a string buffer that will contain the current date and time when the function returns.

nMaxLength

The maximum number of characters that can be copied into the string buffer.

Return Values

If the function succeeds, the return value is the number of characters copied into the buffer, not including the null-terminator. If the function fails, the return value is SMTP_ERROR. To get extended error information, call **SmtpGetLastError**.

Remarks

The date value that is returned is adjusted for the local timezone.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmtpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

SmtpGetDeliveryOptions Function

```
BOOL WINAPI SmtpGetDeliveryOptions(  
    HCLIENT hClient,  
    LPDWORD LpdwOptions  
);
```

The **SmtpGetDeliveryOptions** function returns the delivery status notification options for the current session.

Parameters

hClient

Handle to the client session.

lpdwOptions

Address of a variable that will be set to the current delivery options. This bitmask is created by combining one or more of the following values with a bitwise Or operator:

Constant	Description
SMTP_NOTIFY_NEVER	Never return information about the success or failure of the message delivery process.
SMTP_NOTIFY_SUCCESS	Return a message to the sender if the message has been successfully delivered to the recipient's mail server.
SMTP_NOTIFY_FAILURE	Return a message to the sender if the message could not be delivered to the recipient's mail server.
SMTP_NOTIFY_DELAY	Return a message to the sender if delivery of the message was delayed.
SMTP_RETURN_HEADERS	Return only the message headers to the sender.
SMTP_RETURN_MESSAGE	Return the complete message headers and body to the sender.

Return Values

If the function succeeds, the return value is a non-zero value. If the function fails, the return value is zero. To get extended error information, call **SmtpGetLastError**.

Remarks

The **SmtpGetDeliveryOptions** function returns the current delivery options for the client session. Note that delivery options are only available on those mail servers which support delivery status notification (DSN) using the extended SMTP protocol. The client must connect specifying SMTP_OPTION_EXTENDED in order to use extended server options.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmtpv10.lib

See Also

SmtpGetErrorString Function

```
INT WINAPI SmtpGetErrorString(  
    DWORD dwErrorCode,  
    LPTSTR lpszDescription,  
    INT nMaxLength  
);
```

The **SmtpGetErrorString** function is used to return a description of a specific error code. Typically this is used in conjunction with the **SmtpGetLastError** function for use with warning dialogs or as diagnostic messages.

Parameters

dwErrorCode

The error code for which a description should be returned. If this value is zero, then the description of the last error will be returned. If the last error code is zero, indicating no error, then this function will return zero.

lpszDescription

A pointer to the buffer that will contain a description of the specified error code. It is recommended that this buffer be at least 128 characters in length. If a NULL pointer is specified, then no message will be returned but the function will return the length of the error string, not including the terminating null byte.

nMaxLength

The maximum number of characters that may be copied into the description buffer.

Return Value

If the function succeeds, the return value is the length of the description string. If the function fails, the return value is 0, meaning that no description exists for the specified error code. Typically this indicates that the error code passed to the function is invalid.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csmtpv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

See Also

SmtpGetExtendedOptions Function

```
BOOL WINAPI SmtpGetExtendedOptions(  
    HCLIENT hClient,  
    LPDWORD lpdwOptions  
);
```

The **SmtpGetExtendedOptions** function returns the extended server options for the current session.

Parameters

hClient

Handle to the client session.

lpdwOptions

Address of a variable that will be set to the current server options. This bitmask is created by combining one or more of the following values with a bitwise Or operator:

Constant	Description
SMTP_EXTOPT_EXPN	The server supports address expansion using the EXPN command. The SmtpExpandAddress function can be used to expand addresses, which typically returns the email addresses associated with a mailing list. Most public mail servers restrict or disable this functionality because it can present a security risk. If a server does permit the use of the command, it is often limited to specific authorized users.
SMTP_EXTOPT_VRFY	The server supports verification of addresses using the VRFY command. The SmtpVerifyAddress function can be used to verify addresses. Most public mail servers restrict the ability for clients to verify email addresses to prevent potential abuse. If a server does permit the use of the command, it is often limited to specific authorized users.
SMTP_EXTOPT_DSN	The server supports delivery status notification (DSN) which allows the sender to be notified when a message has been delivered, or when an error occurs during the delivery process. The SmtpSetDeliveryOptions function can be used to specify the delivery options to be used in the current session.
SMTP_EXTOPT_SIZE	The server supports the use of the SIZE parameter, which enables the client to determine the maximum message size that may be delivered through the server. Most public mail servers impose a limit of on the total size of a message, including any encoded attachments.
SMTP_EXTOPT_ETRN	The server supports the use of the ETRN command, instructing the server to start processing its message queues for a specific host. Most public mail servers do not support this capability and its use has been deprecated.
SMTP_EXTOPT_8BITMIME	The server supports the delivery of messages that contain

	characters with the high bit set. Most servers support this option, however it is recommended that you encode any message text which contains non-ASCII characters to ensure the broadest compatibility with other servers and clients.
SMTP_EXTOPT_STARTTLS	The server supports explicit TLS sessions. This extended option is used internally to determine how secure connections should be established, and if a secure connection can be made using the standard submission port.
SMTP_EXTOPT_UTF8	The server supports UTF-8 encoding in email addresses and the message envelope. Not all mail servers will have this extended capability enabled, and applications should not depend on being able to provide internationalized user and domain names unless this option bitflag has been set.

In addition, there are extended options which specify the authentication methods supported by the server. A server will typically support multiple authentication methods and may be one or more of the following values:

Constant	Description
SMTP_EXTOPT_AUTHLOGIN	The server supports client authentication using the AUTH LOGIN command. This is the default authentication method and is supported by most mail servers. The user name and password are encoded in a specific format, but are not encrypted. The client should use a secure connection whenever possible.
SMTP_EXTOPT_AUTHPLAIN	The server supports client authentication using the AUTH PLAIN command. The use name and password are encoded in a specific format, but are not encrypted. If a server supports this authentication method, it is very likely it also supports AUTH LOGIN. It is recommended you use only use AUTH PLAIN authentication if the server does not support AUTH LOGIN.
SMTP_EXTOPT_XOAUTH2	The server supports client authentication using AUTH XOAUTH2 command. Instead of a password, an OAuth 2.0 bearer token is used to authenticate the user which previously authorized access to the mail server using their account information. The connection must be secure to use this authentication method.
SMTP_EXTOPT_BEARER	The server supports client authentication using AUTH OAUTHBEARER command as specified in RFC 7628. Instead of a password, an OAuth 2.0 bearer token is used to authenticate the user which previously authorized access to the mail server using their account information. The connection must be secure to use this authentication method.

Return Value

If the function succeeds, the return value is a non-zero value. If the function fails, the return value is zero. To get extended error information, call **SmtpGetLastError**.

Remarks

The **SmtpGetExtendedOptions** function returns the extended options supported by the server. The use of extended options requires that the server support the ESMTP protocol, and that the client connect using the SMTP_OPTION_EXTENDED option.

You should check these options prior to calling **SmtpAuthenticate** to determine which authentication methods are acceptable to the server. If you wish to use an OAuth 2.0 bearer token, always check to make sure either the SMTP_EXTOPT_XOAUTH2 or SMTP_EXTOPT_BEARER bitflags are set in the options value returned by this function.

Example

```
BOOL bExtended = FALSE;
DWORD dwOptions = 0;

// Determine which extended options and authentication methods
// are supported by this server

bExtended = SmtpGetExtendedOptions(hClient, &dwOptions);

if (bExtended && (dwOptions & SMTP_EXTOPT_XOAUTH2))
{
    INT nResult = SmtpAuthenticate(hClient, SMTP_AUTH_XOAUTH2, lpszUserName,
    lpszBearerToken);

    if (nResult == SMTP_ERROR)
    {
        // An error occurred during authentication; when using an
        // OAuth 2.0 bearer token, this typically means that the token
        // has expired and must be refreshed
        return;
    }
}
else
{
    // The server does not support XOAUTH2
    return;
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmtpv10.lib

See Also

[SmtpAsyncConnect](#), [SmtpAuthenticate](#), [SmtpConnect](#), [SmtpGetDeliveryOptions](#), [SmtpSetDeliveryOptions](#)

Smtplib GetLastError Function

```
DWORD WINAPI Smtplib GetLastError();
```

Parameters

None.

Return Value

The return value is the calling thread's last error code value. Functions set this value by calling the **Smtplib SetLastError** function. The return value section of each reference page notes the conditions under which the function sets the last error code.

Remarks

You should call the **Smtplib GetLastError** function immediately when a function's return value indicates that an error has occurred. That is because some functions call **Smtplib SetLastError(0)** when they succeed, clearing the error code set by the most recently failed function.

Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value error code such as FALSE, NULL, INVALID_CLIENT or SMTP_ERROR. Those functions which call **Smtplib SetLastError** when they succeed are noted on the function reference page.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmtplib10.lib

See Also

[Smtplib GetLastErrorString](#), [Smtplib SetLastError](#)

SmtpGetResultCode Function

```
INT WINAPI SmtpGetResultCode(  
    HCLIENT hClient  
);
```

The **SmtpGetResultCode** function reads the result code returned by the server in response to a command. The result code is an integer value, and indicates if the operation succeeded or failed.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the result code. If the function fails, it returns SMTP_ERROR. To get extended error information, call **SmtpGetLastError**.

Remarks

The following result codes may be returned by the SMTP server:

Value	Description
100-199	Positive preliminary result. This indicates that the requested action is being initiated, and the client should expect another reply from the server before proceeding.
200-299	Positive completion result. This indicates that the server has successfully completed the requested action.
300-399	Positive intermediate result. This indicates that the requested action cannot complete until additional information is provided to the server.
400-499	Transient negative completion result. This indicates that the requested action did not take place, but the error condition is temporary and may be attempted again.
500-599	Permanent negative completion result. This indicates that the requested action did not take place.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmtpv10.lib

See Also

[SmtpCommand](#), [SmtpGetResultString](#)

SmtpGetResultString Function

```
INT WINAPI SmtpGetResultString(  
    HCLIENT hClient,  
    LPTSTR lpszResult,  
    INT nMaxLength  
);
```

The **SmtpGetResultString** function returns the last message sent by the server along with the result code.

Parameters

hClient

Handle to the client session.

lpszResult

A pointer to the buffer that will contain the result string returned by the server.

nMaxLength

The maximum number of characters that may be copied into the result string buffer, including the terminating null character.

Return Value

If the function succeeds, the return value is the length of the result string. If a value of zero is returned, this means that no result string was sent by the server. If the function fails, the return value is SMTP_ERROR. To get extended error information, call **SmtpGetLastError**.

Remarks

The **SmtpGetResultString** function is most useful when an error occurs because the server will typically include a brief description of the cause of the error. This can then be parsed by the application or displayed to the user. The result string is updated each time the client sends a command to the server and then calls **SmtpGetResultCode** to obtain the result code for the operation.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmtpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

SmtplibGetSecurityInformation Function

```
BOOL WINAPI SmtplibGetSecurityInformation(  
    HCLIENT hClient,  
    LPSECURITYINFO lpSecurityInfo  
);
```

The **SmtplibGetSecurityInformation** function returns security protocol, encryption and certificate information about the current client connection.

Parameters

hClient

Handle to the client session.

lpSecurityInfo

A pointer to a [SECURITYINFO](#) structure which contains information about the current client connection. The *dwSize* member of this structure must be initialized to the size of the structure before passing the address of the structure to this function.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **SmtplibGetLastError**.

Remarks

This function is used to obtain security related information about the current client connection to the server. It can be used to determine if a secure connection has been established, what security protocol was selected, and information about the server certificate. Note that a secure connection has not been established, the *dwProtocol* structure member will contain the value `SECURITY_PROTOCOL_NONE`.

Example

The following example notifies the user if the connection is secure or not:

```
SECURITYINFO securityInfo;  
  
securityInfo.dwSize = sizeof(SECURITYINFO);  
if (SmtplibGetSecurityInformation(hClient, &securityInfo))  
{  
    if (securityInfo.dwProtocol == SECURITY_PROTOCOL_NONE)  
    {  
        MessageBox(NULL, _T("The connection is not secure"),  
                    _T("Connection"), MB_OK);  
    }  
    else  
    {  
        if (securityInfo.dwCertStatus == SECURITY_CERTIFICATE_VALID)  
        {  
            MessageBox(NULL, _T("The connection is secure"),  
                        _T("Connection"), MB_OK);  
        }  
        else  
        {  
            MessageBox(NULL, _T("The server certificate not valid"),  
                        _T("Connection"), MB_OK);  
        }  
    }  
}
```

```
}  
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmtpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

SmtpGetStatus Function

```
INT WINAPI SmtpGetStatus(  
    HCLIENT hClient  
);
```

The **SmtpGetStatus** function returns the current status of the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the client status code. If the function fails, the return value is SMTP_ERROR. To get extended error information, call **SmtpGetLastError**.

Remarks

The **SmtpGetStatus** function returns a numeric code which identifies the current state of the client session. The following values may be returned:

Value	Constant	Description
1	SMTP_STATUS_IDLE	The client is current idle and not sending or receiving data.
2	SMTP_STATUS_CONNECT	The client is establishing a connection with the server.
3	SMTP_STATUS_READ	The client is reading data from the server.
4	SMTP_STATUS_WRITE	The client is writing data to the server.
5	SMTP_STATUS_DISCONNECT	The client is disconnecting from the server.

In a multithreaded application, any thread in the current process may call this function to obtain status information for the specified client session.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmtpv10.lib

SntpGetTaskError Function

```
DWORD WINAPI SntpGetTaskError(  
    UINT nTaskId  
);
```

Return the last error code for the specified asynchronous task.

Parameters

nTaskId

The task identifier.

Return Value

If the asynchronous task has completed successfully, this function returns a value of zero. A non-zero return value indicates an error has occurred.

Remarks

The **SntpGetTaskError** function returns the last error code associated with the specified asynchronous task. If the task completed successfully, the return value will be zero. If the task is still active, the function will return the error ST_ERROR_TASK_ACTIVE. If the task has been suspended, the function will return ST_ERROR_TASK_SUSPENDED. Any other value indicates that the task completed, but the operation has failed and the error code will specify the cause of the failure.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmtpv10.lib

See Also

SmtpGetTaskId Function

```
UINT WINAPI SmtpGetTaskId(  
    HCLIENT hClient  
);
```

Return the asynchronous task identifier associated with the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is non-zero integer value that specifies a unique asynchronous task identifier. If the client handle is not associated with an asynchronous task, the function will return a value of zero.

Remarks

The **SmtpGetTaskId** function will return the task ID that is associated with a client session. This is a unique unsigned integer value that references the worker thread that was created to manage the asynchronous client session. This function should only be called within an event handler that is invoked by a background task that has been started using a function such as **SmtpAsyncGetFile**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csmtpv10.lib`

SmtplibTimeout Function

```
INT WINAPI SmtplibTimeout(  
    HCLIENT hClient  
);
```

The **SmtplibTimeout** function returns the number of seconds the client will wait for a response from the server. Once the specified number of seconds has elapsed, the function will fail and return to the caller.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the timeout period in seconds. If the function fails, the return value is SMTP_ERROR. To get extended error information, call **SmtplibGetLastError**.

Remarks

The timeout value is only used with blocking client connections. A value of zero indicates that the default timeout period of 20 seconds should be used.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmtplib10.lib

See Also

[SmtplibSetTimeout](#)

SmtpGetTransferStatus Function

```
INT WINAPI SmtpGetTransferStatus(  
    HCLIENT hClient,  
    LPSMTPTRANSFERSTATUS lpStatus  
);
```

The **SmtpGetTransferStatus** function returns information about the message being submitted to the mail server.

Parameters

hClient

Handle to the client session.

lpStatus

A pointer to an [SMTPTRANSFERSTATUS](#) structure which contains information about the status of the message being submitted for delivery.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is SMTP_ERROR. To get extended error information, call **SmtpGetLastError**.

Remarks

The **SmtpGetTransferStatus** function returns information about the current message being submitted, including the average number of bytes transferred per second and the estimated amount of time until the transfer completes. If there is no message currently being submitted, this function will return the status of the last successful submission made by the client.

In a multithreaded application, any thread in the current process may call this function to obtain the status of a submission for the specified client session.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmtpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

SmtplibInitialize Function

```
BOOL WINAPI SmtplibInitialize(  
    LPCTSTR lpszLicenseKey,  
    LPINITDATA lpData  
);
```

The **SmtplibInitialize** function initializes the library and validates the specified license key at runtime.

Parameters

lpszLicenseKey

Pointer to a string that specifies the runtime license key to be validated. If this parameter is NULL, the library will validate the development license installed on the local system.

lpData

Pointer to an INITDATA data structure. This parameter may be NULL if the initialization data for the library is not required.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **SmtplibGetLastError**. All other client functions will fail until a license key has been successfully validated.

Remarks

This must be the first function that an application calls before using any of the other functions in the library. When a NULL license key is specified, the library will only function on the development system. Before redistributing the application to an end-user, you must insure that this function is called with a valid license key.

If the *lpData* argument is specified, it must point to an INITDATA structure which has been initialized by setting the *dwSize* member to the size of the structure. All other structure members should be set to zero. If the function is successful, then the INITDATA structure will be filled with identifying information about the library.

Although it is only required that **SmtplibInitialize** be called once for the current process, it may be called multiple times; however, each call must be matched by a corresponding call to **SmtplibUninitialize**.

This function dynamically loads other system libraries and allocates thread local storage. If you are calling the functions in this library from within another DLL, it is important that you do not call the **SmtplibInitialize** or **SmtplibUninitialize** functions from the **DllMain** function because it can result in deadlocks or access violation errors. If the DLL is linked with the C runtime library (CRT), it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmtplib10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

SmtplibBlocking Function

```
BOOL WINAPI SmtplibBlocking(  
    HCLIENT hClient  
);
```

The **SmtplibBlocking** function is used to determine if the client is currently performing a blocking operation.

Parameters

hClient

Handle to the client session.

Return Value

If the client is performing a blocking operation, the function returns a non-zero value. If the client is not performing a blocking operation, or the client handle is invalid, the function returns zero.

Remarks

Because a blocking operation can allow the application to be re-entered (for example, by pressing a button while the operation is being performed), it is possible that another blocking function may be called while it is in progress. Since only one thread of execution may perform a blocking operation at any one time, an error would occur. The **SmtplibBlocking** function can be used to determine if the client is already blocked, and if so, take some other action such as warning the user that they must wait for the operation to complete.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmtplib10.lib

See Also

[SmtplibCancel](#), [SmtplibConnected](#), [SmtplibReadable](#), [SmtplibWritable](#)

SmtplibConnected Function

```
BOOL WINAPI SmtplibConnected(  
    HCLIENT hClient  
);
```

The **SmtplibConnected** function is used to determine if the client is currently connected to a server.

Parameters

hClient

Handle to the client session.

Return Value

If the client is connected to a server, the function returns a non-zero value. If the client is not connected, or the client handle is invalid, the function returns zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmtplib10.lib

Unicode: Implemented as Unicode and ANSI versions.

[SmtplibBlocking](#), [SmtplibReadable](#), [SmtplibWritable](#)

SmtpIsReadable Function

```
BOOL WINAPI SmtpIsReadable(  
    HCLIENT hClient,  
    INT nTimeout,  
    LPDWORD lpdwAvail  
);
```

The **SmtpIsReadable** function is used to determine if data is available to be read from the server.

Parameters

hClient

Handle to the client session.

nTimeout

Timeout for server response, in seconds. A value of zero specifies that the connection should be polled without blocking the current thread.

lpdwAvail

A pointer to an unsigned integer which will contain the number of bytes available to read. This parameter may be NULL if this information is not required.

Return Value

If the client can read data from the server within the specified timeout period, the function returns a non-zero value. If the client cannot read any data, the function returns zero.

Remarks

On some platforms, this value will not exceed the size of the receive buffer (typically 64K bytes). Because of differences between TCP/IP stack implementations, it is not recommended that your application exclusively depend on this value to determine the exact number of bytes available. Instead, it should be used as a general indicator that there is data available to be read.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmtpv10.lib

See Also

[SmtpGetStatus](#), [SmtpIsBlocking](#), [SmtpIsConnected](#), [SmtpIsWritable](#), [SmtpWrite](#)

SmtpIsWritable Function

```
BOOL WINAPI SmtpIsWritable(  
    HCLIENT hClient,  
    INT nTimeout  
);
```

The **SmtpIsWritable** function is used to determine if data can be written to the server.

Parameters

hClient

Handle to the client session.

nTimeout

Timeout for server response, in seconds. A value of zero specifies that the connection should be polled without blocking the current thread.

Return Value

If the client can write data to the server within the specified timeout period, the function returns a non-zero value. If the client cannot write any data, the function returns zero.

Remarks

Although this function can be used to determine if some amount of data can be sent to the remote process it does not indicate the amount of data that can be written without blocking the client. In most cases, it is recommended that large amounts of data be broken into smaller logical blocks, typically some multiple of 512 bytes in length.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmtpv10.lib

See Also

[SmtpGetStatus](#), [SmtpIsBlocking](#), [SmtpIsConnected](#), [SmtpIsReadable](#), [SmtpWrite](#)

SmtplibRegisterEvent Function

```
INT WINAPI SmtplibRegisterEvent(  
    HCLIENT hClient,  
    UINT nEvent,  
    SMTPEVENTPROC lpEventProc,  
    DWORD_PTR dwParam  
);
```

The **SmtplibRegisterEvent** function registers a callback function for the specified event.

Parameters

hClient

Handle to the client session.

nEvent

An unsigned integer which specifies which event should be registered with the specified callback function. One of the following values may be used:

Constant	Description
SMTP_EVENT_CONNECT	The connection to the server has completed.
SMTP_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
SMTP_EVENT_READ	Data is available to read by the client. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the calling process is in asynchronous mode.
SMTP_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
SMTP_EVENT_TIMEOUT	The client has timed out while waiting for a response from the server. Note that under some circumstances this event can be generated for a non-blocking connection, such as when the client is establishing a secure connection.
SMTP_EVENT_CANCEL	The client has canceled the current operation.
SMTP_EVENT_COMMAND	The client has processed a command that was sent to the server. The result code and result string can be used to determine if the response to the command.
SMTP_EVENT_PROGRESS	This event notification is sent periodically during lengthy blocking operations, such as retrieving a complete message from the server.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **SmtplibEventProc** callback

function. If this parameter is NULL, the callback for the specified event is disabled.

dwParam

A user-defined integer value that is passed to the callback function. If the application targets the x86 (32-bit) platform, this parameter must be a 32-bit unsigned integer. If the application targets the x64 (64-bit) platform, this parameter must be a 64-bit unsigned integer.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is SMTP_ERROR. To get extended error information, call **SmtplibGetLastError**.

Remarks

The **SmtplibRegisterEvent** function associates a callback function with a specific event. The event handler is an **SmtplibEventProc** function that is invoked when the event occurs. Arguments are passed to the function to identify the client session, the event type and the user-defined value specified when the event handler is registered. If the event occurs because of an error condition, the error code will be provided to the handler.

This function is typically used to register an event handler that is invoked while a message is being submitted to the server for delivery. The SMTP_EVENT_PROGRESS event will only be generated periodically during the transfer to ensure the application is not flooded with event notifications. It is guaranteed that at least one SMTP_EVENT_PROGRESS notification will occur at the beginning of the transfer, and one at the end of the transfer when it has completed.

The callback function specified by the *lpEventProc* parameter must be declared using the **__stdcall** calling convention. This ensures the arguments passed to the event handler are pushed on to the stack in the correct order. Failure to use the correct calling convention will corrupt the stack and cause the application to terminate abnormally.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmtplib10.lib

See Also

Smtplib.Reset Function

```
INT WINAPI Smtplib.Reset(  
    HCLIENT hClient  
);
```

The **Smtplib.Reset** function resets the client state and resynchronizes with the server. This function is typically called after an unexpected error has occurred, or an operation has been canceled.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is SMTP_ERROR. To get extended error information, call **Smtplib.GetLastError**.

Remarks

The client cannot be reset while in a blocked state.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmtplib10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[Smtplib.Cancel](#), [Smtplib.CloseMessage](#), [Smtplib.CreateMessage](#), [Smtplib.IsBlocking](#)

SmtpSendMessage Function

```
INT WINAPI SmtpSendMessage(  
    HCLIENT hClient,  
    LPCTSTR lpszFrom,  
    LPCTSTR lpszRecipient,  
    LPVOID lpvMessage,  
    DWORD dwMessageSize,  
    DWORD dwOptions  
);
```

The **SmtpSendMessage** function sends the contents of a file or memory buffer to the specified recipients.

Parameters

hClient

Handle to the client session.

lpszFrom

Pointer to a string which specifies the email address of the sender.

lpszRecipient

Pointer to a string which specifies the recipient of the message. Multiple recipients may be specified by separating each address with a comma.

lpvMessage

Pointer to a buffer which contains the message to be delivered, or a pointer to the name of the file which contains the data to be written to the data stream. The use of this parameter depends on the value of the **dwOptions** parameter.

dwMessageSize

An unsigned integer which specifies the length of the message in bytes.

dwOptions

Specifies the source of the message data that will be written to the data stream; it may be one of the following values:

Constant	Description
SMTP_MESSAGE_MEMORY	The lpvMessage parameter specifies a pointer to an array of characters. If the value of dwMessageSize is zero, then it is assumed to be a pointer to a string.
SMTP_MESSAGE_HGLOBAL	The lpvMessage parameter specifies an HGLOBAL which contains the data to be written to the data stream. If the value of the dwMessageSize parameter is zero, then the data is assumed to be null-terminated.
SMTP_MESSAGE_FILE	The lpvMessage parameter specifies a pointer to a string which contains the name of a file. The file is opened and the contents of the file are written to the data stream. The value of the dwMessageSize parameter is ignored when this option is specified.
SMTP_MESSAGE_CLIPBOARD	The lpvMessage and dwMessageSize parameters are ignored. The current contents of the clipboard are

written to the data stream.

Return Value

If the function succeeds, the return value is the result code from the server. If the function fails, the return value is SMTP_ERROR. To get extended error information, call **SmtplibGetLastError**.

Remarks

The **SmtplibSendMessage** function is used to send the contents of a memory buffer, file or the system clipboard to the specified recipients. The message must be in the standard format as described in RFC 822 or a MIME multipart message. The MIME API can be used to compose and export a message in the correct format.

This protocol is only concerned with the delivery of a message and not its contents. Header fields in the message are not parsed to determine the recipients. This recipient parameter should be a concatenation of all recipients, including carbon copies and blind carbon copies, with each address separated with a comma.

This function will cause the current thread to block until the complete message has been delivered, a timeout occurs or the operation is canceled. During the transfer, the SMTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **SmtplibEnableEvents**, or by registering a callback function using the **SmtplibRegisterEvent** function.

To determine the current status of the transaction while it is in progress, use the **SmtplibGetTransferStatus** function.

An alternative approach to creating a message without using the MIME API is the **SmtplibSubmitMessage** function. It accepts two structure parameters which define the message contents and the connection information for the mail server. This enables the application to compose the message and submit it for delivery in a single function call.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmtplib10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

SmtpSetDeliveryOptions Function

```
BOOL WINAPI SmtpSetDeliveryOptions(  
    HCLIENT hClient,  
    DWORD dwOptions  
);
```

The **SmtpSetDeliveryOptions** function sets the delivery status notification options for the current session.

Parameters

hClient

Handle to the client session.

dwOptions

A bitmask that defines the current delivery options. This value is created by combining one or more of the following constants with a bitwise Or operator:

Constant	Description
SMTP_NOTIFY_NEVER	Never return information about the success or failure of the message delivery process.
SMTP_NOTIFY_SUCCESS	Return a message to the sender if the message has been successfully delivered to the recipient's mail server.
SMTP_NOTIFY_FAILURE	Return a message to the sender if the message could not be delivered to the recipient's mail server.
SMTP_NOTIFY_DELAY	Return a message to the sender if delivery of the message was delayed.
SMTP_RETURN_HEADERS	Return only the message headers to the sender.
SMTP_RETURN_MESSAGE	Return the complete message headers and body to the sender.

Return Value

If the function succeeds, the return value is a non-zero value. If the function fails, the return value is zero. To get extended error information, call **SmtpGetLastError**.

Remarks

The **SmtpSetDeliveryOptions** function sets the current delivery options for the client session. Note that delivery options are only available on those mail servers which support delivery status notification (DSN) using the extended SMTP protocol. The client must connect specifying SMTP_OPTION_EXTENDED in order to use extended server options.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmtpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

SmtpSetLastError Function

```
VOID WINAPI SmtpSetLastError(  
    DWORD dwErrorCode  
);
```

The **SmtpSetLastError** function sets the last error code for the current thread.

Parameters

dwErrorCode

Specifies the last error code for the caller. A value of zero clears the last error code.

Return Value

None.

Remarks

Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value error code such as FALSE, NULL, INVALID_CLIENT or SMTP_ERROR. Those functions which call **SmtpSetLastError** when they succeed are noted on the function reference page.

Applications can retrieve the value saved by this function by using the **SmtpGetLastError** function. The use of **SmtpGetLastError** is optional. An application can call it to find out the specific reason for a function failure.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmtpv10.lib

SmtpSetTimeout Function

```
INT WINAPI SmtpSetTimeout(  
    HCLIENT hClient,  
    INT nTimeout  
);
```

The **SmtpSetTimeout** function sets the number of seconds the client will wait for a response from the server. Once the specified number of seconds has elapsed, the function will fail and return to the caller.

Parameters

hClient

Handle to the client session.

nTimeout

The number of seconds to wait for a blocking operation to complete.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is SMTP_ERROR. To get extended error information, call **SmtpGetLastError**.

Remarks

The timeout value is only used with blocking client connections.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmtpv10.lib

See Also

[SmtpGetTimeout](#)

SmtpSubmitMessage Function

```
INT WINAPI SmtpSubmitMessage(  
    LPSMTPSERVER LpServer,  
    LPSMTPMESSAGE LpMessage,  
    SMTPEVENTPROC LpEventProc,  
    DWORD_PTR dwParam  
);
```

The **SmtpSubmitMessage** function composes and submits a message for delivery to the specified mail server.

Parameters

lpServer

A pointer to an **SMTPSERVER** structure that contains information about the mail server that the message will be submitted to for delivery. This parameter cannot be NULL and the structure members must be properly initialized prior to calling this function.

lpMessage

A pointer to an **SMTPMESSAGE** structure that contains information about the message, including the sender, recipients and the body of the message. This parameter cannot be NULL and the structure members must be property initialized prior to calling this function.

lpEventProc

A pointer to the procedure-instance address of an application defined callback function. For more information about event handling and the callback function, see the description of the **SmtpEventProc** callback function. If this parameter is NULL, event notification is disabled.

dwParam

A user-defined integer value that is passed to the callback function. If the *lpEventProc* parameter is NULL, this value should be zero.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is SMTP_ERROR. To get extended error information, call **SmtpGetLastError**.

Remarks

The **SmtpSubmitMessage** function provides a high-level interface that enables an application to send an email message with a single function call. The **SMTPSERVER** and **SMTPMESSAGE** structures are used to provide the function with information about the mail server that will accept the message and the contents of the message itself. Note that this function does not require a client session handle, and therefore it is not required that you call the **SmtpConnect** function prior to calling this function.

If you need to specify additional custom headers in the message that is submitted for delivery, you should use the **SmtpSubmitMessageEx** function. That version of the function uses an extended version of the message structure which will allow you to define custom headers to be included in the message.

This function will cause the calling thread to block until the message has been submitted for delivery, an error occurs or the connection to the mail server times out. If an event handler is specified, then the callback function will be periodically invoked as the message is being sent. For large messages, the SMTP_EVENT_PROGRESS event can be used to monitor the submission

process and update the user interface. The **SmtplibGetTransferStatus** function can be used within the callback function to obtain information about the current status of the submission.

Example

```
SMTPSERVER mailServer;
ZeroMemory(&mailServer, sizeof(mailServer));
mailServer.lpszHostName = _T("smtp.gmail.com");
mailServer.nHostPort = SMTP_PORT_SUBMIT;
mailServer.lpszUserName = m_strSender;
mailServer.lpszPassword = m_strPassword;
mailServer.dwOptions = SMTP_OPTION_SECURE;

SMTPMESSAGE mailMessage;
ZeroMemory(&mailMessage, sizeof(mailMessage));
mailMessage.lpszFrom = m_strSender;
mailMessage.lpszTo = m_strRecipients;
mailMessage.lpszSubject = m_strSubject;
mailMessage.lpszText = m_strMessage;

INT nResult = SmtplibSubmitMessage(&mailServer, &mailMessage, NULL, 0);

if (nResult != SMTP_ERROR)
    _tprintf(_T("SmtplibSubmitMessage was successful\n"));
else
{
    DWORD dwError = SmtplibGetLastError();
    _tprintf(_T("SmtplibSubmitMessage failed with error 0x%08lx\n"), dwError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmtplib10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[SmtplibEventProc](#), [SmtplibSendMessage](#), [SmtplibSubmitMessageEx](#), [SMTPMESSAGE](#), [SMTPSERVER](#)

SmtpSubmitMessageEx Function

```
INT WINAPI SmtpSubmitMessageEx(  
    LPSMTPSERVER LpServer,  
    LPSMTPMESSAGEEX LpMessageEx,  
    DWORD dwReserved,  
    SMTPEVENTPROC LpEventProc,  
    DWORD_PTR dwParam  
);
```

The **SmtpSubmitMessageEx** function composes and submits a message for delivery to the specified mail server.

Parameters

lpServer

A pointer to an **SMTPSERVER** structure that contains information about the mail server that the message will be submitted to for delivery. This parameter cannot be NULL and the structure members must be properly initialized prior to calling this function.

lpMessageEx

A pointer to an **SMTPMESSAGEEX** structure that contains information about the message, including the sender, recipients and the body of the message. This parameter cannot be NULL and the structure members must be property initialized prior to calling this function.

dwReserved

An integer value that is reserved for future use. This value must be zero or the function will fail.

lpEventProc

A pointer to the procedure-instance address of an application defined callback function. For more information about event handling and the callback function, see the description of the **SmtpEventProc** callback function. If this parameter is NULL, event notification is disabled.

dwParam

A user-defined integer value that is passed to the callback function. If the *lpEventProc* parameter is NULL, this value should be zero.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is SMTP_ERROR. To get extended error information, call **SmtpGetLastError**.

Remarks

The **SmtpSubmitMessageEx** function provides a high-level interface that enables an application to send an email message with a single function call. The **SMTPSERVER** and **SMTPMESSAGEEX** structures are used to provide the function with information about the mail server that will accept the message and the contents of the message itself. Note that this function does not require a client session handle, and therefore it is not required that you call the **SmtpConnect** function prior to calling this function.

This function will cause the calling thread to block until the message has been submitted for delivery, an error occurs or the connection to the mail server times out. If an event handler is specified, then the callback function will be periodically invoked as the message is being sent. For large messages, the SMTP_EVENT_PROGRESS event can be used to monitor the submission process and update the user interface. The **SmtpGetTransferStatus** function can be used within

the callback function to obtain information about the current status of the submission.

Example

```
SMTPSERVER mailServer;
ZeroMemory(&mailServer, sizeof(mailServer));
mailServer.lpszHostName = _T("smtp.gmail.com");
mailServer.nHostPort = SMTP_PORT_SUBMIT;
mailServer.lpszUserName = m_strSender;
mailServer.lpszPassword = m_strPassword;
mailServer.dwOptions = SMTP_OPTION_SECURE;

SMTPMESSAGEEX mailMessageEx;
ZeroMemory(&mailMessageEx, sizeof(mailMessageEx));
mailMessageEx.dwSize = sizeof(mailMessageEx);
mailMessageEx.lpszFrom = m_strSender;
mailMessageEx.lpszTo = m_strRecipients;
mailMessageEx.lpszSubject = m_strSubject;
mailMessageEx.lpszText = m_strMessage;

INT nResult = SmtplibSubmitMessageEx(&mailServer, &mailMessageEx, 0, NULL, 0);

if (nResult != SMTP_ERROR)
    _tprintf(_T("SmtplibSubmitMessageEx was successful\n"));
else
{
    DWORD dwError = SmtplibGetLastError();
    _tprintf(_T("SmtplibSubmitMessageEx failed with error 0x%08lx\n"), dwError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmtplib10.lib

Unicode: Implemented as Unicode and ANSI versions.

SmtpTaskAbort Function

```
BOOL WINAPI SmtpTaskAbort(  
    UINT nTaskId,  
    DWORD dwMilliseconds  
);
```

Abort the specified asynchronous task.

Parameters

nTaskId

The task identifier.

dwMilliseconds

An unsigned integer that specifies the number of milliseconds to wait for the background task to abort.

Return Value

If the function succeeds and the worker thread has terminated, the return value is non-zero. A return value of zero indicates that the worker thread is still running or an error has occurred. To get extended error information, call the **SmtpGetLastError** function.

Remarks

The **SmtpTaskAbort** function signals the background worker thread associated with the task ID to abort the current operation and terminate as soon as possible. If the *dwMilliseconds* parameter has a value of zero, the function returns immediately after the background thread has been signaled. If the *dwMilliseconds* parameter is non-zero, the function will wait that amount of time for the background thread to terminate.

This function should never be called from within the event handler for an asynchronous task because it can cause the process to deadlock. To abort a file transfer within an event handler, use the **SmtpCancel** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmtpv10.lib

See Also

[SmtpTaskDone](#), [SmtpTaskResume](#), [SmtpTaskSuspend](#), [SmtpTaskWait](#)

SmtpTaskDone Function

```
BOOL WINAPI SmtpTaskDone(  
    UINT nTaskId  
);
```

Determine if an asynchronous task has completed.

Parameters

nTaskId

The task identifier.

Return Value

If the asynchronous task has completed, this function returns a non-zero value. A return value of zero indicates that the worker thread is still running or an error has occurred. To get extended error information, call the **SmtpGetLastError** function.

Remarks

The **SmtpTaskDone** function is used to determine if the specified asynchronous task has completed. If you use this function to poll the status of a background task from within the main UI thread, you must ensure that Windows messages are processed so that the application remains responsive to the end-user. To check if a background transfer has completed, it is recommended that you use a timer to periodically call this function rather than calling it repeatedly within a loop.

To determine if the task completed successfully, the **SmtpGetTaskError** function will return the last error code associated with the task. A return value of zero indicates success, while a non-zero return value specifies an error code that indicates the cause of the failure. The last error code for the task can also be retrieved using the **SmtpTaskWait** function, which causes the application to wait for the asynchronous task to complete.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmtpv10.lib

See Also

[SmtpGetTaskError](#), [SmtpTaskAbort](#), [SmtpTaskResume](#), [SmtpTaskSuspend](#), [SmtpTaskWait](#)

SmtptaskResume Function

```
BOOL WINAPI SmtptaskResume(  
    UINT nTaskId  
);
```

Resume execution of an asynchronous task.

Parameters

nTaskId

The task identifier.

Return Value

If the asynchronous task has resumed, this function returns a non-zero value. A return value of zero indicates that an error has occurred. To get extended error information, call the **SmtptaskGetLastError** function.

Remarks

The **SmtptaskResume** function resumes execution of the background worker thread that was previously suspended using the **SmtptaskSuspend** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmtpv10.lib

SmtptaskSuspend Function

```
BOOL WINAPI SmtptaskSuspend(  
    UINT nTaskId  
);
```

Suspend execution of an asynchronous task.

Parameters

nTaskId

The task identifier.

Return Value

If the asynchronous task has resumed, this function returns a non-zero value. A return value of zero indicates that an error has occurred. To get extended error information, call the **SmtptaskGetLastError** function.

Remarks

The **SmtptaskSuspend** function will suspend execution of the background worker thread associated with the task. Once the task has been suspended, it will no longer be scheduled for execution, however the client session will remain active and the task may be resumed using the **SmtptaskResume** function. Note that if a task is suspended for a long period of time, the background operation may fail because it has exceeded the timeout period imposed by the server.

This function should never be called from within the event handler for an asynchronous task because it can cause the process to deadlock.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmtpv10.lib

See Also

[SmtptaskAbort](#), [SmtptaskDone](#), [SmtptaskResume](#), [SmtptaskWait](#)

SntpTaskWait Function

```
BOOL WINAPI SntpTaskWait(  
    UINT nTaskId,  
    DWORD dwMilliseconds,  
    DWORD dwReserved,  
    LPDWORD lpdwElapsed,  
    LPDWORD lpdwError  
);
```

Wait for an asynchronous task to complete.

Parameters

nTaskId

The task identifier.

dwMilliseconds

An unsigned integer that specifies the number of milliseconds to wait for the background task to complete.

dwReserved

An unsigned integer reserved for future use. This value should always be zero.

lpdwElapsed

A pointer to an unsigned integer that will contain elapsed time in milliseconds when the function returns. If this information is not required, this parameter may be NULL.

lpdwError

A pointer to an unsigned integer that will contain the error code associated with the completed task. If this information is not required, this parameter may be NULL.

Return Value

If the function succeeds and the worker thread has terminated, the return value is non-zero. A return value of zero indicates that the worker thread is still running or an error has occurred. To get extended error information, call the **SntpGetLastError** function.

Remarks

The **SntpTaskWait** function waits for the specified task to complete. If the task is active and the *dwMilliseconds* parameter is non-zero, this function will cause the current working thread to block until the task completes or the amount of time exceeds the number of milliseconds specified by the caller. If the *dwMilliseconds* parameter is zero, then this function will poll the status of the task and return immediately to the caller.

If the specified task has already completed at the time this function is called, the function will return immediately without causing the current thread to block. If the *lpdwElapsed* parameter is not NULL, it will contain the number of milliseconds that it took for the task to complete. If the *lpdwError* parameter is not NULL, it will contain the last error code value that was set by the worker thread before it terminated. If this value is zero, that means that the background operation was successful and no error occurred. A non-zero value will indicate that the background operation has failed.

You should not call this function from the main UI thread with a long timeout period to wait for a background task to complete. Windows messages will not be processed while this function is blocked waiting for the background task to complete, and this can cause your application to

appear non-responsive to the end-user. If you have a GUI application and you need to periodically check to see if a task has completed, create a timer to periodically call the **SmtptaskDone** function. When it returns a non-zero value (indicating that the task has completed), you can safely call **SmtptaskWait** to obtain the elapsed time and last error code without blocking the current thread.

This function should never be called from within the event handler for an asynchronous task because it can cause the process to deadlock.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmtpv10.lib

See Also

[SmtptaskDone](#), [SmtptaskResume](#), [SmtptaskSuspend](#), [SmtptaskWait](#)

SmtpUninitialize Function

```
VOID WINAPI SmtpUninitialize();
```

The **SmtpUninitialize** function terminates the use of the library.

Parameters

There are no parameters.

Return Value

None.

Remarks

An application is required to perform a successful **SmtpInitialize** call before it can call any of the other library functions. When it has completed the use of library, the application must call **SmtpUninitialize** to allow the library to free any resources allocated on behalf of the process. Any pending blocking or asynchronous calls in this process are canceled without posting any notification messages, and all sockets that were opened by the process are closed.

There must be a call to **SmtpUninitialize** for every successful call to **SmtpInitialize** made by a process. In a multithreaded environment, operations for all threads in the client are terminated.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmtpv10.lib

See Also

[SmtpAsyncConnect](#), [SmtpConnect](#), [SmtpDisconnect](#), [SmtpInitialize](#)

SmtplibVerifyAddress Function

```
INT WINAPI SmtplibVerifyAddress(  
    HCLIENT hClient,  
    LPCTSTR lpszAddress,  
    LPTSTR lpszBuffer,  
    INT nMaxLength  
);
```

The **SmtplibVerifyAddress** function verifies the specified address is valid.

Parameters

hClient

Handle to the client session.

lpszAddress

Points to a string which specifies the address that the server should verify.

lpszBuffer

Points to a buffer that the verified address will be copied into.

nMaxLength

Maximum number of characters that may be copied into the buffer, including the terminating null character.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is SMTP_ERROR. To get extended error information, call **SmtplibGetLastError**.

Remarks

The **SmtplibVerifyAddress** function requests that the server verify the specified email address. Typically this is used to verify that a recipient address is valid, and return a fully qualified email address for that recipient. A server may not support this command, or may restrict its usage. An application should not depend on the ability to verify addresses.

This function cannot be called while a mail message is being composed.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmtplib10.lib

Unicode: Implemented as Unicode and ANSI versions.

SmtpWrite Function

```
INT WINAPI SmtpWrite(  
    HCLIENT hClient,  
    LPBYTE lpBuffer,  
    INT cbBuffer  
);
```

The **SmtpWrite** function sends the specified number of bytes to the server.

Parameters

hClient

Handle to the client session.

lpBuffer

The pointer to the buffer which contains the data that is to be sent to the server.

cbBuffer

The number of bytes to send from the specified buffer.

Return Value

If the function succeeds, the return value is the number of bytes actually written. If the function fails, the return value is SMTP_ERROR. To get extended error information, call **SmtpGetLastError**.

Remarks

The return value may be less than the number of bytes specified by the *cbBuffer* parameter. In this case, the data has been partially written and it is the responsibility of the client application to send the remaining data at some later point. For non-blocking clients, the client must wait for the SMTP_EVENT_WRITE asynchronous notification message before it resumes sending data.

If the **SmtpWrite** function is used to send the message contents to the server, the application must first call the **SmtpCreateMessage** function to specify the sender and the length of the message, followed by one or more calls to the **SmtpAddRecipient** function to specify each recipient of the message. When all of the message text has been submitted to the server, the application must call the **SmtpCloseMessage** function.

The message text is filtered by the **SmtpWrite** function, and it will automatically normalize end-of-line character sequences to ensure the message meets the protocol requirements. The message itself must be in a standard RFC 822 or multi-part MIME message format, or the server may reject the message. Binary data, such as file attachments, should always be encoded. The MIME API can be used to compose and export a message in the correct format, which can then be submitted to the server.

It is recommended that most applications use the **SmtpSendMessage** function to submit the message for delivery.

An alternative approach to creating a message without using the MIME API is the **SmtpSubmitMessage** function. It accepts two structure parameters which define the message contents and the connection information for the mail server. This enables the application to compose the message and submit it for delivery in a single function call.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Simple Message Transfer Protocol Data Structures

- INITDATA
- SECURITYCREDENTIALS
- SECURITYINFO
- SMTPMESSAGE
- SMTPMESSAGEEX
- SMTPSERVER
- SMTPTRANSFERSTATUS
- SYSTEMTIME

INITDATA Structure

This structure contains information about the SocketTools library when the initialization function returns.

```
typedef struct _INITDATA
{
    DWORD        dwSize;
    DWORD        dwVersionMajor;
    DWORD        dwVersionMinor;
    DWORD        dwVersionBuild;
    DWORD        dwOptions;
    DWORD_PTR    dwReserved1;
    DWORD_PTR    dwReserved2;
    TCHAR        szDescription[128];
} INITDATA, *LPINITDATA;
```

Members

dwSize

Size of this structure. This structure member must be set to the size of the structure prior to calling the initialization function. Failure to do so will cause the function to fail.

dwVersionMajor

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the major version number for the library.

dwVersionMinor

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the minor version number for the library.

dwVersionBuild

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the build number for the library.

dwOptions

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

dwReserved1

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

dwReserved2

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

szDescription

A null terminated string which describes the library.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Unicode: Implemented as Unicode and ANSI versions.

SECURITYCREDENTIALS Structure

The **SECURITYCREDENTIALS** structure specifies the information needed by the library to specify additional security credentials, such as a client certificate or private key, when establishing a secure connection.

```
typedef struct _SECURITYCREDENTIALS
{
    DWORD    dwSize;
    DWORD    dwProtocol;
    DWORD    dwOptions;
    DWORD    dwReserved;
    LPCTSTR  lpszHostName;
    LPCTSTR  lpszUserName;
    LPCTSTR  lpszPassword;
    LPCTSTR  lpszCertStore;
    LPCTSTR  lpszCertName;
    LPCTSTR  lpszKeyFile;
} SECURITYCREDENTIALS, *LPSECURITYCREDENTIALS;
```

Members

dwSize

Size of this structure. If the structure is being allocated dynamically, this member must be set to the size of the structure and all other unused structure members must be initialized to a value of zero or NULL.

dwProtocol

A bitmask of supported security protocols. The value of this structure member is constructed by using a bitwise operator with any of the following values:

Constant	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_SSL	Either SSL 2.0 or SSL 3.0 should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, TLS will be excluded from the list of supported protocols. Both SSL 2.0 and 3.0 have been deprecated and will never be used unless explicitly specified. It is not recommended that you enable either of these protocols for secure connections because it will cause most servers to reject your connection request, even if a version of TLS is also specified.
SECURITY_PROTOCOL_TLS	Either the TLS 1.0, 1.1 or 1.2 protocol should be used when establishing a secure connection. The correct protocol is automatically selected, based on

	what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers that reject any attempt to use the older SSL protocol and require that only TLS be used.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This is the recommended version of TLS to use with secure connections.

dwOptions

A value which specifies one or options. This member is constructed by using a bitwise operator with any of the following values:

Constant	Description
CREDENTIAL_STORE_CURRENT_USER	The library will attempt to open a store for the current user using the certificate store name provided in this structure. If no options are specified, then this is the default behavior.
CREDENTIAL_STORE_LOCAL_MACHINE	The library will attempt to open a local machine store using the certificate store name provided in this structure. If this option is specified, the library will always search for a local machine store before searching for the store by that name for the current user.
CREDENTIAL_STORE_FILENAME	The certificate store name is a file that contains the certificate and private key that

will be used.

dwReserved

This structure member is reserved for future use and should always be initialized to zero.

lpszHostName

A pointer to a null terminated string which specifies the hostname that will be used when validating the server certificate. If this member is NULL, then the server certificate will be validated against the hostname used to establish the connection.

lpszUserName

A pointer to a null terminated string which identifies the owner of client certificate. Currently this member is not used by the library and should always be initialized as a NULL pointer.

lpszPassword

A pointer to a null terminated string which specifies the password needed to access the certificate. Currently this member is only used if the CREDENTIAL_STORE_FILENAME option has been specified. If there is no password associated with the certificate, then this member should be initialized as a NULL pointer.

lpszCertStore

A pointer to a null terminated string which specifies the name of the certificate store to open. A certificate store is a collection of certificates and their private keys, typically organized by how they are used. If this value is NULL or points to an empty string, the default certificate store "MY" will be used.

Store Name	Description
------------	-------------

CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as VeriSign and Thawte act as certification authorities.
----	---

MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. This corresponds to the "Personal" store that is displayed by the certificate manager utility and is the default store used by the library.
----	--

ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as VeriSign and Thawte are installed as part of the operating system and periodically updated by Microsoft.
------	--

lpszCertName

A pointer to a null terminated string which specifies the name of the certificate to use. The library will first search the certificate store for a certificate with a matching "friendly name"; this is a name for the certificate that is assigned by the user. Note that the name must match completely, but the comparison is not case sensitive. If no matching certificate is found, the library will then attempt to find a certificate that has a matching common name (also called the certificate subject). This comparison is less stringent, and the first partial match will be returned. If this second search fails, the library will return an error indicating that the certificate could not be found. If the SECURITY_PROTOCOL_SSH protocol has been specified, this member should be NULL.

lpszKeyFile

A pointer to a null terminated string which specifies the name of the file which contains the private key required to establish the connection. This member is only used for SSH connections

and should always be NULL when establishing a secure connection using SSL or TLS.

Remarks

A client application only needs to create this structure if the server requires that the client provide a certificate as part of the process of negotiating the secure session. If a certificate is required, note that it must have a private key associated with it. Attempting to use a certificate that does not have a private key will result in an error during the connection process indicating that the client credentials could not be established.

If you are using a local certificate store, with the certificate and private key stored in the registry, you can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU:" for the current user, or "HKLM:" for the local machine. For example, a certificate store name of "HKLM:MY" would specify the personal certificate store for the local machine, rather than the current user. If neither prefix is specified, then it will default to the certificate store for the current user. You can manage these certificates using the CertMgr.msc Microsoft Management Console (MMC) snap-in.

It is possible to load the certificate from a file rather than from current user's certificate store. The *dwOptions* member should be set to CREDENTIAL_STORE_FILENAME and the *lpzCertStore* member should specify the name of the file that contains the certificate and its private key. The file must be in Private Information Exchange (PFX) format, also known as PKCS#12. These certificate files typically have an extension of .pfx or .p12. Note that if a password was specified when the certificate file was created, it must be provided in the *lpzPassword* member or the library will be unable to access the certificate.

Note that the *lpzUserName* and *lpzPassword* members are values which are used to access the certificate store or private key file. They are not the credentials which are used when establishing the connection with the remote host or authenticating the client session.

The TLS 1.1 and TLS 1.2 protocols are only supported on Windows 7, Windows Server 2008 R2 and later versions of the platform. If these options are specified and the application is running on Windows XP or Windows Vista, the protocol version will be downgraded to TLS 1.0 for backwards compatibility with those platforms.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include ctools10.h

Unicode: Implemented as Unicode and ANSI versions.

SECURITYINFO Structure

This structure contains information about a secure connection that has been established.

```
typedef struct _SECURITYINFO
{
    DWORD        dwSize;
    DWORD        dwProtocol;
    DWORD        dwCipher;
    DWORD        dwCipherStrength;
    DWORD        dwHash;
    DWORD        dwHashStrength;
    DWORD        dwKeyExchange;
    DWORD        dwCertStatus;
    SYSTEMTIME   stCertIssued;
    SYSTEMTIME   stCertExpires;
    LPCTSTR      lpszCertIssuer;
    LPCTSTR      lpszCertSubject;
    LPCTSTR      lpszFingerprint;
} SECURITYINFO, *LPSECURITYINFO;
```

Members

dwSize

Specifies the size of the data structure. This member must always be initialized to **sizeof(SECURITYINFO)** prior to passing the address of this structure to the function. Note that if this member is not initialized, an error will be returned indicating that an invalid parameter has been passed to the function.

dwProtocol

A numeric value which specifies the protocol that was selected to establish the secure connection. One of the following values will be returned:

Constant	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_SSL	Either SSL 2.0 or SSL 3.0 should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, TLS will be excluded from the list of supported protocols. Both SSL 2.0 and 3.0 have been deprecated and will never be used unless explicitly specified. It is not recommended that you enable either of these protocols for secure connections because it will cause most servers to reject your connection request, even if a version of TLS is also specified.
SECURITY_PROTOCOL_TLS	Either the TLS 1.0, 1.1 or 1.2 protocol should be used when establishing a secure connection. The

	<p>correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers that reject any attempt to use the older SSL protocol and require that only TLS be used.</p>
SECURITY_PROTOCOL_TLS10	<p>The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.</p>
SECURITY_PROTOCOL_TLS11	<p>The TLS 1.1 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.</p>
SECURITY_PROTOCOL_TLS12	<p>The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This is the recommended version of TLS to use with secure connections.</p>

dwCipher

A numeric value which specifies the cipher that was selected when establishing the secure connection. One of the following values will be returned:

Constant	Description
SECURITY_CIPHER_RC2	The RC2 block cipher was selected. This is a variable key length cipher which supports keys between 40 and 128 bits, in 8-bit increments.
SECURITY_CIPHER_RC4	The RC4 stream cipher was selected. This is a variable key length cipher which supports keys between 40 and 128 bits, in 8-bit increments.
SECURITY_CIPHER_RC5	The RC5 block cipher was selected. This is a variable key length cipher which supports keys up to 2040 bits, in 8-bit increments.
SECURITY_CIPHER_DES	The DES (Data Encryption Standard) block cipher was selected. This is a fixed key length cipher, using 56-bit

	keys.
SECURITY_CIPHER_DES3	The Triple DES block cipher was selected. This cipher encrypts the data three times using different keys, effectively providing a 168-bit length key.
SECURITY_CIPHER_DESX	A variant of the DES block cipher which XORs an extra 64-bits of the key before and after the plaintext has been encrypted, increasing the key size to 184 bits.
SECURITY_CIPHER_AES	The Advanced Encryption Standard cipher (also known as the Rijndael cipher) is a fixed block size cipher which use a key size of 128, 192 or 256 bits. This cipher is supported on Windows XP SP3 and later versions of the operating system.
SECURITY_CIPHER_SKIPJACK	The Skipjack block cipher was selected. This is a fixed key length cipher, using 80-bit keys.
SECURITY_CIPHER_BLOWFISH	The Blowfish block cipher was selected. This is a variable key length cipher up to 448 bits, using a 64-bit block size.

dwCipherStrength

A numeric value which specifies the strength (the length of the cipher key in bits) of the cipher that was selected. Typically this value will be 128 or 256. 40-bit and 56-bit key lengths are considered weak encryption, and subject to brute force attacks. 128-bit and 256-bit key lengths are considered to be secure, and are the recommended key length for secure communications.

dwHash

A numeric value which specifies the hash algorithm which was selected. One of the following values will be returned:

Constant	Description
SECURITY_HASH_MD5	The MD5 algorithm was selected. Its use has been deprecated and is no longer considered to be cryptographically secure.
SECURITY_HASH_SHA1	The SHA-1 algorithm was selected. Its use has been deprecated and is no longer considered to be cryptographically secure.
SECURITY_HASH_SHA256	The SHA-256 algorithm was selected.
SECURITY_HASH_SHA384	The SHA-384 algorithm was selected.
SECURITY_HASH_SHA512	The SHA-512 algorithm was selected.

dwHashStrength

A numeric value which specifies the strength (the length in bits) of the message digest that was selected.

dwKeyExchange

A numeric value which specifies the key exchange algorithm which was selected. One of the following values will be returned:

--	--

Constant	Description
SECURITY_KEYEX_RSA	The RSA public key algorithm was selected.
SECURITY_KEYEX_KEA	The Key Exchange Algorithm (KEA) was selected. This is an improved version of the Diffie-Hellman public key algorithm.
SECURITY_KEYEX_DH	The Diffie-Hellman key exchange algorithm was selected.
SECURITY_KEYEX_ECDH	The Elliptic Curve Diffie-Hellman key exchange algorithm was selected. This is a variant of the Diffie-Hellman algorithm which uses elliptic curve cryptography. This key exchange algorithm is only supported on Windows XP SP3 and later versions of the operating system.

dwCertStatus

A numeric value which specifies the status of the certificate returned by the secure server. This member only has meaning for connections using the SSL or TLS protocols. One of the following values will be returned:

Constant	Description
SECURITY_CERTIFICATE_VALID	The certificate is valid.
SECURITY_CERTIFICATE_NOMATCH	The certificate is valid, but the domain name does not match the common name in the certificate.
SECURITY_CERTIFICATE_EXPIRED	The certificate is valid, but has expired.
SECURITY_CERTIFICATE_REVOKED	The certificate has been revoked and is no longer valid.
SECURITY_CERTIFICATE_UNTRUSTED	The certificate or certificate authority is not trusted on the local system.
SECURITY_CERTIFICATE_INVALID	The certificate is invalid. This typically indicates that the internal structure of the certificate has been damaged.

stCertIssued

A structure which contains the date and time that the certificate was issued by the certificate authority. If the issue date cannot be determined for the certificate, the SYSTEMTIME structure members will have zero values. This member only has meaning for connections using the SSL or TLS protocols.

stCertExpires

A structure which contains the date and time that the certificate expires. If the expiration date cannot be determined for the certificate, the SYSTEMTIME structure members will have zero values. This member only has meaning for connections using the SSL or TLS protocols.

lpszCertIssuer

A pointer to a string which contains information about the organization that issued the certificate. This string consists of one or more comma-separated tokens. Each token consists of an identifier, followed by an equal sign and a value. If the certificate issuer could not be determined, this member may be NULL. This member only has meaning for connections using the SSL or TLS protocols.

lpszCertSubject

A pointer to a string which contains information about the organization that the certificate was issued to. This string consists of one or more comma-separated tokens. Each token consists of an identifier, followed by an equal sign and a value. If the certificate subject could not be determined, this member may be NULL. This member only has meaning for connections using the SSL or TLS protocols.

lpszFingerprint

A pointer to a string which contains a sequence of hexadecimal values that uniquely identify the server. This member is only used when a connection has been established using the Secure Shell (SSH) protocol.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Unicode: Implemented as Unicode and ANSI versions.

SMTPMESSAGE Structure

This structure provides information about the contents of a message and is used by the [SmtSubmitMessage](#) function.

```
typedef struct _SMTPMESSAGE
{
    LPCTSTR    lpszFrom;
    LPCTSTR    lpszTo;
    LPCTSTR    lpszCc;
    LPCTSTR    lpszBcc;
    LPCTSTR    lpszSubject;
    LPCTSTR    lpszText;
    LPCTSTR    lpszHTML;
    LPCTSTR    lpszAttach;
    UINT       nCharSet;
    UINT       nEncType;
    DWORD      dwReserved;
} SMTPMESSAGE, *LPSMTPMESSAGE;
```

Members

lpszFrom

A pointer to a string that specifies the email address of the person sending the message. This structure member must point to a valid address and cannot be NULL.

lpszTo

A pointer to a string that specifies the email addresses of one or more recipients. If multiple addresses are provided, they must be separated by commas or semi-colons. This structure member must point to at least one valid address and cannot be NULL.

lpszCc

A pointer to a string that specifies the email addresses of one or more recipients that will receive copies of the message. If multiple addresses are provided, they must be separated by commas or semi-colons. This structure member may be NULL or point to an empty string.

lpszBcc

A pointer to a string that specifies the email addresses of one or more recipients that will receive blind copies of the message. If multiple addresses are provided, they must be separated by commas or semi-colons. This structure member may be NULL or point to an empty string. Unlike the recipients specified by the *lpszTo* and *lpszCc* members, any addresses specified by this member will not be included in the header of the email message.

lpszSubject

A pointer to a string that specifies the subject of the message. This structure member may be NULL, in which case no subject will be included in the message.

lpszText

A pointer to a string which contains the body of the message as plain text. Each line of text contained in the string should be terminated with a carriage-return and linefeed (CRLF) pair, which is recognized as the end-of-line. If this structure member is NULL or points to an empty string, then the *lpszHTML* member must specify the body of the message.

lpszHTML

A pointer to a string which contains the message using HTML formatting. If the *lpszText* member is not NULL, then a multipart message will be created with both plain text and HTML

text as the alternative. This allows mail clients to select which message body they wish to display. If the *lpszText* member is NULL or points to an empty string, then the message will only contain HTML. Although this is supported, it is not recommended because older mail clients may be unable to display the message correctly.

lpszAttach

A pointer to a string which specifies one or more file attachments for the message. If multiple files are to be attached to the message, each file name must be separated by a semi-colon. It is recommended that you provide the complete path to the file. If this structure member is NULL or points to an empty string, the message will be created without attachments.

nCharSet

A integer value which specifies the character set to use when composing the message. A value of zero specifies that the default USASCII character set should be used. The following values may also be used:

Constant	Description
MIME_CHARSET_USASCII	Each character is encoded in one or more bytes, with each byte being 8 bits long, with the first bit cleared. This encoding is most commonly used with plain text using the US-ASCII character set, where each character is represented by a single byte in the range of 20h to 7Eh.
MIME_CHARSET_ISO8859_1	An 8-bit character set for most western European languages such as English, French, Spanish and German. This character set is also commonly referred to as Latin1.
MIME_CHARSET_ISO8859_2	An 8-bit character set for most central and eastern European languages such as Czech, Hungarian, Polish and Romanian. This character set is also commonly referred to as Latin2.
MIME_CHARSET_ISO8859_5	An 8-bit character set for Cyrillic languages such as Russian, Bulgarian and Serbian.
MIME_CHARSET_ISO8859_6	An 8-bit character set for Arabic languages. Note that the application is responsible for displaying text that uses this character set. In particular, any display engine needs to be able to handle the reverse writing direction and analyze the context of the message to correctly combine the glyphs.
MIME_CHARSET_ISO8859_7	An 8-bit character set for the Greek language.
MIME_CHARSET_ISO8859_8	An 8-bit character set for the Hebrew language. Note that similar to Arabic, Hebrew uses a reverse writing direction. An application which displays this character should be capable of processing bi-directional text where a single message may include both right-to-left and left-to-right languages, such as Hebrew and English.
MIME_CHARSET_ISO8859_9	An 8-bit character set for the Turkish language. This character set is also commonly referred to as Latin5.

nEncType

A numeric identifier which specifies the encoding type to use when composing the message. A value of zero specifies that default 7bit encoding should be used. The following values may also be used:

Constant	Description
MIME_ENCODING_7BIT	Each character is encoded in one or more bytes, with each byte being 8 bits long, with the most significant bit cleared. This encoding is most commonly used with plain text using the US-ASCII character set, where each character is represented by a single byte in the range of 20h to 7Eh.
MIME_ENCODING_8BIT	Each character is encoded in one or more bytes, with each byte being 8 bits long and all bits are used. 8-bit encoding is typically used with multibyte character sets and is the default encoding used with Unicode text.
MIME_ENCODING_QUOTED	Quoted-printable encoding is designed for textual messages where most of the characters are represented by the ASCII character set and is generally human-readable. Non-printable characters or 8-bit characters with the high bit set are encoded as hexadecimal values and represented as 7-bit text. Quoted-printable encoding is typically used for messages which use character sets such as ISO-8859-1, as well as those which use HTML.

dwReserved

An unsigned integer value reserved for future use. This structure member should always have a value of zero.

Remarks

This structure is used to define the contents of a message that will be submitted for delivery using the **SmtplibSubmitMessage** function. It is required that you specify a sender, at least one recipient and a message body. All other structure members may be NULL or have a value of zero to indicate that either the value is not required, or that a default should be used. It is recommended that you initialize all of the structure members to a value of zero using the **ZeroMemory** function prior to populating the structure.

email addresses may be specified as simple addresses, or as commented addresses that include the sender's name or other information. For example, any one of these address formats are acceptable:

```
user@domain.tld
User Name <user@domain.tld>
user@domain.tld (User Name)
```

To specify multiple addresses, you should separate each address by a comma or semi-colon. Note that the *lpszFrom* member cannot specify multiple addresses, however it is permitted with the *lpszTo*, *lpszCc* and *lpszBcc* structure members. Each message must have at least one valid recipient, or the message cannot be submitted for delivery.

To send a message that contains HTML, it is recommended that you provide both a plain text version of the message body and an HTML formatted version. While it is permitted to send a

message that only contains HTML, some older mail clients may not be capable of displaying the message correctly. In some cases, anti-spam software will increase the spam score of messages that do not contain a plain text message body. This can result in your message being rejected or quarantined by the mail server.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Unicode: Implemented as Unicode and ANSI versions.

See Also

[SMTPSERVER](#)

SMTPMESSAGEEX Structure

This structure provides information about the contents of a message and is used by the [SmtplibSubmitMessageEx](#) function.

```
typedef struct _SMTPMESSAGEEX
{
    DWORD    dwSize
    LPCTSTR  lpszFrom;
    LPCTSTR  lpszTo;
    LPCTSTR  lpszCc;
    LPCTSTR  lpszBcc;
    LPCTSTR  lpszDate;
    LPCTSTR  lpszSubject;
    LPCTSTR  lpszHeaders;
    LPCTSTR  lpszText;
    LPCTSTR  lpszHTML;
    LPCTSTR  lpszAttach;
    UINT     nCharSet;
    UINT     nEncType;
    DWORD    dwReserved;
} SMTPMESSAGEEX, *LPSMTPMESSAGEEX;
```

Members

dwSize

An integer value that specifies the size of the **SMTPMESSAGEEX** data structure. This must always be explicitly defined, and if the value is incorrect, an error will be returned. This structure member is used to ensure that the correct version of the structure is being passed to the function.

lpszFrom

A pointer to a string that specifies the email address of the person sending the message. This structure member must point to a valid address and cannot be NULL.

lpszTo

A pointer to a string that specifies the email addresses of one or more recipients. If multiple addresses are provided, they must be separated by commas or semi-colons. This structure member must point to at least one valid address and cannot be NULL.

lpszCc

A pointer to a string that specifies the email addresses of one or more recipients that will receive copies of the message. If multiple addresses are provided, they must be separated by commas or semi-colons. This structure member may be NULL or point to an empty string.

lpszBcc

A pointer to a string that specifies the email addresses of one or more recipients that will receive blind copies of the message. If multiple addresses are provided, they must be separated by commas or semi-colons. This structure member may be NULL or point to an empty string. Unlike the recipients specified by the *lpszTo* and *lpszCc* members, any addresses specified by this member will not be included in the header of the email message.

lpszDate

A pointer to a string that specifies the date and time for the message. This structure member may be NULL or point to an empty string. If the date is not specified, then the current date and time will be used by default. If a date is specified, it should be in the standard format as defined

by RFC822.

lpzSubject

A pointer to a string that specifies the subject of the message. This structure member may be NULL, in which case no subject will be included in the message.

lpzHeaders

A pointer to a string that specifies additional headers that should be included in the message. Header names should be separated from values by a colon, and multiple headers may be defined by separating them with a newline character. This structure member may be NULL, in which case no additional headers will be included in the message.

lpzText

A pointer to a string which contains the body of the message as plain text. Each line of text contained in the string should be terminated with a carriage-return and linefeed (CRLF) pair, which is recognized as the end-of-line. If this structure member is NULL or points to an empty string, then the *lpzHTML* member must specify the body of the message.

lpzHTML

A pointer to a string which contains the message using HTML formatting. If the *lpzText* member is not NULL, then a multipart message will be created with both plain text and HTML text as the alternative. This allows mail clients to select which message body they wish to display. If the *lpzText* member is NULL or points to an empty string, then the message will only contain HTML. Although this is supported, it is not recommended because older mail clients may be unable to display the message correctly.

lpzAttach

A pointer to a string which specifies one or more file attachments for the message. If multiple files are to be attached to the message, each file name must be separated by a semi-colon. It is recommended that you provide the complete path to the file. If this structure member is NULL or points to an empty string, the message will be created without attachments.

nCharSet

An integer value which specifies the character set to use when composing the message. A value of zero specifies that the default USASCII character set should be used. The following values may also be used:

Constant	Description
MIME_CHARSET_USASCII	Each character is encoded in one or more bytes, with each byte being 8 bits long, with the first bit cleared. This encoding is most commonly used with plain text using the US-ASCII character set, where each character is represented by a single byte in the range of 20h to 7Eh.
MIME_CHARSET_ISO8859_1	An 8-bit character set for most western European languages such as English, French, Spanish and German. This character set is also commonly referred to as Latin1.
MIME_CHARSET_ISO8859_2	An 8-bit character set for most central and eastern European languages such as Czech, Hungarian, Polish and Romanian. This character set is also commonly referred to as Latin2.
MIME_CHARSET_ISO8859_5	An 8-bit character set for Cyrillic languages such as Russian, Bulgarian and Serbian.

MIME_CHARSET_ISO8859_6	An 8-bit character set for Arabic languages. Note that the application is responsible for displaying text that uses this character set. In particular, any display engine needs to be able to handle the reverse writing direction and analyze the context of the message to correctly combine the glyphs.
MIME_CHARSET_ISO8859_7	An 8-bit character set for the Greek language.
MIME_CHARSET_ISO8859_8	An 8-bit character set for the Hebrew language. Note that similar to Arabic, Hebrew uses a reverse writing direction. An application which displays this character should be capable of processing bi-directional text where a single message may include both right-to-left and left-to-right languages, such as Hebrew and English.
MIME_CHARSET_ISO8859_9	An 8-bit character set for the Turkish language. This character set is also commonly referred to as Latin5.

nEncType

A numeric identifier which specifies the encoding type to use when composing the message. A value of zero specifies that default 7bit encoding should be used. The following values may also be used:

Constant	Description
MIME_ENCODING_7BIT	Each character is encoded in one or more bytes, with each byte being 8 bits long, with the most significant bit cleared. This encoding is most commonly used with plain text using the US-ASCII character set, where each character is represented by a single byte in the range of 20h to 7Eh.
MIME_ENCODING_8BIT	Each character is encoded in one or more bytes, with each byte being 8 bits long and all bits are used. 8-bit encoding is typically used with multibyte character sets and is the default encoding used with Unicode text.
MIME_ENCODING_QUOTED	Quoted-printable encoding is designed for textual messages where most of the characters are represented by the ASCII character set and is generally human-readable. Non-printable characters or 8-bit characters with the high bit set are encoded as hexadecimal values and represented as 7-bit text. Quoted-printable encoding is typically used for messages which use character sets such as ISO-8859-1, as well as those which use HTML.

dwReserved

An unsigned integer value reserved for future use. This structure member should always have a value of zero.

Remarks

This structure is used to define the contents of a message that will be submitted for delivery using

the **SmtplibSubmitMessageEx** function. It is required that you specify a sender, at least one recipient and a message body. Other structure members may be NULL or have a value of zero to indicate that either the value is not required, or that a default should be used. It is recommended that you initialize all of the structure members to a value of zero using the **ZeroMemory** function prior to populating the structure.

Note that you must explicitly define the size of the structure by setting the value of the **dwSize** member variable. This ensures that the correct version of the structure is being passed to the function. This structure is not compatible with the **SmtplibSubmitMessage** function and must only be used with **SmtplibSubmitMessageEx**.

Email addresses may be specified as simple addresses, or as commented addresses that include the sender's name or other information. For example, any one of these address formats are acceptable:

```
user@domain.tld
User Name <user@domain.tld>
user@domain.tld (User Name)
```

To specify multiple addresses, you should separate each address by a comma or semi-colon. Note that the **lpszFrom** member cannot specify multiple addresses, however it is permitted with the **lpszTo**, **lpszCc** and **lpszBcc** structure members. Each message must have at least one valid recipient, or the message cannot be submitted for delivery.

If you specify a message date by assigning a value to the **lpszDate** member, and it does not include any timezone information, Coordinated Universal Time (UTC) will be used by default. This is an important consideration if you provide input from a user, because in most cases they will not include the timezone and will assume the date and time they enter is for their current timezone.

If you wish to include additional headers in the message, you can specify them in a string. Each header consists of a name and value, separated by a colon (":") character. If you wish to define multiple headers, then you can separate them with a newline (e.g.: a linefeed character or combination of a carriage-return and linefeed). Extraneous leading and trailing whitespace are trimmed from header names and values. Invalid names or values will be ignored and will not generate an error.

To send a message that contains HTML, it is recommended that you provide both a plain text version of the message body and an HTML formatted version. While it is permitted to send a message that only contains HTML, some older mail clients may not be capable of displaying the message correctly. In some cases, anti-spam software will increase the spam score of messages that do not contain a plain text message body. This can result in your message being rejected or quarantined by the mail server.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Unicode: Implemented as Unicode and ANSI versions.

[SMTPSERVER](#)

SMTPSERVER Structure

This structure provides connection information for a mail server and is used by the [SmtpSubmitMessage](#) function.

```
typedef struct _SMTPSERVER
{
    LPCTSTR lpszHostName;
    LPCTSTR lpszUserName;
    LPCTSTR lpszPassword;
    UINT nHostPort;
    UINT nTimeout;
    DWORD dwOptions;
    DWORD dwReserved;
} SMTPSERVER, *LPSMTPSERVER;
```

Members

lpszHostName

A pointer to a string that specifies the host name or IP address of the mail server. This structure member cannot be NULL.

lpszUserName

A pointer to a string that specifies the username that will be used to authenticate the client session. If the mail server does not require authentication, this structure member can be NULL or point to an empty string.

lpszPassword

A pointer to a string that specifies the password that will be used to authenticate the client session. If the mail server does not require authentication, this structure member can be NULL or point to an empty string.

nHostPort

An integer value that specifies the port number used to establish the connection. A value of zero specifies that the default port number should be used. For standard connections, the default port number is 25. An alternative port is 587, which is commonly used by authenticated clients to submit messages for delivery. For implicit SSL connections, the default port number is 465.

nTimeout

An integer value that specifies the number of seconds that the client will wait for a response from the server before failing the operation. A value of zero specifies the default timeout period of 20 seconds.

dwOptions

An unsigned integer that specifies one or more options. The value of this structure member is constructed by using a bitwise operator with any of the following values:

Constant	Description
SMTP_OPTION_NONE	No additional options are specified when establishing a connection with the server. A standard, non-secure connection will be used.
SMTP_OPTION_EXTENDED	Extended SMTP commands should be used if possible. This option enables features such as

	authentication and delivery status notification. If this option is not specified, the library will not attempt to use any extended features. This option is automatically enabled if a username and password are specified, or if the connection is established on port 587, because submitting messages for delivery using this port typically requires client authentication.
SMTP_OPTION_TUNNEL	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established.
SMTP_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using either the SSL or TLS protocols.
SMTP_OPTION_SECURE	This option specifies that a secure connection should be established with the server and requires that the server support either the SSL or TLS protocol. The client will initiate the secure session using the STARTTLS command.
SMTP_OPTION_SECURE_IMPLICIT	This option specifies the client should attempt to establish a secure connection with the server. The server must support secure connections using either the SSL or TLS protocol, and the secure session must be negotiated immediately after the connection has been established.

dwReserved

An unsigned integer value reserved for future use. This structure member should always have a value of zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Unicode: Implemented as Unicode and ANSI versions.

[SMTPMESSAGE](#)

SMTPTTRANSFERSTATUS Structure

This structure is used by the [SmtpGetTransferStatus](#) function to return information about a message being submitted for delivery.

```
typedef struct _SMTPTTRANSFERSTATUS
{
    DWORD    dwBytesTotal;
    DWORD    dwBytesCopied;
    DWORD    dwBytesPerSecond;
    DWORD    dwTimeElapsed;
    DWORD    dwTimeEstimated;
} SMTPTTRANSFERSTATUS, *LPSMTPTTRANSFERSTATUS;
```

Members

dwBytesTotal

The total number of bytes that will be transferred. If the size of the message cannot be determined, this value will be zero.

dwBytesCopied

The total number of bytes that have been copied.

dwBytesPerSecond

The average number of bytes that have been copied per second.

dwTimeElapsed

The number of seconds that have elapsed since the file transfer started.

dwTimeEstimated

The estimated number of seconds until the transfer is completed. This is based on the average number of bytes transferred per second.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

SYSTEMTIME Structure

The **SYSTEMTIME** structure represents a date and time using individual members for the month, day, year, weekday, hour, minute, second, and millisecond.

```
typedef struct _SYSTEMTIME
{
    WORD wYear;
    WORD wMonth;
    WORD wDayOfWeek;
    WORD wDay;
    WORD wHour;
    WORD wMinute;
    WORD wSecond;
    WORD wMilliseconds;
} SYSTEMTIME, *LPSYSTEMTIME;
```

Members

wYear

Specifies the current year. The year value must be greater than 1601.

wMonth

Specifies the current month. January is 1, February is 2 and so on.

wDayOfWeek

Specifies the current day of the week. Sunday is 0, Monday is 1 and so on.

wDay

Specifies the current day of the month

wHour

Specifies the current hour.

wMinute

Specifies the current minute

wSecond

Specifies the current second.

wMilliseconds

Specifies the current millisecond.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include windows.h.

SocketWrench Library

A general purpose TCP/IP networking library for developing client and server applications.

Reference

- [Functions](#)
- [Data Structures](#)
- [Error Codes](#)

Library Information

File Name	CSWSKV10.DLL
Version	10.0.1468.2518
LibID	1437629B-0693-44DE-93ED-1482DBEFE8DC
Import Library	CSWSKV10.LIB
Dependencies	None
Standards	RFC 768, RFC 791, RFC 793

Overview

At the core of all of the SocketTools networking libraries is the Windows Sockets API. This provides a low level interface for sending and receiving data over the Internet or a local intranet using the Transmission Control Protocol (TCP) and/or User Datagram Protocol (UDP). The SocketWrench library provides a simpler interface to the Windows Sockets API, without sacrificing features or functionality. Using SocketWrench, you can easily create client and server applications while avoiding many of the mundane tasks and common problems that developers face when building Internet applications.

This library supports secure connections using the TLS 1.2 protocol and can also be used to create secure, customized server applications. Both implicit and explicit SSL connections are supported, enabling the library to work with a wide variety of client and server applications without requiring that you use third-party libraries or Microsoft's CryptoAPI.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). If you are using Visual C++ 6.0 it is required that you have Service Pack 6 (SP6) installed. You should install all updates for your development tools and have the current Windows SDK installed. The minimum recommended version of Visual Studio is Visual Studio 2010.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are using Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. It is recommended that you install the current service pack and all critical updates available for your version of the operating system.

This library provides an implementation of a multithreaded server which should only be used with languages that support the creation of multithreaded applications. It is important that you do not link against static libraries which were not built with support for threading.

This product includes both 32-bit and 64-bit libraries. Native 64-bit CPU support requires the 64-

bit version of Windows 7 or later versions of the Windows operating system.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

SocketWrench Library Functions

Function	Description
InetAbort	Abort the connection and immediately close the socket
InetAccept	Accept a connection request from a remote host
InetAcceptEx	Accept a client connection on a listening socket with additional options
InetAsyncAccept	Accept an asynchronous connection request from a remote host
InetAsyncAcceptEx	Accept a non-blocking connection on a listening socket
InetAsyncConnect	Connect asynchronously to the specified server
InetAsyncConnectEx	Connect asynchronously to the specified server
InetAsyncListen	Listen for client connections on an asynchronous socket
InetAsyncListenEx	Listen for client connections on an asynchronous socket with additional options
InetAttachSocket	Attach the socket handle to the specified process
InetAttachThread	Attach the specified socket to another thread
InetCancel	Cancel a blocking operation
InetClientBroadcast	Write data to all other clients that are connected to the same server
InetCompareAddress	Compare two IP addresses to determine if they are identical
InetConnect	Connect to the specified server
InetConnectEx	Connect to the specified server
InetCreateSecurityCredentials	Create a new security credentials structure
InetDeleteSecurityCredentials	Delete a previously created security credentials structure
InetDetachSocket	Detach the socket handle from the current process
InetDisableEvents	Disable asynchronous event notification
InetDisableSecurity	Disable secure communication with the remote host
InetDisableTrace	Disable logging of socket function calls to the trace log
InetDisconnect	Disconnect from the current server
InetEnableEvents	Enable asynchronous event notification
InetEnableSecurity	Enable secure communication with the remote host
InetEnableTrace	Enable logging of socket function calls to a file
InetEnumHostAliases	Return a byte array that contains all the aliases for a specified host
InetEnumNetworkAddresses	Return the list of network addresses that are configured for the local host
InetEnumServerClients	Returns a list of active client sessions established with the specified server
InetEnumServerClientsByAddress	Returns a list of active client sessions that match the specified IP address
InetEventProc	Callback method that processes events generated on the socket
InetFindClientMoniker	Returns a handle to the client socket which matches the specified moniker
InetFlush	Flush the send and receive buffers
InetFormatAddress	Convert an IP address in binary format into a printable string
InetFreezeEvents	Suspend or resume event handling by the application
InetGetAdapterAddress	Return the IP or MAC assigned to the specified network adapter
InetGetAddress	Convert an IP address string to a binary format
InetGetAddressFamily	Return the address family for the specified IP address

InetGetBlockingSocket	Return the handle for the socket which is blocked in the current thread
InetGetDefaultHostFile	Return the fully qualified path name of the host file on the local system
InetGetClientData	Returns the application defined data associated with the specified client session
InetGetClientHandle	Returns the handle for a specific client session based on its ID number
InetGetClientId	Returns the unique ID number assigned to the specified client session
InetGetClientIdleTime	Returns the amount of time the specified client session has been idle
InetGetClientMoniker	Returns the string alias associated with the specified client session
InetGetClientPriority	Returns the current priority for the specified client session
InetGetClientServer	Returns a socket handle to the server for the specified client socket
InetGetClientServerById	Returns a socket handle to the server for the specified session identifier
InetGetClientThreadId	Returns the thread ID for the specified client session
InetGetClientThreads	Returns the number of client session threads created by the server
InetGetErrorString	Return a description for the specified error code
InetGetExternalAddress	Return the external IP address assigned to the local system
InetGetHostAddress	Return the IP address assigned to the specified hostname
InetGetHostFile	Return the name of the host file
InetGetHostName	Return the hostname assigned to the specified IP address
InetGetLastError	Return the last error code
InetGetLocalAddress	Return the local IP address and port number for a socket
InetGetLocalName	Return the hostname assigned to the local system
InetGetLockedServer	Return the handle to the server which has been locked
InetGetOption	Return the current socket options
InetGetPeerAddress	Return the IP address of the peer that the socket is connected to
InetGetPhysicalAddress	Return the media access control (MAC) address for the primary network adapter
InetGetSecurityInformation	Return information about the security characteristics of a connection
InetGetServerClient	Return the handle for the last client connection accepted by the server
InetGetServerData	Returns the application defined data associated with the specified server
InetGetServerPriority	Return the current priority assigned to the specified server
InetGetServerStackSize	Return the initial size of the stack allocated for threads created by the server
InetGetServerStatus	Returns the status of the specified server
InetGetServerThreadId	Returns the thread ID for the specified server
InetGetServiceName	Return the service name associated with a specified port number
InetGetServicePort	Return the port number associated with a service name
InetGetStatus	Report what sort of socket operation is in progress
InetGetStreamInfo	Return information about the current stream read or write operation
InetGetThreadClient	Return the handle for the client session that is being managed by the specified thread
InetGetTimeout	Return the timeout interval for blocking operations, in seconds
InetHostNameToUnicode	Converts the canonical form of a host name to its Unicode version
InetInitialize	Initialize the library and validate the specified user license key at runtime
InetIsAddressNull	Determine if the specified IP address is a null address
InetIsAddressRoutable	Determine if the specified IP address is routable over the Internet

InetIsBlocking	Determine if the socket is performing a blocking operation
InetIsClosed	Determine if the remote host has closed its socket
InetIsConnected	Determine if the socket is connected to a remote host
InetIsListening	Determine if the socket is listening for a connection
InetIsProtocolAvailable	Determine if the specified protocol and address family are supported
InetIsReadable	Determine if data can be read from the remote process
InetIsUrgent	Determine if there is any out-of-band (OOB) data available to be read
InetIsWritable	Determine if data can be written to the remote process
InetListen	Listen for client connections on the specified socket
InetListenEx	Listen for client connections on the specified socket with additional options
InetMatchHostName	Match a host name against a list of addresses including wildcards
InetNormalizeHostName	Return the canonical form of a host name
InetPeek	Read data from the socket without removing it from the socket buffer
InetRead	Read data from the socket
InetReadEx	Read data from the socket, with extended functionality
InetReadLine	Read a line of data from the socket, storing it in a string buffer
InetReadStream	Read a stream of data from the socket
InetRegisterEvent	Register an event callback function
InetReject	Reject a pending client connection request
InetServerAsyncNotify	Enable or disable asynchronous notification of changes in server status
InetServerBroadcast	Write data to all active clients currently connected to the specified server
InetServerLock	Lock the specified server, causing all other client threads to block until it is unlocked
InetServerRestart	Restart the server, terminating all active client sessions
InetServerResume	Resume accepting client connections on the specified server
InetServerStart	Begin listening for client connections on the specified address and port
InetServerStop	Stop listening for connections and terminate all client sessions
InetServerStopEx	Stop listening for connections and wait for the server to terminate
InetServerSuspend	Suspend accepting client connections on the specified server
InetServerSuspendEx	Suspend accepting client connections and optionally reject or disconnect clients
InetServerThrottle	Limit the number of active client connections, connections per address and connection rate
InetServerUnlock	Unlock the specified server, allowing other client threads to resume execution
InetSetClientData	Associate application defined data with the specified client session
InetSetClientMoniker	Associate a unique string alias with the specified client session
InetSetClientPriority	Set the priority for the specified client session
InetSetServerData	Associate application defined data with the specified server
InetSetServerPriority	Change the priority assigned to the specified server
InetSetServerStackSize	Change the initial size of the stack allocated for threads created by the server
InetSetHostFile	Specify the name of an alternate host table
InetSetLastError	Set the last error code
InetSetOption	Set one or more options for the current socket
InetSetTimeout	Set the interval used when waiting for a blocking operation to complete

InetShutdown	Disable reception or transmission of data
InetStoreStream	Read a stream of data from the remote host and store it in a file
InetUninitialize	Terminate use of the library by the application
InetWrite	Write data to the socket
InetWriteEx	Write data to the socket, with extended functionality
InetWriteLine	Write a line of data to the socket, terminated with a carriage-return and linefeed
InetWriteStream	Write a stream of data to the socket

InetAbort Function

```
INT WINAPI InetAbort(  
    SOCKET hSocket  
);
```

Immediately close the socket without waiting for any remaining data to be written out.

Parameters

hSocket

Handle to the socket.

Return Value

If the function succeeds, the return value is 0. If the function fails, the return value is `INET_ERROR`. To get extended error information, call **InetGetLastError**.

Remarks

The **InetAbort** function should only be used when the connection must be closed immediately before the application terminates. This function should only be used to abort client connections and should not be used with passive (listening) sockets. Server applications that need to abort an incoming client connection should use the **InetReject** function.

In most cases, the application should call the **InetDisconnect** function to gracefully close the connection to the remote host. Aborting the connection will discard any buffered data and may cause errors or result in unpredictable behavior.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cssock10.h`

Import Library: `cswskv10.lib`

See Also

[InetCancel](#), [InetReject](#), [InetDisconnect](#)

InetAccept Function

```
SOCKET WINAPI InetAccept(  
    SOCKET hSocket,  
    UINT nTimeout  
);
```

The **InetAccept** function is used to accept a client connection on a listening socket.

This function is included for backwards compatibility with legacy applications. New projects should use the **InetServerStart** function to create a server application.

Parameters

hSocket

Handle to the listening socket.

nTimeout

The number of seconds that the server will wait for the connection to complete before failing the operation.

Return Value

If the function succeeds, the return value is a handle to the socket. If the function fails, the return value is INVALID_SOCKET. To get extended error information, call **InetGetLastError**.

Remarks

To prevent this function from blocking the main user interface thread, the application should create a background worker thread and accept the connection by calling **InetAccept** in that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each client session.

When a connection is accepted by the server, the original listening socket continues to listen for more connections. The socket handle returned by **InetAccept** should be used to exchange information with the client.

To enable asynchronous event notification, use the **InetEnableEvents** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cswsock10.h`

Import Library: `cswskv10.lib`

See Also

[InetConnect](#), [InetEnableEvents](#), [InetListen](#), [InetReject](#), [InetServerStart](#)

InetAcceptEx Function

```
SOCKET WINAPI InetAcceptEx(  
    SOCKET hSocket,  
    UINT nTimeout,  
    DWORD dwOptions,  
    LPSECURITYCREDENTIALS LpCredentials  
);
```

The **InetAcceptEx** function is used to accept a client connection on a listening socket, and to set certain attributes of that connection.

This function is included for backwards compatibility with legacy applications. New projects should use the **InetServerStart** function to create a server application.

Parameters

hSocket

Handle to the socket.

nTimeout

The number of seconds that the server will wait for a client connection before failing the current operation.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
INET_OPTION_KEEPALIVE	This option specifies that packets are to be sent to the remote system when no data is being exchanged to keep the connection active. This is only valid for stream sockets.
INET_OPTION_NODELAY	This option disables the Nagle algorithm, which buffers unacknowledged data and insures that a full-size packet can be sent to the remote host.
INET_OPTION_INLINE	This option controls how urgent (out-of-band) data is handled when reading data from the socket. If set, urgent data is placed in the data stream along with non-urgent data.
INET_OPTION_SECURE	This option determines if a secure connection is established with the remote host.
INET_OPTION_SECURE_FALLBACK	This option specifies the server should permit the use of less secure cipher suites for compatibility with legacy clients. If this option is specified, the server will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
INET_OPTION_FREETHREAD	This option specifies the socket returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access

to the socket is synchronized across multiple threads.

lpCredentials

Pointer to credentials structure [SECURITYCREDENTIALS](#). This may be NULL, unless *dwOptions* includes INET_OPTION_SECURE. When INET_OPTION_SECURE is used, the fields *dwSize*, *lpzCertStore*, and *lpzCertName* must be defined, while other fields may be left undefined. Set *dwSize* to the size of the [SECURITYCREDENTIALS](#) structure.

Return Value

If the function succeeds, the return value is a handle to the socket. If the function fails, the return value is INVALID_SOCKET. To get extended error information, call **InetGetLastError**.

Remarks

To prevent this function from blocking the main user interface thread, the application should create a background worker thread and accept the connection by calling **InetAcceptEx** in that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each client session.

When a connection is accepted by the server, the original listening socket continues to listen for more connections. The socket handle returned by **InetAcceptEx** should be used to exchange information with the client.

The *dwOptions* argument can be used to specify the threading model that is used by the library when a connection is established. By default, the handle is initially attached to the thread that created it. From that point on, until the it is released, only the owner may call functions using that handle. The ownership of the handle may be transferred from one thread to another using the **InetAttachThread** function.

Specifying the INET_OPTION_FREETHREAD option enables any thread to call any function using the socket handle, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the socket is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same socket handle.

To enable asynchronous event notification, use the **InetEnableEvents** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cswsock10.h`

Import Library: `cswskv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

See Also

[InetAccept](#), [InetConnect](#), [InetListen](#), [InetConnectEx](#), [InetListenEx](#), [InetServerStart](#)

InetAsyncAccept Function

```
SOCKET WINAPI InetAsyncAccept(  
    SOCKET hSocket,  
    UINT nTimeout,  
    HWND hEventWnd,  
    UINT uEventMsg  
);
```

The **InetAsyncAccept** function is used to accept a client connection on a listening socket.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

New projects should use the **InetServerStart** function to create a server application.

Parameters

hSocket

Handle to the listening socket.

nTimeout

The number of seconds that the server will wait for the connection to complete before failing the operation. This value is used only if *hWnd* is NULL.

hEventWnd

The handle to the event notification window. This window receives messages which notify the application of various asynchronous socket events that occur.

uEventMsg

The message identifier that is used when an asynchronous socket event occurs. This value should be greater than WM_USER as defined in the Windows header files.

Return Value

If the function succeeds, the return value is a handle to the socket. If the function fails, the return value is INVALID_SOCKET. To get extended error information, call **InetGetLastError**.

Remarks

When a connection is accepted by the server, the original listening socket continues to listen for more connections. The socket handle returned by **InetAsyncAccept** should be used to exchange information with the client.

When a message is posted to the notification window, the low word of the *lParam* parameter contains the event identifier. The high word of *lParam* contains the low word of the error code, if an error has occurred. The *wParam* parameter contains the socket handle. One or more of the following event identifiers may be sent:

Constant	Description
INET_EVENT_DISCONNECT	The remote host has closed the connection. The process should read any remaining data and disconnect.
INET_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the process has read at least some

	of the data from the socket. This event is only generated if the socket is in asynchronous mode.
INET_EVENT_WRITE	The process can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the socket is in asynchronous mode.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

Unicode: Implemented as Unicode and ANSI versions.

InetAsyncAcceptEx Function

```
SOCKET WINAPI InetAsyncAcceptEx(  
    SOCKET hSocket,  
    UINT nTimeout,  
    DWORD dwOptions,  
    LPSECURITYCREDENTIALS lpCredentials  
    HWND hEventWnd,  
    UINT uEventMsg  
);
```

The **InetAsyncAcceptEx** function is used to accept a client connection on a listening socket and set certain attributes of that connection.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

New projects should use the **InetServerStart** function to create a server application.

Parameters

hSocket

Handle to the listening socket.

nTimeout

The number of seconds that the server will wait for a client connection before failing the operation. This value is only used with blocking connections.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
INET_OPTION_KEEPALIVE	This option specifies that packets are to be sent to the remote system when no data is being exchanged to keep the connection active. This is only valid for stream sockets.
INET_OPTION_REUSEADDRESS	This option specifies the local address can be reused. This option is commonly used by server applications.
INET_OPTION_NODELAY	This option disables the Nagle algorithm, which buffers unacknowledged data and insures that a full-size packet can be sent to the remote host.
INET_OPTION_INLINE	This option controls how urgent (out-of-band) data is handled when reading data from the socket. If set, urgent data is placed in the data stream along with non-urgent data.
INET_OPTION_SECURE	This option determines if a secure connection is established with the remote host.

INET_OPTION_SECURE_FALLBACK	This option specifies the server should permit the use of less secure cipher suites for compatibility with legacy clients. If this option is specified, the server will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
INET_OPTION_FREETHREAD	This option specifies the socket returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the socket is synchronized across multiple threads.

lpCredentials

Pointer to credentials structure [SECURITYCREDENTIALS](#). This may be NULL, unless dwOptions includes INET_OPTION_SECURE. When INET_OPTION_SECURE is used, the fields *dwSize*, *lpzCertStore*, and *lpzCertName* must be defined, while other fields may be left undefined. Set *dwSize* to the size of the **SECURITYCREDENTIALS** structure.

hEventWnd

The handle to the event notification window. This window receives messages which notify the application of various asynchronous socket events that occur.

uEventMsg

The message identifier that is used when an asynchronous socket event occurs. This value should be greater than WM_USER as defined in the Windows header files.

Return Value

If the function succeeds, the return value is a handle to the socket. If the function fails, the return value is INVALID_SOCKET. To get extended error information, call **InetGetLastError**.

Remarks

When a connection is accepted by the server, the original listening socket continues to listen for more connections. The socket handle returned by **InetAsyncAccept** or **InetAsyncAcceptEx** should be used to exchange information with the client.

When a message is posted to the notification window, the low word of the *lParam* parameter contains the event identifier. The high word of *lParam* contains the low word of the error code, if an error has occurred. The *wParam* parameter contains the socket handle. One or more of the following event identifiers may be sent:

Constant	Description
INET_EVENT_DISCONNECT	The remote host has closed the connection. The process should read any remaining data and disconnect.
INET_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the process has read at least some of the data from the socket. This event is only generated if the socket is in asynchronous mode.
INET_EVENT_WRITE	The process can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the socket is in

It is recommended that you only establish an asynchronous connection if you understand the implications of doing so. In most cases, it is preferable to create a synchronous connection and create threads for each additional session if more than one active client session is required.

The *dwOptions* argument can be used to specify the threading model that is used by the library when a connection is established. By default, the handle is initially attached to the thread that created it. From that point on, until the it is released, only the owner may call functions using that handle. The ownership of the handle may be transferred from one thread to another using the **InetAttachThread** function.

Specifying the INET_OPTION_FREETHREAD option enables any thread to call any function using the socket handle, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the socket is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same socket handle.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

Unicode: Implemented as Unicode and ANSI versions.

InetAsyncConnect Function

```
SOCKET WINAPI InetAsyncConnect(  
    LPCTSTR lpszHostName,  
    UINT nPort,  
    UINT nProtocol,  
    UINT nTimeout,  
    DWORD dwOptions,  
    LPSECURITYCREDENTIALS lpCredentials,  
    HWND hEventWnd,  
    UINT uEventMsg  
);
```

The **InetAsyncConnect** function is used to establish a connection with a server.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

The application should create a background worker thread and establish a connection by calling **InetConnect** within that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each connection.

Parameters

lpszHostName

A pointer to the name of the server to connect to; this may be a fully-qualified domain name or an IP address.

nPort

The port number the server is listening on; a value of zero specifies that the default port number should be used.

nProtocol

The protocol to be used when establishing the connection. This may be one of the following values:

Constant	Description
INET_PROTOCOL_TCP	Specifies the Transmission Control Protocol. This protocol provides a reliable, bi-directional byte stream. This is the default protocol.
INET_PROTOCOL_UDP	Specifies the User Datagram Protocol. This protocol is message oriented, sending data in discrete packets. Note that UDP is unreliable in that there is no way for the sender to know that the receiver has actually received the datagram.

nTimeout

The number of seconds to wait for a response before failing the current operation.

dwOptions

An unsigned integer used to specify one or more socket options. This parameter is constructed by using the bitwise Or operator with any of the following values:

--	--

Constant	Description
INET_OPTION_BROADCAST	This option specifies that broadcasting should be enabled for datagrams. This option is invalid for stream sockets.
INET_OPTION_DONTROUTE	This option specifies default routing should not be used. This option should not be specified unless absolutely necessary.
INET_OPTION_KEEPAIVE	This option specifies that packets are to be sent to the remote system when no data is being exchanged to keep the connection active. This is only valid for stream sockets.
INET_OPTION_NODELAY	This option disables the Nagle algorithm. By default, small amounts of data written to the socket are buffered, increasing efficiency and reducing network congestion. However, this buffering can negatively impact the responsiveness of certain applications. This option disables this buffering and immediately sends data packets as they are written to the socket.
INET_OPTION_RESERVEDPORT	This option specifies the socket should be bound to an unused port number less than 1024, which is typically reserved for well-known system services. If this option is specified, the process may require administrative privileges.
INET_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using either the SSL or TLS protocols.
INET_OPTION_SECURE	This option specifies that a secure connection should be established with the remote host. The specific version of TLS and other security related options are provided in the <i>lpCredentials</i> parameter. If the <i>lpCredentials</i> parameter is NULL, the connection will default to using TLS 1.2 and the strongest cipher suites available. Older versions of Windows prior to Windows 7 and Windows Server 2008 R2 only support TLS 1.0 and secure connections will automatically downgrade on those platforms.
INET_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
INET_OPTION_PREFER_IPV6	This option specifies the client should prefer the

	use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
INET_OPTION_FREETHREAD	This option specifies the socket returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the socket is synchronized across multiple threads.

lpCredentials

A pointer to a [SECURITYCREDENTIALS](#) structure. This parameter is only used if INET_OPTION_SECURE is specified for a TCP connection. This parameter may be NULL, in which case no client credentials will be provided to the server. If client credentials are required, the fields *dwSize*, *lpszCertStore*, and *lpszCertName* must be defined, while other fields may be left undefined. Set *dwSize* to the size of the **SECURITYCREDENTIALS** structure.

hEventWnd

The handle to the event notification window. This window receives messages which notify the application of various asynchronous socket events that occur.

uEventMsg

The message identifier that is used when an asynchronous socket event occurs. This value should be greater than WM_USER as defined in the Windows header files.

Return Value

If the function succeeds, the return value is a handle to the socket. If the function fails, the return value is INVALID_SOCKET. To get extended error information, call **InetGetLastError**.

Remarks

When this function is called with UDP as the specified protocol, it does not actually establish a connection. Instead, it simply establishes a default destination IP address and port that is used with subsequent **InetRead** and **InetWrite** calls.

When a message is posted to the notification window, the low word of the *lParam* parameter contains the event identifier. The high word of *lParam* contains the low word of the error code, if an error has occurred. The *wParam* parameter contains the socket handle. One or more of the following event identifiers may be sent:

Constant	Description
INET_EVENT_CONNECT	The connection to the remote host has completed. The high word of the <i>lParam</i> parameter should be checked, since this notification message will be posted if an error has occurred.
INET_EVENT_DISCONNECT	The remote host has closed the connection. The process should read any remaining data and disconnect.
INET_EVENT_READ	Data is available to read by the calling process. No additional

	messages will be posted until the process has read at least some of the data from the socket. This event is only generated if the socket is in asynchronous mode.
INET_EVENT_WRITE	The process can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the socket is in asynchronous mode.

To cancel asynchronous notification and return the socket to a blocking mode, use the **InetDisableEvents** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cssock10.h`

Import Library: `cswskv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

See Also

[InetAsyncConnectEx](#), [InetConnect](#), [InetDisableEvents](#), [InetDisconnect](#), [InetEnableEvents](#), [InetInitialize](#)

InetAsyncConnectEx Function

```
SOCKET WINAPI InetAsyncConnectEx(  
    LPCTSTR lpszHostName,  
    UINT nPort,  
    UINT nProtocol,  
    UINT nTimeout,  
    DWORD dwOptions,  
    LPCTSTR lpszLocalAddress,  
    UINT nLocalPort,  
    LPSECURITYCREDENTIALS LpCredentials,  
    HWND hEventWnd,  
    UINT uEventMsg  
);
```

The **InetAsyncConnectEx** function is used to establish a connection with a server.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

The application should create a background worker thread and establish a connection by calling **InetConnectEx** within that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each client session.

Parameters

lpszHostName

A pointer to the name of the server to connect to; this may be a fully-qualified domain name or an IP address.

nPort

The port number the server is listening on; a value of zero specifies that the default port number should be used.

nProtocol

The protocol to be used when establishing the connection. This may be one of the following values:

Constant	Description
INET_PROTOCOL_TCP	Specifies the Transmission Control Protocol. This protocol provides a reliable, bi-directional byte stream. This is the default protocol.
INET_PROTOCOL_UDP	Specifies the User Datagram Protocol. This protocol is message oriented, sending data in discrete packets. Note that UDP is unreliable in that there is no way for the sender to know that the receiver has actually received the datagram.

nTimeout

The number of seconds to wait for a response before failing the current operation.

dwOptions

An unsigned integer used to specify one or more socket options. The following values are

recognized:

Constant	Description
INET_OPTION_BROADCAST	This option specifies that broadcasting should be enabled for datagrams. This option is invalid for stream sockets.
INET_OPTION_DONTROUTE	This option specifies default routing should not be used. This option should not be specified unless absolutely necessary.
INET_OPTION_KEEPAIVE	This option specifies that packets are to be sent to the remote system when no data is being exchanged to keep the connection active. This is only valid for stream sockets.
INET_OPTION_NODELAY	This option disables the Nagle algorithm. By default, small amounts of data written to the socket are buffered, increasing efficiency and reducing network congestion. However, this buffering can negatively impact the responsiveness of certain applications. This option disables this buffering and immediately sends data packets as they are written to the socket.
INET_OPTION_RESERVEDPORT	This option specifies the socket should be bound to an unused port number less than 1024, which is typically reserved for well-known system services. If this option is specified, the process may require administrative privileges.
INET_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using either the SSL or TLS protocols.
INET_OPTION_SECURE	This option specifies that a secure connection should be established with the remote host. The specific version of TLS and other security related options are provided in the <i>lpCredentials</i> parameter. If the <i>lpCredentials</i> parameter is NULL, the connection will default to using TLS 1.2 and the strongest cipher suites available. Older versions of Windows prior to Windows 7 and Windows Server 2008 R2 only support TLS 1.0 and secure connections will automatically downgrade on those platforms.
INET_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.

INET_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
INET_OPTION_FREETHREAD	This option specifies the socket returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the socket is synchronized across multiple threads.

lpszLocalAddress

A pointer to a string that specifies the local IP address that the socket should be bound to. If this parameter is NULL, then an appropriate address will automatically be used. A specific address should only be used if it is required by the application.

nLocalPort

The local port number that the socket should be bound to. If this parameter is set to zero, then an appropriate port number will automatically be used. A specific port number should only be used if it is required by the application.

lpCredentials

A pointer to a [SECURITYCREDENTIALS](#) structure. This parameter is only used if INET_OPTION_SECURE is specified for a TCP connection. This parameter may be NULL, in which case no client credentials will be provided to the server. If client credentials are required, the fields *dwSize*, *lpszCertStore*, and *lpszCertName* must be defined, while other fields may be left undefined. Set *dwSize* to the size of the **SECURITYCREDENTIALS** structure.

hEventWnd

The handle to the event notification window. This window receives messages which notify the application of various asynchronous socket events that occur.

uEventMsg

The message identifier that is used when an asynchronous socket event occurs. This value should be greater than WM_USER as defined in the Windows header files.

Return Value

If the function succeeds, the return value is a handle to the socket. If the function fails, the return value is INVALID_SOCKET. To get extended error information, call **InetGetLastError**.

Remarks

It is not recommend that you disable the Nagle algorithm by specifying the INET_OPTION_NODELAY flag unless it is absolutely required. Doing so can have a significant, negative impact on the performance of the application and network.

When a message is posted to the notification window, the low word of the *lParam* parameter contains the event identifier. The high word of *lParam* contains the low word of the error code, if

an error has occurred. The *wParam* parameter contains the socket handle. One or more of the following event identifiers may be sent:

Constant	Description
INET_EVENT_CONNECT	The connection to the remote host has completed. The high word of the <i>lParam</i> parameter should be checked, since this notification message will be posted if an error has occurred.
INET_EVENT_DISCONNECT	The remote host has closed the connection. The process should read any remaining data and disconnect.
INET_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the process has read at least some of the data from the socket. This event is only generated if the socket is in asynchronous mode.
INET_EVENT_WRITE	The process can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the socket is in asynchronous mode.

To cancel asynchronous notification and return the socket to a blocking mode, use the **InetDisableEvents** function.

It is recommended that you only establish an asynchronous connection if you understand the implications of doing so. In most cases, it is preferable to create a synchronous connection and create threads for each additional session if more than one active client session is required.

The *dwOptions* argument can be used to specify the threading model that is used by the library when a connection is established. By default, the handle is initially attached to the thread that created it. From that point on, until the it is released, only the owner may call functions using that handle. The ownership of the handle may be transferred from one thread to another using the **InetAttachThread** function.

Specifying the INET_OPTION_FREETHREAD option enables any thread to call any function using the socket handle, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the socket is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same socket handle.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[InetAsyncConnect](#), [InetConnect](#), [InetDisableEvents](#), [InetDisconnect](#), [InetEnableEvents](#), [InetInitialize](#)

InetAsyncListen Function

```
SOCKET WINAPI InetAsyncListen(  
    LPCTSTR lpszLocalAddress,  
    UINT nLocalPort,  
    HWND hEventWnd,  
    UINT uEventMsg  
);
```

The **InetAsyncListen** function creates a listening socket.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

New projects should use the **InetServerStart** function to create a server application.

Parameters

lpszLocalAddress

A pointer to a string which specifies the local IP address that the socket should be bound to. If this parameter is NULL or points to an empty string, a client may establish a connection using any valid network interface configured on the local system. If an address is specified, then a client may only establish a connection with the system using that address.

nLocalPort

The local port number that the socket should be bound to. This value must be greater than zero. Port numbers less than 1024 are considered reserved ports and may require that the process execute with administrative privileges and/or require changes to the default firewall rules to permit inbound connections.

hEventWnd

The handle to the event notification window. This window receives messages which notify the application of various asynchronous socket events that occur.

uEventMsg

The message identifier that is used when an asynchronous socket event occurs. This value should be greater than WM_USER as defined in the Windows header files.

Return Value

If the function succeeds, the return value is a handle to the socket. If the function fails, the return value is INVALID_SOCKET. To get extended error information, call **InetGetLastError**.

Remarks

To listen for connections on any suitable IPv4 interface, specify the special dotted-quad address "0.0.0.0". You can accept connections from clients using either IPv4 or IPv6 on the same socket by specifying the special IPv6 address "::0", however this is only supported on Windows 7 and Windows Server 2008 R2 or later platforms. If no local address is specified, then the server will only listen for connections from clients using IPv4. This behavior is by design for backwards compatibility with systems that do not have an IPv6 TCP/IP stack installed.

The socket option INET_OPTION_REUSEADDRESS is enabled by default when calling the **InetAsyncListen** function. This allows an application to re-use a local address and port number when creating the listening socket. If this behavior is not desired, use the **InetAsyncListenEx**

function instead.

If an IPv6 address is specified as the local address, the system must have an IPv6 stack installed and configured, otherwise the function will fail.

When a message is posted to the notification window, the low word of the *lParam* parameter contains the event identifier. The high word of *lParam* contains the low word of the error code, if an error has occurred. The *wParam* parameter contains the socket handle. One or more of the following event identifiers may be sent:

Constant	Description
INET_EVENT_ACCEPT	The process has received a connection request from a client and should accept the connection using the InetAsyncAccept function. This event is only generated for server applications which have created an asynchronous socket using the InetAsyncListen function.

To cancel asynchronous notification and return the socket to a blocking mode, use the **InetDisableEvents** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cswsock10.h

Import Library: cswskv10.lib

Unicode: Implemented as Unicode and ANSI versions.

InetAsyncListenEx Function

```
SOCKET WINAPI InetAsyncListenEx(  
    LPCTSTR lpszLocalAddress,  
    UINT nLocalPort,  
    UINT nBackLog,  
    DWORD dwOptions,  
    HWND hEventWnd,  
    UINT uEventMsg  
);
```

The **InetAsyncListenEx** function creates a listening socket and specifies the maximum number of connection requests that will be queued.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

New projects should use the **InetServerStart** function to create a server application.

Parameters

lpszLocalAddress

A pointer to a string which specifies the local IP address that the socket should be bound to. If this parameter is NULL or points to an empty string, a client may establish a connection using any valid network interface configured on the local system. If an address is specified, then a client may only establish a connection with the system using that address.

nLocalPort

The local port number that the socket should be bound to. This value must be greater than zero. Port numbers less than 1024 are considered reserved ports and may require that the process execute with administrative privileges and/or require changes to the default firewall rules to permit inbound connections.

nBacklog

The maximum length of the queue allocated for pending client connections. A value of zero specifies that the size of the queue should be set to a maximum reasonable value. On Windows server platforms, the maximum value is large enough to queue several hundred pending connections.

dwOptions

An unsigned integer used to specify one or more socket options. The following values are supported:

Constant	Description
INET_OPTION_NONE	No option specified. If the address and port number are in use by another application or a closed socket which was listening on this port is still in the TIME_WAIT state, the function will fail.
INET_OPTION_REUSEADDRESS	This option enables a server application to listen for connections using the specified address and port number even if they were in use recently. This is typically used to enable an application to close the

	listening socket and immediately reopen it without getting an error that the address is in use.
INET_OPTION_EXCLUSIVE	This option specifies the local address and port number is for the exclusive use by the current process, preventing another application from forcibly binding to the same address. If another process has already bound a socket to the address provided by the caller, this function will fail.
INET_OPTION_RESERVEDPORT	This option specifies the listening socket should be bound to an unused port number less than 1024, which is typically reserved for well-known system services. If this option is specified, the process may require administrative privileges and firewall rules that will permit a client to establish a connection with the service.

hEventWnd

The handle to the event notification window. This window receives messages which notify the application of various asynchronous socket events that occur.

uEventMsg

The message identifier that is used when an asynchronous socket event occurs. This value should be greater than WM_USER as defined in the Windows header files.

Return Value

If the function succeeds, the return value is a handle to the socket. If the function fails, the return value is INVALID_SOCKET. To get extended error information, call **InetGetLastError**.

Remarks

To listen for connections on any suitable IPv4 interface, specify the special dotted-quad address "0.0.0.0". You can accept connections from clients using either IPv4 or IPv6 on the same socket by specifying the special IPv6 address "::0", however this is only supported on Windows 7 and Windows Server 2008 R2 or later platforms. If no local address is specified, then the server will only listen for connections from clients using IPv4. This behavior is by design for backwards compatibility with systems that do not have an IPv6 TCP/IP stack installed.

If the INET_OPTION_REUSEADDRESS option is not specified, an error may be returned if a listening socket was recently created for the same local address and port number. By default, once a listening socket is closed there is a period of time that all applications must wait before the address can be reused (this is called the TIME_WAIT state). The actual amount of time depends on the operating system and configuration parameters, but is typically two to four minutes. Specifying this option enables an application to immediately re-use a local address and port number that was previously in use.

If the INET_OPTION_EXCLUSIVE option is specified, the local address and port number cannot be used by another process until the listening socket is closed. This can prevent another application from forcibly binding to the same listening address as your server. This option can be useful in determining whether or not another process is already bound to the address you wish to use, but it may also prevent your server application from restarting immediately, regardless if the INET_OPTION_REUSEADDRESS option has also been specified.

If an IPv6 address is specified as the local address, the system must have an IPv6 stack installed

and configured, otherwise the function will fail.

When a message is posted to the notification window, the low word of the *lParam* parameter contains the event identifier. The high word of *lParam* contains the low word of the error code, if an error has occurred. The *wParam* parameter contains the socket handle. One or more of the following event identifiers may be sent:

Constant	Description
INET_EVENT_ACCEPT	An incoming client connection is pending. The connection will be assigned to a new socket. This event is only generated if the socket is in asynchronous mode.

To cancel asynchronous notification and return the socket to a blocking mode, use the **InetDisableEvents** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cswsock10.h

Import Library: cswskv10.lib

Unicode: Implemented as Unicode and ANSI versions.

InetAttachSocket Function

```
SOCKET WINAPI InetAttachSocket(  
    SOCKET hSocket  
    DWORD dwProcessId  
);
```

The **InetAttachThread** function attaches the specified socket handle to another thread.

Parameters

hSocket

Handle to the socket.

dwProcessId

The process ID for the process that currently owns the socket handle. This value may be zero to specify the current process.

Return Value

If the function succeeds, the return value is the handle to the attached socket. If the function fails, the return value is `INVALID_SOCKET`. To get extended error information, call **InetGetLastError**.

Remarks

The **InetAttachSocket** function enables an application to attach an external socket handle to the current thread and initializes it for use by the library. An external socket is any socket handle created directly by the Windows Sockets API or by a third-party library. If the *dwProcessId* parameter is zero or specifies the current process ID, then the function checks to see if the socket was created by this library. If it was, then its owner context is switched to the current thread; if the socket was created externally, then it is initialized for use by the library and attached to the current thread.

If the *dwProcessId* parameter specifies another process, the socket will be duplicated into the current process, attached to the current thread and the original socket handle will be closed in the other process. This enables an application to effectively take control of a connection created by another process. The original socket handle must be inheritable by the by the current process and must be an actual Windows socket handle, not a pseudo-handle. This functionality is only supported on Windows NT 4.0 and later versions of the operating system with the Microsoft TCP/IP stack. Note that Layered Service Providers (LSPs) may interfere with the ability to inherit handles across processes.

The attached socket is initialized in a blocking state, even if was originally using asynchronous socket events. If the application requires that the socket use events, it must explicitly call **InetEnableEvents** using the handle returned by this function.

In most cases, the handle returned by this function will be the same value as the *hSocket* parameter, however an application should never make the assumption that this will be the case. If **InetAttachSocket** returns a socket handle that has a different value than the *hSocket* parameter, this indicates that the original handle has been destroyed and should never be used in subsequent function calls.

This function should never be used with a secure socket connection because the attached socket will not have the security context required to encrypt and decrypt the data exchanged with the remote host.

Example

To demonstrate how to pass sockets between processes, this example will use two programs; one acting as a server to listen for client connections and accept them, the other inheriting the client socket and echoing back anything the client sends. The first program will create the listening socket, and when a client connects, it will call **CreateProcess** to create a new child process to handle that connection.

```
SOCKET hServer;
SOCKET hClient;

// Initialize the library

if (!InetInitialize(CSTOOLS10_LICENSE_KEY, NULL))
    return;

// Listen for incoming client connections

if ((hServer = InetListen(NULL, nLocalPort)) == INVALID_SOCKET)
    return;

while (TRUE)
{
    hClient = InetAccept(hServer, 10);

    if (hClient == INVALID_SOCKET)
    {
        // If InetAccept has timed-out, then simply loop back and attempt
        // to continue accepting connections; otherwise, exit the loop

        if (InetGetLastError() != ST_ERROR_OPERATION_TIMEOUT)
            break;
    }
    else
    {
        STARTUPINFO si;
        PROCESS_INFORMATION pi;
        CHAR szCommandLine[512];
        BOOL bResult;

        // Detach the socket, which will free the memory that the library
        // has allocated for it without actually destroying the socket handle;
        // the child process will close the handle in this process when it
        // attaches to it
        InetDetachSocket(hClient, 0);

        // Initialize the STARTUPINFO structure
        ZeroMemory(&si, sizeof(si));

        // Create the command line arguments, passing the current
        // process ID and socket handle to the new process

        wsprintf(szCommandLine, "%s %lu %lu",
                lpzAppName,
                (DWORD)GetCurrentProcessId(),
                (DWORD)hClient);

        // Create the child process

        bResult = CreateProcess(NULL,
                                szCommandLine,
```

```

        NULL, NULL,
        TRUE,
        CREATE_DEFAULT_ERROR_MODE,
        NULL, NULL,
        &si, &pi);

    if (!bResult)
        InetDisconnect(hClient);
}
}

```

```

InetDisconnect(hServer);
InetUninitialize();

```

The second program attaches to the socket handle that was passed to it by the parent process. It goes into a loop, reading any data sent to it by the client and sending the same data back. When the client disconnects, the **InetRead** function will return 0, it will exit the loop and the process will terminate.

```

SOCKET hSocket;
SOCKET hClient;
DWORD dwProcessId;

// Initialize the library

if (!InetInitialize(CSTOOLS10_LICENSE_KEY, NULL))
    return;

// Process command line arguments that were passed to us
// by the server process

dwProcessId = (DWORD)atoi(argv[1]);
hClient = (SOCKET)atoi(argv[2]);

// Attach to the hClient socket that the server passed
// to us; this will close the socket in the server process

hSocket = InetAttachSocket(hClient, dwProcessId);

if (hSocket != INVALID_SOCKET)
{
    BYTE cBuffer[512];
    int nRead;

    do
    {
        // Read any data sent to us by the client
        nRead = InetRead(hSocket, cBuffer, sizeof(cBuffer));

        // Echo the data we have read back to the client
        if (nRead > 0)
            InetWrite(hSocket, cBuffer, nRead);
    }
    while (nRead > 0);

    InetDisconnect(hSocket);
}
}

```

```
InetUninitialize();
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cswsock10.h

Import Library: cswskv10.lib

See Also

[InetAttachThread](#), [InetDetachSocket](#), [InetInitialize](#)

InetAttachThread Function

```
DWORD WINAPI InetAttachThread(  
    SOCKET hSocket  
    DWORD dwThreadId  
);
```

The **InetAttachThread** function attaches the specified socket handle to another thread.

Parameters

hSocket

Handle to the socket.

dwThreadId

The ID of the thread that will become the new owner of the handle. A value of zero specifies that the current thread should become the owner of the socket handle.

Return Value

If the function succeeds, the return value is the thread ID of the previous owner. If the function fails, the return value is `INET_ERROR`. To get extended error information, call **InetGetLastError**.

Remarks

When a socket handle is created, it is associated with the current thread that created it. Normally, if another thread attempts to perform an operation using that handle, an error is returned since it does not own the handle. This is used to ensure that other threads cannot interfere with an operation being performed by the owner thread. In some cases, it may be desirable for one thread in an application to create the socket, and then pass that handle to another worker thread. The **InetAttachThread** function can be used to change the ownership of the handle to the new worker thread. By preserving the return value from the function, the original owner of the handle can be restored before the worker thread terminates.

This function should be called by the new thread immediately after it has been created, and if the new thread does not release the handle itself, the ownership of the handle should be restored to the parent thread before it terminates. Under no circumstances should **InetAttachThread** be used to forcibly release a handle allocated by another thread while a blocking operation is in progress. To cancel an operation, use the **InetCancel** function and then release the handle after the blocking function exits and control is returned to the current thread.

Note that the *dwThreadId* parameter is presumed to be a valid thread ID and no checks are performed to ensure that the thread actually exists. Specifying an invalid thread ID will orphan the handle until the **InetUninitialize** function is called.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cswsock10.h`

Import Library: `cswskv10.lib`

See Also

[InetAccept](#), [InetCancel](#), [InetAsyncConnect](#), [InetConnect](#), [InetDisconnect](#), [InetUninitialize](#)

InetCancel Function

```
INT WINAPI InetCancel(  
    SOCKET hSocket  
);
```

The **InetCancel** function cancels a blocking operation.

Parameters

hSocket

Handle to the socket.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is INET_ERROR. To get extended error information, call **InetGetLastError**.

Remarks

When the **InetCancel** function is called, the blocking function will not immediately fail. An internal flag is set which causes the blocking operation to exit with an error. This means that the application cannot cancel an operation and immediately perform some other operation. Instead it must allow the calling stack to unwind, returning back to the blocking operation before making any further function calls.

This function is typically called from within an event handler to signal that the current blocking operation should stop. It may also be used to cancel a blocking operation that is occurring on another thread.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

See Also

[InetAbort](#)

InetClientBroadcast Function

```
INT WINAPI InetClientBroadcast(  
    SOCKET hClient,  
    LPBYTE lpBuffer,  
    INT cbBuffer  
);
```

The **InetClientBroadcast** function sends data to all other clients that are connected to the same server.

Parameters

hClient

The socket handle.

lpBuffer

The pointer to the buffer which contains the data that is to be sent to the server clients.

cbBuffer

The number of bytes to send from the specified buffer.

Return Value

If the function succeeds, the return value is the number of clients that the data was sent to. If the function fails, the return value is `INET_ERROR`. To get extended error information, call **InetGetLastError**.

Remarks

The **InetClientBroadcast** function sends the contents of the buffer to all other clients that are connected to the same server as the specified client. This function will block until all clients have been sent a copy of the data. There is no guarantee in which order the clients will receive and process the data that has been broadcast.

This function can only be used with client sessions created as part of the server interface and cannot be used with standard sockets created using the **InetConnect** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cswsock10.h`

Import Library: `cswskv10.lib`

See Also

[InetServerBroadcast](#), [InetWrite](#), [InetWriteLine](#)

InetCompareAddress Function

```
BOOL WINAPI InetCompareAddress(  
    LPINTERNET_ADDRESS lpAddress1,  
    LPINTERNET_ADDRESS lpAddress2  
);
```

The **InetCompareAddress** function compares two Internet addresses in a binary format.

Parameters

lpAddress1

A pointer to an INTERNET_ADDRESS structure that contains the first IP address to be compared.

lpAddress2

A pointer to an INTERNET_ADDRESS structure that contains the second IP address to be compared.

Return Value

If the function succeeds and the two addresses are identical, the return value is non-zero. If the function fails or the two addresses are not identical, the return value is zero. If either parameter is NULL, or the address family for the two addresses are not the same, the last error code will be updated. If the addresses are valid and in the same address family, but are not identical, the last error code will be set to NO_ERROR.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

See Also

[InetGetHostAddress](#), [InetGetLocalAddress](#), [InetGetPeerAddress](#), [INTERNET_ADDRESS](#)

InetConnect Function

```
SOCKET WINAPI InetConnect(  
    LPCTSTR lpszHostName,  
    UINT nPort,  
    UINT nProtocol,  
    UINT nTimeout,  
    DWORD dwOptions,  
    LPSECURITYCREDENTIALS lpCredentials  
);
```

The **InetConnect** function is used to establish a connection with a server.

Parameters

lpszHostName

A pointer to the name of the server to connect to; this may be a fully-qualified domain name or an IP address.

nPort

The port number the server is listening on. This value must be greater than zero.

nProtocol

The protocol to be used when establishing the connection. This may be one of the following values:

Constant	Description
INET_PROTOCOL_TCP	Specifies the Transmission Control Protocol. This protocol provides a reliable, bi-directional byte stream. This is the default protocol.
INET_PROTOCOL_UDP	Specifies the User Datagram Protocol. This protocol is message oriented, sending data in discrete packets. Note that UDP is unreliable in that there is no way for the sender to know that the receiver has actually received the datagram.

nTimeout

The number of seconds to wait for the connection to complete before failing the current operation.

dwOptions

An unsigned integer used to specify one or more socket options. This parameter is constructed by using the bitwise Or operator with any of the following values:

Constant	Description
INET_OPTION_BROADCAST	This option specifies that broadcasting should be enabled for datagrams. This option is invalid for stream sockets.
INET_OPTION_DONTROUTE	This option specifies default routing should not be used. This option should not be specified unless absolutely necessary.
INET_OPTION_KEEPAIVE	This option specifies that packets are to be sent to the remote system when no data is being

	exchanged to keep the connection active. This is only valid for stream sockets.
INET_OPTION_NODELAY	This option disables the Nagle algorithm. By default, small amounts of data written to the socket are buffered, increasing efficiency and reducing network congestion. However, this buffering can negatively impact the responsiveness of certain applications. This option disables this buffering and immediately sends data packets as they are written to the socket.
INET_OPTION_RESERVEDPORT	This option specifies the socket should be bound to an unused port number less than 1024, which is typically reserved for well-known system services. If this option is specified, the process may require administrative privileges.
INET_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using either the SSL or TLS protocols.
INET_OPTION_SECURE	This option specifies that a secure connection should be established with the remote host. The specific version of TLS and other security related options are provided in the <i>lpCredentials</i> parameter. If the <i>lpCredentials</i> parameter is NULL, the connection will default to using TLS 1.2 and the strongest cipher suites available. Older versions of Windows prior to Windows 7 and Windows Server 2008 R2 only support TLS 1.0 and secure connections will automatically downgrade on those platforms.
INET_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
INET_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
INET_OPTION_FREETHREAD	This option specifies the socket returned by this function may be used by any thread, and is not

limited to the thread which created it. The application is responsible for ensuring that access to the socket is synchronized across multiple threads.
--

lpCredentials

A pointer to a [SECURITYCREDENTIALS](#) structure. This parameter is only used if `INET_OPTION_SECURE` is specified for a TCP connection. This parameter may be `NULL`, in which case no client credentials will be provided to the server. If client credentials are required, the fields *dwSize*, *lpszCertStore*, and *lpszCertName* must be defined, while other fields may be left undefined. Set *dwSize* to the size of the **SECURITYCREDENTIALS** structure.

Return Value

If the function succeeds, the return value is a handle to a socket. If the function fails, the return value is `INVALID_SOCKET`. To get extended error information, call **InetGetLastError**.

Remarks

To prevent this function from blocking the main user interface thread, the application should create a background worker thread and establish a connection by calling **InetConnectEx** in that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each client session.

The *dwOptions* argument can be used to specify the threading model that is used by the library when a connection is established. By default, the handle is initially attached to the thread that created it. From that point on, until the it is released, only the owner may call functions using that handle. The ownership of the handle may be transferred from one thread to another using the **InetAttachThread** function.

Specifying the `INET_OPTION_FREETHREAD` option enables any thread to call any function using the socket handle, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the socket is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same socket handle.

It is not recommend that you disable the Nagle algorithm by specifying the `INET_OPTION_NODELAY` flag unless it is absolutely required. Doing so can have a significant, negative impact on the performance of the application and network.

When this function is called with UDP as the specified protocol, it does not actually establish a connection in the same way that a TCP stream connection is created. Instead, it simply establishes a default destination IP address and port that is used with subsequent **InetRead** and **InetWrite** calls.

To enable event notification, use the **InetRegisterEvent** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cssock10.h`

Import Library: `cswskv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

InetConnectEx Function

```
SOCKET WINAPI InetConnectEx(  
    LPCTSTR lpszHostName,  
    UINT nPort,  
    UINT nProtocol,  
    UINT nTimeout,  
    DWORD dwOptions,  
    LPCTSTR lpszLocalAddress,  
    UINT nLocalPort,  
    LPSECURITYCREDENTIALS LpCredentials  
);
```

The **InetConnectEx** function is used to establish a connection with a server.

Parameters

lpszHostName

A pointer to the name of the server to connect to; this may be a fully-qualified domain name or an IP address.

nPort

The port number the server is listening on. This value must be greater than zero.

nProtocol

The protocol to be used when establishing the connection. This may be one of the following values:

Constant	Description
INET_PROTOCOL_TCP	Specifies the Transmission Control Protocol. This protocol provides a reliable, bi-directional byte stream. This is the default protocol.
INET_PROTOCOL_UDP	Specifies the User Datagram Protocol. This protocol is message oriented, sending data in discrete packets. Note that UDP is unreliable in that there is no way for the sender to know that the receiver has actually received the datagram.

nTimeout

The number of seconds to wait for the connection to complete before failing the operation.

dwOptions

An unsigned integer used to specify one or more socket options. This parameter is constructed by using the bitwise Or operator with any of the following values:

Constant	Description
INET_OPTION_BROADCAST	This option specifies that broadcasting should be enabled for datagrams. This option is invalid for stream sockets.
INET_OPTION_KEEPALIVE	This option specifies that packets are to be sent to the remote system when no data is being exchanged to keep the connection active. This is only valid for stream sockets.

INET_OPTION_NODELAY	This option disables the Nagle algorithm. By default, small amounts of data written to the socket are buffered, increasing efficiency and reducing network congestion. However, this buffering can negatively impact the responsiveness of certain applications. This option disables this buffering and immediately sends data packets as they are written to the socket.
INET_OPTION_RESERVEDPORT	This option specifies the socket should be bound to an unused port number less than 1024, which is typically reserved for well-known system services. If this option is specified, the process may require administrative privileges.
INET_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using either the SSL or TLS protocols.
INET_OPTION_SECURE	This option specifies that a secure connection should be established with the remote host. The specific version of TLS and other security related options are provided in the <i>lpCredentials</i> parameter. If the <i>lpCredentials</i> parameter is NULL, the connection will default to using TLS 1.2 and the strongest cipher suites available. Older versions of Windows prior to Windows 7 and Windows Server 2008 R2 only support TLS 1.0 and secure connections will automatically downgrade on those platforms.
INET_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
INET_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
INET_OPTION_FREETHREAD	This option specifies the socket returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access

	to the socket is synchronized across multiple threads.
--	--

lpzLocalAddress

A pointer to a string that specifies the local IP address that the socket should be bound to. If this parameter is NULL, then an appropriate address will automatically be used. A specific address should only be used if it is required by the application.

nLocalPort

The local port number that the socket should be bound to. If this parameter is set to zero, then an appropriate port number will automatically be used. A specific port number should only be used if it is required by the application.

lpCredentials

A pointer to a [SECURITYCREDENTIALS](#) structure. This parameter is only used if INET_OPTION_SECURE is specified for a TCP connection. This parameter may be NULL, in which case no client credentials will be provided to the server. If client credentials are required, the fields *dwSize*, *lpzCertStore*, and *lpzCertName* must be defined, while other fields may be left undefined. Set *dwSize* to the size of the [SECURITYCREDENTIALS](#) structure.

Return Value

If the function succeeds, the return value is a handle to a socket. If the function fails, the return value is INVALID_SOCKET. To get extended error information, call **InetGetLastError**.

Remarks

To prevent this function from blocking the main user interface thread, the application should create a background worker thread and establish a connection by calling **InetConnectEx** in that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each client session.

The *dwOptions* argument can be used to specify the threading model that is used by the library when a connection is established. By default, the handle is initially attached to the thread that created it. From that point on, until the it is released, only the owner may call functions using that handle. The ownership of the handle may be transferred from one thread to another using the **InetAttachThread** function.

Specifying the INET_OPTION_FREETHREAD option enables any thread to call any function using the socket handle, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the socket is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same socket handle.

It is not recommend that you disable the Nagle algorithm by specifying the INET_OPTION_NODELAY flag unless it is absolutely required. Doing so can have a significant, negative impact on the performance of the application and network.

When this function is called with UDP as the specified protocol, it does not actually establish a connection in the same way that a TCP stream connection is created. Instead, it simply establishes a default destination IP address and port that is used with subsequent **InetRead** and **InetWrite** calls.

To enable event notification, use the **InetRegisterEvent** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cswsock10.h

Import Library: cs wskv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[InetConnect](#), [InetDisableEvents](#), [InetDisconnect](#), [InetInitialize](#), [InetRegisterEvent](#)

InetCreateSecurityCredentials Function

```
BOOL WINAPI InetCreateSecurityCredentials(  
    DWORD dwProtocol,  
    DWORD dwOptions,  
    LPCTSTR lpszUserName,  
    LPCTSTR lpszPassword,  
    LPCTSTR lpszCertStore,  
    LPCTSTR lpszCertName,  
    LPVOID lpvReserved,  
    LPSECURITYCREDENTIALS* lppCredentials  
);
```

The **InetCreateSecurityCredentials** function creates a **SECURITYCREDENTIALS** structure.

Parameters

dwProtocol

A bitmask of supported security protocols. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_SSL	Either SSL 2.0 or SSL 3.0 should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, TLS will be excluded from the list of supported protocols. Both SSL 2.0 and 3.0 have been deprecated and will never be used unless explicitly specified. It is not recommended that you enable either of these protocols for secure connections because it will cause most servers to reject your connection request, even if a version of TLS is also specified.
SECURITY_PROTOCOL_TLS	Either the TLS 1.0, 1.1 or 1.2 protocol should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers that reject any attempt to use the older SSL protocol and require that only TLS be used.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol should be used when establishing a secure connection. This version is

	supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This is the recommended version of TLS to use with secure connections.

dwOptions

A value which specifies one or options. This member is constructed by using a bitwise operator with any of the following values:

Constant	Description
CREDENTIAL_STORE_CURRENT_USER	The library will attempt to open a store for the current user using the certificate store name provided in this structure. If no options are specified, then this is the default behavior.
CREDENTIAL_STORE_LOCAL_MACHINE	The library will attempt to open a local machine store using the certificate store name provided in this structure. If this option is specified, the library will always search for a local machine store before searching for the store by that name for the current user.
CREDENTIAL_STORE_FILENAME	The certificate store name is a file that contains the certificate and private key that will be used.

lpszUserName

A pointer to a string which specifies the certificate owner's username. A value of NULL specifies that no username is required. Currently this parameter is not used and any value specified will be ignored.

lpszPassword

A pointer to a string which specifies the certificate owner's password. A value of NULL specifies

that no password is required. This parameter is only used if a PKCS12 (PFX) certificate file is specified and that certificate has been secured with a password. This value will be ignored the current user or local machine certificate store is specified.

lpszCertStore

A pointer to a string which specifies the name of the certificate store to open. A certificate store is a collection of certificates and their private keys, typically organized by how they are used. If this value is NULL or points to an empty string, the default certificate store "MY" will be used.

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as VeriSign and Thawte act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. This corresponds to the "Personal" store that is displayed by the certificate manager utility and is the default store used by the library.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as VeriSign and Thawte are installed as part of the operating system and periodically updated by Microsoft.

lpszCertName

A pointer to a null terminated string which specifies the name of the certificate to use. The function will first search the certificate store for a certificate with a matching "friendly name"; this is a name for the certificate that is assigned by the user. Note that the name must match completely, but the comparison is not case sensitive. If no matching certificate is found, the function will then attempt to find a certificate that has a matching common name (also called the certificate subject). This comparison is less stringent, and the first partial match will be returned. If this second search fails, the function will return an error indicating that the certificate could not be found.

lpvReserved

Pointer reserved for future use. Set it to NULL when using this function.

lppCredentials

Pointer to an [LPSECURITYCREDENTIALS](#) pointer. The memory for the credentials structure will be allocated by this function and must be released by calling the **InetDeleteSecurityCredentials** function when it is no longer needed. The pointer value must be set to NULL before the function is called. It is important to note that this is a pointer to a pointer variable, not a pointer to the SECURITYCREDENTIALS structure itself.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **InetGetLastError**.

Remarks

The structure that is created by this function may be used as client credentials when establishing a secure connection. This is particularly useful for programming languages other than C/C++ which may not support C structures or pointers. The pointer to the SECURITYCREDENTIALS structure can

be declared as an unsigned integer variable which is passed by reference to this function, and then passed by value to the **InetAcceptEx**, **InetAsyncAcceptEx**, **InetAsyncConnectEx** or **InetConnectEx** functions.

Example

```
LPSECURITYCREDENTIALS lpSecCred = NULL;
InetCreateSecurityCredentials(SEcurity_PROTOCOL_DEFAULT,
                             CREDENTIAL_STORE_CURRENT_USER,
                             NULL,
                             NULL,
                             strCertStore,
                             strCertName,
                             NULL,
                             &lpSecCred);

hAcceptSocket = InetAsyncAcceptEx(hListenSocket,
                                  nTimeout,
                                  dwOptions,
                                  lpSecCred,
                                  hEventWnd,
                                  uEventMsg);
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[InetAcceptEx](#), [InetAsyncAcceptEx](#), [InetAsyncConnectEx](#), [InetConnectEx](#),
[InetDeleteSecurityCredentials](#)

InetDeleteSecurityCredentials Function

```
VOID WINAPI InetDeleteSecurityCredentials(  
    LPSECURITYCREDENTIALS* LppCredentials  
);
```

The **InetDeleteSecurityCredentials** function deletes an existing SECURITYCREDENTIALS structure.

Parameters

lppCredentials

Pointer to an LPSECURITYCREDENTIALS pointer. On exit from the function, the pointer value will be NULL.

Return Value

None.

Example

```
if (lpSecCred != NULL)  
    InetDeleteSecurityCredentials(&lpSecCred);
```

Remarks

This function can be used to release the memory allocated to the client or server credentials after a secure connection has been established.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: csoskv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[InetCreateSecurityCredentials](#), [InetUninitialize](#)

InetDetachSocket Function

```
BOOL WINAPI InetDetachSocket(  
    SOCKET hSocket  
    DWORD dwThreadId  
);
```

The **InetDetachSocket** function detaches the specified socket from the current process.

Parameters

hSocket

Handle to the socket.

dwThreadId

The ID of the thread that owns the socket handle. A value of zero specifies that the current thread is the owner.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **InetGetLastError**.

Remarks

The **InetDetachSocket** function will release the memory that the library has allocated for the socket without destroying the socket handle. After the function returns, the socket can no longer be used with other functions in the library, however the socket handle remains valid. This is typically used when passing a socket handle between processes, where the parent process detaches the socket prior to creating the child process. The child then calls **InetAttachSocket** to attach the socket handle to its own process.

This function should never be used with a secure socket connection because detaching a secure socket will force the security context for that session to be released. If the socket is attached to another process, it will not have the security context originally created when the connection was established and will be unable to encrypt or decrypt the data stream.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cssock10.h`

Import Library: `cswskv10.lib`

See Also

[InetAttachThread](#), [InetAttachSocket](#), [InetDisconnect](#)

InetDisableEvents Function

```
INT WINAPI InetDisableEvents(  
    SOCKET hSocket  
);
```

The **InetDisableEvents** function disables the event notification mechanism, preventing subsequent event notification messages from being posted to the application's message queue.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Parameters

hSocket

The socket handle.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is INET_ERROR. To get extended error information, call **InetGetLastError**.

Remarks

This function affects both event notification and event callbacks. Any outstanding events in the message queue should be ignored by the application.

This function cannot be used with sockets that are created by the SocketWrench server interface. Those sockets are managed separately in their own thread, and event notifications are handled inside the callback function specified when the server is created using the **InetServerStart** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

See Also

[InetEnableEvents](#), [InetFreezeEvents](#), [InetRegisterEvent](#)

InetDisableSecurity Function

```
INT WINAPI InetDisableSecurity(  
    SOCKET hSocket,  
    DWORD dwReserved  
);
```

The **InetDisableSecurity** function disables a secure session with the remote host.

Parameters

hSocket

The socket handle.

dwReserved

Reserved parameter. This value should always be zero.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is INET_ERROR. To get extended error information, call **InetGetLastError**.

Remarks

The **InetDisableSecurity** function disables a secure session, with subsequent calls to **InetRead** and **InetWrite** sending and receiving unencrypted data. It is important to note that because this function sends a shutdown message to terminate the secure session, this may cause connection to be closed by the remote host.

This function does not close the socket. Use the **InetDisconnect** function to close the socket and release the resources allocated for the current session.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: csosk10.lib

See Also

[InetCreateSecurityCredentials](#), [InetDeleteSecurityCredentials](#), [InetEnableSecurity](#)

InetDisableTrace Function

```
BOOL WINAPI InetDisableTrace();
```

The **InetDisableTrace** function disables the logging of socket function calls to the trace log.

Parameters

None.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero.
To get extended error information, call **InetGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cswsock10.h`

Import Library: `cswskv10.lib`

See Also

[InetEnableTrace](#)

InetDisconnect Function

```
INT WINAPI InetDisconnect(  
    SOCKET hSocket  
);
```

The **InetDisconnect** function terminates the connection, closing the socket and releasing the memory allocated for the session.

Parameters

hSocket

The socket handle.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is INET_ERROR. To get extended error information, call **InetGetLastError**.

Remarks

Once the connection has been terminated, the socket handle is no longer valid and should no longer be used. Note that it is possible that the actual handle value may be re-used at a later point when a new connection is established. An application should always consider the socket handle to be opaque and never depend on it being a specific value.

After a socket is closed, it will go into a TIME-WAIT state which prevents an application from using the same source and destination address and port numbers bound to that socket for a brief period of time, typically two to four minutes. This is normal behavior designed to prevent delayed or misrouted packets of data from being read by a subsequent connection. This can have an impact on an application that rapidly connects and disconnects over a short period of time because it can exhaust the pool of ephemeral ports.

If this function is called using a server socket handle returned by the **InetServerStart** function, all active client connections will be disconnected, the listening socket will be closed and the server thread will terminate. If this function is called using a client socket handle that was allocated as part of the SocketWrench server interface, it will terminate the client connection and the thread that manages it.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cswskv10.lib

See Also

[InetAsyncConnect](#), [InetAsyncConnectEx](#), [InetConnect](#), [InetConnectEx](#), [InetDisableEvents](#), [InetEnableEvents](#), [InetUninitialize](#)

InetEnableEvents Function

```
INT WINAPI InetEnableEvents(  
    SOCKET hSocket,  
    HWND hEventWnd,  
    UINT nEventMsg  
);
```

The **InetEnableEvents** function enables event notifications using Windows messages.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Applications should use the **InetRegisterEvent** function to register an event handler which is invoked when an event occurs.

Parameters

hSocket

The socket handle.

hEventWnd

Handle to the event notification window. This window receives a user-defined message which specifies the event that has occurred. If this value is NULL, event notification is disabled.

nEventMsg

An unsigned integer which specifies the user-defined message that is sent when an event occurs. This parameter's value must be greater than the value of WM_USER.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is INET_ERROR. To get extended error information, call **InetGetLastError**.

Remarks

When a message is posted to the notification window, the low word of the *lParam* parameter contains the event identifier. The high word of *lParam* contains the low word of the error code, if an error has occurred. The *wParam* parameter contains the socket handle. One or more of the following event identifiers may be sent:

Constant	Description
INET_EVENT_ACCEPT	The process has received a connection request from a client and should accept the connection using the InetAsyncAccept function. This event is only generated for server applications which have created an asynchronous socket using the InetAsyncListen function.
INET_EVENT_CONNECT	The connection to the remote host has completed. The high word of the <i>lParam</i> parameter should be checked, since this notification message will also be posted if an error has occurred.
INET_EVENT_DISCONNECT	The remote host has closed the connection. The process should read any remaining data and disconnect.

INET_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the process has read at least some of the data from the socket. This event is only generated if the socket is in asynchronous mode.
INET_EVENT_WRITE	The process can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the socket is in asynchronous mode.
INET_EVENT_TIMEOUT	The process has timed-out waiting for a blocking operation to complete. This event is only generated for synchronous sockets.
INET_EVENT_CANCEL	The application has canceled a blocking operation. This event is fired once an operation has been terminated by the InetCancel function, and control has been returned to the calling process.

This function cannot be used with sockets that are created by the SocketWrench server interface. Those sockets are managed separately in their own thread, and event notifications are handled inside the callback function specified when the server is created using the **InetServerStart** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

See Also

[InetDisableEvents](#), [InetFreezeEvents](#), [InetRegisterEvent](#)

InetEnableSecurity Function

```
INT WINAPI InetEnableSecurity(  
    SOCKET hSocket,  
    DWORD dwOptions,  
    LPSECURITYCREDENTIALS lpCredentials  
);
```

The **InetEnableSecurity** function enables a secure session with the remote host.

Parameters

hSocket

The socket handle.

dwOptions

An unsigned integer value that specifies additional security options. It may have a value of zero or one of the following options:

Constant	Description
INET_SECURE_CLIENT	The certificate specified by the <i>lpCredentials</i> parameter will be used as a client certificate, and the application will begin to negotiate the secure session as a client by initiating the handshake with the server. The certificate that is used must be a valid client certificate with a private key associated with it. If the <i>lpCredentials</i> parameter is NULL, then a secure client session will be initiated without a client certificate.
INET_SECURE_SERVER	The certificate specified by the <i>lpCredentials</i> parameter will be used as a server certificate, and the application will wait for the remote host to initiate the handshake that establishes the parameters of the secure session. The certificate that is used must be a valid server certificate and have a private key associated with it. The <i>lpCredentials</i> parameter cannot be NULL if this option is specified.

lpCredentials

Pointer to a SECURITYCREDENTIALS structure. This parameter may be NULL, in which case no client credentials will be provided. If client credentials are required, the fields *dwSize*, *lpzCertStore*, and *lpzCertName* must be defined, while other fields may be left undefined. Set *dwSize* to the size of the SECURITYCREDENTIALS structure.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is INET_ERROR. To get extended error information, call **InetGetLastError**.

Remarks

The **InetEnableSecurity** function enables a secure communications session with the remote host, automatically negotiating the encryption algorithm and validating the certificate. This function is useful if the application needs to establish a standard connection to the remote host and then negotiate a secure connection at a later point. If the function succeeds, all subsequent calls to **InetRead** and **InetWrite** to receive and send data will be encrypted.

If the *dwOptions* parameter has a value of zero and the socket was created using **InetConnect** or related functions to establish a client connection, then **InetEnableSecurity** will initiate the handshake with the remote host to establish a secure session. If the **InetAccept** or related functions were used to accept a connection from a client, then the function will block and wait for the client to initiate the handshake.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cssock10.h`

Import Library: `cswskv10.lib`

See Also

[InetCreateSecurityCredentials](#), [InetDeleteSecurityCredentials](#), [InetDisableSecurity](#)

InetEnableTrace Function

```
BOOL WINAPI InetEnableTrace(  
    LPCTSTR lpszTraceFile,  
    DWORD dwTraceFlags  
);
```

The **InetEnableTrace** function enables the logging of socket function calls to a file.

Parameters

lpszTraceFile

Name of the trace log file. If this parameter is NULL or empty, the file CSTRACE.LOG is used. The directory for CSTRACE.LOG is given by the TEMP environment variable, if it is defined; otherwise, the directory given by the TMP environment variable is used, if it is defined; otherwise, the current working directory is used.

dwTraceFlags

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Constant	Description
0	TRACE_DEFAULT	All function calls are written to the trace file. This is the default value.
1	TRACE_ERROR	Only those function calls which fail are recorded in the trace file.
2	TRACE_WARNING	Only those function calls which fail, or return values which indicate a warning, are recorded in the trace file.
4	TRACE_HEXDUMP	All functions calls are written to the trace file, plus all the data that is sent or received is displayed, in both ASCII and hexadecimal format.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call [InetGetLastError](#).

Remarks

When trace logging is enabled, the logfile is opened, appended to and closed for each socket function call. Using the same logfile name, you can do the same in your application to add additional information to the logfile if needed. This can provide an application-level context for the entries made by the library. Make sure that the logfile is closed after the data has been written.

The TRACE_HEXDUMP option can produce very large logfiles, since all data that is being sent and received by the application is logged. To reduce the size of the file, you can enable and disable logging around limited sections of code that you wish to analyze.

All of the SocketTools networking components that use the Windows Sockets API support logging. If you are using multiple components, you only need to enable tracing once in your application or once per thread in a multithreaded application.

To redistribute an application that includes logging functionality, the **cstrcv10.dll** library must be included as part of the installation package. This library provides the trace logging features, and if

it is not available the **InetEnableTrace** function will fail. Note that this is a standard Windows DLL and does not need to be registered, it only needs to be redistributed with your application.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

Unicode: Implemented as Unicode and ANSI versions.

[InetDisableTrace](#)

InetEnumHostAliases Function

```
INT WINAPI InetEnumHostAliases(  
    LPCTSTR LpszHostName,  
    LPTSTR LpszBuffer,  
    INT cbMaxBuffer  
);
```

The **InetEnumHostAliases** function returns a byte array that contains all the aliases for a specified host.

Parameters

lpszHostName

Host name

lpszBuffer

Buffer where aliases are to be written. The first name written to the buffer is the primary host name. Each name or alias is terminated by a null, followed by the next alias, if there is one.

cbMaxBuffer

Maximum number of bytes to be written to *lpszBuffer*.

Return Value

If the function succeeds, the return value is the number of bytes written to *lpszBuffer*. If the function fails, the return value is INET_ERROR. To get extended error information, call **InetGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cswsock10.h`

Import Library: `cswskv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

InetEnumNetworkAddresses Function

```
INT WINAPI InetEnumNetworkAddresses(  
    INT nAddressFamily,  
    LPINTERNET_ADDRESS lpAddressList,  
    INT nMaxAddresses  
);
```

The **InetEnumNetworkAddresses** function returns the list of network addresses that are configured for the local host.

Parameters

nAddressFamily

An integer which identifies the type of IP address that should be returned by this function. It may be one of the following values:

Constant	Description
INET_ADDRESS_ANY	Return both IPv4 or IPv6 addresses assigned to the local host, depending on how the system is configured and which network interfaces are enabled. This option is only recommended for applications that require support for IPv6 connections.
INET_ADDRESS_IPV4	Return only the IPv4 addresses assigned to the local host. The first four bytes of the <i>ipNumber</i> array are significant and contains the IP address. The remaining bytes are not significant and an application should not depend on them having any particular value, including zero.
INET_ADDRESS_IPV6	Return only the IPv6 addresses assigned to the local host. All bytes in the <i>ipNumber</i> array are significant. This option is only recommended for those applications that require support for IPv6 connections.

lpAddressList

A pointer to an array of [INTERNET_ADDRESS](#) structures that will contain the IP address of each local network interface. This parameter may be NULL, in which case the method will only return the number of available addresses.

nMaxAddresses

Maximum number of addresses to be returned. If the *lpAddressList* parameter is NULL, this value must be zero.

Return Value

If the function succeeds, the return value is the number of network addresses that are configured for the local host. If the function fails, the return value is INET_ERROR. To get extended error information, call **InetGetLastError**.

Remarks

If the *nAddressFamily* parameter is specified as INET_ADDRESS_ANY, the application must be prepared to accept IPv6 addresses returned by this function. On Windows Vista and later versions of the operating system, IPv6 support is enabled and the local network adapter will have IPv6 addresses assigned to them by default. For legacy applications that only recognize IPv4 addresses,

the *nAddressFamily* parameter should always be specified as INET_ADDRESS_IPV4 to ensure that only IPv4 addresses are returned.

This function will ignore addresses that are bound to a disabled interface, as well as those addresses bound to a virtual loopback interface. For example, although the loopback address 127.0.0.1 is a valid network address, it will not be included in list of addresses returned by this function.

The first IPv4 or IPv6 address returned by this function is typically the address assigned to the primary network adapter on the local system. However, your application should not depend on addresses being returned in any particular order. If the system has dial-up networking or virtualization software installed, this function may also include the IP addresses assigned to any virtualized network adapters installed by that software.

Example

```
INTERNET_ADDRESS *lpAddressList = NULL;
INT nAddressCount = InetEnumNetworkAddresses(INET_ADDRESS_IPV4, NULL, 0);

if (nAddressCount > 0)
{
    // Allocate memory for the array of IP addresses
    lpAddressList = (INTERNET_ADDRESS *)LocalAlloc(LPTR, nAddressCount *
sizeof(INTERNET_ADDRESS));

    if (lpAddressList == NULL)
    {
        // Virtual memory exhausted
        return;
    }

    // Populate the array with the addresses
    nAddressCount = InetEnumNetworkAddresses(INET_ADDRESS_IPV4, lpAddressList,
nAddressCount);
}

_tprintf(_T("There are %d local network addresses assigned\n"), nAddressCount);

// Display each IP address assigned to the local system
for (INT nIndex = 0; nIndex < nAddressCount; nIndex++)
{
    TCHAR szValue[64];

    // Convert the IP address to a printable string
    InetFormatAddress(lpAddressList + nIndex, szValue, 64);
    _tprintf(_T("%d: %s\n"), nIndex, szValue);
}

// Free the memory allocated for the IP address list
if (lpAddressList != NULL)
    LocalFree((HLOCAL)lpAddressList);
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

InetEnumServerClients Function

```
INT WINAPI InetEnumServerClients(  
    SOCKET hServer,  
    SOCKET * lpClients,  
    INT nMaxClients  
);
```

The **InetEnumServerClients** function returns a list of active client sessions established with the specified server.

Parameters

hServer

Handle to the server socket.

lpClients

Pointer to an array of socket handles which identifies all client connections. If this parameter is NULL, then the function will return the number of active client connections established with the server.

nMaxClients

Maximum number of client socket handles to be returned. If the *lpClients* parameter is NULL, this parameter should be specified with a value of zero.

Return Value

If the function succeeds, the return value is the number of active client connections to the server. A return value of zero indicates that there are no active client sessions. If the function fails, the return value is INET_ERROR. To get extended error information, call **InetGetLastError**.

Remarks

If the *nMaxClients* parameter is less than the number of active client connections, the function will fail. To dynamically determine the number of active connections, call the function with the *lpClients* parameter with a value of NULL, and the *nMaxClients* parameter with a value of zero. To enumerate the active clients that match a specific IP address, use the **InetEnumServerClientsByAddress** function.

This function will not enumerate clients that have disconnected from the server, even if the session thread is still active. If the server is in the process of shutting down, this function will return zero, indicating no active client sessions, even though there may be clients that are still in the process of disconnecting from the server. To determine the actual number of client sessions regardless of their status, use the **InetGetClientThreads** function.

The socket handle for the server must be one that was created using the **InetServerStart** function, and cannot be a socket that was created using **InetListen** or **InetListenEx**.

Example

```
INT nMaxClients = InetEnumServerClients(hServer, NULL, 0);  
  
if (nMaxClients > 0)  
{  
    SOCKET *lpClients = NULL;  
  
    // Allocate memory for client sockets  
    lpClients = (SOCKET *)LocalAlloc(LPTR, nMaxClients * sizeof(SOCKET));
```

```
if (lpClients == NULL)
{
    // Virtual memory has been exhausted
    return;
}

nMaxClients = InetEnumServerClients(hServer, lpClients, nMaxClients);
if (nMaxClients == INET_ERROR)
{
    // Unable to obtain list of connected clients
    return;
}

for (INT nClient = 0; nClient < nMaxClients; nClient++)
{
    // Perform some action with each client socket
    SOCKET hClient = lpClients[nClient];
}

// Free memory allocated for client sockets
LocalFree((HLOCAL)lpClients);
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

See Also

[InetEnumServerClientsByAddress](#), [InetGetClientThreads](#), [InetServerBroadcast](#), [InetServerStart](#)

InetEnumServerClientsByAddress Function

```
INT WINAPI InetEnumServerClientsByAddress(  
    SOCKET hServer,  
    LPINTERNET_ADDRESS LpAddress,  
    SOCKET * LpClients,  
    INT nMaxClients  
);
```

The **InetEnumServerClientsByAddress** function returns a list of active client sessions established with the specified server that match the specified IP address.

Parameters

hServer

Handle to the server socket.

lpAddress

Pointer to an INTERNET_ADDRESS structure that specifies the client IP address. If this parameter is NULL, then all active client sessions will be enumerated.

lpClients

Pointer to an array of socket handles which identifies all client connections that match the specified IP address. If this parameter is NULL, then the function will return the number of active client connections established with the server.

nMaxClients

Maximum number of client socket handles to be returned. If the *lpClients* parameter is NULL, this parameter should be specified with a value of zero.

Return Value

If the function succeeds, the return value is the number of active client connections to the server that match the specified IP address. A return value of zero indicates that no clients have connected from the specified IP address. If the function fails, the return value is INET_ERROR. To get extended error information, call **InetGetLastError**.

Remarks

If the *nMaxClients* parameter is less than the number of active client connections that match the specified address, the function will fail. To dynamically determine the number of active connections, call the function with the *lpClients* parameter with a value of NULL, and the *nMaxClients* parameter with a value of zero. If the *lpAddress* parameter is NULL, this function will return a list of all active clients connected to the server and is effectively the same as calling the **InetEnumServerClients** function. If an address is provided, it must be a valid IP address in a supported address family.

This function will not enumerate clients that have disconnected from the server, even if the session thread is still active. If the server is in the process of shutting down, this function will return zero, indicating no active client sessions, even though there may be clients that are still in the process of disconnecting from the server.

The socket handle for the server must be one that was created using the **InetServerStart** function, and cannot be a socket that was created using **InetListen** or **InetListenEx**.

Example

```
INTERNET_ADDRESS ipAddress;
```

```

if (InetGetPeerAddress(hSocket, &ipAddress, NULL) == INET_ERROR)
{
    // Unable to get the peer IP address for the socket
    return;
}

// Determine the number of clients that have the same IP address
INT nMaxClients = InetEnumServerClientsByAddress(hServer, &ipAddress, NULL, 0);

if (nMaxClients > 0)
{
    SOCKET *lpClients = NULL;

    // Allocate memory for client sockets
    lpClients = (SOCKET *)LocalAlloc(LPTR, nMaxClients * sizeof(SOCKET));
    if (lpClients == NULL)
    {
        // Virtual memory has been exhausted
        return;
    }

    nMaxClients = InetEnumServerClientsByAddress(hServer, &ipAddress, lpClients,
nMaxClients);
    if (nMaxClients == INET_ERROR)
    {
        // Unable to obtain list of connected clients
        return;
    }

    for (INT nClient = 0; nClient < nMaxClients; nClient++)
    {
        // Perform some action with each client socket
        SOCKET hClient = lpClients[nClient];
    }

    // Free memory allocated for client sockets
    LocalFree((HLOCAL)lpClients);
}

```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

[InetEnumServerClients](#), [InetGetClientThreads](#), [InetServerBroadcast](#), [InetServerStart](#)

InetEventProc Function

```
VOID CALLBACK InetEventProc(  
    SOCKET hSocket,  
    UINT nEvent,  
    DWORD dwError,  
    DWORD_PTR dwParam  
);
```

The **InetEventProc** function is an application-defined callback function that processes events generated by the calling process.

Parameters

hSocket

The socket handle.

nEvent

An unsigned integer which specifies which event occurred. For a complete list of events, refer to the [InetRegisterEvent](#) function.

dwError

An unsigned integer which specifies any error that occurred. If no error occurred, then this parameter will be zero.

dwParam

A user-defined integer value which was specified when the event callback was registered.

Return Value

None.

Remarks

An application must register this callback function by passing its address to the **InetRegisterEvent** function. The **InetEventProc** function is a placeholder for the application-defined function name.

If the callback function is being used with the **InetServerStart** function, the function will be called in the context of the thread that is currently managing the server or client session. You must ensure that any access to global or static variables is synchronized, otherwise the results may be unpredictable. It is recommended that you do not declare any static variables within the callback function itself. If you need to manage state information for a specific client, then use the **InetGetClientData** and **InetSetClientData** functions which will allow you to access application defined data for that client session in a thread-safe manner.

When this callback function is used for event notifications from the server interface, the the *hSocket* parameter specifies the client socket handle, except for the INET_EVENT_ACCEPT event, in which case the handle references the server socket handle. To obtain the handle of the client connection that was just accepted, use the **InetGetServerClient** function. To obtain the handle to the server using the client socket handle, use the **InetGetClientServer** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

InetFindClientMoniker Function

```
SOCKET WINAPI InetFindClientMoniker(  
    SOCKET hServer,  
    LPCTSTR LpszMoniker  
);
```

The **InetFindClientMoniker** function returns a handle to the client socket which matches the specified moniker.

Parameters

hServer

A handle to the server.

lpszMoniker

A pointer to a string which specifies the client moniker to search for. This parameter cannot be NULL and cannot specify an empty string.

Return Value

If the function succeeds, the return value is the handle to the client socket for the session that matches the specified moniker. If the function fails, the return value is INVALID_SOCKET. To get extended error information, call **InetGetLastError**.

Remarks

A client moniker is a string which can be used to uniquely identify a specific client session aside from its socket handle. A moniker can be assigned to the client session using the **InetSetClientMoniker** function. This function will search all active client sessions for the server, and returns the socket handle to the client that matches the specified moniker. If there is no match, an error will be returned.

The moniker can be any string value, however monikers are not case sensitive and may not contain embedded null characters. The maximum length of a moniker is 127 characters.

The socket handle for the server must be one that was created using the **InetServerStart** function, and cannot be a socket that was created using **InetListen** or **InetListenEx**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

InetFlush Function

```
INT WINAPI InetFlush(  
    SOCKET hSocket  
);
```

The **InetFlush** function flushes the internal send and receive buffers used by the socket.

Parameters

hSocket

The socket handle.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is INET_ERROR. To get extended error information, call **InetGetLastError**.

Remarks

The **InetFlush** function will flush any data waiting to be read or written to the remote host . It is important to note that this function is not similar to flushing data to a disk file; it does not ensure that a specific block of data has been written to the socket. For example, you should never call this function immediately after calling **InetWrite** or prior to calling **InetDisconnect**.

An application never needs to use **InetFlush** under normal circumstances. This function is only to be used when the application needs to immediately return the socket to an inactive state with no pending data to be read or written. Calling this function may result in data loss and should only be used if you understand the implications of discarding any data which has been sent by the remote host.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

See Also

[InetIsReadable](#), [InetIsWritable](#), [InetPeek](#), [InetRead](#), [InetWrite](#)

InetFormatAddress Function

```
INT WINAPI InetFormatAddress(  
    LPINTERNET_ADDRESS LpAddress,  
    LPTSTR LpszAddress,  
    INT cchAddress  
);
```

The **InetFormatAddress** function converts a numeric IP address to a printable string. The format of the string depends on whether an IPv4 or IPv6 address is specified.

Parameters

lpAddress

A pointer to an [INTERNET_ADDRESS](#) structure which specifies the numeric IP address that should be converted to a string.

lpszAddress

A pointer to a string buffer that will contain the formatted IP address, terminated with a null character. To accommodate both IPv4 and IPv6 addresses, this buffer should be at least 46 characters in length.

cchAddress

The maximum number of characters that can be copied into the address buffer.

Return Value

If the function succeeds, the return value is the length of the IP address string. If the function fails, the return value is `INET_ERROR`, meaning that the IP address could not be converted into a string. Typically this indicates that the pointer to the `INTERNET_ADDRESS` structure is invalid, or the data does not specify a valid IP address family.

Remarks

The format and length of IPv4 and IPv6 address strings are very different. An IPv4 address string looks like "192.168.0.20", while an IPv6 address string can look something like "fd7c:2f6a:4f4f:ba34::a32". If your application checks for the format of these address strings, it needs to be aware of the differences. You also need to make sure that you're providing enough space to display or store an address to avoid buffer overruns.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cssock10.h`

Import Library: `cswskv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

See Also

[InetGetExternalAddress](#), [InetGetHostAddress](#), [InetGetLocalAddress](#), [InetGetPeerAddress](#), [INTERNET_ADDRESS](#)

InetFreezeEvents Function

```
INT WINAPI InetFreezeEvents(  
    SOCKET hSocket,  
    BOOL bFreeze  
);
```

The **InetFreezeEvents** function is used to suspend and resume event handling.

Parameters

hSocket

Socket handle.

bFreeze

A non-zero value specifies that event handling should be suspended. A zero value specifies that event handling should be resumed.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is `INET_ERROR`. To get extended error information, call **InetGetLastError**.

Remarks

This function should be used when the application does not want to process events, such as when a modal dialog is being displayed. When events are suspended, all events are queued. If events are re-enabled at a later point, those queued events will be sent to the application for processing. Note that only one of each event will be generated. For example, if event handling has been suspended, and four read events occur, only one of those read events will be posted to the application when even handling is resumed. This prevents the application from being flooded by a potentially large number of queued events.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cssock10.h`

Import Library: `cswskv10.lib`

See Also

[InetDisableEvents](#), [InetEnableEvents](#), [InetRegisterEvent](#)

InetGetAdapterAddress Function

```
INT WINAPI InetGetAdapterAddress(  
    INT nAdapterIndex,  
    INT nAddressType,  
    LPTSTR lpszAddress,  
    INT nMaxLength  
);
```

Return the IP or MAC assigned to the specified network adapter.

Parameters

nAdapterIndex

An integer value that identifies the network adapter.

nAddressType

An integer value which specifies the type of address that should be returned:

Constant	Description
INET_ADAPTER_IPV4	The address string will contain the primary IPv4 unicast address assigned to the network adapter.
INET_ADAPTER_IPV6	The address string will contain the primary IPv6 unicast address assigned to the network adapter.
INET_ADAPTER_MAC	The address string will contain the media access control (MAC) address assigned to the network adapter.

lpszAddress

A string buffer that will contain the IP or MAC address assigned to the adapter. This parameter cannot be NULL and it is recommended that it be at least 64 characters in length to provide enough space for any address type.

nMaxLength

The maximum number of characters that can be copied into the string buffer, including the terminating null character. If the buffer is too small to store the complete address, this function will fail.

Return Value

If the function succeeds, the return value is the number of characters copied to the string buffer, not including the terminating null character. A return value of zero indicates that the requested address type has not been assigned to the adapter. If the function fails, the return value is `INET_ERROR` and this typically indicates that either the adapter index is invalid or the string buffer is not large enough to store the complete address. To get extended error information, call **InetGetLastError**.

Remarks

The **InetGetAdapterAddress** function will return the IPv4, IPv6 or MAC address assigned to a specific network adapter. The primary network adapter has an index value of zero, and it increments for each adapter that is configured on the local system.

The media access control (MAC) address is a 48 bit or 64 bit value that is assigned to each network interface and is used for identification and access control. All network devices on the

same subnet must be assigned their own unique MAC address. Unlike IP addresses which may be assigned dynamically and can be frequently changed, MAC addresses are considered to be more permanent because they are usually assigned by the device manufacturer and stored in firmware. Note that in some cases it is possible to change the address assigned to a device, and virtual network interfaces may have configurable MAC addresses.

This function returns the MAC address string as sequence of hexadecimal values separated by a colon. An example of a 48 bit MAC address would be "01:23:45:67:89:AB". Note that some virtual network adapters may not have a MAC address assigned to them, in which case this function would return zero.

This function will ignore network adapters that have been disabled, as well as those that are bound to a virtual loopback interface. If the system has dial-up networking or virtualization software installed, this function may also return IP addresses assigned to a virtualized network adapters installed by that software.

Example

```
// Display the IPv4 address assigned to each network adapter
for (INT nIndex = 0;; nIndex++)
{
    TCHAR szAddress[64];
    INT cchAddress;

    cchAddress = InetGetAdapterAddress(nIndex, INET_ADAPTER_IPV4, szAddress,
64);

    if (cchAddress == INET_ERROR)
        break;

    _tprintf(_T("Adapter %d: %s\n"), nIndex, szAddress);
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

See Also

[InetEnumNetworkAddresses](#), [InetGetLocalAddress](#), [InetGetLocalName](#)

InetGetAddress Function

```
INT WINAPI InetGetAddress(  
    LPCTSTR LpszAddress,  
    INT nAddressFamily,  
    LPINTERNET_ADDRESS LpAddress  
);
```

The **InetGetAddress** function converts an IP address string to binary format.

Parameters

LpszAddress

A pointer to a null terminated string which specifies an IP address. This function recognizes the format for both IPv4 and IPv6 format addresses.

nAddressFamily

An integer which identifies the type of IP address specified by the *LpszAddress* parameter. It may be one of the following values:

Constant	Description
INET_ADDRESS_UNKNOWN	Return the IP address for the specified host in either IPv4 or IPv6 format, depending on the value of the <i>LpszAddress</i> parameter.
INET_ADDRESS_IPV4	Specifies that the address should be in IPv4 format. The first four bytes of the <i>ipNumber</i> array are significant and contains the IP address. The remaining bytes are not significant and an application should not depend on them having any particular value, including zero. If the <i>LpszAddress</i> parameter does not specify a valid IPv4 address string, this function will fail.
INET_ADDRESS_IPV6	Specifies that the address should be in IPv6 format. All bytes in the <i>ipNumber</i> array are significant. If the <i>LpszAddress</i> parameter does not specify a valid IPv6 address string, this function will fail.

LpAddress

A pointer to an [INTERNET_ADDRESS](#) structure that will contain the IP address.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is INET_ERROR. To get extended error information, call **InetGetLastError**.

Remarks

If the *nAddressFamily* parameter is specified as INET_ADDRESS_UNKNOWN, the application must be prepared to handle IPv6 addresses because it is possible that an IPv6 address string has been specified. For legacy applications that only recognize IPv4 addresses, the *nAddressFamily* member should always be specified as INET_ADDRESS_IPV4 to ensure that only IPv4 addresses are returned and any attempt to specify an IPv6 address string would result in an error.

To determine if the local system has an IPv6 TCP/IP stack installed and configured on the local system, use the **InetIsProtocolAvailable** function. If an IPv6 stack is not installed, this function will

fail if the *lpszAddress* parameter specifies an IPv6 address, even if the address itself is valid.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cssock10.h`

Import Library: `cswskv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

[INTERNET_ADDRESS](#)

InetGetAddressFamily Function

```
INT WINAPI InetGetAddressFamily(  
    LPCTSTR lpszAddress,  
);
```

Return the address family for the specified IP address.

Parameters

lpszAddress

A pointer to a string which specifies an IP address. This function recognizes the format for both IPv4 and IPv6 format addresses.

Return Value

If the function succeeds, the return value is the address family for the specified IP address and may be one of the values listed below. If the function fails, the return value is INET_ADDRESS_UNKNOWN. To get extended error information, call **InetGetLastError**.

Constant	Description
INET_ADDRESS_IPV4	The address passed to the function is a valid IPv4 address.
INET_ADDRESS_IPV6	The address passed to the function is a valid IPv6 address.

Remarks

The **InetGetAddressFamily** function returns the address family associated with the specified IP address string. This can be used to determine if a string specifies a valid IPv4 or IPv6 address that can be passed to other functions such as **InetConnect**. Note that this function will not attempt to resolve hostnames, it will only accept IP addresses.

To determine if the local system has an IPv6 TCP/IP stack installed and configured on the local system, use the **InetIsProtocolAvailable** function. If an IPv6 stack is not installed, this function will fail if the *lpszAddress* parameter specifies an IPv6 address, even if the address itself is valid.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

Unicode: Implemented as Unicode and ANSI versions.

InetGetBlockingSocket Function

```
SOCKET InetGetBlockingSocket();
```

The **InetGetBlockingSocket** function returns the handle for the socket in the current thread which is currently blocking, if there is one.

Parameters

None.

Return Value

If the function succeeds, the return value is the handle for the socket in the current thread which is currently blocking. If the function fails, the return value is `INET_ERROR`. To get extended error information, call **InetGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cssock10.h`

Import Library: `cswskv10.lib`

InetGetClientData Function

```
BOOL WINAPI InetGetClientData(  
    SOCKET hClient,  
    LPVOID * lppvData  
);
```

The **InetGetClientData** function returns the application defined data associated with the specified client session.

Parameters

hSocket

The socket handle.

lppvData

Pointer to a void pointer which will contain an application defined value associated with the client session.

Return Value

If the function succeeds, the return value is non-zero. A return value of zero indicates that application defined data for the client session could not be retrieved. To get extended error information, call **InetGetLastError**.

Remarks

The **InetGetClientData** function is used to retrieve the application defined data that was previously associated with a client session using the **InetSetClientData** function. This is typically used to associate a pointer to a data structure or a class instance with a specific client handle.

This function can only be used with client socket handles created using the server interface. It cannot be used with socket handles created using the **InetConnect** or **InetAccept** functions. If the socket handle is invalid, or does not reference a client socket handle created by the server, the *lppvData* pointer passed to this function will be initialized to a value of NULL and the function will return a value of zero.

If this function is called with a valid socket handle and there is no data associated with the socket, the function will return a non-zero value and the *lppvData* pointer will be returned with a NULL value. Before dereferencing the pointer returned by this function, the application should always check the return value to ensure the function succeeded and make sure that the pointer is not NULL.

Example

```
UINT *pnValue1 = (UINT *)LocalAlloc(LPTR, sizeof(UINT));  
UINT *pnValue2 = NULL;  
  
*pnValue1 = 1234;  
  
if (InetSetClientData(hSocket, pnValue1) == FALSE)  
{  
    // Unable to associate the data with this session  
    return;  
}  
  
if (InetGetClientData(hSocket, &pnValue2) == FALSE)  
{
```

```
    // Unable to retrieve the data associated with this session
    return;
}

// *pnValue2 == 1234
printf("The value of user defined data is %u\n", *pnValue2);
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

See Also

[InetGetServerData](#), [InetSetClientData](#), [InetSetServerData](#)

InetGetClientHandle Function

```
SOCKET WINAPI InetGetClientHandle(  
    SOCKET hServer,  
    UINT nClientId  
);
```

The **InetGetClientHandle** function returns the handle for a specific client session based on its ID number.

Parameters

hServer

Handle to the server socket.

nClientId

An unsigned integer value which uniquely identifies the client session.

Return Value

If the function succeeds, the return value is the socket handle for the specified client session. If the function fails, the return value is `INVALID_SOCKET`. To get extended error information, call **InetGetLastError**.

Remarks

Each client connection that is accepted by the server is assigned a unique numeric value. This value can be obtained by calling the **InetGetClientId** function and used by the application to identify that client session. The **InetGetClientHandle** function can then be used to obtain the client socket handle for the session, based on that client ID.

The socket handle for the server must be one that was created by calling the **InetServerStart** function, and cannot be a socket that was created using the **InetListen** or **InetListenEx** functions.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cswsock10.h`

Import Library: `cswskv10.lib`

See Also

[InetGetClientId](#), [InetGetClientMoniker](#), [InetSetClientMoniker](#), [InetGetServerClient](#), [InetGetThreadClient](#)

InetGetClientId Function

```
UINT WINAPI InetGetClientId(  
    SOCKET hClient  
);
```

The **InetGetClientId** function returns the unique ID number assigned to the specified client session.

Parameters

hClient

Handle to the client socket.

Return Value

If the function succeeds, the return value is an unsigned integer value which uniquely identifies the client session. If the function fails, the return value is zero. To get extended error information, call **InetGetLastError**.

Remarks

Each client connection that is accepted by the server is assigned a unique numeric value. This value can be obtained by calling the **InetGetClientId** function and used by the application to identify that client session. The **InetGetClientHandle** function can then be used to obtain the client socket handle for the session, based on that client ID. It is important to note that the actual value of the client ID should be considered opaque. It is only guaranteed that the value will be greater than zero, and that it will be unique to the client session.

While it is possible for a client socket handle to be reused by the operating system, client IDs are unique throughout the life of the server session and are never duplicated.

The socket handle for the client must be one that was created as part of the SocketWrench server interface, and cannot be a socket that was created using the **InetConnect** or **InetAccept** functions.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cssock10.h`

Import Library: `cswskv10.lib`

See Also

[InetGetClientHandle](#), [InetGetClientMoniker](#), [InetSetClientMoniker](#), [InetGetServerClient](#)

InetGetClientIdleTime Function

```
DWORD WINAPI InetGetClientIdleTime(  
    SOCKET hClient  
);
```

Returns the number of milliseconds that the specified client session has been idle.

Parameters

hClient

Handle to the client socket.

Return Value

If the function succeeds, the return value is an unsigned integer value which specifies the number of milliseconds the client session has been idle. If the function fails, the return value is INFINITE. To get extended error information, call **InetGetLastError**.

Remarks

The **InetGetClientIdleTime** function will return the number of milliseconds that have elapsed since data was exchanged with the client. The elapsed time is limited to the resolution of the system timer, which is typically in the range of 10 milliseconds to 16 milliseconds.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cswsock10.h`

Import Library: `cswskv10.lib`

See Also

[InetGetClientHandle](#), [InetGetClientMoniker](#), [InetGetServerClient](#)

InetGetClientMoniker Function

```
INT WINAPI InetGetClientMoniker(  
    SOCKET hSocket,  
    LPTSTR LpszMoniker,  
    INT nMaxLength  
);
```

The **InetGetClientMoniker** function returns the moniker associated with the specified client session.

Parameters

hSocket

Handle to the client socket.

lpszMoniker

Pointer to a string buffer that will contain the moniker for the specified client session when the function returns.

nMaxLength

The maximum number of characters that may be copied into the string buffer. The buffer must be large enough to store the moniker and a terminating null character. The maximum length of a moniker is 127 characters.

Return Value

If the function succeeds, the return value is the number of characters in the moniker string. A return value of zero specifies that no moniker was assigned to the socket. If the function fails, the return value is INET_ERROR. To get extended error information, call **InetGetLastError**.

Remarks

A client moniker is a string which can be used to uniquely identify a specific client session aside from its socket handle. A moniker can be assigned to the client session using the **InetSetClientMoniker** function. This function will return the moniker that was previously assigned to the client, if any. To obtain the socket handle associated with a given moniker, use the **InetFindClientMoniker** function.

The socket handle for the client must be one that was created as part of the SocketWrench server interface, and cannot be a socket that was created using the **InetConnect** or **InetAccept** functions.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

See Also

[InetFindClientMoniker](#), [InetGetClientHandle](#), [InetGetClientId](#), [InetSetClientMoniker](#)

InetGetClientPriority Function

```
INT WINAPI InetGetClientPriority(  
    SOCKET hClient  
);
```

The **InetGetClientPriority** function returns the current priority for the specified client session.

Parameters

hClient

Handle to the client socket.

Return Value

If the function succeeds, the return value is the priority for the specified client session. If the function fails, the return value is INET_ERROR. To get extended error information, call **InetGetLastError**.

Remarks

The **InetGetClientPriority** function can be used to determine the current priority assigned to the specified client session. The client priority is inherited from the priority specified when the server is started using the **InetServerStart** function. It may be one of the following values:

Constant	Description
INET_PRIORITY_NORMAL	The default priority which balances resource and processor utilization. It is recommended that most applications use this priority.
INET_PRIORITY_BACKGROUND	This priority significantly reduces the memory, processor and network resource utilization for the client session. It is typically used with lightweight services running in the background that are designed for few client connections. The client thread will be assigned a lower scheduling priority and will be frequently forced to yield execution to other threads.
INET_PRIORITY_LOW	This priority lowers the overall resource utilization for the client session and meters the processor utilization for the client session. The client thread will be assigned a lower scheduling priority and will occasionally be forced to yield execution to other threads.
INET_PRIORITY_HIGH	This priority increases the overall resource utilization for the client session and the thread will be given higher scheduling priority. It is not recommended that this priority be used on a system with a single processor.
INET_PRIORITY_CRITICAL	This priority can significantly increase processor, memory and network utilization. The client thread will be given higher scheduling priority and will be more responsive to network events. It is not recommended that this priority be used on a system with a single processor.

The socket handle for the client must be one that was created as part of the SocketWrench server interface, and cannot be a socket that was created using the **InetConnect** or **InetAccept**

functions.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: csoskv10.lib

See Also

[InetGetServerPriority](#), [InetServerStart](#), [InetSetClientPriority](#), [InetSetServerPriority](#)

InetGetClientServer Function

```
SOCKET WINAPI InetGetClientServer(  
    SOCKET hClient  
);
```

The **InetGetClientServer** function returns a socket handle to the server for the specified client socket.

Parameters

hClient

Handle to the client socket.

Return Value

If the function succeeds, the return value is the handle to the server that created the client session. If the function fails, the return value is INVALID_SOCKET. To get extended error information, call **InetGetLastError**.

Remarks

The **InetGetClientServer** function returns the handle to the server that created the client session. The **InetGetClientServerById** function can be used to obtain the server handle using the client session ID rather than the client socket handle.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cswskv10.lib

See Also

[InetGetClientHandle](#), [InetGetClientId](#), [InetGetClientServerById](#)

InetGetClientServerById Function

```
SOCKET WINAPI InetGetClientServerById(  
    UINT nClientId  
);
```

The **InetGetClientServerById** function returns a socket handle to the server for the specified client session identifier.

Parameters

nClientId

Client session identifier.

Return Value

If the function succeeds, the return value is the handle to the server that created the client session. If the function fails, the return value is INVALID_SOCKET. To get extended error information, call **InetGetLastError**.

Remarks

The **InetGetClientServerById** function returns the handle to the server that created the client session using the client's unique identifier. The **InetGetClientServer** function can be used to obtain the server handle using the client socket handle rather than the client session ID. This function is typically used in conjunction with the INET_NOTIFY_CONNECT notification message to obtain the handle to the server that generated the event using the client ID passed in the *wParam* message parameter.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cswskv10.lib

See Also

[InetGetClientHandle](#), [InetGetClientId](#), [InetGetClientServer](#), [InetServerAsyncNotify](#)

InetGetClientThreadId Function

```
DWORD WINAPI InetGetClientThreadId(  
    SOCKET hClient  
);
```

The **InetGetClientThreadId** function returns the thread ID for the specified client session.

Parameters

hClient

Handle to the client socket.

Return Value

If the function succeeds, the return value is an unsigned integer value which identifies the thread that was created to manage the client session. If the function fails, the return value is zero. To get extended error information, call **InetGetLastError**.

Remarks

The thread ID returned by this function can be used with the **OpenThread** function to obtain a handle to the thread. Until the thread terminates, the thread identifier uniquely identifies the thread throughout the system.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cswsock10.h`

Import Library: `cswskv10.lib`

See Also

[InetGetClientPriority](#), [InetGetServerThreadId](#), [InetGetThreadClient](#), [InetSetClientPriority](#)

InetGetClientThreads Function

```
INT WINAPI InetGetClientThreads(  
    SOCKET hServer  
);
```

Returns the number of client session threads created by the server.

Parameters

hServer

Handle to the server socket.

Return Value

If the function succeeds, the return value is the number of client session threads that have been created by the server. If the function fails, the return value is `INET_ERROR`. To get extended error information, call **InetGetLastError**.

Remarks

The **InetGetClientThreads** function returns the number of threads that are managing client sessions for the specified server. If there are no clients connected to the server, this function will return a value of zero. Because this function returns the number of session threads, the value returned will include those clients that are in the process of disconnecting from the server but their session thread has not yet terminated. This differs from the **InetEnumServerClients** function which will only enumerate active clients.

If you wish to determine when the last client has disconnected from the server, call this function within an event handler for the `INET_EVENT_DISCONNECT` event. If the function returns a value greater than one, then there are other client sessions that are either connected or in the process of terminating.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cssock10.h`

Import Library: `cswskv10.lib`

See Also

[InetEnumServerClients](#), [InetEnumServerClientsByAddress](#)

InetGetDefaultHostFile Function

```
INT WINAPI InetGetDefaultHostFile(  
    LPTSTR lpszFileName,  
    INT nMaxLength  
);
```

The **InetGetDefaultHostFile** function returns the fully qualified path name of the host file on the local system. The host file is used as a database that maps an IP address to one or more hostnames, and is used by the **InetGetHostAddress** and **InetGetHostNames** function. The file is a plain text file, with each line in the file specifying a record, and each field separated by spaces or tabs. The format of the file must be as follows:

```
ipaddress hostname [hostalias ...]
```

For example, one typical entry maps the name "localhost" to the local loopback IP address. This would be entered as:

```
127.0.0.1 localhost
```

The hash character (#) may be used to specify a comment in the file, and all characters after it are ignored up to the end of the line. Blank lines are ignored, as are any lines which do not follow the required format.

The location of the default host file depends on the operating system. For Windows 95/98 and Windows Me the file is stored in C:\Windows\hosts and for Windows NT and later versions the file is stored in C:\Windows\system32\drivers\etc\hosts. Regardless of platform, there is no filename extension and this file may or may not exist on a given system.

Parameters

lpszFileName

Pointer to a string buffer that will contain the fully qualified file name to the default host file. It is recommended that this buffer be at least MAX_PATH characters in size. This parameter may be NULL, in which case the function will return the length of the string, not including the terminating null byte.

nMaxLength

The maximum number of characters that may be copied to the string buffer.

Return Value

If the function succeeds, the return value is length of the string. A return value of zero indicates that the default host file could not be determined for the current platform. To get extended error information, call **InetGetLastError**.

Remarks

This function only returns the default location of the host file and does not determine if the file actually exists. It is not required that a host file be present on the system.

The default host file is processed before performing a nameserver lookup when resolving a hostname into an IP address, or an IP address into a hostname.

To specify an alternate local host file, use the **InetSetHostFile** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cswsock10.h

Import Library: cswskv10.lib

Unicode: Implemented as Unicode and ANSI versions.

InetGetErrorString Function

```
INT WINAPI InetGetErrorString(  
    DWORD dwErrorCode,  
    LPTSTR lpszDescription,  
    INT cbDescription  
);
```

The **InetGetErrorString** function is used to return a description of a specific error code. Typically this is used in conjunction with the [InetGetLastError](#) function for use with warning dialogs or as diagnostic messages.

Parameters

dwErrorCode

The last-error code for which a description is returned.

lpszDescription

A pointer to the buffer that will contain a description of the specified error code. This buffer should be at least 128 characters in length.

cbDescription

The maximum number of characters that may be copied into the description buffer.

Return Value

If the function succeeds, the return value is the length of the description string. If the function fails, the return value is 0, meaning that no description exists for the specified error code. Typically this indicates that the error code passed to the function is invalid.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cssock10.h`

Import Library: `cswskv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

[InetGetLastError](#), [InetSetLastError](#)

InetGetExternalAddress Function

```
INT WINAPI InetGetExternalAddress(  
    INT nAddressFamily,  
    LPINTERNET_ADDRESS lpAddress  
);
```

The **InetGetExternalAddress** function returns the external IP address for the local system.

Parameters

nAddressFamily

An integer which identifies the type of IP address that should be returned by this function. It may be one of the following values:

Constant	Description
INET_ADDRESS_IPV4	Specifies that the address should be in IPv4 format. The method will attempt to determine the external IP address using an IPv4 network connection.
INET_ADDRESS_IPV6	Specifies that the address should be in IPv6 format. The method will attempt to determine the external IP address using an IPv6 network connection and requires that the local host have an IPv6 network interface installed and enabled.

lpAddress

A pointer to an [INTERNET_ADDRESS](#) structure that will contain the external IP address of the local host.

Return Value

If the function succeeds, the return value is zero and the [INTERNET_ADDRESS](#) structure contains the external IP address for the local host in binary form. If the function fails, the return value is [INET_ERROR](#). To get extended error information, call **InetGetLastError**.

Remarks

The **InetGetExternalAddress** function returns the IP address assigned to the router that connects the local host to the Internet. This is typically used by an application executing on a system in a local network that uses a router which performs Network Address Translation (NAT). In that network configuration, the **InetGetLocalAddress** function will only return the IP address for the local system on the LAN side of the network unless a connection has already been established to a remote host. The **InetGetExternalAddress** function can be used to determine the IP address assigned to the router on the Internet side of the connection and can be particularly useful for servers running on a system behind a NAT router.

This function requires that you have an active connection to the Internet and calling this function on a system that uses dial-up networking may cause the operating system to automatically connect to the Internet service provider. An application should always check the return value in case there is an error; never assume that the return value is always a valid address. The function may be unable to determine the external IP address for the local host for a number of reasons, particularly if the system is behind a firewall or uses a proxy server that restricts access to external sites on the Internet. If the function is able to obtain a valid external address for the local host, that address will be cached by the library for sixty minutes. Because dial-up connections typically have different IP addresses assigned to them each time the system is connected to the Internet, it is

recommended that this function only be used with broadband connections where a NAT router is being used.

Calling this function may cause the current thread to block until the external IP address can be resolved and should never be used in conjunction with asynchronous socket connections. If you need to call this function in an application which uses asynchronous sockets, it is recommended that you create a new thread and call this function from within that thread.

To convert the address from its binary form into a string, use the **InetFormatAddress** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cssock10.h`

Import Library: `cssock10.lib`

See Also

[InetFormatAddress](#), [InetGetHostAddress](#), [InetGetLocalAddress](#), [InetGetPeerAddress](#)

InetGetHostAddress Function

```
INT WINAPI InetGetHostAddress(  
    LPCTSTR lpszHostName,  
    INT nAddressFamily,  
    LPINTERNET_ADDRESS lpAddress  
);
```

The **InetGetHostAddress** function resolves the specified host name into an IP address in binary format.

Parameters

lpszHostName

A pointer to the name of the host to resolve; this may be a fully-qualified domain name or an IP address. This function recognizes the format for both IPv4 and IPv6 format addresses.

nAddressFamily

An integer which identifies the type of IP address to return. It may be one of the following values:

Constant	Description
INET_ADDRESS_UNKNOWN	Return the IP address for the specified host in either IPv4 or IPv6 format, depending on how the host name can be resolved. By default, a preference will be given for returning an IPv4 address. However, if the host only has an IPv6 address, that value will be returned.
INET_ADDRESS_IPV4	Specifies that the address should be returned in IPv4 format. The first four bytes of the <i>ipNumber</i> array are significant and contains the IP address. The remaining bytes are not significant and an application should not depend on them having any particular value, including zero.
INET_ADDRESS_IPV6	Specifies that the address should be returned in IPv6 format. All bytes in the <i>ipNumber</i> array are significant. Note that it is possible for an IPv6 address to actually represent an IPv4 address. This is indicated by the first 10 bytes of the address being zero.

lpAddress

A pointer to an [INTERNET_ADDRESS](#) structure that will contain the IP address of the specified host.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is INET_ERROR. To get extended error information, call **InetGetLastError**.

Remarks

This function can also be used to convert an address in dot notation to a binary format. If the function must perform a DNS lookup to resolve the hostname, the calling thread will block. To ensure future compatibility with IPv6 networks, it is important that the application does not make

any assumptions about the format of the address. If the function returns successfully, the *ipFamily* member of the **INTERNET_ADDRESS** structure should always be checked to determine the type of address.

The *nAddressFamily* parameter is used to specify a preference for the type of address returned, however it is possible that a host may not have an IPv4 or IPv6 address record, in which case this function will fail. Although IPv4 is still the most common address used at this time, an application should not assume that because a given host name does not have an IPv4 address, that the host name is invalid.

If the *nAddressFamily* parameter is specified as `INET_ADDRESS_UNKNOWN`, the application must be prepared to handle IPv6 addresses because it is possible for a host name to have an IPv6 address assigned to it and no IPv4 address. For legacy applications that only recognize IPv4 addresses, the *nAddressFamily* member should always be specified as `INET_ADDRESS_IPV4` to ensure that only IPv4 addresses are returned.

To determine if the local system has an IPv6 TCP/IP stack installed and configured on the local system, use the **InetIsProtocolAvailable** function. If an IPv6 stack is not installed, this function will fail if the *lpszHostName* parameter specifies an host that only has an IPv6 (AAAA) DNS record.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cswsock10.h`

Import Library: `cswskv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

See Also

[InetGetHostName](#), [InetGetLocalAddress](#), [InetGetLocalName](#), [InetGetPeerAddress](#), [InetIsProtocolAvailable](#), [INTERNET_ADDRESS](#)

InetGetHostFile Function

```
INT WINAPI InetGetHostFile(  
    LPTSTR lpszFileName,  
    INT nMaxLength  
);
```

The **InetGetHostFile** function returns the name of the host file previously set using the **InetSetHostFile** function. The host file is used as a database that maps an IP address to one or more hostnames, and is used by the **InetGetHostAddress** and **InetGetHostNames** function.

Parameters

lpszFileName

Pointer to a string buffer that will contain the host file name. It is recommended that this buffer be at least MAX_PATH characters in size. This parameter may be NULL, in which case the function will return the length of the string, not including the terminating null character.

nMaxLength

The maximum number of characters that may be copied to the string buffer.

Return Value

If the function succeeds, the return value is length of the string. A return value of zero indicates that no host file has been specified or the function was unable to determine the file name. To get extended error information, call **InetGetLastError**. If the last error is zero, this indicates that no host file name has been specified for the current thread. If the last error is non-zero, this indicates the reason that the function failed.

Remarks

This function only returns the name of the host file that is cached in memory for the current thread. The contents of the file on the disk may have changed after the file was loaded into memory. To reload the host file or clear the cache, call the **InetSetHostFile** function.

If a host file has been specified, it is processed before the default host file when resolving a hostname into an IP address, or an IP address into a hostname. If the host name or address is not found, or no host file has been specified, a nameserver lookup is performed.

The host file returned by this function may be different than the default host file for the local system. To determine the file name for the default host file, use the **InetGetDefaultHostFile** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[InetGetDefaultHostFile](#), [InetGetHostAddress](#), [InetGetHostName](#), [InetSetHostFile](#)

InetGetHostName Function

```
INT WINAPI InetGetHostName(  
    LPINTERNET_ADDRESS LpAddress,  
    LPTSTR LpszHostName,  
    INT cchHostName  
);
```

The **InetGetHostName** function performs a reverse lookup, returning the host name associated with a given IP address.

Parameters

lpAddress

A pointer to an [INTERNET_ADDRESS](#) structure which specifies the IP address that should be resolved into a host name.

lpszHostName

A pointer to the buffer that will contain the host name. It is recommended that this buffer be at least 256 characters in length to accommodate the longest possible fully qualified domain name.

cchHostName

The maximum number of characters that can be copied into the buffer.

Return Value

If the function succeeds, the return value is the length of the hostname. If the function fails, the return value is `INET_ERROR`. To get extended error information, call **InetGetLastError**.

Remarks

If the function must perform a reverse DNS lookup to resolve the IP address into a host name, the calling thread will block. This function requires that the host have a PTR record, otherwise it will fail. Because many hosts do not have a PTR record, calling this function frequently may have a negative impact on the overall performance of the application.

To determine if the local system has an IPv6 TCP/IP stack installed and configured on the local system, use the **InetIsProtocolAvailable** function. If an IPv6 stack is not installed, this function will fail if the *lpAddress* parameter specifies an IPv6 address, even if the address itself is valid.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cswsock10.h`

Import Library: `cswskv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

See Also

[InetGetHostAddress](#), [InetGetLocalAddress](#), [InetGetLocalName](#), [InetGetPeerAddress](#), [InetIsProtocolAvailable](#), [INTERNET_ADDRESS](#)

InetGetLastError Function

```
DWORD WINAPI InetGetLastError();
```

Parameters

None.

Return Value

Functions set this value by calling the [InetSetLastError](#) function. The return value section of each reference page notes the conditions under which the function sets the last-error code.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. You should call the **InetGetLastError** function immediately when a function's return value indicates that an error has occurred. That is because some functions call **InetSetLastError(0)** when they succeed, clearing the error code set by the most recently failed function.

Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_SOCKET or INET_ERROR. Those functions which call **InetSetLastError** when they succeed are noted on the function reference page.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

[InetGetErrorString](#), [InetSetLastError](#)

InetGetLocalAddress Function

```
INT WINAPI InetGetLocalAddress(  
    SOCKET hSocket,  
    INT nAddressFamily,  
    LPINTERNET_ADDRESS LpAddress,  
    UINT* LpnPort  
);
```

The **InetGetLocalAddress** function returns the local IP address and port number for the specified socket.

Parameters

hSocket

The socket handle.

nAddressFamily

An integer which identifies the type of IP address to return. It may be one of the following values:

Constant	Description
INET_ADDRESS_UNKNOWN	Return the IP address for the specified host in either IPv4 or IPv6 format, depending on the type of connection that was established. If the <i>hSocket</i> parameter is INVALID_SOCKET, a preference will be given for returning an IPv4 address. However, if the local host only has an IPv6 address, that value will be returned.
INET_ADDRESS_IPV4	Specifies that the address should be returned in IPv4 format. The first four bytes of the <i>ipNumber</i> array are significant and contains the IP address. The remaining bytes are not significant and an application should not depend on them having any particular value, including zero.
INET_ADDRESS_IPV6	Specifies that the address should be returned in IPv6 format. All bytes in the <i>ipNumber</i> array are significant. Note that it is possible for an IPv6 address to actually represent an IPv4 address. This is indicated by the first 10 bytes of the address being zero.

lpAddress

A pointer to an [INTERNET_ADDRESS](#) structure that will contain the IP address of the local host. If the *hSocket* parameter is specified as INVALID_SOCKET, this function will attempt to determine the IP address of the local host assigned by the system. If the address is not required, this parameter may be NULL.

lpnPort

A pointer to an unsigned integer that will contain the local port number. If the *hSocket* parameter specifies a valid socket, this parameter will be set to the local port that the socket was bound to. If the *hSocket* parameter is specified as INVALID_SOCKET, this parameter is ignored. If the port number is not required, this parameter may be NULL.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is `INET_ERROR`. To get extended error information, call **InetGetLastError**.

Remarks

To ensure future compatibility with IPv6 networks, it is important that the application does not make any assumptions about the format of the address. If the function returns successfully, the *ipFamily* member of the **INTERNET_ADDRESS** structure should always be checked to determine the type of address.

If the *nAddressFamily* parameter is specified as `INET_ADDRESS_UNKNOWN`, the application must be prepared to handle IPv6 addresses because it is possible for the local host to have an IPv6 address assigned to it and no IPv4 address. For legacy applications that only recognize IPv4 addresses, the *nAddressFamily* member should always be specified as `INET_ADDRESS_IPV4` to ensure that only IPv4 addresses are returned.

If the system is connected to the Internet through a local network and/or uses a router that performs Network Address Translation (NAT), the **InetGetLocalAddress** function will return the local, non-routable IP address assigned to the system. To determine the public IP address has been assigned to the system, you should use the **InetGetExternalAddress** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cswsock10.h`

Import Library: `cswskv10.lib`

See Also

InetGetLocalName Function

```
INT WINAPI InetGetLocalName(  
    LPTSTR LpszHostName,  
    INT cchHostName  
);
```

The **InetGetLocalName** function returns the hostname assigned to the local system.

Parameters

lpszHostName

A pointer to the buffer that will contain the hostname.

cchHostName

The maximum number of characters that can be copied into the address buffer.

Return Value

If the function succeeds, the return value is the length of the hostname. If the function fails, the return value is INET_ERROR. To get extended error information, call **InetGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cssock10.h`

Import Library: `cswskv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

See Also

InetGetLockedServer Function

```
SOCKET WINAPI InetGetLockedServer(  
    LPDWORD LpdwThreadId  
);
```

The **InetGetLockedServer** function unlocks the specified server, allowing other server threads to resume execution.

Parameters

LpdwThreadId

A pointer to an unsigned integer which identifies the thread that established the server lock. If this information is not required, this parameter may be NULL.

Return Value

If the function succeeds, the return value is the handle to the locked server. If no server is in a locked state, the function will return a value of INVALID_SOCKET.

Remarks

The **InetGetLockedServer** function can be used to determine if there is a server in a locked state. If there is, the function will return a handle to the server and will identify the thread which established the lock. This function may be called from any thread, however only the thread which established the server lock may interact with the server or release the lock.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

See Also

[InetServerLock](#), [InetServerUnlock](#)

InetGetOption Function

```
INT WINAPI InetGetOption(  
    SOCKET hSocket,  
    DWORD dwOption,  
    LPBOOL lpbEnabled  
);
```

The **InetGetOption** function is used to determine if a specific socket option has been enabled.

Parameters

hSocket

The socket handle.

dwOption

An unsigned integer used to specify one of the socket options. These options cannot be combined. The following values are recognized:

Constant	Description
INET_OPTION_BROADCAST	This option specifies that broadcasting should be enabled for datagrams. This option is invalid for stream sockets.
INET_OPTION_KEEPAIVE	This option specifies that packets are to be sent to the remote system when no data is being exchanged to keep the connection active. This is only valid for stream sockets.
INET_OPTION_REUSEADDRESS	This option specifies the local address can be reused. This option is commonly used by server applications.
INET_OPTION_NODELAY	This option disables the Nagle algorithm, which buffers unacknowledged data and insures that a full-size packet can be sent to the remote host.

lpbEnabled

A pointer to a boolean flag. If the option is enabled, the flag is set to a non-zero value, otherwise it is set to a value of zero.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is INET_ERROR. To get extended error information, call **InetGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

See Also

[InetAsyncConnectEx](#), [InetConnectEx](#), [InetSetOption](#)

InetGetPeerAddress Function

```
INT WINAPI InetGetPeerAddress(  
    SOCKET hSocket,  
    LPINTERNET_ADDRESS lpAddress,  
    UINT* lpnPort  
);
```

The **InetGetPeerAddress** function returns the peer IP address and remote port number for the specified socket.

Parameters

hSocket

The socket handle.

lpAddress

A pointer to an [INTERNET_ADDRESS](#) structure that will contain the IP address of the remote host that the socket is connected to.

lpnPort

A pointer to an unsigned integer that will contain the remote port that the socket is connected to.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is INET_ERROR. To get extended error information, call **InetGetLastError**.

Remarks

If this function is called by a server application in response to a INET_EVENT_ACCEPT event, it will return the IP address and port number for the client that is attempting to establish the connection. If the peer address is unavailable, the *ipFamily* member of the INTERNET_ADDRESS structure will be zero. To convert the IP address to a printable string, use the **InetFormatAddress** function.

It is not recommended that you use the port number for anything other than informational and logging purposes. Server applications should not make any assumptions about the specific port number or range of port numbers that a client is using when establishing a connection to the server. The ephemeral port number that a client is bound to can vary based on the client operating system.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cswskv10.lib

See Also

[InetFormatAddress](#), [InetGetHostAddress](#), [InetGetHostName](#), [InetGetLocalAddress](#), [InetGetLocalName](#), [INTERNET_ADDRESS](#)

InetGetPhysicalAddress Function

```
BOOL WINAPI InetGetPhysicalAddress(  
    LPTSTR lpszAddress,  
    UINT nMaxLength  
);
```

Return the media access control (MAC) address for the primary network adapter.

Parameters

lpszAddress

A string buffer that will contain the address in a printable format when the function returns. This parameter cannot be NULL.

nMaxLength

The maximum number of characters that can be copied into the buffer, including the terminating null character.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **InetGetLastError**.

Remarks

The **InetGetPhysicalAddress** function returns the media access control (MAC) address for the primary network adapter. This is a 48 bit or 64 bit address that is assigned to each network interface and is used for identification and access control. All network devices on the same subnet must be assigned their own unique MAC address. Unlike IP addresses which may be assigned dynamically and can be frequently changed, MAC addresses are considered to be more permanent because they are usually assigned by the device manufacturer and stored in firmware. Note that in some cases it is possible to change the address assigned to a device, and virtual network interfaces may have configurable MAC addresses.

This function returns the MAC address as a printable string, with each byte of the address as a two-digit hexadecimal value separated by a colon. The string buffer passed to the function should be at least 20 characters long to accommodate the address and terminating null character. An example of a 48 bit address would be "01:23:45:67:89:AB". If the local system is multi-homed (having more than one network adapter) then this function will return the MAC address for the primary network adapter.

This function is provided for backwards compatibility with previous versions of the library and it is recommended that new applications use the **InetGetAdapterAddress** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cssock10.h`

Import Library: `cswskv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

See Also

[InetEnumNetworkAddresses](#), [InetGetAdapterAddress](#), [InetGetLocalName](#), [InetGetHostAddress](#)

InetGetSecurityInformation Function

```
BOOL WINAPI InetGetSecurityInformation(  
    SOCKET hSocket,  
    LPSECURITYINFO lpSecurityInfo  
);
```

The **InetGetSecurityInformation** function fills a structure with information about the security characteristics of a connection.

Parameters

hSocket

Handle to the socket.

lpSecurityInfo

A pointer to a [SECURITYINFO](#) structure which contains information about the current client connection. The *dwSize* member of this structure must be initialized to the size of the structure before passing the address of the structure to this function.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **InetGetLastError**.

Remarks

This function is used to obtain security related information about the current client connection to the server. It can be used to determine if a secure connection has been established, what security protocol was selected, and information about the server certificate. Note that a secure connection has not been established, the *dwProtocol* structure member will contain the value `SECURITY_PROTOCOL_NONE`.

Example

The following example notifies the user if the connection is secure or not:

```
SECURITYINFO securityInfo;  
  
securityInfo.dwSize = sizeof(SECURITYINFO);  
if (InetGetSecurityInformation(hClient, &securityInfo))  
{  
    if (securityInfo.dwProtocol == SECURITY_PROTOCOL_NONE)  
    {  
        MessageBox(NULL, _T("The connection is not secure"),  
                    _T("Connection"), MB_OK);  
    }  
    else  
    {  
        if (securityInfo.dwCertStatus == SECURITY_CERTIFICATE_VALID)  
        {  
            MessageBox(NULL, _T("The connection is secure"),  
                        _T("Connection"), MB_OK);  
        }  
        else  
        {  
            MessageBox(NULL, _T("The server certificate not valid"),  
                        _T("Connection"), MB_OK);  
        }  
    }  
}
```

```
}  
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: csoskv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[InetConnectEx](#), [InetAsyncConnectEx](#)

InetGetServerClient Function

```
SOCKET WINAPI InetGetServerClient(  
    SOCKET hServer  
);
```

The **InetGetServerClient** function returns the handle for the last client connection accepted by the server.

Parameters

hServer

Handle to the server socket.

Return Value

If the function succeeds, the return value is the handle to the last client connection that was accepted by the server. If the function fails, the return value is `INVALID_SOCKET`. To get extended error information, call **InetGetLastError**.

Remarks

The **InetGetServerClient** function can be used inside the service event handler to determine the client connection that was just accepted by the server. This would typically be used in conjunction with the `INET_EVENT_ACCEPT` handler, enabling the application to obtain the handle of the new client session.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cswsock10.h`

Import Library: `cswskv10.lib`

See Also

InetGetServerData Function

```
BOOL WINAPI InetGetServerData(  
    SOCKET hServer,  
    LPVOID * lppvData  
);
```

The **InetGetServerData** function returns the application defined data associated with the specified server.

Parameters

hSocket

The server socket handle.

lppvData

Pointer to a void pointer which will contain an application defined value associated with the server.

Return Value

If the function succeeds, the return value is non-zero. A return value of zero indicates that application defined data for the server could not be retrieved. To get extended error information, call **InetGetLastError**.

Remarks

The **InetGetServerData** function is used to retrieve the application defined data that was previously associated with a server using the **InetSetServerData** function. This is typically used to associate a pointer to a data structure or a class instance with a specific instance of a server.

This function can only be used with socket handles created using **InetServerStart** function. It cannot be used with socket handles created using the **InetListen** or **InetListenEx** functions. If the socket handle is invalid, or does not reference a server handle, the *lppvData* pointer passed to this function will be initialized to a value of NULL and the function will return a value of zero.

If this function is called with a valid socket handle and there is no data associated with the socket, the function will return a non-zero value and the *lppvData* pointer will be returned with a NULL value. Before dereferencing the pointer returned by this function, the application should always check the return value to ensure the function succeeded and make sure that the pointer is not NULL.

Example

```
UINT *pnValue1 = (UINT *)LocalAlloc(LPTR, sizeof(UINT));  
UINT *pnValue2 = NULL;  
  
*pnValue1 = 1234;  
  
if (InetSetServerData(hServer, pnValue1) == FALSE)  
{  
    // Unable to associate the data with this server  
    return;  
}  
  
if (InetGetServerData(hServer, &pnValue2) == FALSE)  
{  
    // Unable to retrieve the data associated with this server
```

```
    return;  
}  
  
// *pnValue2 == 1234  
printf("The value of user defined data is %u\n", *pnValue2);
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

See Also

[InetGetClientData](#), [InetSetClientData](#), [InetSetServerData](#)

InetGetServerPriority Function

```
INT WINAPI InetGetServerPriority(  
    SOCKET hServer  
);
```

The **InetGetServerPriority** function returns the current priority for the specified server.

Parameters

hServer

Handle to the server socket.

Return Value

If the function succeeds, the return value is the priority for the specified server. If the function fails, the return value is `INET_PRIORITY_INVALID`. To get extended error information, call **InetGetLastError**.

Remarks

The **InetGetServerPriority** function can be used to determine the current priority assigned to the specified server. It will be one of the following values:

Constant	Description
<code>INET_PRIORITY_BACKGROUND</code>	This priority significantly reduces the memory, processor and network resource utilization for the server. It is typically used with lightweight services running in the background that are designed for few client connections. The server thread will be assigned a lower scheduling priority and will be frequently forced to yield execution to other threads.
<code>INET_PRIORITY_LOW</code>	This priority lowers the overall resource utilization for the server and meters the processor utilization for the server thread. The server thread will be assigned a lower scheduling priority and will occasionally be forced to yield execution to other threads.
<code>INET_PRIORITY_NORMAL</code>	The default priority which balances resource and processor utilization. This is the priority that is initially assigned to the server when it is started, and it is recommended that most applications use this priority.
<code>INET_PRIORITY_HIGH</code>	This priority increases the overall resource utilization for the server and the thread will be given higher scheduling priority. It is not recommended that this priority be used on a system with a single processor.
<code>INET_PRIORITY_CRITICAL</code>	This priority can significantly increase processor, memory and network utilization. The server thread will be given higher scheduling priority and will be more responsive to client connection requests. It is not recommended that this priority be used on a system with a single processor.

The socket handle for the server must be one that was created using the **InetServerStart** function, and cannot be a socket that was created using the **InetListen** or **InetListenEx** functions.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

See Also

InetGetServerStackSize Function

```
DWORD WINAPI InetGetServerStackSize(  
    SOCKET hServer  
);
```

Return the initial size of the stack allocated for threads created by the server.

Parameters

hServer

Handle to the server socket.

Return Value

If the function succeeds, the return value is the amount of memory that will be allocated for the stack in bytes. If the function fails, the return value is zero. To get extended error information, call **InetGetLastError**.

Remarks

The **InetGetServerStackSize** function returns the initial amount of memory that is committed to the stack for each thread created by the server. By default, the stack size for each thread is set to 256K for 32-bit processes and 512K for 64-bit processes.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cswsock10.h`

Import Library: `cswskv10.lib`

See Also

[InetServerStart](#), [InetSetServerStackSize](#)

InetGetServerStatus Function

```
INT WINAPI InetGetServerStatus(  
    SOCKET hServer  
);
```

The **InetGetServerStatus** function returns the current status of the specified server.

Parameters

hServer

Handle to the server socket.

Return Value

If the function succeeds, the return value is the status for the specified server. If the function fails, the return value is INET_ERROR. To get extended error information, call **InetGetLastError**.

Remarks

The **InetGetServerStatus** function can be used to determine the current status for the specified server. It may be one of the following values:

Constant	Description
INET_SERVER_INACTIVE	The server is currently inactive.
INET_SERVER_STARTED	The server has initialized and is preparing to listen for client connections.
INET_SERVER_LISTENING	The server is actively listening for incoming client connections.
INET_SERVER_SUSPENDED	The server has been suspended and is no longer accepting client connections.
INET_SERVER_SHUTDOWN	The server has been stopped and is in the process of terminating all active client connections.

The socket handle for the server must be one that was created by calling the **InetServerStart** function, and cannot be a socket that was created using the **InetListen** or **InetListenEx** functions.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

See Also

InetGetServerThreadId Function

```
DWORD WINAPI InetGetServerThreadId(  
    SOCKET hServer  
);
```

The **InetGetServerThreadId** function returns the thread ID for the specified server.

Parameters

hServer

Handle to the server socket.

Return Value

If the function succeeds, the return value is an unsigned integer value which identifies the thread that was created to manage the server. If the function fails, the return value is zero. To get extended error information, call **InetGetLastError**.

Remarks

The thread ID returned by this function can be used with the **OpenThread** function to obtain a handle to the thread.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cswsock10.h`

Import Library: `cswskv10.lib`

See Also

InetGetServiceName Function

```
BOOL WINAPI InetGetServiceName(  
    UINT nServicePort,  
    LPTSTR lpszServiceName,  
    INT nMaxLength  
);
```

The **InetGetServiceName** function returns the service name associated with a specified port number.

Parameters

nServicePort

Port number associated with some network service.

lpszServiceName

A pointer to a string buffer that will contain the name of the service associated with the specified port number. This string should be at least 32 characters long.

cchServiceName

An integer value which specifies the maximum number of characters that can be copied into the string buffer.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **InetGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cswsock10.h`

Import Library: `cswskv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

See Also

[InetGetServicePort](#)

InetGetServicePort Function

```
UINT WINAPI InetGetServicePort(  
    LPCTSTR lpszServiceName  
);
```

The **InetGetServicePort** function returns the port number associated with a service name.

Parameters

lpszServiceName

A pointer to a string which specifies the name of the service to return the port number for.

Return Value

If the function succeeds, the return value is the port number associated with a service name. If the function fails, the return value is INET_ERROR. To get extended error information, call **InetGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cswskv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[InetGetServiceName](#)

InetGetStatus Function

```
INT WINAPI InetGetStatus(  
    SOCKET hSocket  
);
```

The **InetGetStatus** function is used to report what sort of socket operation is in progress.

Parameters

hSocket

The socket handle.

Return Value

If the function succeeds, the return value is the client status code. If the function fails, the return value is `INET_ERROR`. To get extended error information, call **InetGetLastError**.

Remarks

The return value is one of the following values:

Value	Constant	Description
0	<code>INET_STATUS_UNUSED</code>	No connection has been established.
1	<code>INET_STATUS_IDLE</code>	The socket is idle and not in a blocked state
2	<code>INET_STATUS_LISTEN</code>	The socket is listening for inbound connections from a client
3	<code>INET_STATUS_CONNECT</code>	The socket is establishing a connection with a server
4	<code>INET_STATUS_ACCEPT</code>	The socket is accepting a connection from a client
5	<code>INET_STATUS_READ</code>	Data is being read from the socket
6	<code>INET_STATUS_WRITE</code>	Data is being written to the socket
7	<code>INET_STATUS_FLUSH</code>	The socket is being flushed; all data in the receive buffers is being discarded
8	<code>INET_STATUS_DISCONNECT</code>	The socket is disconnecting from the remote host

In a multithreaded application, any thread in the current process may call this function to obtain status information for the specified socket.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cswsock10.h`

Import Library: `cswskv10.lib`

See Also

InetGetStreamInfo Function

```
BOOL WINAPI InetGetStreamInfo(  
    SOCKET hSocket,  
    LPINETSTREAMINFO lpStreamInfo  
);
```

The **InetGetStreamInfo** function fills a structure with information about the current stream I/O operation.

Parameters

hSocket

Handle to the socket.

lpSecurityInfo

A pointer to an **INETSTREAMINFO** structure which contains information about the status of the current operation.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **InetGetLastError**.

Remarks

The **InetGetStreamInfo** function returns information about the current streaming socket operation, including the average number of bytes transferred per second and the estimated amount of time until the operation completes. If there is no operation currently in progress, this function will return the status of the last successful streaming read or write performed by the client.

In a multithreaded application, any thread in the current process may call this function to obtain status information for the specified socket.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cswsock10.h`

Import Library: `cswskv10.lib`

See Also

[InetReadStream](#), [InetStoreStream](#), [InetWriteStream](#), [INETSTREAMINFO](#)

InetGetThreadClient Function

```
SOCKET WINAPI InetGetThreadClient(  
    DWORD dwThreadId  
);
```

The **InetGetThreadClient** function returns the socket handle for the client session that is being managed by the specified thread.

Parameters

dwThreadId

An unsigned integer value which identifies the thread managing the client session. If this parameter has a value of zero, then the client handle for the current thread is returned.

Return Value

If the function succeeds, the return value is the socket handle for the specified client session. If the function fails, the return value is INVALID_SOCKET. To get extended error information, call **InetGetLastError**.

Remarks

The **InetGetThreadClient** is used to obtain the socket handle for the client session that is being managed by the specified thread. If the specified thread ID is zero, then the function will return the client socket for the current thread, otherwise it will search the internal table of all active client sessions and return the handle to the session that is being managed by that thread.

This function will fail if the thread ID does not specify an active client session thread.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

InetGetTimeout Function

```
INT WINAPI InetGetTimeout(  
    SOCKET hSocket  
);
```

The **InetGetTimeout** function returns the timeout interval for blocking operations, in seconds.

Parameters

hSocket

Handle to the socket.

Return Value

If the function succeeds, the return value is the timeout interval for blocking operations, in seconds. If the function fails, the return value is `INET_ERROR`. To get extended error information, call **InetGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cswsock10.h`

Import Library: `cswskv10.lib`

See Also

[InetSetTimeout](#)

InetHostNameToUnicode Function

```
INT WINAPI InetHostNameToUnicode(  
    LPCTSTR LpszHostName,  
    LPTSTR LpszUnicodeName,  
    INT nMaxLength  
);
```

The **InetHostNameToUnicode** function converts the canonical form of a host name to its Unicode version.

Parameters

LpszHostName

Pointer to the host name as a null-terminated string. This parameter cannot be a NULL pointer or a zero length string.

LpszUnicodeName

Pointer to the string buffer that will contain the original Unicode version of the host name, including the terminating null character. It is recommended that this buffer be at least 256 characters in size. This parameter cannot be a NULL pointer.

nMaxLength

The maximum number of characters that can be copied to the *LpszUnicodeName* string buffer. This parameter cannot be zero, and must include the terminating null character.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer. If the function fails, the return value is INET_ERROR. To get extended error information, call **DnsGetLastError**.

Remarks

The **InetHostNameToUnicode** function will convert the encoded ASCII version of a host name to its Unicode version. Although any valid host name is accepted by this function, it is intended to convert a Punycode encoded host name to its original Unicode character encoding.

If the Unicode version of this function is used, the value returned in *LpszUnicodeName* will be a Unicode string using UTF-16 encoding. If the ANSI version of this function, the value returned will be a Unicode string using UTF-8 encoding. To display a UTF-8 encoded host name, your application will need to convert it to UTF-16 using the **MultiByteToWideChar** function.

Although this function performs checks to ensure that the *LpszHostName* parameter is in the correct format and does not contain any illegal characters or malformed encoding, it does not validate the existence of the domain name. To check if the host name exists and has a valid IP address, use the [InetGetHostAddress](#) function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cssock10.h

Import Library: cssock10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

InetInitialize Function

```
BOOL WINAPI InetInitialize(  
    LPCTSTR lpszLicenseKey,  
    LPINITDATA lpData  
);
```

The **InetInitialize** function initializes the library and validates the specified license key at runtime.

Parameters

lpszLicenseKey

Pointer to a string that specifies the runtime license key to be validated. If this parameter is NULL, the library will validate the development license installed on the local system.

lpData

Pointer to an INITDATA data structure. This parameter may be NULL if the initialization data for the library is not required.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **InetGetLastError**. All other functions will fail until a license key has been successfully validated.

Remarks

This must be the first function that an application calls before using any of the other functions in the library. When a NULL license key is specified, the library will only function on the development system. Before redistributing the application to an end-user, you must insure that this function is called with a valid license key.

If the *lpData* argument is specified, it must point to an INITDATA structure which has been initialized by setting the *dwSize* member to the size of the structure. All other structure members should be set to zero. If the function is successful, then the INITDATA structure will be filled with identifying information about the library.

Although it is only required that **InetInitialize** be called once for the current process, it may be called multiple times; however, each call must be matched by a corresponding call to **InetUninitialize**.

This function dynamically loads other system libraries and allocates thread local storage. If you are calling the functions in this library from within another DLL, it is important that you do not call the **InetInitialize** or **InetUninitialize** functions from the **DllMain** function because it can result in deadlocks or access violation errors. If the DLL is linked with the C runtime library (CRT), it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cswsock10.h`

Import Library: `cswskv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

See Also

InetIsAddressNull Function

```
BOOL WINAPI InetIsAddressNull(  
    LPINTERNET_ADDRESS lpAddress  
);
```

The **InetIsAddressNull** function determines if the IP address is null.

Parameters

lpAddress

A pointer to an INTERNET_ADDRESS structure that contains the address to check.

Return Value

If the function succeeds and the IP address is null, or the *lpAddress* parameter is a NULL pointer, the return value is non-zero. If the function fails or the address is not null, the return value is zero. If the address family is not supported, the last error code will be updated. If the address is valid but not null, the last error code will be set to NO_ERROR.

Remarks

A null IP address is one where all bits for the address (32 bits for IPv4 or 128 bits for IPv6) are zero. This is a special address that is typically used when creating a passive socket that should listen for connections on all available network interfaces.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

See Also

[InetGetAddress](#), [InetIsAddressRoutable](#), [INTERNET_ADDRESS](#)

InetIsAddressRoutable Function

```
BOOL WINAPI InetIsAddressRoutable(  
    LPINTERNET_ADDRESS lpAddress  
);
```

The **InetIsAddressRoutable** function determines if the IP address is routable over the Internet.

Parameters

lpAddress

A pointer to an INTERNET_ADDRESS structure that contains the address to check. This parameter cannot be NULL.

Return Value

If the function succeeds and the IP address is routable over the Internet, the return value is non-zero. If the function fails or the address is not routable, the return value is zero. If the parameter is NULL, or the address family is not supported, the last error code will be updated. If the address is valid but not routable, the last error code will be set to NO_ERROR.

Remarks

A routable IP address is one that can be reached by anyone over the public Internet. These are also commonly referred to as "public addresses" which are typically assigned to networks and individual hosts by an Internet service provider. There are also certain addresses that are not routable over the Internet, and used to address systems over a local network or private intranet. This function can be used to determine if a given IP address is public (routable) or private.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

See Also

InetIsBlocking Function

```
BOOL WINAPI InetIsBlocking(  
    SOCKET hSocket  
);
```

The **InetIsBlocking** function is used to determine if the socket is performing a blocking operation.

Parameters

hSocket

Socket handle.

Return Value

If the socket is currently performing a blocking operation, the function returns a non-zero value. If the socket is not performing a blocking operation, or the socket handle is invalid, the function returns zero.

Remarks

This function is typically used to determine if an open socket that is being used by another thread is currently blocked. A socket may block when waiting to receive data from a remote host or while data is actively being exchanged. Because there can only be one blocking socket operation per thread, this function can be used to determine if a function such as **InetRead** or **InetWrite** would fail because another thread is currently sending or receiving data on that socket. This socket handle that is passed to this function does not need to be owned by the current thread.

It is important to note that if this function returns a non-zero value, it does not guarantee that a subsequent read or write on the socket will succeed. The application should always check the return value from functions such as **InetRead** and **InetWrite** to ensure they were successful.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cswsock10.h`

Import Library: `cswskv10.lib`

See Also

InetIsClosed Function

```
BOOL WINAPI InetIsClosed(  
    SOCKET hSocket  
);
```

The **InetIsClosed** function is used to determine if the remote host has closed its socket.

Parameters

hSocket

Socket handle.

Return Value

If the remote host has closed its socket, the function returns a non-zero value. If the remote host has not closed its connection, or the socket handle is invalid, the function returns zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

See Also

[InetIsConnected](#), [InetIsListening](#), [InetIsReadable](#), [InetIsWritable](#)

InetIsConnected Function

```
BOOL WINAPI InetIsConnected(  
    SOCKET hSocket  
);
```

The **InetIsConnected** function is used to determine if the socket is currently connected to a remote host.

Parameters

hSocket

Socket handle.

Return Value

If the socket is connected to a remote host, the function returns a non-zero value. If the socket is not connected, or the socket handle is invalid, the function returns zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cswsock10.h`

Import Library: `cswskv10.lib`

See Also

[InetIsClosed](#), [InetIsListening](#), [InetIsReadable](#), [InetIsWritable](#)

InetIsListening Function

```
BOOL WINAPI InetIsListening(  
    SOCKET hSocket  
);
```

The **InetIsListening** function determines if the socket is listening for connection requests.

Parameters

hSocket

Socket handle.

Return Value

If the socket is being used to listen for connection requests, the function returns a non-zero value. If the socket is not listening or the socket handle is invalid, the function returns zero.

Remarks

The **InetIsListening** function determines if the socket is being used in a server application to actively listen for incoming connection requests from client applications. A listening socket can be created using either the **InetAsyncListen** or **InetListen** functions.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

See Also

[InetAsyncListen](#), [InetIsReadable](#), [InetIsWritable](#), [InetIsConnected](#), [InetListen](#)

InetIsProtocolAvailable Function

```
BOOL WINAPI InetIsProtocolAvailable(  
    INT nAddressFamily,  
    INT nProtocol  
);
```

The **InetIsProtocolAvailable** function determines if the operating system supports creating a socket for the specified address family and protocol.

Parameters

nAddressFamily

An integer which identifies the address family that should be checked. It should be one of the following values:

Constant	Description
INET_ADDRESS_IPV4	Specifies that the function should determine if it can create an Internet Protocol version 4 (IPv4) socket. This requires that the system have an IPv4 TCP/IP stack bound to at least one network adapter on the local system. All Windows systems include support for IPv4 by default.
INET_ADDRESS_IPV6	Specifies that the function should determine if it can create an Internet Protocol version 6 (IPv6) socket. This requires that the system have an IPv6 TCP/IP stack bound to at least one network adapter on the local system. Windows XP and Windows Server 2003 includes support for IPv6, however it is not installed by default. Windows Vista and later versions include support for IPv6 and enable it by default.

nProtocol

An integer which identifies the protocol that should be checked. It should be one of the following values:

Constant	Description
INET_PROTOCOL_TCP	Specifies the Transmission Control Protocol. This protocol provides a reliable, bi-directional byte stream. This requires that the system be capable of creating a stream socket using the specified address family.
INET_PROTOCOL_UDP	Specifies the User Datagram Protocol. This protocol is message oriented, sending data in discrete packets. This requires that the system be capable of creating a datagram socket using the specified address family.

Return Value

If the the system is capable of creating a socket using the specified address family and protocol, this function will return a non-zero value. If the combination of address family and protocol is not supported, this function will return a value of zero.

Remarks

The **InetIsProtocolAvailable** function is used to determine if the operating system supports creating a particular type of socket. Typically it is used by an application to determine if the system has an IPv6 TCP/IP stack installed and configured. By default, all Windows systems will have an IPv4 stack installed if the system has a network adapter. However, not all systems may have an IPv6 stack installed, particularly older Windows XP and Windows Server 2003 systems. Note that if an IPv6 stack is not installed, the library will not recognize IPv6 addresses and cannot resolve host names that only have an IPv6 (AAAA) record, even if the address or host name is valid.

Example

```
if (!InetIsProtocolAvailable(INET_ADDRESS_IPV6, INET_PROTOCOL_TCP))
{
    AfxMessageBox(_T("This system does not support IPv6"), MB_ICONEXCLAMATION);
    return;
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

See Also

[InetAddress](#), [InetGetHostAddress](#), [InetGetHostName](#)

InetIsReadable Function

```
BOOL WINAPI InetIsReadable(  
    SOCKET hSocket,  
    DWORD dwTimeout,  
    LPDWORD lpdwAvail  
);
```

The **InetIsReadable** function is used to determine if data is available to be read from the socket.

Parameters

hSocket

Socket handle.

dwTimeout

Timeout value in milliseconds. If the socket cannot be read within this time period, the function will return a value of zero. A timeout value of zero specifies that the socket should be polled without blocking the current thread.

lpdwAvail

A pointer to an unsigned integer which will contain the number of bytes available to read.

Return Value

If the current thread can read data from the socket without blocking, the function returns a non-zero value. If the current thread cannot read any data without blocking, the function returns zero.

Remarks

On some platforms, the value returned in *lpdwAvail* will not exceed the size of the receive buffer (typically 64K bytes). Because of differences between TCP/IP stack implementations, it is not recommended that your application exclusively depend on this value to determine the exact number of bytes available. Instead, it should be used as a general indicator that there is data available to be read.

If the connection is secure, the value returned in *lpdwAvail* will reflect the number of bytes available in the encrypted data stream. The actual amount of data available to the application after it has been decrypted will vary.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cswsock10.h`

Import Library: `cswskv10.lib`

See Also

[InetIsClosed](#), [InetIsWritable](#), [InetPeek](#), [InetRead](#), [InetReadLine](#), [InetReadStream](#)

InetIsUrgent Function

```
BOOL WINAPI InetIsUrgent(  
    SOCKET hSocket  
);
```

The **InetIsUrgent** function determines if there is any out-of-band (OOB) data available to be read.

Parameters

hSocket

Handle to the socket.

Return Value

If there is out-of-band data, the return value is non-zero. If there is no out-of-band data, or an error occurs the return value is zero. To determine if an error has occurred, use the **InetGetLastError** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cswsock10.h`

Import Library: `cswskv10.lib`

See Also

[InetSetOption \(INET_OPTION_INLINE\)](#)

InetIsWritable Function

```
BOOL WINAPI InetIsWritable(  
    SOCKET hSocket,  
    DWORD dwTimeout  
);
```

The **InetIsWritable** function is used to determine if data can be written to the socket.

Parameters

hSocket

Socket handle.

dwTimeout

Timeout value in milliseconds. If the socket cannot be written to within this time period, the function will return a value of zero. A timeout value of zero specifies that the socket should be polled without blocking the current thread.

Return Value

If the current thread can write data to the socket within the timeout period, the function returns a non-zero value. The function will return zero if the socket send buffer is full.

Remarks

The **InetIsWritable** function cannot be used to determine the amount of data that can be sent to the remote host without blocking the current thread. A non-zero return value only indicates that the send buffer is not full and can accept some data. In most cases, it is recommended that larger blocks of data be broken into smaller logical blocks rather than attempting to send it all of the data at once. For very large streams of data, it is recommended that you use the **InetWriteStream** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cssock10.h`

Import Library: `cswskv10.lib`

See Also

[InetIsReadable](#), [InetWrite](#), [InetWriteLine](#), [InetWriteStream](#)

InetListen Function

```
SOCKET WINAPI InetListen(  
    LPCTSTR lpszLocalAddress,  
    UINT nLocalPort  
);
```

The **InetListen** function creates a passive socket used to listen for connections from a client application.

This function is included for backwards compatibility with legacy applications. New projects should use the **InetServerStart** function to create a server application.

Parameters

lpszLocalAddress

A pointer to a string which specifies the local IP address that the socket should be bound to. If this parameter is NULL or points to an empty string, a client may establish a connection using any valid network interface configured on the local system. If an address is specified, then a client may only establish a connection with the system using that address.

nLocalPort

The local port number that the socket should be bound to. This value must be greater than zero. Port numbers less than 1024 are considered reserved ports and may require that the process execute with administrative privileges and/or require changes to the default firewall rules to permit inbound connections.

Return Value

If the function succeeds, the return value is a socket handle. If the function fails, the return value is INVALID_SOCKET. To get extended error information, call **InetGetLastError**.

Remarks

To listen for connections on any suitable IPv4 interface, specify the special dotted-quad address "0.0.0.0". You can accept connections from clients using either IPv4 or IPv6 on the same socket by specifying the special IPv6 address "::0", however this is only supported on Windows 7 and Windows Server 2008 R2 or later platforms. If no local address is specified, then the server will only listen for connections from clients using IPv4. This behavior is by design for backwards compatibility with systems that do not have an IPv6 TCP/IP stack installed.

The socket option INET_OPTION_REUSEADDRESS is enabled by default when calling the **InetListen** function. This allows an application to re-use a local address and port number when creating the listening socket. If this behavior is not desired, use the **InetListenEx** function instead.

If an IPv6 address is specified as the local address, the system must have an IPv6 stack installed and configured, otherwise the function will fail.

After the listening socket has been created, the application should then call the **InetAccept** function to wait for a client to establish a connection. For servers that need to handle multiple simultaneous client connections, it is recommended that the asynchronous functions be used.

Example

```
SOCKET hServer = INVALID_SOCKET;  
LPCTSTR lpszAddress = _T("192.168.0.48");  
  
// Accept connections from clients that connect to
```

```
// address 192.168.0.48 on port 7000

hServer = InetListen(lpszAddress, 7000);
if (hServer == INVALID_SOCKET)
{
    DWORD dwError;
    TCHAR szError[256];

    dwError = InetGetLastError();
    InetGetErrorString(dwError, szError, 256);

    MessageBox(NULL, szError, NULL, MB_OK|MB_TASKMODAL);
    return;
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cswsock10.h

Import Library: cswskv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[InetAccept](#), [InetAddress](#), [InetEnableEvents](#), [InetInitialize](#), [InetListenEx](#), [InetReject](#), [InetServerStart](#)

InetListenEx Function

```
SOCKET WINAPI InetListenEx(  
    LPCTSTR lpszLocalAddress,  
    UINT nLocalPort,  
    UINT nBackLog,  
    DWORD dwOptions  
);
```

The **InetListenEx** function creates a passive socket, and specifies the maximum number of connection requests that will be queued.

Parameters

lpszLocalAddress

A pointer to a string which specifies the local IP address that the socket should be bound to. If this parameter is NULL or points to an empty string, a client may establish a connection using any valid network interface configured on the local system. If an address is specified, then a client may only establish a connection with the system using that address.

nLocalPort

The local port number that the socket should be bound to. This value must be greater than zero. Port numbers less than 1024 are considered reserved ports and may require that the process execute with administrative privileges and/or require changes to the default firewall rules to permit inbound connections.

nBacklog

The maximum length of the queue allocated for pending client connections. A value of zero specifies that the size of the queue should be set to a maximum reasonable value. On Windows server platforms, the maximum value is large enough to queue several hundred pending connections.

dwOptions

An unsigned integer used to specify one or more socket options. The following values are supported:

Constant	Description
INET_OPTION_NONE	No option specified. If the address and port number are in use by another application or a closed socket which was listening on this port is still in the TIME_WAIT state, the function will fail.
INET_OPTION_REUSEADDRESS	This option specifies the local address can be reused. This option enables a server application to listen for connections using the specified address and port number even if they were in use recently. This is typically used to enable an application to close the listening socket and immediately reopen it without getting an error that the address is in use.
INET_OPTION_EXCLUSIVE	This option specifies the local address and port number is for the exclusive use by the current process, preventing another application from forcibly binding to the same address. If another process has

	already bound a socket to the address provided by the caller, this function will fail.
INET_OPTION_RESERVEDPORT	This option specifies the listening socket should be bound to an unused port number less than 1024, which is typically reserved for well-known system services. If this option is specified, the process may require administrative privileges and firewall rules that will permit a client to establish a connection with the service.

Return Value

If the function succeeds, the return value is a socket handle. If the function fails, the return value is `INVALID_SOCKET`. To get extended error information, call **InetGetLastError**.

Remarks

To listen for connections on any suitable IPv4 interface, specify the special dotted-quad address "0.0.0.0". You can accept connections from clients using either IPv4 or IPv6 on the same socket by specifying the special IPv6 address "::0", however this is only supported on Windows 7 and Windows Server 2008 R2 or later platforms. If no local address is specified, then the server will only listen for connections from clients using IPv4. This behavior is by design for backwards compatibility with systems that do not have an IPv6 TCP/IP stack installed.

If the `INET_OPTION_REUSEADDRESS` option is not specified, an error may be returned if a listening socket was recently created for the same local address and port number. By default, once a listening socket is closed there is a period of time that all applications must wait before the address can be reused (this is called the `TIME_WAIT` state). The actual amount of time depends on the operating system and configuration parameters, but is typically two to four minutes. Specifying this option enables an application to immediately re-use a local address and port number that was previously in use. Note that this does not permit more than one server to bind to the same address.

If the `INET_OPTION_EXCLUSIVE` option is specified, the local address and port number cannot be used by another process until the listening socket is closed. This can prevent another application from forcibly binding to the same listening address as your server. This option can be useful in determining whether or not another process is already bound to the address you wish to use, but it may also prevent your server application from restarting immediately, regardless if the `INET_OPTION_REUSEADDRESS` option has also been specified.

If an IPv6 address is specified as the local address, the system must have an IPv6 stack installed and configured, otherwise the function will fail.

After the listening socket has been created, the application should then call the **InetAccept** or **InetAcceptEx** function to wait for a client to establish a connection. For servers that need to handle multiple simultaneous client connections, it is recommended that the asynchronous functions be used.

To enable asynchronous event notification, use the **InetEnableEvents** function.

Example

```
SOCKET hServer = INVALID_SOCKET;
LPCTSTR lpszAddress = _T("192.168.0.48");

// Accept connections from clients that connect to
```

```
// address 192.168.0.48 on port 7000 with a standard
// backlog of 5 connections

hServer = InetListenEx(lpszAddress,
                      7000,
                      INET_BACKLOG,
                      INET_OPTION_REUSEADDRESS);

if (hServer == INVALID_SOCKET)
{
    DWORD dwError;
    TCHAR szError[256];

    dwError = InetGetLastError();
    InetGetErrorString(dwError, szError, 256);

    MessageBox(NULL, szError, NULL, MB_OK|MB_TASKMODAL);
    return;
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cssock10.h

Import Library: cssock10.lib

Unicode: Implemented as Unicode and ANSI versions.

[InetAddress](#), [InetListen](#)

InetMatchHostName Function

```
BOOL WINAPI InetMatchHostName(  
    LPCTSTR lpszHostName,  
    LPCTSTR lpszHostMask  
    BOOL bResolve  
);
```

The **InetMatchHostName** function matches a host name against one or more strings that may contain wildcards.

Parameters

lpszHostName

A pointer to a string which specifies the host name or IP address to match.

lpszHostMask

A pointer to a string which specifies one or more values to match against the host name. The asterisk character can be used to match any number of characters in the host name, and the question mark can be used to match any single character. Multiple values may be specified by separating them with a semicolon.

bResolve

A boolean value which specifies if the host name or IP address should be resolved when matching the host against the mask string. If this parameter is non-zero, two checks against the host mask string will be performed; once for the host name specified and once for its IP address. If this parameter is zero, then the match is made only against the host name string provided.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **InetGetLastError**.

Remarks

The **InetMatchHostName** function provides a convenient way for an application to determine if a given host name matches one or more mask strings which may contain wildcard characters. For example, the host name could be "www.microsoft.com" and the host mask string could be "*.microsoft.com". In this example, the function would return a non-zero value indicating the host name matched the mask. However, if the mask string was "*.net" then the function would return zero, indicating that there was no match. Multiple mask values can be combined by separating them with a semicolon; for example, the mask "*.com;*.org" would match any host name in either the .com or .org top-level domains.

If an internationalized domain name (IDN) is specified, it will be converted internally to an ASCII string using Punycode encoding. The host mask will be matched against this encoded version of the host name, not its Unicode version.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

Unicode: Implemented as Unicode and ANSI versions.

InetNormalizeHostName Function

```
INT WINAPI InetNormalizeHostName(  
    LPCTSTR lpszHostName,  
    LPTSTR lpszNormalized,  
    INT nMaxLength  
);
```

The **InetNormalizeHostName** function returns the canonical form of a host name in the specified buffer.

Parameters

lpszHostName

Pointer to the host name as a null-terminated string. This parameter cannot be a NULL pointer or a zero length string.

lpszNormalized

Pointer to the string buffer that will contain the canonical form of the host name, including the terminating null character. It is recommended that this buffer be at least 256 characters in size. This parameter cannot be a NULL pointer.

nMaxLength

The maximum number of characters that can be copied to the *lpszNormalized* string buffer. This parameter cannot be zero, and must include the terminating null character.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer. If the function fails, the return value is INET_ERROR. To get extended error information, call **InetGetLastError**.

Remarks

The **InetNormalizeHostName** function will remove all leading and trailing whitespace characters from the host name and fold all upper-case characters to lower-case. If an internationalized domain name (IDN) containing Unicode characters is passed to this function, it will be converted to an ASCII compatible format for domain names.

If the Unicode version of this function is used, the host name will be converted from UTF-16 to UTF-8 and then processed. If you are unsure if an internationalized domain name will be specified as the host name, it is recommended that you use the Unicode version.

Although this function performs checks to ensure that the *lpszHostName* parameter is in the correct format and does not contain any illegal characters or malformed encoding, it does not validate the existence of the domain name. To check if the host name exists and has a valid IP address, use the [InetGetHostAddress](#) function.

It is recommended that you use this function if your application needs to store the host name, and if accepts a host name as user input. It is not necessary to call this function prior to calling the other INET API functions that accept a host name as a parameter. Those functions already normalize the host name and perform checks to ensure it is in the correct format.

If the *lpszHostName* parameter specifies a valid IPv4 or IPv6 address string instead of a host name, this function will return a copy of that IP address in the buffer provided by the caller. This allows the function to be used in cases where a user may input either a host name or IP address. To determine if the IP address has a corresponding host name, use the [InetGetHostName](#) method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cswsock10.h

Import Library: cswskv10.lib

Unicode: Implemented as Unicode and ANSI versions.

InetPeek Function

```
INT WINAPI InetPeek(  
    SOCKET hSocket,  
    LPBYTE lpBuffer,  
    INT cbBuffer  
);
```

The **InetPeek** function reads the specified number of bytes from the socket and copies them into the buffer, but it does not remove the data from the internal socket buffer. The data may be of any type, and is not terminated with a null character.

Parameters

hSocket

The socket handle.

lpBuffer

Pointer to the buffer in which the data will be copied. This argument may be NULL, in which case no data is copied from the socket buffers, however the function will return the number of bytes available to read.

cbBuffer

The maximum number of bytes to read and copy into the specified buffer. If the *lpBuffer* parameter is not NULL, this value must be greater than zero.

Return Value

If the function succeeds, the return value is the number of bytes available to read from the socket. A return value of zero indicates that there is no data available to read at that time. If the function fails, the return value is INET_ERROR. To get extended error information, call **InetGetLastError**.

Remarks

The **InetPeek** function returns data that is available to read from the socket, up to the number of bytes specified. The data returned by this function is not removed from the socket buffers. It must be consumed by a subsequent call to the **InetRead** or **InetReadEx** function. The return value indicates the number of bytes that can be read in a single operation, up to the specified buffer size. However, it is important to note that it may not indicate the total amount of data available to be read from the socket at that time.

If no data is available to be read, the method will return a value of zero. Using this method in a loop to poll a non-blocking socket may cause the application to become non-responsive. To determine if there is data available to be read, use the **InetIsReadable** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

See Also

[InetFlush](#), [InetRead](#), [InetReadEx](#), [InetWrite](#), [InetWriteEx](#)

InetRead Function

```
INT WINAPI InetRead(  
    SOCKET hSocket,  
    LPBYTE lpBuffer,  
    INT cbBuffer  
);
```

The **InetRead** function reads the specified number of bytes from the socket and copies them into the buffer. The data may be of any type, and is not terminated with a null character.

Parameters

hSocket

The socket handle.

lpBuffer

Pointer to the buffer in which the data will be copied.

cbBuffer

The maximum number of bytes to read and copy into the specified buffer. This value must be greater than zero.

Return Value

If the function succeeds, the return value is the number of bytes actually read. A return value of zero indicates that the remote host has closed the connection and there is no more data available to be read. If the function fails, the return value is `INET_ERROR`. To get extended error information, call **InetGetLastError**.

Remarks

The **InetRead** function will read up to the specified number of bytes and store the data in the buffer provided by the caller. If there is no data available to be read at the time this function is called, the current thread will block until at least one byte of data becomes available, the timeout period elapses or an error occurs. This function will return if any amount of data is sent by the remote host, and will not block until the entire buffer has been filled. To avoid blocking the current thread, either create an asynchronous socket or use the **InetIsReadable** function to determine if there is data available to be read prior to calling this function.

The application should never make an assumption about the amount of data that will be available to read. TCP considers all data to be an arbitrary stream of bytes and does not impose any structure on the data itself. For example, if the remote host is sending data to the server in fixed 512 byte blocks of data, it is possible that a single call to the **Read** function will return only a partial block of data, or it may return multiple blocks combined together. It is the responsibility of the application to buffer and process this data appropriately.

For applications that are built using the Unicode character set, it is important to note that the buffer is an array of bytes, not characters. If the remote host is writing string data to the socket, it must be read as a stream of bytes and converted using the **MultiByteToWideChar** function. If the remote host is sending lines of text terminated with a linefeed or carriage return and linefeed pair, the **InetReadLine** function will return a line of text at a time and perform this conversion for you.

When **InetRead** is called and the socket is in non-blocking mode, it is possible that the function will fail because there is no available data to read at that time. This should not be considered a

fatal error. Instead, the application should simply wait to receive the next asynchronous notification that data is available.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cswsock10.h`

Import Library: `cswskv10.lib`

See Also

[InetIsReadable](#), [InetPeek](#), [InetReadEx](#), [InetWrite](#), [InetWriteEx](#)

InetReadEx Function

```
INT WINAPI InetReadEx(  
    SOCKET hSocket,  
    LPVOID LpvBuffer,  
    INT cbBuffer,  
    DWORD dwReserved,  
    LPINTERNET_ADDRESS LpRemoteAddress,  
    UINT * LpnRemotePort  
);
```

The **InetReadEx** function reads the specified number of bytes from the socket and copies them into the buffer. The data may be of any type, and is not terminated with a null character.

Parameters

hSocket

The socket handle.

lpvBuffer

Pointer to the buffer in which the data will be copied.

cbBuffer

The maximum number of bytes to read and copy into the specified buffer. This value must be greater than zero.

dwReserved

Reserved parameter. This value must always be zero.

lpRemoteAddress

Pointer to an [INTERNET_ADDRESS](#) structure which will contain the IP address of the remote host that sent the data being read. If this information is not required, the parameter may be specified as NULL.

lpnRemotePort

Pointer to an unsigned integer which will contain the remote port number. If this information is not required, the parameter may be specified as NULL.

Return Value

If the function succeeds, the return value is the number of bytes actually read. A return value of zero indicates that the remote host has closed the connection and there is no more data available to be read. If the function fails, the return value is `INET_ERROR`. To get extended error information, call **InetGetLastError**.

Remarks

When **InetReadEx** is called and the socket is in non-blocking mode, it is possible that the function will fail because there is no available data to read at that time. This should not be considered a fatal error. Instead, the application should simply wait to receive the next asynchronous notification that data is available.

This function extends the **InetRead** function to return additional information about the peer who sent the data being received. For a client TCP socket, the IP address and remote port are the same values that were used to establish the connection. For a server TCP socket, it is the IP address and port number of the client which sent the data. When reading data from a UDP socket, this is the IP address and remote port of the peer that sent the datagram. This information can be used in

conjunction with the **InetWriteEx** function to send a datagram back to that host.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cssock10.h`

Import Library: `cswskv10.lib`

InetReadLine Function

```
BOOL WINAPI InetReadLine(  
    SOCKET hSocket,  
    LPTSTR lpszBuffer,  
    LPINT lpnLength  
);
```

The **InetReadLine** function reads up to a line of data from the socket and returns it in a string buffer.

Parameters

hSocket

The socket handle. The socket must reference a stream socket, not a datagram or raw socket. If the socket type is not valid, the function will return an error.

lpszBuffer

Pointer to the string buffer that will contain the data when the function returns. The string will be terminated with a null byte, and will not contain the end-of-line characters.

lpnLength

A pointer to an integer value which specifies the length of the buffer. The value should be initialized to the maximum number of characters that can be copied into the string buffer, including the terminating null character. When the function returns, its value will updated with the actual length of the string.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **InetGetLastError**.

Remarks

The **InetReadLine** function reads data from the socket and copies into a specified string buffer. Unlike the **InetRead** function which reads arbitrary bytes of data, this function is specifically designed to return a single line of text data in a null-terminated string. When an end-of-line character sequence is encountered, the function will stop and return the data up to that point. The string buffer is guaranteed to be null-terminated and will not contain the end-of-line characters.

There are some limitations when using **InetReadLine**. The function should only be used to read text, never binary data. In particular, the function will discard nulls, linefeed and carriage return control characters. The Unicode version of this function will return a Unicode string, however this function does not support reading raw Unicode data from the socket. Any data read from the socket is internally buffered as octets (eight-bit bytes) and converted to Unicode using the **MultiByteToWideChar** function.

This function will force the thread to block until an end-of-line character sequence is processed, the read operation times out or the remote host closes its end of the socket connection. If this function is called with asynchronous events enabled, it will automatically switch the socket into a blocking mode, read the data and then restore the socket to asynchronous operation. If another socket operation is attempted while **InetReadLine** is blocked waiting for data from the remote host, an error will occur. It is recommended that this function only be used with blocking (synchronous) socket connections; if the application needs to establish multiple simultaneous connections, it should create worker threads to manage each connection.

The **InetRead** and **InetReadLine** function calls can be intermixed, however be aware that **InetRead** will consume any data that has already been buffered by the **InetReadLine** function and this may have unexpected results.

Unlike the **InetRead** function, it is possible for data to be returned in the buffer even if the return value is zero. Applications should also check the value of the *lpnLength* argument to determine if any data was copied into the buffer. For example, if a timeout occurs while the function is waiting for more data to arrive on the socket, it will return zero; however, data may have already been copied into the string buffer prior to the error condition. It is the responsibility of the application to process that data, regardless of the function return value.

Example

```
TCHAR szBuffer[MAXBUFLEN];
INT nLength;
BOOL bResult;

do
{
    nLength = sizeof(szBuffer);
    bResult = InetReadLine(hSocket, szBuffer, &nLength);

    if (nLength > 0)
    {
        // Process the line of data returned in the string
        // buffer; the string is always null-terminated
    }
} while (bResult);

DWORD dwError = InetGetLastError();
if (dwError == ST_ERROR_CONNECTION_CLOSED)
{
    // The remote host has closed its side of the connection and
    // there is no more data available to be read
}
else if (dwError != 0)
{
    // An error has occurred while reading a line of data
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cswskv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[InetIsReadable](#), [InetRead](#), [InetWrite](#), [InetWriteLine](#)

InetReadStream Function

```
BOOL WINAPI InetReadStream(  
    SOCKET hSocket,  
    LPVOID lpvBuffer,  
    LPDWORD lpdwLength,  
    DWORD dwOptions,  
    LPBYTE lpMarker,  
    DWORD cbMarker,  
    DWORD dwReserved  
);
```

The **InetReadStream** function reads the socket data stream and stores the contents in the specified buffer.

Parameters

hSocket

The socket handle. The socket must reference a stream socket, not a datagram or raw socket. If the socket type is not valid, the function will return an error.

lpvBuffer

Pointer to the buffer that will contain or reference the data when the function returns. The actual argument depends on the value of the **dwOptions** parameter which specifies how the data stream will be stored.

lpdwLength

A pointer to an unsigned integer value which specifies the maximum length of the buffer and contains the number of bytes read when the function returns. This argument should always point to an initialized value. If the *lpvBuffer* argument specifies a memory buffer, then this argument cannot point to an initialized value of zero; if any other type of stream buffer is used and the initialized value is zero, that indicates that all available data from the socket should be returned until the end-of-stream marker is encountered or the remote host disconnects.

dwOptions

An unsigned integer value which specifies both the stream buffer type and any options to be used when reading the data stream. One of the following stream types may be specified:

Constant	Description
INET_STREAM_DEFAULT	The default stream buffer type is determined by the value passed as the <i>lpvBuffer</i> parameter. If the argument specifies a pointer to a global memory handle initialized to NULL, then the function will return a handle which references the data; otherwise, the function will consider the parameter a pointer to a block of pre-allocated memory which will contain the stream data when the function returns. In most cases, it is recommended that an application explicitly specify the stream buffer type rather than using the default value.
INET_STREAM_MEMORY	The <i>lpvBuffer</i> argument specifies a pointer to a pre-allocated block of memory which will contain the data read from the socket when the function

	returns. If this stream buffer type is used, the <i>lpdwLength</i> argument must point to an unsigned integer which has been initialized with the maximum length of the buffer.
INET_STREAM_HGLOBAL	The <i>lpvBuffer</i> argument specifies a pointer to a global memory handle. When the function returns, the handle will reference a block of memory that contains the stream data. The application should take care to make sure that the handle passed to the function does not currently reference a valid block of memory; it is recommended that the handle be initialized to NULL prior to calling this function.
INET_STREAM_HANDLE	The <i>lpvBuffer</i> argument specifies a Windows handle to an open file, console or pipe. This should be the same handle value returned by the CreateFile function in the Windows API. The data read from the socket will be written to this handle using the WriteFile function.
INET_STREAM_SOCKET	The <i>lpvBuffer</i> argument specifies a socket handle. The data read from the socket specified by the <i>hSocket</i> argument will be written to this socket. The socket handle passed to this function must have been created by this library; if it is a socket created by an third-party library or directly by the Windows Sockets API, you should either attach the socket using the InetAttachSocket function or use the INET_STREAM_HANDLE stream buffer type instead.

In addition to the stream buffer types listed above, the *dwOptions* parameter may also have one or more of the following bit flags set. Programs should use a bitwise operator to combine values.

Constant	Description
INET_STREAM_CONVERT	The data stream is considered to be textual and will be modified so that end-of-line character sequences are converted to follow standard Windows conventions. This will ensure that all lines of text are terminated with a carriage-return and linefeed sequence. Because this option modifies the data stream, it should never be used with binary data. Using this option may result in the amount of data returned in the buffer to be larger than the source data. For example, if the source data only terminates a line of text with a single linefeed, this option will have the effect of inserting a carriage-return character before each linefeed.

INET_STREAM_UNICODE	The data stream should be converted to Unicode. This option should only be used with text data, and will result in the stream data being returned as 16-bit wide characters rather than 8-bit bytes. The amount of data returned will be twice the amount read from the source data stream; if the application is using a pre-allocated memory buffer, this must be considered before calling this function.
---------------------	--

lpMarker

A pointer to an array of bytes which marks the end of the data stream. When this byte sequence is encountered by the function, it will stop reading and return to the caller. The buffer will contain all of the data read from the socket up to and including the end-of-stream marker. If this argument is NULL, then the function will continue to read from the socket until the maximum buffer size is reached, the remote host closes its socket or an error is encountered.

cbMarker

An unsigned integer value which specifies the length of the end-of-stream marker in bytes. If the *lpMarker* parameter is NULL, then this value must be zero.

dwReserved

A reserved parameter. This value must always be zero.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **InetGetLastError**.

Remarks

The **InetReadStream** function enables an application to read an arbitrarily large stream of data and store it in memory, write it to a file or even another socket. Unlike the **InetRead** method, which will return immediately when any amount of data has been read, **InetReadStream** will only return when the buffer is full as specified by the *lpdwLength* parameter, the logical end-of-stream marker has been read, the socket closed by the remote host or when an error occurs.

This function will force the thread to block until the operation completes. If this function is called with asynchronous events enabled, it will automatically switch the socket into a blocking mode, read the data stream and then restore the socket to asynchronous operation when it has finished. If another socket operation is attempted while **InetReadStream** is blocked waiting for data from the remote host, an error will occur. It is recommended that this function only be used with blocking (synchronous) socket connections; if the application needs to establish multiple simultaneous connections, it should create worker threads to manage each connection.

It is possible for data to be returned in the buffer even if the function returns a value of zero. Applications should also check the value of the *lpdwLength* argument to determine if any data was copied into the buffer. For example, if a timeout occurs while the function is waiting for more data to arrive on the socket, it will return zero; however, data may have already been copied into the buffer prior to the error condition. It is the responsibility of the application to process that data, regardless of the function return value.

Because **InetReadStream** can potentially cause the application to block for long periods of time as the data stream is being read, the function will periodically generate INET_EVENT_PROGRESS events. An application can register an event handler using the **InetRegisterEvent** function, and can obtain information about the current operation by calling the **InetGetStreamInfo** function.

Example

```
HGLOBAL hgblBuffer = NULL; // Return data in a global memory buffer
DWORD cbBuffer = 102400; // Read up to 100K bytes
BOOL bResult;

bResult = InetReadStream(hSocket,
                        &hgblBuffer,
                        &cbBuffer,
                        INET_STREAM_HGLOBAL | INET_STREAM_CONVERT,
                        NULL, 0, 0);

if (bResult && cbBuffer > 0)
{
    LPBYTE lpBuffer = (LPBYTE)GlobalLock(hgblBuffer);

    // Use data in the stream buffer

    GlobalUnlock(hgblBuffer);
    GlobalFree(hgblBuffer);
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cswsock10.h

Import Library: cswskv10.lib

See Also

InetRegisterEvent Function

```
INT WINAPI InetRegisterEvent(  
    SOCKET hSocket,  
    UINT nEventId,  
    INETEVENTPROC LpEventProc,  
    DWORD_PTR dwParam  
);
```

The **InetRegisterEvent** function registers a callback function for the specified event.

Parameters

hSocket

Socket handle.

nEventId

An unsigned integer which specifies which event should be registered with the specified callback function. This parameter is ignored if the socket handle specifies a server created using the **InetServerStart** function. One or more of the following values may be used:

Constant	Description
INET_EVENT_ACCEPT	A network event that indicates the process has received a connection request from a client and should accept the connection using the InetAsyncAccept function. This event is only generated for server applications which have created an asynchronous socket using the InetAsyncListen function.
INET_EVENT_CONNECT	A network event that indicates the connection to the remote host has completed.
INET_EVENT_DISCONNECT	A network event that indicates the remote host has closed the connection. The process should read any remaining data and disconnect.
INET_EVENT_READ	A network event which indicates data is available to read. No additional messages will be posted until the process has read at least some of the data from the socket. This event is only generated if the socket is in asynchronous mode.
INET_EVENT_WRITE	A network event which indicates the application can send data to the remote host. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the socket is in asynchronous mode.
INET_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The application may attempt to retry the operation, or may disconnect from the remote host and report an error to the user.
INET_EVENT_CANCEL	The application has canceled a blocking operation. This

event is fired once an operation has been terminated by the InetCancel function, and control has been returned to the calling process.

lpEventProc

Specifies the address of the application defined callback function. For more information about the callback function, see the description of the **InetEventProc** callback function. If this parameter is NULL, the callback for the specified event is disabled. This parameter cannot be NULL if the socket handle specifies a server created using the **InetServerStart** function.

dwParam

A user-defined integer value that is passed to the callback function. If the application targets the x86 (32-bit) platform, this parameter must be a 32-bit unsigned integer. If the application targets the x64 (64-bit) platform, this parameter must be a 64-bit unsigned integer.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is INET_ERROR. To get extended error information, call **InetGetLastError**.

Remarks

The **InetRegisterEvent** function associates a callback function with a specific event. The event handler is an **InetEventProc** function that is invoked when the event occurs. Arguments are passed to the function to identify the client session, the event type and the user-defined value specified when the event handler is registered. If the event occurs because of an error condition, the error code will be provided to the handler.

The callback function specified by the *lpEventProc* parameter must be declared using the **__stdcall** calling convention. This ensures the arguments passed to the event handler are pushed on to the stack in the correct order. Failure to use the correct calling convention will corrupt the stack and cause the application to terminate abnormally.

This function can be used to change the callback function and user defined parameter for a server created using the **InetServerStart** function. However, it cannot be used with client sockets automatically created by the server interface. Those sockets are managed separately in their own thread, and individual client event notifications are not supported.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cswskv10.lib

See Also

[InetDisableEvents](#), [InetEnableEvents](#), [InetEventProc](#), [InetFreezeEvents](#)

InetReject Function

```
BOOL WINAPI InetReject(  
    SOCKET hSocket  
);
```

The **InetReject** function is used to reject a client connection request.

Parameters

hSocket

Handle to a listening socket.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **InetGetLastError**.

Remarks

The **InetReject** function rejects a pending client connection and the remote host will see this as the connection being aborted. If there are no pending client connections at the time, this function will immediately return with an error indicating that the operation would cause the thread to block.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cswsock10.h`

Import Library: `cswskv10.lib`

InetServerAsyncNotify Function

```
BOOL WINAPI InetServerAsyncNotify(  
    SOCKET hServer,  
    HWND hWnd,  
    UINT uMsg  
);
```

Enable or disable asynchronous notification of changes in server status.

Parameters

hServer

The socket handle.

hWnd

A handle to the window whose window procedure will receive the notification message.

uMsg

The user-defined message that will be sent to the notification window.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **InetGetLastError**.

Remarks

The **InetServerAsyncNotify** function is used by an application to enable or disable asynchronous notifications. The message window is typically the main UI window and these notifications are used signal to the application that it should update the user interface. If the *hWnd* parameter is not NULL, it must specify a valid window handle and the user-defined message must have a value of **WM_USER** or higher. The application cannot specify a notification message that is reserved by the operating system. The pseudo-handle **HWND_BROADCAST** cannot be specified as the notification window. If the *hWnd* parameter is NULL, notifications for the specified server will be disabled.

When asynchronous notifications are enabled for a server, the server will post the user-defined message to the window whenever there is a change in status or after a client has connected or disconnected from the server. The *wParam* message parameter will contain the notification message and the *lParam* message parameter will contain the handle to the server or the unique client ID. The following notification messages are defined:

Constant	Description
INET_NOTIFY_STARTUP	This notification is sent when the server has started and is preparing to accept client connections. This notification is only sent once, and only if asynchronous notifications are enabled immediately after the InetServerStart function is called. This message will not be sent once the server has begun accepting client connections or when notification messages are disabled and then subsequently re-enabled at a later time. The <i>lParam</i> message parameter will specify the handle to the server.
INET_NOTIFY_LISTEN	This notification is sent when the server is listening for

	<p>client connections. This notification message may be sent to the application multiple times over the lifetime of the server. If the server was suspended, this notification will be sent after the application calls the InetServerResume function to resume accepting client connections. The <i>lParam</i> message parameter will specify the handle to the server.</p>
INET_NOTIFY_SUSPEND	<p>This notification is sent when the server suspends accepting new connections because the application has called either the InetServerSuspend or InetServerSuspendEx function. This notification message may be sent to the application multiple times over the lifetime of the server. The <i>lParam</i> message parameter will specify the handle to the server.</p>
INET_NOTIFY_RESTART	<p>This notification is sent when the server is restarted using the InetServerRestart function. Note that the server socket handle provided by the <i>lParam</i> message parameter will specify the new socket handle of the restarted server instance, not the original socket handle. The <i>lParam</i> message parameter will specify the handle to the server.</p>
INET_NOTIFY_CONNECT	<p>This notification is sent when the server accepts a client connection and the thread that manages the client session has begun processing network events for that client. This message notification will not be sent if the client connection is rejected by the server. The <i>lParam</i> message parameter will specify the unique ID of the client that connected to the server.</p>
INET_NOTIFY_DISCONNECT	<p>This notification is sent when the client disconnects from the server and the client socket has been closed. This notification message may not occur for each client session that is forced to terminate as the result of the server being stopped using the InetServerStop function. The <i>lParam</i> message parameter will specify the unique ID of the client that disconnected from the server.</p>
INET_NOTIFY_SHUTDOWN	<p>This notification is sent when the server thread is in the process of terminating. At the time the application processes this notification message, the server handle in <i>lParam</i> will reference the defunct server and cannot be used with other server functions. The <i>lParam</i> message parameter will specify the handle to the server.</p>

If asynchronous notifications are enabled, you should never use those notifications as a replacement for an event handler. When an event occurs, the callback function that handles the event is invoked in the context of the thread that manages the client session. The application should exchange data with the client within that event handler and not in response to a notification message. These notification messages should only be used to update the application

UI in response to changes in the status of the server.

The INET_NOTIFY_CONNECT and INET_NOTIFY_DISCONNECT notifications are different from the other server notifications because the *lParam* message parameter does not specify the server handle, but rather the unique client ID associated with the session that connected to or disconnected from the server. If you need to obtain the handle to the client session using the ID, call the **InetGetClientHandle** function. To obtain the server handle in response to the INET_NOTIFY_CONNECT message, use the **InetGetClientServerById** function. Note that at the time the application processes the INET_NOTIFY_DISCONNECT notification message, the client session will have already terminated.

This function can only be used with a handle returned by the **InetServerStart** function and cannot be used with sockets created using the **InetListen** or **InetListenEx** functions.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cswskv10.lib

See Also

[InetGetClientServerById](#), [InetGetServerStatus](#), [InetServerStart](#)

InetServerBroadcast Function

```
INT WINAPI InetServerBroadcast(  
    SOCKET hServer,  
    LPBYTE lpBuffer,  
    INT cbBuffer  
);
```

The **InetServerBroadcast** function sends data to clients that are connected to the specified server.

Parameters

hServer

The socket handle.

lpBuffer

The pointer to the buffer which contains the data that is to be sent to the server clients.

cbBuffer

The number of bytes to send from the specified buffer.

Return Value

If the function succeeds, the return value is the number of clients that the data was sent to. If the function fails, the return value is `INET_ERROR`. To get extended error information, call **InetGetLastError**.

Remarks

The **InetServerBroadcast** function sends the contents of the buffer to all of the clients that are connected to the specified server. This function will block until all clients have been sent a copy of the data. There is no guarantee in which order the clients will receive and process the data that has been broadcast.

This function can only be used with a socket handle created using the **InetServerStart** function and cannot be used with sockets created using the **InetListen** or **InetListenEx** functions.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cssock10.h`

Import Library: `cswskv10.lib`

See Also

[InetClientBroadcast](#), [InetWrite](#), [InetWriteLine](#)

InetServerLock Function

```
BOOL WINAPI InetServerLock(  
    SOCKET hServer  
);
```

The **InetServerLock** function locks the specified server, causing other client threads to block until it is unlocked.

Parameters

hServer

The socket handle to the server.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **InetGetLastError**.

Remarks

The **InetServerLock** function causes the specified server to enter a locked state where only the current thread may interact with the server and the clients that are connected to it. While a server is locked, all other threads will block when they attempt to perform a network operation. When the server is unlocked, the blocked threads will resume normal execution.

This function should be used carefully, and a server should never be left in a locked state for an extended period of time. It is meant to be used when the server process updates a global data structure and it must prevent any other threads from performing a network operation during the update. Only one server can be locked at any one time, and once a server has been locked, it can only be unlocked by the same thread.

The program should always check the return value from this function, and should never assume that the lock has been established. If more than one thread attempts to lock a server at the same time, there is no guarantee as to which thread will actually establish the lock. If a potential deadlock situation is detected, this function will fail and return a value of zero.

Every time the **InetServerLock** function is called, an internal lock counter is incremented, and the lock will not be released until the lock count drops to zero. This means that each call to **InetServerLock** must be matched by an equal number of calls to the **InetServerUnlock** function. Failure to do so will result in the server becoming non-responsive as it remains in a locked state.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cswsock10.h`

Import Library: `cswskv10.lib`

See Also

[InetGetLockedServer](#), [InetServerUnlock](#)

InetServerRestart Function

```
SOCKET WINAPI InetServerRestart(  
    SOCKET hServer  
);
```

The **InetServerRestart** function restarts the server, terminating all active client sessions.

Parameters

hServer

Handle to the server socket.

Return Value

If the function succeeds, the return value is the new socket handle for the specified server. If the function fails, the return value is `INVALID_SOCKET`. To get extended error information, call **InetGetLastError**.

Remarks

The **InetServerRestart** function will restart the specified server, terminating all active client sessions and recreating the listening socket. The socket handle that is returned by the function is the handle for the new listening socket, and the old handle value is no longer valid. If the function is unable to recreate the listening socket for any reason, the server thread is terminated.

The socket handle for the server must be one that was created by calling the **InetServerStart** function, and cannot be a socket that was created using the **InetListen** or **InetListenEx** functions.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cssock10.h`

Import Library: `cswskv10.lib`

See Also

[InetGetServerStatus](#), [InetServerResume](#), [InetServerStart](#), [InetServerStop](#), [InetServerSuspend](#)

InetServerResume Function

```
BOOL WINAPI InetServerResume(  
    SOCKET hServer  
);
```

The **InetServerResume** function resumes accepting client connections on the specified server.

Parameters

hServer

Handle to the server socket.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **InetGetLastError**.

Remarks

The **InetServerResume** function instructs the server to resume accepting client connections. Any pending client connections that were requested while the server was suspended will be accepted.

The socket handle for the server must be one that was created by calling the **InetServerStart** function, and cannot be a socket that was created using the **InetListen** or **InetListenEx** functions.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cswsock10.h`

Import Library: `cswskv10.lib`

See Also

[InetGetServerStatus](#), [InetServerRestart](#), [InetServerStart](#), [InetServerStop](#), [InetServerSuspend](#)

InetServerStart Function

```
SOCKET WINAPI InetServerStart(  
    LPCTSTR lpszLocalHost,  
    UINT nLocalPort,  
    UINT nBacklog,  
    UINT nMaxClients,  
    UINT nTimeout,  
    UINT nPriority,  
    DWORD dwOptions,  
    INETEVENTPROC lpEventProc,  
    DWORD_PTR dwEventParam,  
    LPSECURITYCREDENTIALS lpCredentials  
);
```

The **InetServerStart** function begins listening for client connections on the specified local address and port number. The server is started in its own thread and manages the client sessions independently of the calling thread. All interaction with the server and its client sessions takes place inside the callback function specified by the caller.

Parameters

lpszLocalHost

A pointer to a string which specifies the local hostname or IP address address that the socket should be bound to. If this parameter is NULL or an empty string, then an appropriate address will automatically be used. A specific address should only be used if it is required by the application.

nLocalPort

The local port number that the socket should be bound to. This value must be greater than zero.

nBacklog

The maximum length of the queue allocated for pending client connections. A value of zero specifies that the size of the queue should be set to a maximum reasonable value. On Windows server platforms, the maximum value is large enough to queue several hundred pending connections.

nMaxClients

The maximum number of client connections that can be established with the server. A value of zero specifies that there should not be any fixed limit on the number of active client connections. This value can be adjusted after the server has been created by calling the **InetServerThrottle** function.

nTimeout

The number of seconds the server should wait for a client to perform a network operation. If the client does not exchange any information with the server within this period of time, a timeout event will occur. The timeout value affects all clients that are connected to the server.

nPriority

An integer value which specifies the priority for the server and all client sessions. The priority for a specific client session may be modified by calling the **InetSetClientPriority** function. This parameter may be one of the following values:

Constant	Description
----------	-------------

INET_PRIORITY_NORMAL	The default priority which balances resource and processor utilization. It is recommended that most applications use this priority.
INET_PRIORITY_BACKGROUND	This priority significantly reduces the memory, processor and network resource utilization for the client session. It is typically used with lightweight services running in the background that are designed for few client connections. The client thread will be assigned a lower scheduling priority and will be frequently forced to yield execution to other threads.
INET_PRIORITY_LOW	This priority lowers the overall resource utilization for the client session and meters the processor utilization for the client session. The client thread will be assigned a lower scheduling priority and will occasionally be forced to yield execution to other threads.
INET_PRIORITY_HIGH	This priority increases the overall resource utilization for the client session and the thread will be given higher scheduling priority. It can be used when it is important for the client session thread to be highly responsive. It is not recommended that this priority be used on a system with a single processor.
INET_PRIORITY_CRITICAL	This priority can significantly increase processor, memory and network utilization. The thread will be given higher scheduling priority and will be more responsive to the remote host. It is not recommended that this priority be used on a system with a single processor.

dwOptions

An unsigned integer used to specify one or more socket options. The following values are supported:

Constant	Description
INET_OPTION_NONE	No option specified. If the address and port number are in use by another application or a closed socket which was listening on this port is still in the TIME_WAIT state, the function will fail.
INET_OPTION_REUSEADDRESS	This option specifies the local address can be reused. This option enables a server application to listen for connections using the specified address and port number even if they were in use recently. This is typically used to enable an application to close the listening socket and immediately reopen it without getting an error that the address is in use.
INET_OPTION_KEEPALIVE	This option specifies that packets are to be sent to the remote system when no data is being exchanged to

	keep the connection active. Enabling this option will also help applications detect the physical loss of a network connection, such as an Ethernet cable being unplugged. This option does not guarantee that persistent connections will be maintained over long periods of time.
INET_OPTION_NODELAY	This option disables the Nagle algorithm, which buffers unacknowledged data and combines smaller packets into a single larger packet when sending data to a remote host. Specifying this option can improve the responsiveness and overall throughput of applications that implement their own buffering and exchange large amounts of information.
INET_OPTION_SECURE	This option specifies that a secure connection should be established with the client, where the client immediately initiates the SSL handshake when it connects to the server. To implement an explicit SSL session, where the client establishes a standard, non-secure connection and then sends a command to the server to initiate a secure session, you should not use this option. Instead, use the InetEnableSecurity function to selectively enable SSL for the client session.

lpEventProc

Specifies the address of the application defined callback function. For more information about the callback function, see the description of the **InetEventProc** callback function. This parameter cannot be NULL.

dwEventParam

A user-defined integer value that is passed to the callback function.

lpCredentials

Pointer to credentials structure [SECURITYCREDENTIALS](#). This may be NULL, unless the *dwOptions* parameter includes INET_OPTION_SECURE. When a secure session is specified, the fields *dwSize*, *lpszCertStore*, and *lpszCertName* must be defined, while other fields may be left undefined. Set *dwSize* to the size of the **SECURITYCREDENTIALS** structure.

Return Value

If the function succeeds, the return value is a socket handle. If the function fails, the return value is INVALID_SOCKET. To get extended error information, call **InetGetLastError**.

Remarks

In most cases, the *lpszLocalHost* parameter should be a NULL pointer or an empty string. On a multihomed system, this will enable the server to accept connections on any appropriately configured network adapter. Specifying a hostname or IP address will limit client connections to that particular address. Note that the hostname or address must be one that is assigned to the local system, otherwise an error will occur.

If an IPv6 address is specified as the local address, the system must have an IPv6 stack installed and configured, otherwise the function will fail.

To listen for connections on any suitable IPv4 interface, specify the special dotted-quad address "0.0.0.0". You can accept connections from clients using either IPv4 or IPv6 on the same socket by specifying the special IPv6 address ":::0", however this is only supported on Windows 7 and Windows Server 2008 R2 or later platforms. If no local address is specified, then the server will only listen for connections from clients using IPv4. This behavior is by design for backwards compatibility with systems that do not have an IPv6 TCP/IP stack installed.

If the `INET_OPTION_REUSEADDRESS` option is not specified, an error may be returned if a listening socket was recently created for the same local address and port number. By default, once a listening socket is closed there is a period of time that all applications must wait before the address can be reused (this is called the `TIME_WAIT` state). The actual amount of time depends on the operating system and configuration parameters, but is typically two to four minutes. Specifying this option enables an application to immediately re-use a local address and port number that was previously in use. Note that this does not permit more than one server to bind to the same address.

When the event handler callback function is invoked by the server, it normally executes in the context of the worker thread that manages that client session. This means that even if you do not explicitly create any threads in your application, you must design your program to be thread-safe, with synchronized access to global objects and data. If your application has a user interface, only the main UI thread should attempt to modify controls. If you attempt to modify a control from a worker thread, such as adding a row to a listbox control, it can result the application becoming deadlocked. This means that you should not attempt to directly update the UI from within the event handler function. To enable asynchronous server notifications for a GUI application, use the **`InetServerAsyncNotify`** function.

The socket handle returned by this function references the listening socket that was created when the server was started. The service is managed in another thread, and all interaction with the server and active client connections are performed inside the event handler. To disconnect all active connections, close the listening socket and terminate the server thread, call the **`InetServerStop`** function.

Example

```
#define SERVER_PORT      7000
#define SERVER_CLIENTS  100

SOCKET hServer = INVALID_SOCKET;

// Accept connections from clients that connection on port 7000 with a default
// backlog of 5 connections and a maximum of 100 client connections.

hServer = InetServerStart(NULL,
                          SERVER_PORT,
                          INET_BACKLOG,
                          SERVER_CLIENTS,
                          INET_TIMEOUT,
                          INET_PRIORITY_NORMAL,
                          INET_OPTION_REUSEADDRESS,
                          MyEventHandler,
                          0,
                          NULL);

if (hServer == INVALID_SOCKET)
{
    DWORD dwError;
```

```
TCHAR szError[256];

dwError = InetGetLastError();
InetGetErrorString(dwError, szError, 256);

MessageBox(NULL, szError, NULL, MB_OK|MB_TASKMODAL);
return;
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

See Also

[InetGetServerData](#), [InetGetServerPriority](#), [InetGetServerStatus](#), [InetServerLock](#), [InetServerRestart](#), [InetServerResume](#), [InetServerStop](#), [InetServerSuspend](#), [InetServerThrottle](#), [InetServerUnlock](#), [InetSetServerData](#), [InetSetServerPriority](#)

InetServerStop Function

```
BOOL WINAPI InetServerStop(  
    SOCKET hServer  
);
```

The **InetServerStop** function signals the server to stop listening for connections and terminates all client sessions.

Parameters

hServer

Handle to the server socket.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **InetGetLastError**.

Remarks

The **InetServerStop** function signals the server to stop accepting client connections, disconnects all active client connections and terminates the thread that is managing the server session. The socket handle is no longer valid after the server has been stopped and should no longer be used. Note that it is possible that the actual handle value may be re-used at a later point when a new server is started. An application should always consider the socket handle to be opaque and never depend on it being a specific value.

If this function is called when there is one or more clients connected to the server, it will signal each client thread to terminate and then wait for the server thread to terminate. As the client sessions are terminated, the event handler will not be invoked. If you wish to ensure that all clients are disconnected normally before stopping the server, call the **InetServerSuspendEx** function with the INET_SUSPEND_DISCONNECT option and then stop the server after the last client has disconnected.

Because the **InetServerStop** function waits for the server thread to terminate, this function may cause your application to block. If this is not desirable, use the **InetServerStopEx** function which can perform the shutdown sequence asynchronously.

After the server thread has been terminated, the listening socket will go into a TIME-WAIT state which prevents an application from reusing the same address and port number bound to that socket for a brief period of time, typically two to four minutes. This is normal behavior designed to prevent delayed or misrouted packets of data from being read by a subsequent connection. To immediately start a new server using the same local address and port number, the option INET_OPTION_REUSEADDRESS must be specified when calling the **InetServerStart** function.

The socket handle for the server must be one that was created by calling the **InetServerStart** function, and cannot be a socket that was created using the **InetListen** or **InetListenEx** functions.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cswskv10.lib

See Also

InetServerStopEx Function

```
BOOL WINAPI InetServerStopEx(  
    SOCKET hServer,  
    DWORD dwMilliseconds  
);
```

The **InetServerStopEx** function signals the server to stop listening for connections and terminates all client sessions.

Parameters

hServer

Handle to the server socket.

dwMilliseconds

An unsigned integer value that specifies the number of milliseconds to wait for all active clients to disconnect and the server thread to terminate.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **InetGetLastError**.

Remarks

The **InetServerStopEx** function signals the server to stop accepting client connections, disconnects all active client connections and terminates the thread that is managing the server session. The socket handle is no longer valid after the server has been stopped and should no longer be used. Note that it is possible that the actual handle value may be re-used at a later point when a new server is started. An application should always consider the socket handle to be opaque and never depend on it being a specific value.

Unlike the **InetServerStop** function, which waits for fixed period of time for the server thread to terminate, the **InetServerStopEx** allows the caller to determine how much time should be spent waiting for the clients to disconnect and the server thread to terminate. If the *dwMilliseconds* parameter has a value of INFINITE, the function will wait for an indefinite period of time until all clients have disconnected, the listening socket closed and the server thread has terminated. If the *dwMilliseconds* parameter has a value of zero, the function does not wait for the server to shutdown. Instead, it returns immediately and the shutdown process continues in the background.

If your application specifies a value of zero for the *dwMilliseconds* parameter, the event handler will be invoked with the INET_EVENT_DISCONNECT event as each client disconnects from the server during the shutdown process. If you depend on this event to perform some cleanup on a per-client basis, you must ensure that the application does not exit until the server thread has terminated. To perform a graceful shutdown of the server, it is recommended that you use the **InetServerSuspendEx** function and specify the INET_SUSPEND_DISCONNECT option. After all clients have disconnected, call the **InetServerStop** function to terminate the server thread.

After the server thread has been terminated, the listening socket will go into a TIME-WAIT state which prevents an application from reusing the same address and port number bound to that socket for a brief period of time, typically two to four minutes. This is normal behavior designed to prevent delayed or misrouted packets of data from being read by a subsequent connection. To immediately start a new server using the same local address and port number, the option INET_OPTION_REUSEADDRESS must be specified when calling the **InetServerStart** function.

The socket handle for the server must be one that was created by calling the **InetServerStart** function, and cannot be a socket that was created using the **InetListen** or **InetListenEx** functions.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cswsock10.h

Import Library: cs wskv10.lib

See Also

[InetGetServerStatus](#), [InetServerRestart](#), [InetServerStart](#), [InetServerStop](#), [InetServerSuspendEx](#)

InetServerSuspend Function

```
BOOL WINAPI InetServerSuspend(  
    SOCKET hServer  
);
```

Suspend accepting client connections on the specified server.

Parameters

hServer

Handle to the server socket.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **InetGetLastError**.

Remarks

The **InetServerSuspend** function instructs the server to suspend accepting new client connections. Any incoming client connections will be queued up to the maximum backlog value specified when the server was started. To resume accepting client connections, call the **InetServerResume** function.

It is recommended that you only suspend a server if absolutely necessary, and only for brief periods of time. If you want to limit the number of active client connections or control the connection rate for clients, use the **InetServerThrottle** function.

The socket handle for the server must be one that was created by calling the **InetServerStart** function, and cannot be a socket that was created using the **InetListen** or **InetListenEx** functions.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: csuskv10.lib

See Also

[InetGetServerStatus](#), [InetServerRestart](#), [InetServerResume](#), [InetServerStart](#), [InetServerStop](#), [InetServerThrottle](#)

InetServerSuspendEx Function

```
BOOL WINAPI InetServerSuspendEx(  
    SOCKET hServer,  
    DWORD dwOptions  
);
```

Suspend accepting client connections and optionally reject or disconnect clients.

Parameters

hServer

Handle to the server socket.

dwOptions

An unsigned integer that specifies one or more options.

Constant	Description
INET_SUSPEND_DEFAULT	Specifies that the server should suspend accepting new connections. New incoming client connections will be queued and clients that have already established a connection to the server will remain connected.
INET_SUSPEND_REJECT	Specifies that the server should suspend accepting new connections and reject any new client connections. Clients that have already established a connection to the server will remain connected.
INET_SUSPEND_DISCONNECT	Specifies that the server should suspend accepting new connections and disconnect all active clients that are currently connected to the server. If the INET_SUSPEND_REJECT option is also specified, new client connections will be rejected by the server.
INET_SUSPEND_WAIT	Specifies that the function should wait for the clients to disconnect from the server rather than return immediately to the caller. This option is only meaningful when used in conjunction with INET_SUSPEND_DISCONNECT.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **InetGetLastError**.

Remarks

The **InetServerSuspendEx** function instructs the server to suspend accepting new client connections. Additional options can be used to control how the server suspends connections. If you plan on suspending the server for any period of time greater than a few seconds, it is recommended that you specify the INET_SUSPEND_REJECT option so that clients are not forced to wait.

If the INET_SUSPEND_DISCONNECT option is specified, the server will signal each client to disconnect and will stop accepting new connections. The event handler will be invoked for each client that disconnects. If the INET_SUSPEND_WAIT option is also specified, the function will wait

until the last client has disconnected from the server before returning to the caller. If there are a large number of clients connected to the server, this process may cause the application to block for an extended period of time and appear to be non-responsive to the user. For this reason, you should not specify the `INET_SUSPEND_WAIT` option if the function is being called from the application's main UI thread.

To perform a graceful shutdown of the server, it is recommended that you call **InetServerSuspendEx** with the `INET_SUSPEND_REJECT` and `INET_SUSPEND_DISCONNECT` options. This will allow each client to disconnect from the server and the server will reject any new incoming connections. After the last client has disconnected from the server, call the **InetServerStop** function to complete the shutdown process. The **InetGetClientThreads** function can be used to determine if all client session threads have terminated.

The socket handle for the server must be one that was created by calling the **InetServerStart** function, and cannot be a socket that was created using the **InetListen** or **InetListenEx** functions.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cssock10.h`

Import Library: `cswskv10.lib`

See Also

[InetGetServerStatus](#), [InetServerRestart](#), [InetServerResume](#), [InetServerStart](#), [InetServerStop](#), [InetServerThrottle](#)

InetServerThrottle Function

```
BOOL WINAPI InetServerThrottle(  
    SOCKET hServer,  
    UINT nMaxClients,  
    UINT nMaxClientsPerAddress,  
    DWORD dwConnectionRate  
);
```

The **InetServerThrottle** function limits the number of active client connections, connections per address and connection rate.

Parameters

hServer

Handle to the server socket.

nMaxClients

A value which specifies the maximum number of clients that may connect to the server. A value of zero specifies that there is no fixed limit to the number of client connections.

nMaxClientsPerAddress

A value which specifies the maximum number of clients that may connect to the server from the same IP address. A value of zero specifies that there is no fixed limit to the number of client connections per address. By default, there is no limit on the number of client connections per address.

dwConnectionRate

A value which specifies a restriction on the rate of client connections, limiting the number of connections that will be accepted within that period of time. A value of zero specifies that there is no restriction on the rate of client connections. The higher this value, the fewer the number of connections that will be accepted within a specific period of time. By default, there is no limit on the client connection rate.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **InetGetLastError**.

Remarks

The **InetServerThrottle** function is used to limit the number of connections and the connection rate to minimize the potential impact of a large number of client connections over a short period of time. This can be used to protect the server from a client application that is malfunctioning or a deliberate denial-of-service attack in which the attacker attempts to flood the server with connection attempts.

If the maximum number of client connections or maximum number of connections per address is exceeded, the server will reject subsequent connection attempts until the number of active client sessions drops below the specified threshold. Note that adjusting these values lower than the current connection limits will not affect clients that have already connected to the server. For example, if the **InetServerStart** function is called with the maximum number of clients set to 100, and then **InetServerThrottle** is called lowering that value to 75, no existing client connections will be affected by the change. However, the server will not accept any new connections until the number of active clients drops below 75.

Increasing the connection rate value will force the server to slow down the rate at which it will accept incoming client connection requests. For example, setting this parameter to a value of 1000 would limit the server to accepting one client connection every second, while a value of 250 would allow the server to accept four client connections per second. Note that significantly increasing the amount of time the server must wait to accept client connections can exceed the connection backlog queue, resulting in client connections being rejected.

The socket handle for the server must be one that was created by calling the **InetServerStart** function, and cannot be a socket that was created using the **InetListen** or **InetListenEx** functions.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cssock10.h`

Import Library: `cswskv10.lib`

See Also

[InetGetServerStatus](#), [InetServerLock](#), [InetServerRestart](#), [InetServerResume](#), [InetServerStart](#), [InetServerSuspend](#), [InetServerUnlock](#)

InetServerUnlock Function

```
BOOL WINAPI InetServerUnlock(  
    SOCKET hServer  
);
```

The **InetServerUnlock** function unlock the specified server, allowing other client threads to resume execution.

Parameters

hServer

The socket handle to the server.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **InetGetLastError**.

Remarks

The **InetServerUnlock** function releases the lock on the specified server and allows any blocked threads to resume execution. Only one server may be locked at any one time, and only the thread which established the lock can unlock the server.

Every time the **InetServerLock** function is called, an internal lock counter is incremented, and the lock will not be released until the lock count drops to zero. This means that each call to **InetServerLock** must be matched by an equal number of calls to the **InetServerUnlock** function. Failure to do so will result in the server becoming non-responsive as it remains in a locked state.

The program should always check the return value from this function, and should never assume that the lock has been released. If a potential deadlock situation is detected, this function will fail and return a value of zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cssock10.h`

Import Library: `cswskv10.lib`

See Also

InetSetClientData Function

```
BOOL WINAPI InetSetClientData(  
    SOCKET hClient,  
    VOID LpvData  
);
```

The **InetSetClientData** function sets the application defined data associated with the specified client session.

Parameters

hSocket

The socket handle.

lppvData

Pointer to the application defined data associated with the specified client session.

Return Value

If the function succeeds, the return value is non-zero. A return value of zero indicates that application defined data for the client session could not be modified. To get extended error information, call **InetGetLastError**.

Remarks

The **InetSetClientData** function is used to associate application defined data with a specific client session. This is typically used to associate a pointer to a data structure or a class instance with the client socket. A pointer to the data can be retrieved using the **InetGetClientData** function.

You should never specify a pointer to a local variable or data structure that will go out of scope when the calling function exits. If you do this, the pointer will no longer be valid after the function exits and attempting to dereference that pointer at some later time can cause an exception to be thrown and terminate the program. You should always allocate a block of memory for the data using a function such as **HeapAlloc** or **LocalAlloc**. If you specify the address of a static or global data structure, you must use thread synchronization functions when dereferencing and modifying that structure.

This function can only be used with client socket handles created using the SocketWrench server interface. It cannot be used with socket handles created using the **InetConnect** or **InetAccept** functions.

Example

```
UINT *pnValue1 = (UINT *)LocalAlloc(LPTR, sizeof(UINT));  
UINT *pnValue2 = NULL;  
  
*pnValue1 = 1234;  
  
if (InetSetClientData(hSocket, pnValue1) == FALSE)  
{  
    // Unable to associate the data with this session  
    return;  
}  
  
if (InetGetClientData(hSocket, &pnValue2) == FALSE)  
{  
    // Unable to retrieve the data associated with this session
```

```
    return;  
}  
  
// *pnValue2 == 1234  
printf("The value of user defined data is %u\n", *pnValue2);
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

See Also

[InetGetClientData](#), [InetGetServerData](#), [InetSetServerData](#)

InetSetClientMoniker Function

```
INT WINAPI InetSetClientMoniker(  
    SOCKET hSocket,  
    LPCTSTR LpszMoniker  
);
```

The **InetSetClientMoniker** function associates a unique string moniker with the specified client session.

Parameters

hSocket

Handle to the client socket.

lpszMoniker

Pointer to a string which specifies the moniker for the specified client socket. If this parameter is NULL or specifies an empty string, a moniker will no longer be associated with the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is INET_ERROR. To get extended error information, call **InetGetLastError**.

Remarks

A client moniker is a string which can be used to uniquely identify a specific client session aside from its socket handle. The **InetGetClientMoniker** function will return the moniker that was previously assigned to the client, if any. To obtain the socket handle associated with a given moniker, use the **InetFindClientMoniker** function.

Monikers are not case-sensitive, and they must be unique so that no client socket for a particular server can have the same moniker. The maximum length for a moniker is 127 characters.

The socket handle for the client must be one that was created as part of the SocketWrench server interface, and cannot be a socket that was created using the **InetConnect** or **InetAccept** functions.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

See Also

InetSetClientPriority Function

```
INT WINAPI InetSetClientPriority(  
    SOCKET hClient,  
    INT nPriority  
);
```

The **InetSetClientPriority** function sets the current priority for the specified client session.

Parameters

hClient

Handle to the client session.

nPriority

An integer value which specifies the new priority for the client session. It may be one of the following values:

Constant	Description
INET_PRIORITY_NORMAL	The default priority which balances resource and processor utilization. It is recommended that most applications use this priority.
INET_PRIORITY_BACKGROUND	This priority significantly reduces the memory, processor and network resource utilization for the client session. It is typically used with lightweight services running in the background that are designed for few client connections. The client thread will be assigned a lower scheduling priority and will be frequently forced to yield execution to other threads.
INET_PRIORITY_LOW	This priority lowers the overall resource utilization for the client session and meters the processor utilization for the client session. The client thread will be assigned a lower scheduling priority and will occasionally be forced to yield execution to other threads.
INET_PRIORITY_HIGH	This priority increases the overall resource utilization for the client session and the thread will be given higher scheduling priority. It is not recommended that this priority be used on a system with a single processor.
INET_PRIORITY_CRITICAL	This priority can significantly increase processor, memory and network utilization. The client thread will be given higher scheduling priority and will be more responsive to network events. It is not recommended that this priority be used on a system with a single processor.

Return Value

If the function succeeds, the return value is the previous priority for the specified client session. If the function fails, the return value is INET_ERROR. To get extended error information, call

InetGetLastError.

Remarks

The **InetSetClientPriority** function can be used to change the current priority assigned to the specified client session. The client priority is inherited from the priority specified when the server is started using the **InetServerStart** function.

The socket handle for the client must be one that was created as part of the SocketWrench server interface, and cannot be a socket that was created using the **InetConnect** or **InetAccept** functions.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

See Also

[InetGetClientPriority](#), [InetGetServerPriority](#), [InetServerStart](#), [InetSetServerPriority](#)

InetSetHostFile Function

```
INT WINAPI InetSetHostFile(  
    LPCTSTR lpszFileName  
);
```

The **InetSetHostFile** function specifies the name of an alternate file to use when resolving hostnames and IP addresses. The host file is used as a database that maps an IP address to one or more hostnames, and is used by the **InetGetHostAddress** and **InetGetHostNames** function. The file is a plain text file, with each line in the file specifying a record, and each field separated by spaces or tabs. The format of the file must be as follows:

```
ipaddress hostname [hostalias ...]
```

For example, one typical entry maps the name "localhost" to the local loopback IP address. This would be entered as:

```
127.0.0.1 localhost
```

The hash character (#) may be used to specify a comment in the file, and all characters after it are ignored up to the end of the line. Blank lines are ignored, as are any lines which do not follow the required format.

Parameters

lpszFileName

Pointer to a string that specifies the name of the file. If the parameter is NULL, then the current host file is cleared from the cache and only the default host file will be used to resolve hostnames and addresses.

Return Value

If the function succeeds, the return value is the number of entries in the host file. A return value of INET_ERROR indicates failure. To get extended error information, call **InetGetLastError**.

Remarks

This function loads the file into memory allocated for the current thread. If the contents of the file have changed after the function has been called, those changes will not be reflected when resolving hostnames or addresses. To reload the host file from disk, call this function again with the same file name. To remove the alternate host file from memory, specify a NULL pointer as the parameter.

If a host file has been specified, it is processed before the default host file when resolving a hostname into an IP address, or an IP address into a hostname. If the host name or address is not found, or no host file has been specified, a nameserver lookup is performed.

To determine if an alternate host file has been specified, use the **InetGetHostFile** function. A return value of zero indicates that no alternate host file has been cached for the current thread.

A system may have a default host file, which is used to resolve hostnames before performing a nameserver lookup. To determine the name of this file, use the **InetGetDefaultHostFile** function. It is not necessary to specify this default host file, since it is always used to resolve host names and addresses.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cssock10.h`

Import Library: `cswskv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

See Also

[InetGetDefaultHostFile](#), [InetGetHostAddress](#), [InetGetHostFile](#), [InetGetHostName](#)

InetSetLastError Function

```
VOID WINAPI InetSetLastError(  
    DWORD dwErrorCode  
);
```

The **InetSetLastError** function sets the last-error code for the caller. This function is typically used to clear the last error by passing a value of zero as the parameter.

Parameters

dwErrorCode

Specifies the last-error code for the caller.

Return Value

None.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_SOCKET or INET_ERROR. Those functions which call **InetSetLastError** when they succeed are noted on the function reference page.

Applications can retrieve the value saved by this function by using the [InetGetLastError](#) function. The use of **InetGetLastError** is optional; an application can call it to find out the specific reason for a function failure.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cswskv10.lib

See Also

[InetGetErrorString](#), [InetGetLastError](#)

InetSetOption Function

```
INT WINAPI InetSetOption(  
    SOCKET hSocket,  
    DWORD dwOption,  
    BOOL bEnabled  
);
```

The **InetSetOption** function is used to enable or disable a specific socket option.

Parameters

hSocket

The socket handle.

dwOption

An unsigned integer used to specify one of the socket options. These options cannot be combined. The following values are recognized:

Constant	Description
INET_OPTION_BROADCAST	This option specifies that broadcasting should be enabled for datagrams. This option is invalid for stream sockets.
INET_OPTION_KEEPAIVE	This option specifies that packets are to be sent to the remote system when no data is being exchanged to keep the connection active. This is only valid for stream sockets.
INET_OPTION_REUSEADDRESS	This option specifies the local address can be reused. This option is commonly used by server applications.
INET_OPTION_NODELAY	This option disables the Nagle algorithm, which buffers unacknowledged data and insures that a full-size packet can be sent to the remote host.

bEnabled

A boolean flag. If the flag is set to a non-zero value, the option is enabled. Otherwise the socket option is disabled.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is `INET_ERROR`. To get extended error information, call **InetGetLastError**.

Remarks

It is not recommend that you disable the Nagle algorithm by specifying the `INET_OPTION_NODELAY` flag unless it is absolutely required. Doing so can have a significant, negative impact on the performance of the application and network.

If if the `INET_OPTION_KEEPAIVE` option is enabled, keep-alive packets will start being generated five seconds after the socket has become idle with no data being sent or received. Enabling this option can be used by applications to detect when a physical network connection has been lost. However, it is recommended that most applications query the remote host directly to determine if the connection is still active. This is typically accomplished by sending specific commands to the

server to query its status, or checking the elapsed time since the last response from the server.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cssock10.h`

Import Library: `cswskv10.lib`

InetSetServerData Function

```
BOOL WINAPI InetSetServerData(  
    SOCKET hServer,  
    VOID LpvData  
);
```

The **InetSetServerData** function sets the application defined data associated with the specified server.

Parameters

hSocket

The socket handle.

lppvData

Pointer to the application defined data associated with the specified server.

Return Value

If the function succeeds, the return value is non-zero. A return value of zero indicates that application defined data for the server could not be modified. To get extended error information, call **InetGetLastError**.

Remarks

The **InetSetServerData** function is used to associate application defined data with a specific server. A pointer to the data can be retrieved using the **InetGetServerData** function.

You should never specify a pointer to a local variable or data structure that will go out of scope when the calling function exits. If you do this, the pointer will no longer be valid after the function exits and attempting to dereference that pointer at some later time can cause an exception to be thrown and terminate the program. You should always allocate a block of memory for the data using a function such as **HeapAlloc** or **LocalAlloc**. If you specify the address of a static or global data structure, you must use thread synchronization functions when dereferencing and modifying that structure.

This function can only be used with server socket handles created using the **InetServerStart** function. It cannot be used with socket handles created using the **InetListen** or **InetListenEx** functions.

Example

```
UINT *pnValue1 = (UINT *)LocalAlloc(LPTR, sizeof(UINT));  
UINT *pnValue2 = NULL;  
  
*pnValue1 = 1234;  
  
if (InetSetServerData(hServer, pnValue1) == FALSE)  
{  
    // Unable to associate the data with this server  
    return;  
}  
  
if (InetGetServerData(hServer, &pnValue2) == FALSE)  
{  
    // Unable to retrieve the data associated with this server  
    return;  
}
```

```
// *pnValue2 == 1234  
printf("The value of user defined data is %u\n", *pnValue2);
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: csuskv10.lib

See Also

[InetGetClientData](#), [InetGetServerData](#), [InetSetClientData](#)

InetSetServerPriority Function

```
INT WINAPI InetSetServerPriority(  
    SOCKET hServer,  
    INT nPriority  
);
```

The **InetSetServerPriority** function sets the current priority for the specified server.

Parameters

hServer

Handle to the server socket.

nPriority

An integer value which specifies the new priority for the server. It may be one of the following values:

Constant	Description
INET_PRIORITY_BACKGROUND	This priority significantly reduces the memory, processor and network resource utilization for the server. It is typically used with lightweight services running in the background that are designed for few client connections. The server thread will be assigned a lower scheduling priority and will be frequently forced to yield execution to other threads.
INET_PRIORITY_LOW	This priority lowers the overall resource utilization for the server and meters the processor utilization for the server thread. The server thread will be assigned a lower scheduling priority and will occasionally be forced to yield execution to other threads.
INET_PRIORITY_NORMAL	The default priority which balances resource and processor utilization. This is the priority that is initially assigned to the server when it is started, and it is recommended that most applications use this priority.
INET_PRIORITY_HIGH	This priority increases the overall resource utilization for the server and the thread will be given higher scheduling priority. It is not recommended that this priority be used on a system with a single processor.
INET_PRIORITY_CRITICAL	This priority can significantly increase processor, memory and network utilization. The server thread will be given higher scheduling priority and will be more responsive to client connection requests. It is not recommended that this priority be used on a system with a single processor.

Return Value

If the function succeeds, the return value is the previous priority assigned to the server. If the function fails, the return value is INET_PRIORITY_INVALID. To get extended error information, call **InetGetLastError**.

Remarks

The **InetSetServerPriority** function can be used to change the current priority assigned to the specified server. Client connections that are accepted after this function is called will inherit the new priority as their default priority. Previously existing client connections will not be affected by this function. To modify the priority for an active client session, use the **InetSetClientPriority** function.

Higher priority values increase the thread priority and processor utilization for each client session. You should only change the server priority if you understand the impact it will have on the system and have thoroughly tested your application. Configuring the server to run with a higher priority can have a negative effect on the performance of other programs running on the system.

The socket handle for the server must be one that was created using the **InetServerStart** function, and cannot be a socket that was created using the **InetListen** or **InetListenEx** functions.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: csuskv10.lib

See Also

[InetGetClientPriority](#), [InetGetServerPriority](#), [InetServerStart](#), [InetSetClientPriority](#)

InetSetServerStackSize Function

```
BOOL WINAPI InetSetServerStackSize(  
    SOCKET hServer,  
    DWORD dwStackSize  
);
```

Change the initial size of the stack allocated for threads created by the server.

Parameters

hServer

Handle to the server socket.

dwStackSize

The amount of memory that will be committed to the stack for each thread created by the server. If this value is zero, a default stack size will be used.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **InetGetLastError**.

Remarks

The **InetSetServerStackSize** function changes the initial amount of memory that is committed to the stack for each thread created by the server. By default, the stack size for each thread is set to 256K for 32-bit processes and 512K for 64-bit processes. Increasing or decreasing the stack size will only affect new threads that are created by the server, it will not affect those threads that have already been created to manage active client sessions. It is recommended that most applications use the default stack size.

You should not change the stack size unless you understand the impact that it will have on your system and have thoroughly tested your application. Increasing the initial commit size of the stack will remove pages from the total system commit limit, and every page of memory that is reserved for stack cannot be used for any other purpose.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cswsock10.h`

Import Library: `cswskv10.lib`

See Also

[InetGetServerStackSize](#), [InetServerStart](#)

InetSetTimeout Function

```
INT WINAPI InetSetTimeout(  
    SOCKET hSocket,  
    UINT nTimeout  
);
```

The **InetSetTimeout** function sets the interval that is used when waiting for a blocking operation to complete.

Parameters

hSocket

Handle to the socket.

nTimeout

Duration of timeout interval, in seconds. If a value over 1000 is specified, it is assumed that milliseconds are intended by the user, and the value actually used will be adjusted accordingly.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is `INET_ERROR`. To get extended error information, call **InetGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cswsock10.h`

Import Library: `cswskv10.lib`

See Also

[InetGetTimeout](#), [InetConnect](#), [InetAccept](#), [InetIsReadable](#), [InetIsWritable](#)

InetShutdown Function

```
INT WINAPI InetShutdown(  
    SOCKET hSocket,  
    DWORD dwOption  
);
```

The **InetShutdown** function is used to disable reception or transmission of data, or both.

Parameters

hSocket

The socket handle.

dwOption

An unsigned integer used to specify one of the shutdown options. These options cannot be combined. The following values are recognized:

Value	Constant	Description
0	INET_SHUTDOWN_READ	Disable reception of data.
1	INET_SHUTDOWN_WRITE	Disable transmission of data.
2	INET_SHUTDOWN_BOTH	Disable both reception and transmission of data.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is `INET_ERROR`. To get extended error information, call **InetGetLastError**.

Remarks

This function is rarely needed. It is provided as an interface to the Windows Sockets **shutdown** function.

In some asynchronous applications, it may be desirable for a client to inform the server that no further communication is wanted, while allowing the client to read any residual data that may reside in internal buffers on the client side. **InetShutdown** accomplishes this because the socket handle is still valid after it has been called, although some or all communication with the remote host has ceased.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cswsock10.h`

Import Library: `cswskv10.lib`

See Also

[InetDisconnect](#)

InetStoreStream Function

```
BOOL WINAPI InetStoreStream(  
    SOCKET hSocket,  
    LPCTSTR lpszFileName,  
    DWORD dwLength,  
    LPDWORD lpdwCopied  
    DWORD dwOffset,  
    DWORD dwOptions  
);
```

The **InetStoreStream** function reads the socket data stream and stores the contents in the specified file.

Parameters

hSocket

The socket handle. The socket must reference a stream socket, not a datagram or raw socket. If the socket type is not valid, the function will return an error.

lpszFileName

Pointer to a string which specifies the name of the file to create or overwrite.

dwLength

An unsigned integer which specifies the maximum number of bytes to read from the socket and write to the file. If this value is zero, then the function will continue to read data from the socket until the remote host disconnects or an error occurs.

lpdwCopied

A pointer to an unsigned integer value which will contain the number of bytes written to the file when the function returns.

dwOffset

An unsigned integer which specifies the byte offset into the file where the function will start storing data read from the socket. Note that all data after this offset will be truncated. A value of zero specifies that the file should be completely overwritten if it already exists.

dwOptions

An unsigned integer value which specifies one or more options. Programs can use a bitwise operator to combine any of the following values:

Constant	Description
INET_STREAM_CONVERT	The data stream is considered to be textual and will be modified so that end-of-line character sequences are converted to follow standard Windows conventions. This will ensure that all lines of text are terminated with a carriage-return and linefeed sequence. Because this option modifies the data stream, it should never be used with binary data. Using this option may result in the amount of data written to the file to be larger than the source data. For example, if the source data only terminates a line of text with a single linefeed, this option will have the effect of inserting a

	carriage-return character before each linefeed.
INET_STREAM_UNICODE	The data stream should be converted to Unicode. This option should only be used with text data, and will result in the stream data being written as 16-bit wide characters rather than 8-bit bytes. The amount of data returned will be twice the amount read from the source data stream. If the <i>dwOffset</i> parameter has a value of zero, the Unicode byte order mark (BOM) will be written to the beginning of the file.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **InetGetLastError**.

Remarks

The **InetStoreStream** function enables an application to read an arbitrarily large stream of data and store it in a file. This function is essentially a simplified version of the **InetReadStream** function, designed specifically to be used with files rather than memory buffers or handles.

This function will force the thread to block until the operation completes. If this function is called with asynchronous events enabled, it will automatically switch the socket into a blocking mode, read the data stream and then restore the socket to asynchronous operation when it has finished. If another socket operation is attempted while **InetStoreStream** is blocked waiting for data from the remote host, an error will occur. It is recommended that this function only be used with blocking (synchronous) socket connections; if the application needs to establish multiple simultaneous connections, it should create worker threads to manage each connection.

Because **InetStoreStream** can potentially cause the application to block for long periods of time as the data stream is being read, the function will periodically generate INET_EVENT_PROGRESS events. An application can register an event handler using the **InetRegisterEvent** function, and can obtain information about the current operation by calling the **InetGetStreamInfo** function.

Example

```
DWORD dwCopied;
BOOL bResult;

bResult = InetStoreStream(hSocket,
                          lpzFileName,
                          &dwCopied,
                          0,
                          INET_STREAM_CONVERT);

if (bResult && dwCopied > 0)
{
    // The data has been written to the file
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cssock10.h`

Import Library: `cswskv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

InetUninitialize Function

```
VOID WINAPI InetUninitialize();
```

The **InetUninitialize** function terminates the use of the library.

Parameters

None.

Return Value

None.

Remarks

An application is required to perform a successful **InetInitialize** call before it can call any of the other library functions. When it has completed the use of library, the application must call **InetUninitialize** to allow the library to free any resources allocated on behalf of the process. Any pending blocking or asynchronous calls in this process are canceled without posting any notification messages, and all sockets that were opened by the process are closed.

There must be a call to **InetUninitialize** for every successful call to **InetInitialize** made by a process. In a multithreaded environment, operations for all threads are terminated.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

InetWrite Function

```
INT WINAPI InetWrite(  
    SOCKET hSocket,  
    LPBYTE lpBuffer,  
    INT cbBuffer  
);
```

The **InetWrite** function sends the specified number of bytes to the remote host.

Parameters

hSocket

The socket handle.

lpBuffer

The pointer to the buffer which contains the data that is to be sent to the remote host.

cbBuffer

The number of bytes to send from the specified buffer.

Return Value

If the function succeeds, the return value is the number of bytes actually written. If the function fails, the return value is INET_ERROR. To get extended error information, call **InetGetLastError**.

Remarks

The return value may be less than the number of bytes specified by the *cbBuffer* parameter. In this case, the data has been partially written and it is the responsibility of the application to send the remaining data at some later point. For non-blocking connections, the program must wait for the INET_EVENT_WRITE asynchronous notification message before it resumes sending data.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cswskv10.lib

See Also

[InetFlush](#), [InetRead](#), [InetReadEx](#), [InetWriteEx](#)

InetWriteEx Function

```
INT WINAPI InetWriteEx(  
    SOCKET hSocket,  
    LPVOID lpvBuffer,  
    INT cbBuffer,  
    DWORD dwReserved,  
    LPINTERNET_ADDRESS lpRemoteAddress,  
    UINT nRemotePort  
);
```

The **InetWriteEx** function sends the specified number of bytes to the remote host.

Parameters

hSocket

The socket handle.

lpvBuffer

The pointer to the buffer which contains the data that is to be sent to the remote host.

cbBuffer

The number of bytes to send from the specified buffer.

dwReserved

Reserved parameter. This value must always be zero.

lpRemoteAddress

Pointer to an [INTERNET_ADDRESS](#) structure that specifies the address of the remote host that is to receive the data being written. For TCP stream sockets, this parameter must always be NULL or specify the same address that was used to establish the connection. For UDP datagram sockets, this may specify any valid IP address.

nRemotePort

The port number of the remote host that is to receive the data being written. For TCP stream sockets, this value must always be zero, or specify the same port number that was used to establish the connection. For UDP datagram sockets, this may specify any valid port number.

Return Value

If the function succeeds, the return value is the number of bytes actually written. If the function fails, the return value is `INET_ERROR`. To get extended error information, call **InetGetLastError**.

Remarks

The return value may be less than the number of bytes specified by the *cbBuffer* parameter. In this case, the data has been partially written and it is the responsibility of the application to send the remaining data at some later point. For non-blocking connections, the program must wait for the `INET_EVENT_WRITE` asynchronous notification message before it resumes sending data.

This function extends the **InetWrite** function to additional information about the destination IP address and port number for the data being written. For a client TCP connection, the IP address and remote port must be the same values that were used to establish the connection. When writing on a UDP socket, this is the IP address and remote port of the peer that will receive the datagram. This information can be used in conjunction with the **InetReadEx** function to send a datagram back to that host.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

InetWriteLine Function

```
BOOL WINAPI InetWriteLine(  
    SOCKET hSocket,  
    LPCTSTR lpszBuffer,  
    LPINT lpnLength  
);
```

The **InetWriteLine** function sends a line of text to the remote host, terminated by a carriage-return and linefeed.

Parameters

hSocket

The socket handle. The socket must reference a stream socket, not a datagram or raw socket. If the socket type is not valid, the function will return an error.

lpszBuffer

The pointer to a string buffer which contains the data that will be sent to the remote host. All characters up to, but not including, the terminating null character will be written to the socket. The data will always be terminated with a carriage-return and linefeed control character sequence. If this parameter points to an empty string or NULL pointer, then a only a carriage-return and linefeed are written to the socket.

lpnLength

A pointer to an integer value which will contain the number of characters written to the socket, including the carriage-return and linefeed sequence. If this information is not required, a NULL pointer may be specified.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **InetGetLastError**.

Remarks

The **InetWriteLine** function writes a line of text to the remote host and terminates the line with a carriage-return and linefeed control character sequence. Unlike the **InetWrite** function which writes arbitrary bytes of data to the socket, this function is specifically designed to write a single line of text data from a string.

If the *lpszBuffer* string is terminated with a linefeed (LF) or carriage return (CR) character, it will be automatically converted to a standard CRLF end-of-line sequence. Because the string will be sent with a terminating CRLF sequence, the value returned in the *lpnLength* parameter will typically be larger than the original string length (reflecting the additional CR and LF characters), unless the string was already terminated with CRLF.

There are some limitations when using **InetWriteLine**. The function should only be used to send text, never binary data. In particular, the function will discard nulls and append linefeed and carriage return control characters to the data stream. The Unicode version of this function will accept a Unicode string, however this function does not support writing raw Unicode data to the socket. Unicode strings will be automatically converted to UTF-8 encoding using the **WideCharToMultiByte** function and then written to the socket as a stream of bytes.

This function will force the thread to block until the complete line of text has been written, the write operation times out or the remote host aborts the connection. If this function is called with

asynchronous events enabled, it will automatically switch the socket into a blocking mode, send the data and then restore the socket to asynchronous operation. If another socket operation is attempted while **InetWriteLine** is blocked sending data to the remote host, an error will occur. It is recommended that this function only be used with blocking (synchronous) socket connections; if the application needs to establish multiple simultaneous connections, it should create worker threads to manage each connection.

The **InetWrite** and **InetWriteLine** function calls can be safely intermixed.

Unlike the **InetWrite** function, it is possible for data to have been written to the socket if the return value is zero. For example, if a timeout occurs while the function is waiting to send more data to the remote host, it will return zero; however, some data may have already been written prior to the error condition. If this is the case, the *lpnLength* argument will specify the number of characters actually written up to that point.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

Unicode: Implemented as Unicode and ANSI versions.

InetWriteStream Function

```
BOOL WINAPI InetWriteStream(  
    SOCKET hSocket,  
    LPVOID lpvBuffer,  
    LPDWORD lpdwLength,  
    DWORD dwOptions  
);
```

The **InetWriteStream** function writes data from the stream buffer to the specified socket.

Parameters

hSocket

The socket handle. The socket must reference a stream socket, not a datagram or raw socket. If the socket type is not valid, the function will return an error.

lpvBuffer

Pointer to the buffer that contains or references the data to be written to the socket. The actual argument depends on the value of the *dwOptions* parameter which specifies how the data stream will be accessed.

lpdwLength

A pointer to an unsigned integer value which specifies the size of the buffer and contains the number of bytes written when the function returns. This argument should always point to an initialized value. If the *lpvBuffer* argument specifies a memory buffer or global memory handle, then this argument cannot point to an initialized value of zero.

dwOptions

An unsigned integer value which specifies the stream buffer type to be used when writing the data stream to the socket. One of the following stream types may be specified:

Constant	Description
INET_STREAM_DEFAULT	The default stream buffer type is determined by the value passed as the <i>lpvBuffer</i> parameter. If the argument specifies a global memory handle, then the function will write the data referenced by that handle; otherwise, the function will consider the parameter a pointer to a block of memory which contains data to be written. In most cases, it is recommended that an application explicitly specify the stream buffer type rather than using the default value.
INET_STREAM_MEMORY	The <i>lpvBuffer</i> argument specifies a pointer to a block of memory which contains the data to be written to the socket. If this stream buffer type is used, the <i>lpdwLength</i> argument must point to an unsigned integer which has been initialized with the size of the buffer.
INET_STREAM_HGLOBAL	The <i>lpvBuffer</i> argument specifies a global memory handle that references the data to be written to the socket. The handle must have been created by a

	call to the GlobalAlloc or GlobalReAlloc function. If this stream buffer type is used, the <i>lpdwLength</i> argument must point to an unsigned integer which has been initialized with the size of the buffer.
INET_STREAM_HANDLE	The <i>lpvBuffer</i> argument specifies a Windows handle to an open file, console or pipe. This should be the same handle value returned by the CreateFile function in the Windows API. The data read using the ReadFile function with this handle will be written to the socket.
INET_STREAM_SOCKET	The <i>lpvBuffer</i> argument specifies a socket handle. The data read from the socket specified by this handle will be written to the socket specified by the <i>hSocket</i> parameter. The socket handle passed to this function must have been created by this library; if it is a socket created by a third-party library or directly by the Windows Sockets API, you should either attach the socket using the InetAttachSocket function or use the INET_STREAM_HANDLE stream buffer type instead.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **InetGetLastError**.

Remarks

The **InetWriteStream** function enables an application to write an arbitrarily large stream of data from memory or a file to the specified socket. Unlike the **InetWrite** function, which may not write all of the data in a single function call, **InetWriteStream** will only return when all of the data has been written or an error occurs.

This function will force the thread to block until the operation completes. If this function is called with asynchronous events enabled, it will automatically switch the socket into a blocking mode, write the data stream and then restore the socket to asynchronous operation when it has finished. If another socket operation is attempted while **InetWriteStream** is blocked sending data to the remote host, an error will occur. It is recommended that this function only be used with blocking (synchronous) socket connections; if the application needs to establish multiple simultaneous connections, it should create worker threads to manage each connection.

It is possible for some data to have been written even if the function returns a value of zero. Applications should also check the value of the *lpdwLength* argument to determine if any data was sent. For example, if a timeout occurs while the function is waiting to write more data, it will return zero; however, some data may have already been written to the socket prior to the error condition.

Because **InetWriteStream** can potentially cause the application to block for long periods of time as the data stream is being written, the function will periodically generate INET_EVENT_PROGRESS events. An application can register an event handler using the **InetRegisterEvent** function, and can obtain information about the current operation by calling the **InetGetStreamInfo** function.

Example

```
HANDLE hFile;
DWORD dwLength;

hFile = CreateFile(lpszFileName,
                  GENERIC_READ,
                  FILE_SHARE_READ,
                  NULL,
                  OPEN_EXISTING,
                  FILE_FLAG_SEQUENTIAL_SCAN,
                  NULL);

if (hFile == INVALID_HANDLE_VALUE)
    return;

dwLength = GetFileSize(hFile, NULL);

if (dwLength > 0)
{
    BOOL bResult = InetWriteStream(
        hSocket,
        hFile,
        &dwLength,
        INET_STREAM_HANDLE);
}

CloseHandle(hFile);
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

SocketWrench Data Structures

- INETSTREAMINFO
- INITDATA
- INTERNET_ADDRESS
- SECURITYCREDENTIALS
- SECURITYINFO

INETSTREAMINFO Structure

This structure contains information about the data stream being currently read or written.

```
typedef struct _INETSTREAMINFO
{
    DWORD    dwStreamThread;
    DWORD    dwStreamSize;
    DWORD    dwStreamCopied;
    DWORD    dwStreamMode;
    DWORD    dwStreamError;
    DWORD    dwBytesPerSecond;
    DWORD    dwTimeElapsed;
    DWORD    dwTimeEstimated;
} INETSTREAMINFO, *LPINETSTREAMINFO;
```

Members

dwStreamThread

Specifies the numeric ID for the thread that created the socket.

dwStreamSize

The maximum number of bytes that will be read or written. This is the same value as the buffer length specified by the caller, and may be zero which indicates that no maximum size was specified. Note that if this value is zero, the application will be unable to calculate a completion percentage or estimate the amount of time for the operation to complete.

dwStreamCopied

The total number of bytes that have been copied to or from the stream buffer.

dwStreamMode

A numeric value which specifies the stream operation that is current being performed. It may be one of the following values:

Constant	Description
INET_STREAM_READ	Data is being read from the socket and stored in the specified stream buffer.
INET_STREAM_WRITE	Data is being written from the specified stream buffer to the socket.

dwStreamError

The last error that occurred when reading or writing the data stream. If no error has occurred, this value will be zero.

dwBytesPerSecond

The average number of bytes that have been copied per second.

dwTimeElapsed

The number of seconds that have elapsed since the file transfer started.

dwTimeEstimated

The estimated number of seconds until the operation is completed. This is based on the average number of bytes transferred per second and requires that a maximum stream buffer size be specified by the caller.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cssock10.h`

INITDATA Structure

This structure contains information about the SocketTools library when the initialization function returns.

```
typedef struct _INITDATA
{
    DWORD      dwSize;
    DWORD      dwVersionMajor;
    DWORD      dwVersionMinor;
    DWORD      dwVersionBuild;
    DWORD      dwOptions;
    DWORD_PTR  dwReserved1;
    DWORD_PTR  dwReserved2;
    TCHAR      szDescription[128];
} INITDATA, *LPINITDATA;
```

Members

dwSize

Size of this structure. This structure member must be set to the size of the structure prior to calling the initialization function. Failure to do so will cause the function to fail.

dwVersionMajor

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the major version number for the library.

dwVersionMinor

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the minor version number for the library.

dwVersionBuild

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the build number for the library.

dwOptions

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

dwReserved1

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

dwReserved2

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

szDescription

A null terminated string which describes the library.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Unicode: Implemented as Unicode and ANSI versions.

INTERNET_ADDRESS Structure

This structure represents a numeric IPv4 or IPv6 address in network byte order.

```
typedef struct _INTERNET_ADDRESS
{
    INT    ipFamily;
    BYTE   ipNumber[16];
} INTERNET_ADDRESS, *LPINTERNET_ADDRESS;
```

Members

ipFamily

An integer which identifies the type of IP address. It will be one of the following values:

Constant	Description
INET_ADDRESS_UNKNOWN	The address has not been specified or the bytes in the <i>ipNumber</i> array does not represent a valid address. Functions which populate this structure will use this value to indicate that the address cannot be determined.
INET_ADDRESS_IPV4	Specifies that the address is in IPv4 format. The first four bytes of the <i>ipNumber</i> array are significant and contains the IP address. The remaining bytes are not significant and an application should not depend on them having any particular value, including zero.
INET_ADDRESS_IPV6	Specifies that the address is in IPv6 format. All bytes in the <i>ipNumber</i> array are significant. Note that it is possible for an IPv6 address to actually represent an IPv4 address. This is indicated by the first 10 bytes of the address being zero.

ipNumber

A byte array which contains the numeric form of the IP address. This array is large enough to store both IPv4 (32 bit) and IPv6 (128 bit) addresses. The values are stored in network byte order.

Remarks

The **INTERNET_ADDRESS** structure is used by some functions to represent an Internet address in a binary format that is compatible with both IPv4 and IPv6 addresses. Applications that use this structure should consider it to be opaque, and should not modify the contents of the structure directly.

For compatibility with legacy applications that expect an IP address to be 32 bits and stored in an unsigned integer, you can copy the first four bytes of the *ipNumber* array using the **CopyMemory** function or equivalent. Note that if this is done, your application should always check the *ipFamily* member first to make sure that it is actually an IPv4 address.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cswsock10.h

SECURITYCREDENTIALS Structure

The **SECURITYCREDENTIALS** structure specifies the information needed by the library to specify additional security credentials, such as a client certificate or private key, when establishing a secure connection.

```
typedef struct _SECURITYCREDENTIALS
{
    DWORD    dwSize;
    DWORD    dwProtocol;
    DWORD    dwOptions;
    DWORD    dwReserved;
    LPCTSTR  lpszHostName;
    LPCTSTR  lpszUserName;
    LPCTSTR  lpszPassword;
    LPCTSTR  lpszCertStore;
    LPCTSTR  lpszCertName;
    LPCTSTR  lpszKeyFile;
} SECURITYCREDENTIALS, *LPSECURITYCREDENTIALS;
```

Members

dwSize

Size of this structure. If the structure is being allocated dynamically, this member must be set to the size of the structure and all other unused structure members must be initialized to a value of zero or NULL.

dwProtocol

A bitmask of supported security protocols. The value of this structure member is constructed by using a bitwise operator with any of the following values:

Constant	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_SSL	Either SSL 2.0 or SSL 3.0 should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, TLS will be excluded from the list of supported protocols. Both SSL 2.0 and 3.0 have been deprecated and will never be used unless explicitly specified. It is not recommended that you enable either of these protocols for secure connections because it will cause most servers to reject your connection request, even if a version of TLS is also specified.
SECURITY_PROTOCOL_TLS	Either the TLS 1.0, 1.1 or 1.2 protocol should be used when establishing a secure connection. The correct protocol is automatically selected, based on

	what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers that reject any attempt to use the older SSL protocol and require that only TLS be used.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This is the recommended version of TLS to use with secure connections.

dwOptions

A value which specifies one or options. This member is constructed by using a bitwise operator with any of the following values:

Constant	Description
CREDENTIAL_STORE_CURRENT_USER	The library will attempt to open a store for the current user using the certificate store name provided in this structure. If no options are specified, then this is the default behavior.
CREDENTIAL_STORE_LOCAL_MACHINE	The library will attempt to open a local machine store using the certificate store name provided in this structure. If this option is specified, the library will always search for a local machine store before searching for the store by that name for the current user.
CREDENTIAL_STORE_FILENAME	The certificate store name is a file that contains the certificate and private key that

will be used.

dwReserved

This structure member is reserved for future use and should always be initialized to zero.

lpszHostName

A pointer to a null terminated string which specifies the hostname that will be used when validating the server certificate. If this member is NULL, then the server certificate will be validated against the hostname used to establish the connection.

lpszUserName

A pointer to a null terminated string which identifies the owner of client certificate. Currently this member is not used by the library and should always be initialized as a NULL pointer.

lpszPassword

A pointer to a null terminated string which specifies the password needed to access the certificate. Currently this member is only used if the CREDENTIAL_STORE_FILENAME option has been specified. If there is no password associated with the certificate, then this member should be initialized as a NULL pointer.

lpszCertStore

A pointer to a null terminated string which specifies the name of the certificate store to open. A certificate store is a collection of certificates and their private keys, typically organized by how they are used. If this value is NULL or points to an empty string, the default certificate store "MY" will be used.

Store Name	Description
------------	-------------

CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as VeriSign and Thawte act as certification authorities.
----	---

MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. This corresponds to the "Personal" store that is displayed by the certificate manager utility and is the default store used by the library.
----	--

ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as VeriSign and Thawte are installed as part of the operating system and periodically updated by Microsoft.
------	--

lpszCertName

A pointer to a null terminated string which specifies the name of the certificate to use. The library will first search the certificate store for a certificate with a matching "friendly name"; this is a name for the certificate that is assigned by the user. Note that the name must match completely, but the comparison is not case sensitive. If no matching certificate is found, the library will then attempt to find a certificate that has a matching common name (also called the certificate subject). This comparison is less stringent, and the first partial match will be returned. If this second search fails, the library will return an error indicating that the certificate could not be found. If the SECURITY_PROTOCOL_SSH protocol has been specified, this member should be NULL.

lpszKeyFile

A pointer to a null terminated string which specifies the name of the file which contains the private key required to establish the connection. This member is only used for SSH connections

and should always be NULL when establishing a secure connection using SSL or TLS.

Remarks

A client application only needs to create this structure if the server requires that the client provide a certificate as part of the process of negotiating the secure session. If a certificate is required, note that it must have a private key associated with it. Attempting to use a certificate that does not have a private key will result in an error during the connection process indicating that the client credentials could not be established.

If you are using a local certificate store, with the certificate and private key stored in the registry, you can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU:" for the current user, or "HKLM:" for the local machine. For example, a certificate store name of "HKLM:MY" would specify the personal certificate store for the local machine, rather than the current user. If neither prefix is specified, then it will default to the certificate store for the current user. You can manage these certificates using the CertMgr.msc Microsoft Management Console (MMC) snap-in.

It is possible to load the certificate from a file rather than from current user's certificate store. The *dwOptions* member should be set to CREDENTIAL_STORE_FILENAME and the *lpzCertStore* member should specify the name of the file that contains the certificate and its private key. The file must be in Private Information Exchange (PFX) format, also known as PKCS#12. These certificate files typically have an extension of .pfx or .p12. Note that if a password was specified when the certificate file was created, it must be provided in the *lpzPassword* member or the library will be unable to access the certificate.

Note that the *lpzUserName* and *lpzPassword* members are values which are used to access the certificate store or private key file. They are not the credentials which are used when establishing the connection with the remote host or authenticating the client session.

The TLS 1.1 and TLS 1.2 protocols are only supported on Windows 7, Windows Server 2008 R2 and later versions of the platform. If these options are specified and the application is running on Windows XP or Windows Vista, the protocol version will be downgraded to TLS 1.0 for backwards compatibility with those platforms.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Unicode: Implemented as Unicode and ANSI versions.

SECURITYINFO Structure

This structure contains information about a secure connection that has been established.

```
typedef struct _SECURITYINFO
{
    DWORD        dwSize;
    DWORD        dwProtocol;
    DWORD        dwCipher;
    DWORD        dwCipherStrength;
    DWORD        dwHash;
    DWORD        dwHashStrength;
    DWORD        dwKeyExchange;
    DWORD        dwCertStatus;
    SYSTEMTIME   stCertIssued;
    SYSTEMTIME   stCertExpires;
    LPCTSTR      lpszCertIssuer;
    LPCTSTR      lpszCertSubject;
    LPCTSTR      lpszFingerprint;
} SECURITYINFO, *LPSECURITYINFO;
```

Members

dwSize

Specifies the size of the data structure. This member must always be initialized to **sizeof(SECURITYINFO)** prior to passing the address of this structure to the function. Note that if this member is not initialized, an error will be returned indicating that an invalid parameter has been passed to the function.

dwProtocol

A numeric value which specifies the protocol that was selected to establish the secure connection. One of the following values will be returned:

Constant	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_SSL	Either SSL 2.0 or SSL 3.0 should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, TLS will be excluded from the list of supported protocols. Both SSL 2.0 and 3.0 have been deprecated and will never be used unless explicitly specified. It is not recommended that you enable either of these protocols for secure connections because it will cause most servers to reject your connection request, even if a version of TLS is also specified.
SECURITY_PROTOCOL_TLS	Either the TLS 1.0, 1.1 or 1.2 protocol should be used when establishing a secure connection. The

	<p>correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers that reject any attempt to use the older SSL protocol and require that only TLS be used.</p>
SECURITY_PROTOCOL_TLS10	<p>The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.</p>
SECURITY_PROTOCOL_TLS11	<p>The TLS 1.1 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.</p>
SECURITY_PROTOCOL_TLS12	<p>The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This is the recommended version of TLS to use with secure connections.</p>

dwCipher

A numeric value which specifies the cipher that was selected when establishing the secure connection. One of the following values will be returned:

Constant	Description
SECURITY_CIPHER_RC2	The RC2 block cipher was selected. This is a variable key length cipher which supports keys between 40 and 128 bits, in 8-bit increments.
SECURITY_CIPHER_RC4	The RC4 stream cipher was selected. This is a variable key length cipher which supports keys between 40 and 128 bits, in 8-bit increments.
SECURITY_CIPHER_RC5	The RC5 block cipher was selected. This is a variable key length cipher which supports keys up to 2040 bits, in 8-bit increments.
SECURITY_CIPHER_DES	The DES (Data Encryption Standard) block cipher was selected. This is a fixed key length cipher, using 56-bit

	keys.
SECURITY_CIPHER_DES3	The Triple DES block cipher was selected. This cipher encrypts the data three times using different keys, effectively providing a 168-bit length key.
SECURITY_CIPHER_DESX	A variant of the DES block cipher which XORs an extra 64-bits of the key before and after the plaintext has been encrypted, increasing the key size to 184 bits.
SECURITY_CIPHER_AES	The Advanced Encryption Standard cipher (also known as the Rijndael cipher) is a fixed block size cipher which use a key size of 128, 192 or 256 bits. This cipher is supported on Windows XP SP3 and later versions of the operating system.
SECURITY_CIPHER_SKIPJACK	The Skipjack block cipher was selected. This is a fixed key length cipher, using 80-bit keys.
SECURITY_CIPHER_BLOWFISH	The Blowfish block cipher was selected. This is a variable key length cipher up to 448 bits, using a 64-bit block size.

dwCipherStrength

A numeric value which specifies the strength (the length of the cipher key in bits) of the cipher that was selected. Typically this value will be 128 or 256. 40-bit and 56-bit key lengths are considered weak encryption, and subject to brute force attacks. 128-bit and 256-bit key lengths are considered to be secure, and are the recommended key length for secure communications.

dwHash

A numeric value which specifies the hash algorithm which was selected. One of the following values will be returned:

Constant	Description
SECURITY_HASH_MD5	The MD5 algorithm was selected. Its use has been deprecated and is no longer considered to be cryptographically secure.
SECURITY_HASH_SHA1	The SHA-1 algorithm was selected. Its use has been deprecated and is no longer considered to be cryptographically secure.
SECURITY_HASH_SHA256	The SHA-256 algorithm was selected.
SECURITY_HASH_SHA384	The SHA-384 algorithm was selected.
SECURITY_HASH_SHA512	The SHA-512 algorithm was selected.

dwHashStrength

A numeric value which specifies the strength (the length in bits) of the message digest that was selected.

dwKeyExchange

A numeric value which specifies the key exchange algorithm which was selected. One of the following values will be returned:

--	--

Constant	Description
SECURITY_KEYEX_RSA	The RSA public key algorithm was selected.
SECURITY_KEYEX_KEA	The Key Exchange Algorithm (KEA) was selected. This is an improved version of the Diffie-Hellman public key algorithm.
SECURITY_KEYEX_DH	The Diffie-Hellman key exchange algorithm was selected.
SECURITY_KEYEX_ECDH	The Elliptic Curve Diffie-Hellman key exchange algorithm was selected. This is a variant of the Diffie-Hellman algorithm which uses elliptic curve cryptography. This key exchange algorithm is only supported on Windows XP SP3 and later versions of the operating system.

dwCertStatus

A numeric value which specifies the status of the certificate returned by the secure server. This member only has meaning for connections using the SSL or TLS protocols. One of the following values will be returned:

Constant	Description
SECURITY_CERTIFICATE_VALID	The certificate is valid.
SECURITY_CERTIFICATE_NOMATCH	The certificate is valid, but the domain name does not match the common name in the certificate.
SECURITY_CERTIFICATE_EXPIRED	The certificate is valid, but has expired.
SECURITY_CERTIFICATE_REVOKED	The certificate has been revoked and is no longer valid.
SECURITY_CERTIFICATE_UNTRUSTED	The certificate or certificate authority is not trusted on the local system.
SECURITY_CERTIFICATE_INVALID	The certificate is invalid. This typically indicates that the internal structure of the certificate has been damaged.

stCertIssued

A structure which contains the date and time that the certificate was issued by the certificate authority. If the issue date cannot be determined for the certificate, the SYSTEMTIME structure members will have zero values. This member only has meaning for connections using the SSL or TLS protocols.

stCertExpires

A structure which contains the date and time that the certificate expires. If the expiration date cannot be determined for the certificate, the SYSTEMTIME structure members will have zero values. This member only has meaning for connections using the SSL or TLS protocols.

lpszCertIssuer

A pointer to a string which contains information about the organization that issued the certificate. This string consists of one or more comma-separated tokens. Each token consists of an identifier, followed by an equal sign and a value. If the certificate issuer could not be determined, this member may be NULL. This member only has meaning for connections using the SSL or TLS protocols.

lpszCertSubject

A pointer to a string which contains information about the organization that the certificate was issued to. This string consists of one or more comma-separated tokens. Each token consists of an identifier, followed by an equal sign and a value. If the certificate subject could not be determined, this member may be NULL. This member only has meaning for connections using the SSL or TLS protocols.

lpszFingerprint

A pointer to a string which contains a sequence of hexadecimal values that uniquely identify the server. This member is only used when a connection has been established using the Secure Shell (SSH) protocol.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Unicode: Implemented as Unicode and ANSI versions.

SocketWrench Library Error Codes

Value	Constant	Description
0x80042711	ST_ERROR_NOT_HANDLE_OWNER	Handle not owned by the current thread
0x80042712	ST_ERROR_FILE_NOT_FOUND	The specified file or directory does not exist
0x80042713	ST_ERROR_FILE_NOT_CREATED	The specified file could not be created
0x80042714	ST_ERROR_OPERATION_CANCELED	The blocking operation has been canceled
0x80042715	ST_ERROR_INVALID_FILE_TYPE	The specified file is a block or character device, not a regular file
0x80042716	ST_ERROR_INVALID_DEVICE	The specified device or address does not exist
0x80042717	ST_ERROR_TOO_MANY_PARAMETERS	The maximum number of function parameters has been exceeded
0x80042718	ST_ERROR_INVALID_FILE_NAME	The specified file name contains invalid characters or is too long
0x80042719	ST_ERROR_INVALID_FILE_HANDLE	Invalid file handle passed to function
0x8004271A	ST_ERROR_FILE_READ_FAILED	Unable to read data from the specified file
0x8004271B	ST_ERROR_FILE_WRITE_FAILED	Unable to write data to the specified file
0x8004271C	ST_ERROR_OUT_OF_MEMORY	Out of memory
0x8004271D	ST_ERROR_ACCESS_DENIED	Access denied
0x8004271E	ST_ERROR_INVALID_PARAMETER	Invalid argument passed to function
0x8004271F	ST_ERROR_CLIPBOARD_UNAVAILABLE	The system clipboard is currently unavailable
0x80042720	ST_ERROR_CLIPBOARD_EMPTY	The system clipboard is empty or does not contain any text data
0x80042721	ST_ERROR_FILE_EMPTY	The specified file does not contain any data
0x80042722	ST_ERROR_FILE_EXISTS	The specified file already exists
0x80042723	ST_ERROR_END_OF_FILE	End of file
0x80042724	ST_ERROR_DEVICE_NOT_FOUND	The specified device could not be found
0x80042725	ST_ERROR_DIRECTORY_NOT_FOUND	The specified directory could not be found
0x80042726	ST_ERROR_INVALID_BUFFER	Invalid memory address passed to function
0x80042728	ST_ERROR_NO_HANDLES	No more handles available to this process
0x80042733	ST_ERROR_OPERATION_WOULD_BLOCK	The specified operation would block the current thread
0x80042734	ST_ERROR_OPERATION_IN_PROGRESS	A blocking operation is currently in progress
0x80042735	ST_ERROR_ALREADY_IN_PROGRESS	The specified operation is already in progress
0x80042736	ST_ERROR_INVALID_HANDLE	Invalid handle passed to function

0x80042737	ST_ERROR_INVALID_ADDRESS	Invalid network address specified
0x80042738	ST_ERROR_INVALID_SIZE	Datagram is too large to fit in specified buffer
0x80042739	ST_ERROR_INVALID_PROTOCOL	Invalid network protocol specified
0x8004273A	ST_ERROR_PROTOCOL_NOT_AVAILABLE	The specified network protocol is not available
0x8004273B	ST_ERROR_PROTOCOL_NOT_SUPPORTED	The specified protocol is not supported
0x8004273C	ST_ERROR_SOCKET_NOT_SUPPORTED	The specified socket type is not supported
0x8004273D	ST_ERROR_INVALID_OPTION	The specified option is invalid
0x8004273E	ST_ERROR_PROTOCOL_FAMILY	Specified protocol family is not supported
0x8004273F	ST_ERROR_PROTOCOL_ADDRESS	The specified address is invalid for this protocol family
0x80042740	ST_ERROR_ADDRESS_IN_USE	The specified address is in use by another process
0x80042741	ST_ERROR_ADDRESS_UNAVAILABLE	The specified address cannot be assigned
0x80042742	ST_ERROR_NETWORK_UNAVAILABLE	The networking subsystem is unavailable
0x80042743	ST_ERROR_NETWORK_UNREACHABLE	The specified network is unreachable
0x80042744	ST_ERROR_NETWORK_RESET	Network dropped connection on remote reset
0x80042745	ST_ERROR_CONNECTION_ABORTED	Connection was aborted due to timeout or other failure
0x80042746	ST_ERROR_CONNECTION_RESET	Connection was reset by remote network
0x80042747	ST_ERROR_OUT_OF_BUFFERS	No buffer space is available
0x80042748	ST_ERROR_ALREADY_CONNECTED	Connection already established with remote host
0x80042749	ST_ERROR_NOT_CONNECTED	No connection established with remote host
0x8004274A	ST_ERROR_CONNECTION_SHUTDOWN	Unable to send or receive data after connection shutdown
0x8004274C	ST_ERROR_OPERATION_TIMEOUT	The specified operation has timed out
0x8004274D	ST_ERROR_CONNECTION_REFUSED	The connection has been refused by the remote host
0x80042750	ST_ERROR_HOST_UNAVAILABLE	The specified host is unavailable
0x80042751	ST_ERROR_HOST_UNREACHABLE	Remote host is unreachable
0x80042753	ST_ERROR_TOO_MANY_PROCESSES	Too many processes are using the networking subsystem
0x8004276B	ST_ERROR_NETWORK_NOT_READY	Network subsystem is not ready for communication
0x8004276C	ST_ERROR_INVALID_VERSION	This version of the operating system is not supported

0x8004276D	ST_ERROR_NETWORK_NOT_INITIALIZED	The networking subsystem has not been initialized
0x80042775	ST_ERROR_REMOTE_SHUTDOWN	The remote host has initiated a graceful shutdown sequence
0x80042AF9	ST_ERROR_INVALID_HOSTNAME	The specified hostname is invalid or could not be resolved
0x80042AFA	ST_ERROR_HOSTNAME_NOT_FOUND	The specified hostname could not be found
0x80042AFB	ST_ERROR_HOSTNAME_REFUSED	Unable to resolve hostname, request refused
0x80042AFC	ST_ERROR_HOSTNAME_NOT_RESOLVED	Unable to resolve hostname, no address for specified host
0x80042EE1	ST_ERROR_INVALID_LICENSE	The license for this product is invalid
0x80042EE2	ST_ERROR_PRODUCT_NOT_LICENSED	This product is not licensed to perform this operation
0x80042EE3	ST_ERROR_NOT_IMPLEMENTED	This function has not been implemented on this platform
0x80042EE4	ST_ERROR_UNKNOWN_LOCALHOST	Unable to determine local host name
0x80042EE5	ST_ERROR_INVALID_HOSTADDRESS	Invalid host address specified
0x80042EE6	ST_ERROR_INVALID_SERVICE_PORT	Invalid service port number specified
0x80042EE7	ST_ERROR_INVALID_SERVICE_NAME	Invalid or unknown service name specified
0x80042EE8	ST_ERROR_INVALID_EVENTID	Invalid event identifier specified
0x80042EE9	ST_ERROR_OPERATION_NOT_BLOCKING	No blocking operation in progress on this socket
0x80042F45	ST_ERROR_SECURITY_NOT_INITIALIZED	Unable to initialize security interface for this process
0x80042F46	ST_ERROR_SECURITY_CONTEXT	Unable to establish security context for this session
0x80042F47	ST_ERROR_SECURITY_CREDENTIALS	Unable to open client certificate store or establish client credentials
0x80042F48	ST_ERROR_SECURITY_CERTIFICATE	Unable to validate the certificate chain for this session
0x80042F49	ST_ERROR_SECURITY_DECRYPTION	Unable to decrypt data stream
0x80042F4A	ST_ERROR_SECURITY_ENCRYPTION	Unable to encrypt data stream
0x80043031	ST_ERROR_MAXIMUM_CONNECTIONS	The maximum number of client connections exceeded
0x80043032	ST_ERROR_THREAD_CREATION_FAILED	Unable to create a new thread for the current process
0x80043033	ST_ERROR_INVALID_THREAD_HANDLE	The specified thread handle is no longer valid
0x80043034	ST_ERROR_THREAD_TERMINATED	The specified thread has been terminated
0x80043035	ST_ERROR_THREAD_DEADLOCK	The operation would result in the current

		thread becoming deadlocked
0x80043036	ST_ERROR_INVALID_CLIENT_MONIKER	The specified moniker is not associated with any client session
0x80043037	ST_ERROR_CLIENT_MONIKER_EXISTS	The specified moniker has been assigned to another client session
0x80043038	ST_ERROR_SERVER_INACTIVE	The specified server is not listening for client connections
0x80043039	ST_ERROR_SERVER_SUSPENDED	The specified server is suspended and not accepting client connections

Telnet Protocol Library

Establish an interactive terminal session with a server.

Reference

- [Data Structures](#)
- [Error Codes](#)

Library Information

File Name	CSTNTV10.DLL
Version	10.0.1468.2518
LibID	A081335C-B907-4179-949F-FCE154F7C456
Import Library	CSTNTV10.LIB
Dependencies	None
Standards	RFC 854

Overview

The Telnet protocol is used to establish a connection with a server which provides a virtual terminal session for a user. Its functionality is similar to how character based consoles and serial terminals work, enabling a user to login to the server, execute commands and interact with applications running on the server. The class provides an interface for establishing the connection, negotiating certain options (such as whether characters will be echoed back to the client) and handling the standard I/O functions needed by the program.

The API also includes functions that enable a program to easily scan the data stream for specific sequences of characters, making it very simple to write light-weight client interfaces to applications running on the server. This library can be combined with the SocketTools Terminal Emulation API to provide complete terminal emulation services for a standard ANSI or DEC-VT220 terminal.

This library supports secure connections using the standard SSL and TLS protocols. To establish a secure connection to the server using the Secure Shell (SSH) protocol, use the SocketTools Secure Shell API.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). If you are using Visual C++ 6.0 it is required that you have Service Pack 6 (SP6) installed. You should install all updates for your development tools and have the current Windows SDK installed. The minimum recommended version of Visual Studio is Visual Studio 2010.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are using Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. It is recommended that you install the current service pack and all critical updates available for your version of the operating system.

This product includes both 32-bit and 64-bit libraries. Native 64-bit CPU support requires the 64-bit version of Windows 7 or later versions of the Windows operating system.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

Telnet Protocol Functions

Function	Description
TelnetAbort	Abort the current session and close the connection with the server
TelnetAsyncConnect	Connect asynchronously to the specified server
TelnetAttachThread	Attach the specified client handle to another thread
TelnetBreak	Send a break signal to the server
TelnetCancel	Cancel the current blocking operation
TelnetConnect	Connect to the specified server
TelnetCreateSecurityCredentials	Create a new security credentials structure
TelnetDeleteSecurityCredentials	Delete a previously created security credentials structure
TelnetDisableEvents	Disable asynchronous event notification
TelnetDisableTrace	Disable logging of socket function calls to the trace log
TelnetDisconnect	Disconnect from the current server
TelnetEnableEvents	Enable asynchronous event notification
TelnetEnableTrace	Enable logging of socket function calls to a file
TelnetEventProc	Callback function that processes events generated by the client
TelnetFreezeEvents	Suspend asynchronous event processing
TelnetGetErrorString	Return a description for the specified error code
TelnetGetLastError	Return the last error code
TelnetGetMode	Return the current client mode
TelnetGetSecurityInformation	Return security information about the current client connection
TelnetGetStatus	Return the current client status
TelnetGetTerminalType	Return the current terminal type
TelnetGetTimeout	Return the number of seconds until an operation times out
TelnetInitialize	Initialize the library and validate the specified license key at runtime
TelnetIsBlocking	Determine if the client is blocked, waiting for information
TelnetIsConnected	Determine if the client is connected to the server
TelnetIsReadable	Determine if data can be read from the server
TelnetIsThere	Determine if the server is available
TelnetIsWritable	Determine if data can be written to the server
TelnetLogin	Login to the server using the specified username and password
TelnetRead	Read data returned by the server
TelnetReadLine	Read a line of text from the server and return it in a string buffer
TelnetRegisterEvent	Register an event callback function

TelnetSearch	Search for a specific character sequence in the data stream
TelnetSetLastError	Set the last error code
TelnetSetMode	Set the current client mode
TelnetSetTerminalType	Set the current terminal type
TelnetSetTimeout	Set the number of seconds until an operation times out
TelnetUninitialize	Terminate use of the library by the application
TelnetWrite	Write data to the server
TelnetWriteLine	Write a line of text to the server

TelnetAbort Function

```
INT WINAPI TelnetAbort(  
    HCLIENT hClient  
);
```

The **TelnetAbort** function aborts the current session and terminates the connection.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is TELNET_ERROR. To get extended error information, call **TelnetGetLastError**.

Remarks

When the **TelnetAbort** function is called, the Telnet abort sequence is sent to the server and the connection to the server is terminated. Once this function returns, the client handle is no longer valid. If a program is currently executing on the server at the time this function is called, that program may be terminated as a result of the session being aborted. Applications should normally call **TelnetDisconnect** to gracefully disconnect from the server and should only use this function when the connection must be aborted immediately.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cstntv10.lib

TelnetAsyncConnect Function

```
HCLIENT WINAPI TelnetAsyncConnect(  
    LPCTSTR lpszRemoteHost,  
    UINT nRemotePort,  
    UINT nTimeout,  
    DWORD dwOptions,  
    LPSECURITYCREDENTIALS LpCredentials,  
    HWND hEventWnd,  
    UINT uEventMsg  
);
```

The **TelnetAsyncConnect** function is used to establish a connection with the server.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

The application should create a background worker thread and establish a connection by calling **TelnetConnect** within that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each client session.

Parameters

lpszRemoteHost

A pointer to the name of the server to connect to; this may be a fully-qualified domain name or an IP address.

nRemotePort

The port number the server is listening on; a value of zero specifies that the default port number should be used.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
TELNET_OPTION_NONE	No connection options specified. A standard connection to the server will be established using the specified host name and port number.
TELNET_OPTION_TUNNEL	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established.

TELNET_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using either the SSL or TLS protocols.
TELNET_OPTION_SECURE	This option specifies the client should attempt to establish a secure connection with the server. Note that the server must support secure connections using either the SSL or TLS protocol.
TELNET_OPTION_SECURE_EXPLICIT	This option specifies the client should attempt to establish a secure connection with the server using the START_TLS option. The client initiates a standard connection with the server, then requests a secure connection during the option negotiation process.
TELNET_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
TELNET_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
TELNET_OPTION_FREETHREAD	This option specifies the handle returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the handle is synchronized across multiple threads.

lpCredentials

Pointer to credentials structure [SECURITYCREDENTIALS](#). This parameter is only used if the TELNET_OPTION_SECURE option is specified for the connection. This parameter may be NULL, in which case no client credentials will be provided to the server. If client credentials are required, the fields *dwSize*, *lpCertStore*, and *lpCertName* must be defined, while other fields may be left undefined. Set *dwSize* to the size of the **SECURITYCREDENTIALS** structure.

hEventWnd

The handle to the event notification window. This window receives messages which notify the

client of various asynchronous socket events that occur.

uEventMsg

The message identifier that is used when an asynchronous socket event occurs. This value should be greater than WM_USER as defined in the Windows header files.

Return Value

If the function succeeds, the return value is a handle to a client session. If the function fails, the return value is INVALID_CLIENT. To get extended error information, call **TelnetGetLastError**.

Remarks

When a message is posted to the notification window, the low word of the *lParam* parameter contains the event identifier. The high word of *lParam* contains the low word of the error code, if an error has occurred. The *wParam* parameter contains the client handle. One or more of the following event identifiers may be sent:

Constant	Description
TELNET_EVENT_CONNECT	The connection to the server has completed. The high word of the <i>lParam</i> parameter should be checked, since this notification message will be posted if an error has occurred.
TELNET_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
TELNET_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
TELNET_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
TELNET_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
TELNET_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.

To cancel asynchronous notification and return the client to a blocking mode, use the **TelnetDisableEvents** function.

It is recommended that you only establish an asynchronous connection if you understand the implications of doing so. In most cases, it is preferable to create a synchronous connection and create threads for each additional session if more than one active client session is required.

The *dwOptions* argument can be used to specify the threading model that is used by the library when a connection is established. By default, the handle is initially attached to the thread that

created it. From that point on, until the it is released, only the owner may call functions using that handle. The ownership of the handle may be transferred from one thread to another using the **TelnetAttachThread** function.

Specifying the TELNET_OPTION_FREETHREAD option enables any thread to call any function using the handle, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the handle is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same handle.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstntv10.lib

Unicode: Implemented as Unicode and ANSI versions.

TelnetAttachThread Function

```
DWORD WINAPI TelnetAttachThread(  
    HCLIENT hClient  
    DWORD dwThreadId  
);
```

The **TelnetAttachThread** function attaches the specified client handle to another thread.

Parameters

hClient

Handle to the client session.

dwThreadId

The ID of the thread that will become the new owner of the handle. A value of zero specifies that the current thread should become the owner of the client handle.

Return Value

If the function succeeds, the return value is the thread ID of the previous owner. If the function fails, the return value is `TELNET_ERROR`. To get extended error information, call

TelnetGetLastError.

Remarks

When a client handle is created, it is associated with the current thread that created it. Normally, if another thread attempts to perform an operation using that handle, an error is returned since it does not own the handle. This is used to ensure that other threads cannot interfere with an operation being performed by the owner thread. In some cases, it may be desirable for one thread in a client application to create the client handle, and then pass that handle to another worker thread. The **TelnetAttachThread** function can be used to change the ownership of the handle to the new worker thread. By preserving the return value from the function, the original owner of the handle can be restored before the worker thread terminates.

This function should be called by the new thread immediately after it has been created, and if the new thread does not release the handle itself, the ownership of the handle should be restored to the parent thread before it terminates. Under no circumstances should **TelnetAttachThread** be used to forcibly release a handle allocated by another thread while a blocking operation is in progress. To cancel an operation, use the **TelnetCancel** function and then release the handle after the blocking function exits and control is returned to the current thread.

Note that the *dwThreadId* parameter is presumed to be a valid thread ID and no checks are performed to ensure that the thread actually exists. Specifying an invalid thread ID will orphan the handle until the **TelnetUninitialize** function is called.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `cstntv10.lib`

See Also

[TelnetCancel](#), [TelnetAsyncConnect](#), [TelnetConnect](#), [TelnetDisconnect](#), [TelnetUninitialize](#)

TelnetBreak Function

```
INT WINAPI TelnetBreak(  
    HCLIENT hClient  
);
```

The **TelnetBreak** function sends a signal to the server which may terminate an application that is currently running. The actual response to the break signal depends on the application.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is TELNET_ERROR. To get extended error information, call **TelnetGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cstntv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[TelnetAbort](#), [TelnetCancel](#), [TelnetRead](#), [TelnetWrite](#)

TelnetCancel Function

```
INT WINAPI TelnetCancel(  
    HCLIENT hClient  
);
```

The **TelnetCancel** function cancels any outstanding blocking operation in the client, causing the blocking function to fail. The application may then retry the operation or terminate the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is TELNET_ERROR. To get extended error information, call **TelnetGetLastError**.

Remarks

When the **TelnetCancel** function is called, the blocking function will not immediately fail. An internal flag is set which causes the blocking operation to exit with an error. This means that the application cannot cancel an operation and immediately perform some other operation. Instead it must allow the calling stack to unwind, returning back to the blocking operation before making any further function calls.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstntv10.lib

See Also

[TelnetAbort](#), [TelnetBreak](#), [TelnetIsBlocking](#)

TelnetConnect Function

```
HCLIENT WINAPI TelnetConnect(  
    LPCTSTR lpszRemoteHost,  
    UINT nRemotePort,  
    UINT nTimeout,  
    DWORD dwOptions,  
    LPSECURITYCREDENTIALS LpCredentials  
);
```

The **TelnetConnect** function is used to establish a connection with the server.

Parameters

lpszRemoteHost

A pointer to the name of the server to connect to; this may be a fully-qualified domain name or an IP address.

nRemotePort

The port number the server is listening on; a value of zero specifies that the default port number should be used.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
TELNET_OPTION_NONE	No connection options specified. A standard connection to the server will be established using the specified host name and port number.
TELNET_OPTION_TUNNEL	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established.
TELNET_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using either the SSL or TLS protocols.
TELNET_OPTION_SECURE	This option specifies the client should attempt to establish a secure connection with the server. Note that the server must support secure

	connections using either the SSL or TLS protocol.
TELNET_OPTION_SECURE_EXPLICIT	This option specifies the client should attempt to establish a secure connection with the server using the START_TLS option. The client initiates a standard connection with the server, then requests a secure connection during the option negotiation process.
TELNET_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
TELNET_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
TELNET_OPTION_FREETHREAD	This option specifies the handle returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the handle is synchronized across multiple threads.

lpCredentials

Pointer to credentials structure [SECURITYCREDENTIALS](#). This parameter is only used if the TELNET_OPTION_SECURE option is specified for the connection. This parameter may be NULL, in which case no client credentials will be provided to the server. If client credentials are required, the fields *dwSize*, *lpCertStore*, and *lpCertName* must be defined, while other fields may be left undefined. Set *dwSize* to the size of the **SECURITYCREDENTIALS** structure.

Return Value

If the function succeeds, the return value is a handle to a client session. If the function fails, the return value is INVALID_CLIENT. To get extended error information, call **TelnetGetLastError**.

Remarks

To prevent this function from blocking the main user interface thread, the application should create a background worker thread and establish a connection by calling **TelnetConnect** in that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each client session.

The *dwOptions* argument can be used to specify the threading model that is used by the library

when a connection is established. By default, the handle is initially attached to the thread that created it. From that point on, until the it is released, only the owner may call functions using that handle. The ownership of the handle may be transferred from one thread to another using the **TelnetAttachThread** function.

Specifying the TELNET_OPTION_FREETHREAD option enables any thread to call any function using the handle, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the handle is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same handle.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstntv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[TelnetCreateSecurityCredentials](#), [TelnetDeleteSecurityCredentials](#), [TelnetDisconnect](#), [TelnetInitialize](#), [TelnetUninitialize](#)

TelnetCreateSecurityCredentials Function

```
BOOL WINAPI TelnetCreateSecurityCredentials(  
    DWORD dwProtocol,  
    DWORD dwOptions,  
    LPCTSTR lpszUserName,  
    LPCTSTR lpszPassword,  
    LPCTSTR lpszCertStore,  
    LPCTSTR lpszCertName,  
    LPVOID lpvReserved,  
    LPSECURITYCREDENTIALS* lppCredentials  
);
```

The **TelnetCreateSecurityCredentials** function creates a **SECURITYCREDENTIALS** structure.

Parameters

dwProtocol

A bitmask of supported security protocols. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_SSL	Either SSL 2.0 or SSL 3.0 should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, TLS will be excluded from the list of supported protocols. Both SSL 2.0 and 3.0 have been deprecated and will never be used unless explicitly specified. It is not recommended that you enable either of these protocols for secure connections because it will cause most servers to reject your connection request, even if a version of TLS is also specified.
SECURITY_PROTOCOL_TLS	Either the TLS 1.0, 1.1 or 1.2 protocol should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers that reject any attempt to use the older SSL protocol and require that only TLS be used.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol should be used when establishing a secure connection. This version is

	supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This is the recommended version of TLS to use with secure connections.

dwOptions

A value which specifies one or options. This member is constructed by using a bitwise operator with any of the following values:

Constant	Description
CREDENTIAL_STORE_CURRENT_USER	The library will attempt to open a store for the current user using the certificate store name provided in this structure. If no options are specified, then this is the default behavior.
CREDENTIAL_STORE_LOCAL_MACHINE	The library will attempt to open a local machine store using the certificate store name provided in this structure. If this option is specified, the library will always search for a local machine store before searching for the store by that name for the current user.
CREDENTIAL_STORE_FILENAME	The certificate store name is a file that contains the certificate and private key that will be used.

lpszUserName

A pointer to a string which specifies the certificate owner's username. A value of NULL specifies that no username is required. Currently this parameter is not used and any value specified will be ignored.

lpszPassword

A pointer to a string which specifies the certificate owner's password. A value of NULL specifies

that no password is required. This parameter is only used if a PKCS12 (PFX) certificate file is specified and that certificate has been secured with a password. This value will be ignored the current user or local machine certificate store is specified.

lpszCertStore

A pointer to a string which specifies the name of the certificate store to open. A certificate store is a collection of certificates and their private keys, typically organized by how they are used. If this value is NULL or points to an empty string, the default certificate store "MY" will be used.

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as VeriSign and Thawte act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. This corresponds to the "Personal" store that is displayed by the certificate manager utility and is the default store used by the library.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as VeriSign and Thawte are installed as part of the operating system and periodically updated by Microsoft.

lpszCertName

A pointer to a null terminated string which specifies the name of the certificate to use. The function will first search the certificate store for a certificate with a matching "friendly name"; this is a name for the certificate that is assigned by the user. Note that the name must match completely, but the comparison is not case sensitive. If no matching certificate is found, the function will then attempt to find a certificate that has a matching common name (also called the certificate subject). This comparison is less stringent, and the first partial match will be returned. If this second search fails, the function will return an error indicating that the certificate could not be found.

lpvReserved

Pointer reserved for future use. Set it to NULL when using this function.

lppCredentials

Pointer to an [LPSECURITYCREDENTIALS](#) pointer. The memory for the credentials structure will be allocated by this function and must be released by calling the **TelnetDeleteSecurityCredentials** function when it is no longer needed. The pointer value must be set to NULL before the function is called. It is important to note that this is a pointer to a pointer variable, not a pointer to the SECURITYCREDENTIALS structure itself.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **TelnetGetLastError**.

Remarks

The structure that is created by this function may be used as client credentials when establishing a secure connection. This is particularly useful for programming languages other than C/C++ which may not support C structures or pointers. The pointer to the SECURITYCREDENTIALS structure can

be declared as an unsigned integer variable which is passed by reference to this function, and then passed by value to the **TelnetAsyncConnect** or **TelnetConnect** functions.

Example

```
LPSECURITYCREDENTIALS lpSecCred = NULL;
TelnetCreateSecurityCredentials(SEcurity_PROTOCOL_DEFAULT,
                               0,
                               NULL,
                               NULL,
                               lpzCertStore,
                               lpzCertName,
                               NULL,
                               &lpSecCred);

hClient = TelnetConnect(lpzHostName,
                       TELNET_PORT_SECURE,
                       TELNET_TIMEOUT,
                       TELNET_OPTION_SECURE,
                       lpSecCred);
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstntv10.lib

Unicode: Implemented as Unicode and ANSI versions.

TelnetDeleteSecurityCredentials Function

```
VOID WINAPI TelnetDeleteSecurityCredentials(  
    LPSECURITYCREDENTIALS* lppCredentials  
);
```

The **TelnetDeleteSecurityCredentials** function deletes an existing **SECURITYCREDENTIALS** structure.

Parameters

lppCredentials

Pointer to an **LPSECURITYCREDENTIALS** pointer. On exit from the function, the pointer will be NULL.

Return Value

None.

Example

```
if (lpSecCred)  
    TelnetDeleteSecurityCredentials(&lpSecCred);  
  
TelnetUninitialize();
```

Remarks

This function can be used to release the memory allocated to the client or server credentials after a secure connection has been terminated.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cstntv10.lib

Unicode: Implemented as Unicode and ANSI versions.

TelnetDisableEvents Function

```
INT WINAPI TelnetDisableEvents(  
    HCLIENT hClient  
);
```

The **TelnetDisableEvents** function disables the event notification mechanism, preventing subsequent event notification messages from being posted to the application's message queue.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is `TELNET_ERROR`. To get extended error information, call **TelnetGetLastError**.

Remarks

This function affects both event notification and event callbacks. Any outstanding events in the message queue should be ignored by the client application.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `cstntv10.lib`

See Also

[TelnetEnableEvents](#), [TelnetFreezeEvents](#), [TelnetRegisterEvent](#)

TelnetDisableTrace Function

```
BOOL WINAPI TelnetDisableTrace();
```

The **TelnetDisableTrace** function disables the logging of socket function calls to the trace log.

Parameters

None.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cstntv10.lib

See Also

[TelnetEnableTrace](#)

TelnetDisconnect Function

```
INT WINAPI TelnetDisconnect(  
    HCLIENT hClient  
);
```

The **TelnetDisconnect** function terminates the connection with the server, closing the socket and releasing the memory allocated for the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is TELNET_ERROR. To get extended error information, call **TelnetGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstntv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[TelnetAsyncConnect](#), [TelnetConnect](#), [TelnetUninitialize](#)

TelnetEnableEvents Function

```
INT WINAPI TelnetEnableEvents(  
    HCLIENT hClient,  
    HWND hEventWnd,  
    UINT uEventMsg  
);
```

The **TelnetEnableEvents** function enables event notifications using Windows messages.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Applications should use the **TelnetRegisterEvent** function to register an event handler which is invoked when an event occurs.

Parameters

hClient

Handle to the client session.

hEventWnd

Handle to the event notification window. This window receives a user-defined message which specifies the event that has occurred. If this value is NULL, event notification is disabled.

uEventMsg

An unsigned integer which specifies the user-defined message that is sent when an event occurs. This parameter's value must be greater than the value of WM_USER. If the *hEventWnd* parameter is NULL, this value must be specified as WM_NULL.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is TELNET_ERROR. To get extended error information, call **TelnetGetLastError**.

Remarks

When a message is posted to the notification window, the low word of the *lParam* parameter contains the event identifier. The high word of *lParam* contains the low word of the error code, if an error has occurred. The *wParam* parameter contains the client handle. One or more of the following event identifiers may be sent:

Constant	Description
TELNET_EVENT_CONNECT	The connection to the server has completed. The high word of the <i>lParam</i> parameter should be checked, since this notification message will be posted if an error has occurred.
TELNET_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
TELNET_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.

TELNET_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
TELNET_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
TELNET_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.

As noted, some events are only generated when the client is asynchronous mode. These events depend on the Windows Sockets asynchronous notification mechanism.

If event notification is disabled by specifying a NULL window handle, there may still be outstanding events in the message queue that must be processed. Since event handling has been disabled, these events should be ignored by the client application.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstntv10.lib

See Also

[TelnetDisableEvents](#), [TelnetFreezeEvents](#), [TelnetRegisterEvent](#)

TelnetEnableTrace Function

```
BOOL WINAPI TelnetEnableTrace(  
    LPCTSTR lpszTraceFile,  
    DWORD dwTraceFlags  
);
```

The **TelnetEnableTrace** function enables the logging of Windows Sockets function calls to a file.

Parameters

lpszTraceFile

A pointer to a string which specifies the name of the trace log file. If this parameter is NULL or an empty string, the default file name **cstrace.log** is used. The file is stored in the directory specified by the TEMP environment variable, if it is defined; otherwise, the current working directory is used.

dwTraceFlags

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
TRACE_INFO	All function calls are written to the trace file. This is the default value.
TRACE_ERROR	Only those function calls which fail are recorded in the trace file.
TRACE_WARNING	Only those function calls which fail or return values which indicate a warning are recorded in the trace file.
TRACE_HEXDUMP	All functions calls are written to the trace file, plus all the data that is sent or received is displayed, in both ASCII and hexadecimal format.
TRACE_PROCESS	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for multithreaded applications that are using worker threads.

Return Value

If the function succeeds, the return value is non-zero. A return value of zero indicates an error. Failure typically indicates that the tracing library **cstrcv10.dll** cannot be loaded on the local system.

Remarks

When trace logging is enabled, the file is opened, appended to and closed for each socket function call. This makes it possible for an application to append its own logging information, however care should be taken to ensure that the file is closed before the next network operation is performed. To limit the size of the log files, enable and disable logging only around those sections of code that you wish to trace.

Note that the TRACE_HEXDUMP trace level generates very large log files since it includes all of the data exchanged between your application and the server.

Trace function logging is managed on a per-thread basis, not for each client handle. This means that all SocketTools libraries and components share the same settings in the current thread. If you

are using multiple SocketTools libraries or components in your application, you only need to enable logging once.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstntv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[TelnetDisableTrace](#)

TelnetEventProc Function

```
VOID CALLBACK TelnetEventProc(  
    HCLIENT hClient,  
    UINT nEvent,  
    DWORD dwError,  
    DWORD_PTR dwParam  
);
```

The **TelnetEventProc** function is an application-defined callback function that processes events generated by the client.

Parameters

hClient

Handle to the client session.

nEvent

An unsigned integer which specifies which event occurred. For a complete list of events, refer to the **TelnetRegisterEvent** function.

dwError

An unsigned integer which specifies any error that occurred. If no error occurred, then this parameter will be zero.

dwParam

A user-defined integer value which was specified when the event callback was registered.

Return Value

None.

Remarks

An application must register this callback function by passing its address to the **TelnetRegisterEvent** function. The **TelnetEventProc** function is a placeholder for the application-defined function name.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstntv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[TelnetDisableEvents](#), [TelnetEnableEvents](#), [TelnetFreezeEvents](#), [TelnetRegisterEvent](#)

TelnetFreezeEvents Function

```
INT WINAPI TelnetFreezeEvents(  
    HCLIENT hClient,  
    BOOL bFreeze  
);
```

The **TelnetFreezeEvents** function is used to suspend and resume event handling by the client.

Parameters

hClient

Handle to the client session.

bFreeze

A non-zero value specifies that event handling should be suspended by the client. A zero value specifies that event handling should be resumed.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is TELNET_ERROR. To get extended error information, call **TelnetGetLastError**.

Remarks

This function should be used when the application does not want to process events, such as when a modal dialog is being displayed. When events are suspended, all client events are queued. If events are re-enabled at a later point, those queued events will be sent to the application for processing. Note that only one of each event will be generated. For example, if the client has suspended event handling, and four read events occur, once event handling is resumed only one of those read events will be posted to the client. This prevents the application from being flooded by a potentially large number of queued events.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstntv10.lib

See Also

[TelnetDisableEvents](#), [TelnetEnableEvents](#), [TelnetRegisterEvent](#)

TelnetGetErrorString Function

```
INT WINAPI TelnetGetErrorString(  
    DWORD dwErrorCode,  
    LPTSTR lpszDescription,  
    INT cbDescription  
);
```

The **TelnetGetErrorString** function is used to return a description of a specific error code. Typically this is used in conjunction with the **TelnetGetLastError** function for use with warning dialogs or as diagnostic messages.

Parameters

dwErrorCode

The error code for which a description is returned.

lpszDescription

A pointer to the buffer that will contain a description of the specified error code. This buffer should be at least 128 characters in length.

cbDescription

The maximum number of characters that may be copied into the description buffer.

Return Value

If the function succeeds, the return value is the length of the description string. If the function fails, the return value is zero, meaning that no description exists for the specified error code. Typically this indicates that the error code passed to the function is invalid.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `cstntv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

See Also

[TelnetGetLastError](#), [TelnetSetLastError](#)

TelnetGetLastError Function

```
DWORD WINAPI TelnetGetLastError();
```

Parameters

None.

Return Value

The return value is the last error code value for the current thread. Functions set this value by calling the **TelnetSetLastError** function. The Return Value section of each reference page notes the conditions under which the function sets the last error code.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. You should call the **TelnetGetLastError** function immediately when a function's return value indicates that an error has occurred. That is because some functions call **TelnetSetLastError(0)** when they succeed, clearing the error code set by the most recently failed function.

Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or TELNET_ERROR. Those functions which call **TelnetSetLastError** when they succeed are noted on the function reference page.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstntv10.lib

TelnetGetMode Function

```
UINT WINAPI TelnetGetMode(  
    HCLIENT hClient  
);
```

The **TelnetGetMode** function returns the current client mode.

Parameters

hClient

A handle to the client session.

Return Values

If the function succeeds, the return value is the current client mode. If the function fails, the return value is TELNET_ERROR. To get extended error information, call **TelnetGetLastError**.

Remarks

The client mode is a combination of one or more flags which determines how the client handles local character echo and character processing. The following values are recognized:

Value	Description
TELNET_MODE_LOCALECHO	The local client is responsible for echoing data entered by the user. By default, this mode is not set which means that the server is responsible for echoing back each character written to it.
TELNET_MODE_BINARY	Data exchanged between the client and server should not be converted or line buffered. If this option is not specified, the high-bit will be cleared on all characters and single linefeeds will be automatically converted to carriage-return/linefeed sequences.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstntv10.lib

Unicode: Implemented as Unicode and ANSI versions.

TelnetGetSecurityInformation Function

```
BOOL WINAPI TelnetGetSecurityInformation(  
    HCLIENT hClient,  
    LPSECURITYINFO lpSecurityInfo  
);
```

The **TelnetGetSecurityInformation** function returns security protocol, encryption and certificate information about the current client connection.

Parameters

hClient

Handle to the client session.

lpSecurityInfo

A pointer to a [SECURITYINFO](#) structure which contains information about the current client connection. The *dwSize* member of this structure must be initialized to the size of the structure before passing the address of the structure to this function.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **TelnetGetLastError**.

Remarks

This function is used to obtain security related information about the current client connection to the server. It can be used to determine if a secure connection has been established, what security protocol was selected, and information about the server certificate. Note that a secure connection has not been established, the *dwProtocol* structure member will contain the value `SECURITY_PROTOCOL_NONE`.

Example

The following example notifies the user if the connection is secure or not:

```
SECURITYINFO securityInfo;  
  
securityInfo.dwSize = sizeof(SECURITYINFO);  
if (TelnetGetSecurityInformation(hClient, &securityInfo))  
{  
    if (securityInfo.dwProtocol == SECURITY_PROTOCOL_NONE)  
    {  
        MessageBox(NULL, _T("The connection is not secure"),  
                    _T("Connection"), MB_OK);  
    }  
    else  
    {  
        if (securityInfo.dwCertStatus == SECURITY_CERTIFICATE_VALID)  
        {  
            MessageBox(NULL, _T("The connection is secure"),  
                        _T("Connection"), MB_OK);  
        }  
        else  
        {  
            MessageBox(NULL, _T("The server certificate not valid"),  
                        _T("Connection"), MB_OK);  
        }  
    }  
}
```

```
}  
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstntv10.lib

Unicode: Implemented as Unicode and ANSI versions.

TelnetGetStatus Function

```
INT WINAPI TelnetGetStatus(  
    HCLIENT hClient  
);
```

The **TelnetGetStatus** function returns the current status of the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the client status code. If the function fails, the return value is TELNET_ERROR. To get extended error information, call **TelnetGetLastError**.

Remarks

The **TelnetGetStatus** function returns a numeric code which identifies the current state of the client session. The following values may be returned:

Value	Constant	Description
1	TELNET_STATUS_IDLE	The client is current idle and not sending or receiving data.
2	TELNET_STATUS_CONNECT	The client is establishing a connection with the server.
3	TELNET_STATUS_READ	The client is reading data from the server.
4	TELNET_STATUS_WRITE	The client is writing data to the server.
5	TELNET_STATUS_DISCONNECT	The client is disconnecting from the server.

In a multithreaded application, any thread in the current process may call this function to obtain status information for the specified client session.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstntv10.lib

TelnetGetTerminalType Function

```
INT WINAPI TelnetGetTerminalType(  
    HCLIENT hClient,  
    LPCTSTR lpszTermType,  
    INT nMaxLength  
);
```

The **TelnetGetTerminalType** function returns the terminal type for the current client session.

Parameters

hClient

Handle to the client session.

lpszTermType

Points to a buffer which the current terminal type is copied into. This buffer should be at least 32 characters in length, including the terminating null character.

nMaxLength

Maximum number of characters that may be copied to the buffer, including the terminating null character.

Return Value

If the function succeeds, the return value is the length of the terminal type name. A value of zero indicates that no terminal type has been specified. If the function fails, the return value is TELNET_ERROR. To get extended error information, call **TelnetGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cstntv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[TelnetSetTerminalType](#)

TelnetGetTimeout Function

```
INT WINAPI TelnetGetTimeout(  
    HCLIENT hClient  
);
```

The **TelnetGetTimeout** function returns the number of seconds the client will wait for a response from the server. Once the specified number of seconds has elapsed, the function will fail and return to the caller.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the timeout period in seconds. If the function fails, the return value is TELNET_ERROR. To get extended error information, call **TelnetGetLastError**.

Remarks

The timeout value is only used with blocking client connections. A value of zero indicates that the default timeout period of 20 seconds should be used.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstntv10.lib

See Also

[TelnetSetTimeout](#)

TelnetInitialize Function

```
BOOL WINAPI TelnetInitialize(  
    LPCTSTR lpszLicenseKey,  
    LPINITDATA lpData  
);
```

The **TelnetInitialize** function initializes the library and validates the specified license key at runtime.

Parameters

lpszLicenseKey

Pointer to a string that specifies the runtime license key to be validated. If this parameter is NULL, the library will validate the development license installed on the local system.

lpData

Pointer to an INITDATA data structure. This parameter may be NULL if the initialization data for the library is not required.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **TelnetGetLastError**. All other client functions will fail until a license key has been successfully validated.

Remarks

This must be the first function that an application calls before using any of the other functions in the library. When a NULL license key is specified, the library will only function on the development system. Before redistributing the application to an end-user, you must insure that this function is called with a valid license key.

If the *lpData* argument is specified, it must point to an INITDATA structure which has been initialized by setting the *dwSize* member to the size of the structure. All other structure members should be set to zero. If the function is successful, then the INITDATA structure will be filled with identifying information about the library.

Although it is only required that **TelnetInitialize** be called once for the current process, it may be called multiple times; however, each call must be matched by a corresponding call to **TelnetUninitialize**.

This function dynamically loads other system libraries and allocates thread local storage. If you are calling the functions in this library from within another DLL, it is important that you do not call the **TelnetInitialize** or **TelnetUninitialize** functions from the **DllMain** function because it can result in deadlocks or access violation errors. If the DLL is linked with the C runtime library (CRT), it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstntv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

TelnetIsBlocking Function

```
BOOL WINAPI TelnetIsBlocking(  
    HCLIENT hClient  
);
```

The **TelnetIsBlocking** function is used to determine if the client is currently performing a blocking operation.

Parameters

hClient

Handle to the client session.

Return Value

If the client is performing a blocking operation, the function returns a non-zero value. If the client is not performing a blocking operation, or the client handle is invalid, the function returns zero.

Remarks

Because a blocking operation can allow the application to be re-entered (for example, by pressing a button while the operation is being performed), it is possible that another blocking function may be called while it is in progress. Since only one thread of execution may perform a blocking operation at any one time, an error would occur. The **TelnetIsBlocking** function can be used to determine if the client is already blocked, and if so, take some other action such as warning the user that they must wait for the operation to complete.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstntv10.lib

See Also

[TelnetCancel](#)

TelnetIsConnected Function

```
BOOL WINAPI TelnetIsConnected(  
    HCLIENT hClient  
);
```

The **TelnetIsConnected** function is used to determine if the client is currently connected to a server.

Parameters

hClient

Handle to the client session.

Return Value

If the client is connected to a server, the function returns a non-zero value. If the client is not connected, or the client handle is invalid, the function returns zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstntv10.lib

Unicode: Implemented as Unicode and ANSI versions.

TelnetIsReadable Function

```
BOOL WINAPI TelnetIsReadable(  
    HCLIENT hClient,  
    INT nTimeout,  
    LPDWORD lpdwAvail  
);
```

The **TelnetIsReadable** function is used to determine if data is available to be read from the server.

Parameters

hClient

Handle to the client session.

nTimeout

Timeout for server response, in seconds. A value of zero specifies that the connection should be polled without blocking the current thread.

lpdwAvail

A pointer to an unsigned integer which will contain the number of bytes available to read. This parameter may be NULL if this information is not required.

Return Value

If the client can read data from the server within the specified timeout period, the function returns a non-zero value. If the client cannot read any data, the function returns zero.

Remarks

On some platforms, this value will not exceed the size of the receive buffer (typically 64K bytes). Because of differences between TCP/IP stack implementations, it is not recommended that your application exclusively depend on this value to determine the exact number of bytes available. Instead, it should be used as a general indicator that there is data available to be read.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstntv10.lib

See Also

[TelnetGetStatus](#), [TelnetIsBlocking](#), [TelnetIsConnected](#), [TelnetIsThere](#), [TelnetIsWritable](#), [TelnetRead](#)

TelnetIsThere Function

```
BOOL WINAPI TelnetIsThere(  
    HCLIENT hClient  
);
```

The **TelnetIsThere** function reports the response of the client to a "Are you there" command to the telnet server.

Parameters

hClient

Handle to the client session.

Return Value

The function returns a non-zero value if the server acknowledges a specific control sequence used to determine if a Telnet server is responsive. If the server does not respond, the function will return a value of zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstntv10.lib

[TelnetGetStatus](#), [TelnetIsBlocking](#), [TelnetIsConnected](#), [TelnetIsReadable](#), [TelnetIsWritable](#)

TelnetIsWritable Function

```
BOOL WINAPI TelnetIsWritable(  
    HCLIENT hClient,  
    INT nTimeout  
);
```

The **TelnetIsWritable** function is used to determine if data can be written to the server.

Parameters

hClient

Handle to the client session.

nTimeout

Timeout for server response, in seconds. A value of zero specifies that the connection should be polled without blocking the current thread.

Return Value

If the client can write data to the server within the specified timeout period, the function returns a non-zero value. If the client cannot write any data, the function returns zero.

Remarks

Although this function can be used to determine if some amount of data can be sent to the remote process it does not indicate the amount of data that can be written without blocking the client. In most cases, it is recommended that large amounts of data be broken into smaller logical blocks, typically some multiple of 512 bytes in length.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `cstntv10.lib`

See Also

[TelnetGetStatus](#), [TelnetIsBlocking](#), [TelnetIsConnected](#), [TelnetIsReadable](#), [TelnetIsThere](#), [TelnetWrite](#)

TelnetLogin Function

```
BOOL WINAPI TelnetLogin(  
    HCLIENT hClient,  
    LPCTSTR lpszUserName,  
    LPCTSTR lpszPassword  
);
```

The **TelnetLogin** function attempts to authenticate the user and log them in to the current session.

Parameters

hClient

Handle to the client session.

lpszUserName

A pointer to a string which specifies the name of the user to authenticate.

lpszPassword

A pointer to a string which specifies the password to be used when authenticating the user. If the user does not require a password, this parameter may be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **TelnetGetLastError**.

Remarks

The **TelnetLogin** function is used to authenticate a user, logging them into the server. This function is specifically designed to work with most UNIX based servers, and may work with other servers that use a similar login process. The function works by scanning the data stream for a username prompt and then replying with the specified username. If that is successful, it will then scan for a password prompt and provide the specified password. If no recognized prompt is found, or if the server responds with an error indicating that the username or password is invalid, the function will fail.

If the **TelnetLogin** function succeeds, the next call to **TelnetRead** by the client will return any welcome message to the user. This is typically followed by a command prompt where the user can enter commands to be executed on the server. The data sent by the server during the login process is discarded and not available when the function returns. If the client requires this information, use the **TelnetSearch** function to automate the login process instead.

Because the **TelnetLogin** function is designed for UNIX based systems, it may not work with servers running on other operating system platforms such as Windows or VMS. In this case, applications should use the **TelnetSearch** function to search for the appropriate login prompts in the data stream.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstntv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[TelnetSearch](#)

TelnetRead Function

```
INT WINAPI TelnetRead(  
    HCLIENT hClient,  
    LPBYTE lpBuffer,  
    INT cbBuffer  
);
```

The **TelnetRead** function reads the specified number of bytes from the client socket and copies them into the buffer. The data may be of any type, and is not terminated with a null character.

Parameters

hClient

Handle to the client session.

lpBuffer

Pointer to the buffer in which the data will be copied.

cbBuffer

The maximum number of bytes to read and copy into the specified buffer. This value must be greater than zero.

Return Value

If the function succeeds, the return value is the number of bytes actually read. A return value of zero indicates that the server has closed the connection and there is no more data available to be read. If the function fails, the return value is TELNET_ERROR. To get extended error information, call **TelnetGetLastError**.

Remarks

When **TelnetRead** is called and the client is in non-blocking mode, it is possible that the function will fail because there is no available data to read at that time. This should not be considered a fatal error. Instead, the application should simply wait to receive the next asynchronous notification that data is available.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cstntv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[TelnetIsReadable](#), [TelnetSearch](#), [TelnetWrite](#)

TelnetReadLine Function

```
BOOL WINAPI TelnetReadLine(  
    HCLIENT hClient,  
    LPTSTR lpszBuffer,  
    LPINT lpnLength  
);
```

The **TelnetReadLine** function reads up to a line of data and returns it in a string buffer.

Parameters

hSocket

Handle to the client session.

lpszBuffer

Pointer to the string buffer that will contain the data when the function returns. The string will be terminated with a null byte, and will not contain the end-of-line characters.

lpnLength

A pointer to an integer value which specifies the length of the buffer. The value should be initialized to the maximum number of characters that can be copied into the string buffer, including the terminating null character. When the function returns, its value will be updated with the actual length of the string.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **TelnetGetLastError**.

Remarks

The **TelnetReadLine** function reads data sent by the server and copies it into a specified string buffer. Unlike the **TelnetRead** function which reads arbitrary bytes of data, this function is specifically designed to return a single line of text data in a string. When an end-of-line character sequence is encountered, the function will stop and return the data up to that point. The string buffer is guaranteed to be null-terminated and will not contain the end-of-line characters.

There are some limitations when using **TelnetReadLine**. The function should only be used to read text, never binary data. In particular, the function will discard nulls, linefeed and carriage return control characters. The Unicode version of this function will return a Unicode string, however this function does not support reading raw Unicode data from the server. The data is internally buffered as octets (eight-bit bytes) and converted to Unicode using the **MultiByteToWideChar** function.

This function will force the thread to block until an end-of-line character sequence is processed, the read operation times out or the server closes its end of the connection. If this function is called with asynchronous events enabled, it will automatically switch the client into a blocking mode, read the data and then restore the client to asynchronous operation. If another client operation is attempted while **TelnetReadLine** is blocked waiting for data from the server, an error will occur. It is recommended that this function only be used with blocking (synchronous) client connections; if the application needs to establish multiple simultaneous connections, it should create worker threads to manage each connection.

The **TelnetRead** and **TelnetReadLine** function calls can be intermixed, however be aware that **TelnetRead** will consume any data that has already been buffered by the **TelnetReadLine**

function and this may have unexpected results.

Unlike the **TelnetRead** function, it is possible for data to be returned in the buffer even if the return value is zero. Applications should also check the value of the *lpnLength* argument to determine if any data was copied into the buffer. For example, if a timeout occurs while the function is waiting for more data to arrive, it will return zero; however, data may have already been copied into the string buffer prior to the error condition. It is the responsibility of the application to process that data, regardless of the function return value.

Example

```
TCHAR szBuffer[MAXBUFLEN];
INT nLength;
BOOL bResult;

do
{
    nLength = sizeof(szBuffer);
    bResult = TelnetReadLine(hSocket, szBuffer, &nLength);

    if (nLength > 0)
    {
        // Process the line of data returned in the string
        // buffer; the string is always null-terminated
    }
} while (bResult);

DWORD dwError = TelnetGetLastError();
if (dwError == ST_ERROR_CONNECTION_CLOSED)
{
    // The server has closed its side of the connection and
    // there is no more data available to be read
}
else if (dwError != 0)
{
    // An error has occurred while reading a line of data
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstntv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[TelnetIsReadable](#), [TelnetRead](#), [TelnetWrite](#), [TelnetWriteLine](#)

TelnetRegisterEvent Function

```
INT WINAPI TelnetRegisterEvent(  
    HCLIENT hClient,  
    UINT nEvent,  
    TELNETEVENTPROC lpEventProc,  
    DWORD_PTR dwParam  
);
```

The **TelnetRegisterEvent** function registers a callback function for the specified event.

Parameters

hClient

Handle to the client session.

nEvent

An unsigned integer which specifies which event should be registered with the specified callback function. One of the following values may be used:

Constant	Description
TELNET_EVENT_CONNECT	The connection to the server has completed.
TELNET_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
TELNET_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
TELNET_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
TELNET_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
TELNET_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **TelnetEventProc** callback function. If this parameter is NULL, the callback for the specified event is disabled.

dwParam

A user-defined integer value that is passed to the callback function. If the application targets the x86 (32-bit) platform, this parameter must be a 32-bit unsigned integer. If the application targets the x64 (64-bit) platform, this parameter must be a 64-bit unsigned integer.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is `TELNET_ERROR`. To get extended error information, call **TelnetGetLastError**.

Remarks

The **TelnetRegisterEvent** function associates a callback function with a specific event. The event handler is an **TelnetEventProc** function that is invoked when the event occurs. Arguments are passed to the function to identify the client session, the event type and the user-defined value specified when the event handler is registered. If the event occurs because of an error condition, the error code will be provided to the handler.

The callback function specified by the *lpEventProc* parameter must be declared using the `__stdcall` calling convention. This ensures the arguments passed to the event handler are pushed on to the stack in the correct order. Failure to use the correct calling convention will corrupt the stack and cause the application to terminate abnormally.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `cstntv10.lib`

See Also

TelnetSearch Function

```
BOOL WINAPI TelnetSearch(  
    HCLIENT hClient,  
    LPCTSTR lpszString,  
    LPVOID lpvBuffer,  
    LPDWORD lpdwLength,  
    DWORD dwReserved  
);
```

The **TelnetSearch** function searches for a specific character sequence in the data stream and stops reading if the sequence is encountered.

Parameters

hClient

Handle to the client session.

lpszString

A pointer to a string which specifies the sequence of characters to search for in the data stream. This parameter cannot be NULL or point to an empty string.

lpvBuffer

A pointer to a byte buffer which will contain the output from the server, or a pointer to a global memory handle which will reference the output when the function returns. If the output from the server is not required, this parameter may be NULL.

lpdwLength

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the *lpvBuffer* parameter. If the *lpvBuffer* parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the actual number of bytes of output stored in the buffer. If the *lpvBuffer* parameter is NULL, this parameter should also be NULL.

dwReserved

A reserved parameter. This value must be zero.

Return Value

If the function succeeds and the character sequences was found in the data stream, the return value is non-zero. If the function fails or a timeout occurs before the sequence is found, the return value is zero. To get extended error information, call **TelnetGetLastError**.

Remarks

The **TelnetSearch** function searches for a character sequence in the data stream and stops reading when it is found. This is useful when the client wants to automate responses to the server, such as logging in a user and executing a command. The function collects the output from the server and stores it in the buffer specified by the *lpvBuffer* parameter. When the function returns, the buffer will contain everything sent by the server up to and including the search string.

The *lpvBuffer* parameter may be specified in one of two ways, depending on the needs of the application. The first method is to pre-allocate a buffer large enough to store the a fixed amount of output. In this case, the *lpvBuffer* parameter will point to the buffer that was allocated, the value that the *lpdwLength* parameter points to should be initialized to the size of that buffer. If the server sends more output than can be stored in the buffer, the remaining output will be discarded.

```

        0);
    }

    // If the shell prompt was found, issue the command
    // and capture the output into the hgblBuffer global
    // memory buffer; the cbBuffer variable will contain
    // the actual number of bytes in the buffer when the
    // function returns

    if (bResult)
    {
        TelnetWrite(hClient,
                    (LPBYTE)lpszCommand,
                    lstrlen(lpszCommand));

        bResult = TelnetSearch(hClient,
                               _T("$ "),
                               &hgblOutput,
                               &cbOutput,
                               0);
    }

    // Write the contents of the output buffer to the
    // standard output stream

    if (bResult)
    {
        LPBYTE lpBuffer = (LPBYTE)GlobalLock(hgblBuffer);

        if (lpBuffer)
            fwrite(lpBuffer, 1, cbBuffer, stdout);

        GlobalUnlock(hgblBuffer);
        GlobalFree(hgblBuffer);
    }
}

```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstntv10.lib

Unicode: Implemented as Unicode and ANSI versions.

TelnetSetLastError Function

```
VOID WINAPI TelnetSetLastError(  
    DWORD dwErrorCode  
);
```

The **TelnetSetLastError** function sets the last error code for the current thread. This function is typically used to clear the last error by specifying a value of zero as the parameter.

Parameters

dwErrorCode

Specifies the last error code for the current thread.

Return Value

None.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or TELNET_ERROR. Those functions which call **TelnetSetLastError** when they succeed are noted on the function reference page.

Applications can retrieve the value saved by this function by using the **TelnetGetLastError** function. The use of **TelnetGetLastError** is optional; an application can call the function to determine the specific reason for a function failure.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cstntv10.lib

TelnetSetMode Function

```
UINT WINAPI TelnetSetMode(  
    HCLIENT hClient,  
    UINT nMode,  
    BOOL bEnable  
);
```

The **TelnetSetMode** function sets one or more client modes for the specified session.

Parameters

hClient

Handle to the client session.

nMode

The client mode. This value is a combination of one or more flags which determines how the client handles local character echo and character processing. The following values are recognized:

Value	Description
TELNET_MODE_LOCALECHO	The local client is responsible for echoing data entered by the user. By default, this mode is not set which means that the server is responsible for echoing back each character written to it.
TELNET_MODE_BINARY	Data exchanged between the client and server should not be converted or line buffered. If this option is not specified, the high-bit will be cleared on all characters, and single linefeed characters will be converted to carriage-return/linefeed sequences.

bEnable

This boolean flag specifies if the specified mode is to be enabled or disabled.

Return Value

If the function succeeds, the return value is the previous mode. If the function fails, the return value is TELNET_ERROR. To get extended error information, call **TelnetGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstntv10.lib

[TelnetGetMode](#)

TelnetSetTerminalType Function

```
INT WINAPI TelnetSetTerminalType(  
    HCLIENT hClient,  
    LPCTSTR LpszTermType  
);
```

The **TelnetSetTerminalType** function sets the terminal type for the current client session.

Parameters

hClient

Handle to the client session.

lpszTermType

Points to a string which specifies the terminal type.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is TELNET_ERROR. To get extended error information, call **TelnetGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstntv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[TelnetGetTerminalType](#)

TelnetSetTimeout Function

```
INT WINAPI TelnetSetTimeout(  
    HCLIENT hClient,  
    INT nTimeout  
);
```

The **TelnetSetTimeout** function sets the number of seconds the client will wait for a response from the server. Once the specified number of seconds has elapsed, the function will fail and return to the caller.

Parameters

hClient

Handle to the client session.

nTimeout

The number of seconds to wait for a blocking operation to complete.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is TELNET_ERROR. To get extended error information, call **TelnetGetLastError**.

Remarks

The timeout value is only used with blocking client connections.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstntv10.lib

See Also

[TelnetGetTimeout](#)

TelnetUninitialize Function

```
VOID WINAPI TelnetUninitialize();
```

The **TelnetUninitialize** function terminates the use of the library.

Parameters

There are no parameters.

Return Value

None.

Remarks

An application is required to perform a successful **TelnetInitialize** call before it can call any of the other library functions. When it has completed the use of library, the application must call **TelnetUninitialize** to allow the library to free any resources allocated on behalf of the process. Any pending blocking or asynchronous calls in this process are canceled without posting any notification messages, and all sockets that were opened by the process are closed.

There must be a call to **TelnetUninitialize** for every successful call to **TelnetInitialize** made by a process. In a multithreaded environment, operations for all threads in the client are terminated.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstntv10.lib

Unicode: Implemented as Unicode and ANSI versions.

TelnetWrite Function

```
INT WINAPI TelnetWrite(  
    HCLIENT hClient,  
    LPBYTE lpBuffer,  
    INT cbBuffer  
);
```

The **TelnetWrite** function sends the specified number of bytes to the server.

Parameters

hClient

Handle to the client session.

lpBuffer

The pointer to the buffer which contains the data that is to be sent to the server.

cbBuffer

The number of bytes to send from the specified buffer.

Return Value

If the function succeeds, the return value is the number of bytes actually written. If the function fails, the return value is TELNET_ERROR. To get extended error information, call **TelnetGetLastError**.

Remarks

The return value may be less than the number of bytes specified by the *cbBuffer* parameter. In this case, the data has been partially written and it is the responsibility of the client application to send the remaining data at some later point. For non-blocking clients, the client must wait for the TELNET_EVENT_WRITE asynchronous notification message before it resumes sending data.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cstntv10.lib

Unicode: Implemented as Unicode and ANSI versions.

TelnetWriteLine Function

```
BOOL WINAPI TelnetWriteLine(  
    HCLIENT hClient,  
    LPCTSTR lpszBuffer,  
    LPINT lpnLength  
);
```

The **TelnetWriteLine** function sends a line of text to the server, terminated by a carriage-return and linefeed.

Parameters

hClient

Handle to the client session.

lpszBuffer

The pointer to a string buffer which contains the data that will be sent to the server. All characters up to, but not including, the terminating null character will be written to the server. The data will always be terminated with a carriage-return and linefeed control character sequence. If this parameter points to an empty string or NULL pointer, then a only a carriage-return and linefeed are written to the server.

lpnLength

A pointer to an integer value which will contain the number of characters written to the server, including the carriage-return and linefeed sequence. If this information is not required, a NULL pointer may be specified.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **TelnetGetLastError**.

Remarks

The **TelnetWriteLine** function writes a line of text to the server and terminates the line with a carriage-return and linefeed control character sequence. Unlike the **TelnetWrite** function which writes arbitrary bytes of data to the server, this function is specifically designed to write a single line of text data from a string.

If the *lpszBuffer* string is terminated with a linefeed (LF) or carriage return (CR) character, it will be automatically converted to a standard CRLF end-of-line sequence. Because the string will be sent with a terminating CRLF sequence, the value returned in the *lpnLength* parameter will typically be larger than the original string length (reflecting the additional CR and LF characters), unless the string was already terminated with CRLF.

There are some limitations when using **TelnetWriteLine**. The function should only be used to send text, never binary data. In particular, the function will discard nulls and append linefeed and carriage return control characters to the data stream. The Unicode version of this function will accept a Unicode string, however this function does not support sending raw Unicode data to the server. Unicode strings will be automatically converted to UTF-8 encoding using the **WideCharToMultiByte** function and then written as a stream of bytes.

This function will force the thread to block until the complete line of text has been written, the write operation times out or the server aborts the connection. If this function is called with asynchronous events enabled, it will automatically switch the client into a blocking mode, send the

data and then restore the client to asynchronous operation. If another network operation is attempted while **TelnetWriteLine** is blocked sending data to the server, an error will occur. It is recommended that this function only be used with blocking (synchronous) connections; if the application needs to establish multiple simultaneous connections, it should create worker threads to manage each connection.

The **TelnetWrite** and **TelnetWriteLine** function calls can be safely intermixed.

Unlike the **TelnetWrite** function, it is possible for data to have been written to the server if the return value is zero. For example, if a timeout occurs while the function is waiting to send more data to the server, it will return zero; however, some data may have already been written prior to the error condition. If this is the case, the *lpnLength* argument will specify the number of characters actually written up to that point.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Telnet Protocol Data Structures

- INITDATA
- SECURITYCREDENTIALS
- SECURITYINFO

INITDATA Structure

This structure contains information about the SocketTools library when the initialization function returns.

```
typedef struct _INITDATA
{
    DWORD        dwSize;
    DWORD        dwVersionMajor;
    DWORD        dwVersionMinor;
    DWORD        dwVersionBuild;
    DWORD        dwOptions;
    DWORD_PTR    dwReserved1;
    DWORD_PTR    dwReserved2;
    TCHAR        szDescription[128];
} INITDATA, *LPINITDATA;
```

Members

dwSize

Size of this structure. This structure member must be set to the size of the structure prior to calling the initialization function. Failure to do so will cause the function to fail.

dwVersionMajor

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the major version number for the library.

dwVersionMinor

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the minor version number for the library.

dwVersionBuild

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the build number for the library.

dwOptions

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

dwReserved1

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

dwReserved2

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

szDescription

A null terminated string which describes the library.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Unicode: Implemented as Unicode and ANSI versions.

SECURITYINFO Structure

This structure contains information about a secure connection that has been established.

```
typedef struct _SECURITYINFO
{
    DWORD        dwSize;
    DWORD        dwProtocol;
    DWORD        dwCipher;
    DWORD        dwCipherStrength;
    DWORD        dwHash;
    DWORD        dwHashStrength;
    DWORD        dwKeyExchange;
    DWORD        dwCertStatus;
    SYSTEMTIME   stCertIssued;
    SYSTEMTIME   stCertExpires;
    LPCTSTR      lpszCertIssuer;
    LPCTSTR      lpszCertSubject;
    LPCTSTR      lpszFingerprint;
} SECURITYINFO, *LPSECURITYINFO;
```

Members

dwSize

Specifies the size of the data structure. This member must always be initialized to **sizeof(SECURITYINFO)** prior to passing the address of this structure to the function. Note that if this member is not initialized, an error will be returned indicating that an invalid parameter has been passed to the function.

dwProtocol

A numeric value which specifies the protocol that was selected to establish the secure connection. One of the following values will be returned:

Constant	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_SSL	Either SSL 2.0 or SSL 3.0 should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, TLS will be excluded from the list of supported protocols. Both SSL 2.0 and 3.0 have been deprecated and will never be used unless explicitly specified. It is not recommended that you enable either of these protocols for secure connections because it will cause most servers to reject your connection request, even if a version of TLS is also specified.
SECURITY_PROTOCOL_TLS	Either the TLS 1.0, 1.1 or 1.2 protocol should be used when establishing a secure connection. The

	<p>correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers that reject any attempt to use the older SSL protocol and require that only TLS be used.</p>
SECURITY_PROTOCOL_TLS10	<p>The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.</p>
SECURITY_PROTOCOL_TLS11	<p>The TLS 1.1 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.</p>
SECURITY_PROTOCOL_TLS12	<p>The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This is the recommended version of TLS to use with secure connections.</p>

dwCipher

A numeric value which specifies the cipher that was selected when establishing the secure connection. One of the following values will be returned:

Constant	Description
SECURITY_CIPHER_RC2	The RC2 block cipher was selected. This is a variable key length cipher which supports keys between 40 and 128 bits, in 8-bit increments.
SECURITY_CIPHER_RC4	The RC4 stream cipher was selected. This is a variable key length cipher which supports keys between 40 and 128 bits, in 8-bit increments.
SECURITY_CIPHER_RC5	The RC5 block cipher was selected. This is a variable key length cipher which supports keys up to 2040 bits, in 8-bit increments.
SECURITY_CIPHER_DES	The DES (Data Encryption Standard) block cipher was selected. This is a fixed key length cipher, using 56-bit

	keys.
SECURITY_CIPHER_DES3	The Triple DES block cipher was selected. This cipher encrypts the data three times using different keys, effectively providing a 168-bit length key.
SECURITY_CIPHER_DESX	A variant of the DES block cipher which XORs an extra 64-bits of the key before and after the plaintext has been encrypted, increasing the key size to 184 bits.
SECURITY_CIPHER_AES	The Advanced Encryption Standard cipher (also known as the Rijndael cipher) is a fixed block size cipher which use a key size of 128, 192 or 256 bits. This cipher is supported on Windows XP SP3 and later versions of the operating system.
SECURITY_CIPHER_SKIPJACK	The Skipjack block cipher was selected. This is a fixed key length cipher, using 80-bit keys.
SECURITY_CIPHER_BLOWFISH	The Blowfish block cipher was selected. This is a variable key length cipher up to 448 bits, using a 64-bit block size.

dwCipherStrength

A numeric value which specifies the strength (the length of the cipher key in bits) of the cipher that was selected. Typically this value will be 128 or 256. 40-bit and 56-bit key lengths are considered weak encryption, and subject to brute force attacks. 128-bit and 256-bit key lengths are considered to be secure, and are the recommended key length for secure communications.

dwHash

A numeric value which specifies the hash algorithm which was selected. One of the following values will be returned:

Constant	Description
SECURITY_HASH_MD5	The MD5 algorithm was selected. Its use has been deprecated and is no longer considered to be cryptographically secure.
SECURITY_HASH_SHA1	The SHA-1 algorithm was selected. Its use has been deprecated and is no longer considered to be cryptographically secure.
SECURITY_HASH_SHA256	The SHA-256 algorithm was selected.
SECURITY_HASH_SHA384	The SHA-384 algorithm was selected.
SECURITY_HASH_SHA512	The SHA-512 algorithm was selected.

dwHashStrength

A numeric value which specifies the strength (the length in bits) of the message digest that was selected.

dwKeyExchange

A numeric value which specifies the key exchange algorithm which was selected. One of the following values will be returned:

--	--

Constant	Description
SECURITY_KEYEX_RSA	The RSA public key algorithm was selected.
SECURITY_KEYEX_KEA	The Key Exchange Algorithm (KEA) was selected. This is an improved version of the Diffie-Hellman public key algorithm.
SECURITY_KEYEX_DH	The Diffie-Hellman key exchange algorithm was selected.
SECURITY_KEYEX_ECDH	The Elliptic Curve Diffie-Hellman key exchange algorithm was selected. This is a variant of the Diffie-Hellman algorithm which uses elliptic curve cryptography. This key exchange algorithm is only supported on Windows XP SP3 and later versions of the operating system.

dwCertStatus

A numeric value which specifies the status of the certificate returned by the secure server. This member only has meaning for connections using the SSL or TLS protocols. One of the following values will be returned:

Constant	Description
SECURITY_CERTIFICATE_VALID	The certificate is valid.
SECURITY_CERTIFICATE_NOMATCH	The certificate is valid, but the domain name does not match the common name in the certificate.
SECURITY_CERTIFICATE_EXPIRED	The certificate is valid, but has expired.
SECURITY_CERTIFICATE_REVOKED	The certificate has been revoked and is no longer valid.
SECURITY_CERTIFICATE_UNTRUSTED	The certificate or certificate authority is not trusted on the local system.
SECURITY_CERTIFICATE_INVALID	The certificate is invalid. This typically indicates that the internal structure of the certificate has been damaged.

stCertIssued

A structure which contains the date and time that the certificate was issued by the certificate authority. If the issue date cannot be determined for the certificate, the SYSTEMTIME structure members will have zero values. This member only has meaning for connections using the SSL or TLS protocols.

stCertExpires

A structure which contains the date and time that the certificate expires. If the expiration date cannot be determined for the certificate, the SYSTEMTIME structure members will have zero values. This member only has meaning for connections using the SSL or TLS protocols.

lpszCertIssuer

A pointer to a string which contains information about the organization that issued the certificate. This string consists of one or more comma-separated tokens. Each token consists of an identifier, followed by an equal sign and a value. If the certificate issuer could not be determined, this member may be NULL. This member only has meaning for connections using the SSL or TLS protocols.

lpszCertSubject

A pointer to a string which contains information about the organization that the certificate was issued to. This string consists of one or more comma-separated tokens. Each token consists of an identifier, followed by an equal sign and a value. If the certificate subject could not be determined, this member may be NULL. This member only has meaning for connections using the SSL or TLS protocols.

lpszFingerprint

A pointer to a string which contains a sequence of hexadecimal values that uniquely identify the server. This member is only used when a connection has been established using the Secure Shell (SSH) protocol.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Unicode: Implemented as Unicode and ANSI versions.

SECURITYCREDENTIALS Structure

The **SECURITYCREDENTIALS** structure specifies the information needed by the library to specify additional security credentials, such as a client certificate or private key, when establishing a secure connection.

```
typedef struct _SECURITYCREDENTIALS
{
    DWORD    dwSize;
    DWORD    dwProtocol;
    DWORD    dwOptions;
    DWORD    dwReserved;
    LPCTSTR  lpszHostName;
    LPCTSTR  lpszUserName;
    LPCTSTR  lpszPassword;
    LPCTSTR  lpszCertStore;
    LPCTSTR  lpszCertName;
    LPCTSTR  lpszKeyFile;
} SECURITYCREDENTIALS, *LPSECURITYCREDENTIALS;
```

Members

dwSize

Size of this structure. If the structure is being allocated dynamically, this member must be set to the size of the structure and all other unused structure members must be initialized to a value of zero or NULL.

dwProtocol

A bitmask of supported security protocols. The value of this structure member is constructed by using a bitwise operator with any of the following values:

Constant	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_SSL	Either SSL 2.0 or SSL 3.0 should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, TLS will be excluded from the list of supported protocols. Both SSL 2.0 and 3.0 have been deprecated and will never be used unless explicitly specified. It is not recommended that you enable either of these protocols for secure connections because it will cause most servers to reject your connection request, even if a version of TLS is also specified.
SECURITY_PROTOCOL_TLS	Either the TLS 1.0, 1.1 or 1.2 protocol should be used when establishing a secure connection. The correct protocol is automatically selected, based on

	what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers that reject any attempt to use the older SSL protocol and require that only TLS be used.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This is the recommended version of TLS to use with secure connections.

dwOptions

A value which specifies one or options. This member is constructed by using a bitwise operator with any of the following values:

Constant	Description
CREDENTIAL_STORE_CURRENT_USER	The library will attempt to open a store for the current user using the certificate store name provided in this structure. If no options are specified, then this is the default behavior.
CREDENTIAL_STORE_LOCAL_MACHINE	The library will attempt to open a local machine store using the certificate store name provided in this structure. If this option is specified, the library will always search for a local machine store before searching for the store by that name for the current user.
CREDENTIAL_STORE_FILENAME	The certificate store name is a file that contains the certificate and private key that

will be used.

dwReserved

This structure member is reserved for future use and should always be initialized to zero.

lpszHostName

A pointer to a null terminated string which specifies the hostname that will be used when validating the server certificate. If this member is NULL, then the server certificate will be validated against the hostname used to establish the connection.

lpszUserName

A pointer to a null terminated string which identifies the owner of client certificate. Currently this member is not used by the library and should always be initialized as a NULL pointer.

lpszPassword

A pointer to a null terminated string which specifies the password needed to access the certificate. Currently this member is only used if the CREDENTIAL_STORE_FILENAME option has been specified. If there is no password associated with the certificate, then this member should be initialized as a NULL pointer.

lpszCertStore

A pointer to a null terminated string which specifies the name of the certificate store to open. A certificate store is a collection of certificates and their private keys, typically organized by how they are used. If this value is NULL or points to an empty string, the default certificate store "MY" will be used.

Store Name	Description
------------	-------------

CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as VeriSign and Thawte act as certification authorities.
----	---

MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. This corresponds to the "Personal" store that is displayed by the certificate manager utility and is the default store used by the library.
----	--

ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as VeriSign and Thawte are installed as part of the operating system and periodically updated by Microsoft.
------	--

lpszCertName

A pointer to a null terminated string which specifies the name of the certificate to use. The library will first search the certificate store for a certificate with a matching "friendly name"; this is a name for the certificate that is assigned by the user. Note that the name must match completely, but the comparison is not case sensitive. If no matching certificate is found, the library will then attempt to find a certificate that has a matching common name (also called the certificate subject). This comparison is less stringent, and the first partial match will be returned. If this second search fails, the library will return an error indicating that the certificate could not be found. If the SECURITY_PROTOCOL_SSH protocol has been specified, this member should be NULL.

lpszKeyFile

A pointer to a null terminated string which specifies the name of the file which contains the private key required to establish the connection. This member is only used for SSH connections

and should always be NULL when establishing a secure connection using SSL or TLS.

Remarks

A client application only needs to create this structure if the server requires that the client provide a certificate as part of the process of negotiating the secure session. If a certificate is required, note that it must have a private key associated with it. Attempting to use a certificate that does not have a private key will result in an error during the connection process indicating that the client credentials could not be established.

If you are using a local certificate store, with the certificate and private key stored in the registry, you can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU:" for the current user, or "HKLM:" for the local machine. For example, a certificate store name of "HKLM:MY" would specify the personal certificate store for the local machine, rather than the current user. If neither prefix is specified, then it will default to the certificate store for the current user. You can manage these certificates using the CertMgr.msc Microsoft Management Console (MMC) snap-in.

It is possible to load the certificate from a file rather than from current user's certificate store. The *dwOptions* member should be set to CREDENTIAL_STORE_FILENAME and the *lpzCertStore* member should specify the name of the file that contains the certificate and its private key. The file must be in Private Information Exchange (PFX) format, also known as PKCS#12. These certificate files typically have an extension of .pfx or .p12. Note that if a password was specified when the certificate file was created, it must be provided in the *lpzPassword* member or the library will be unable to access the certificate.

Note that the *lpzUserName* and *lpzPassword* members are values which are used to access the certificate store or private key file. They are not the credentials which are used when establishing the connection with the remote host or authenticating the client session.

The TLS 1.1 and TLS 1.2 protocols are only supported on Windows 7, Windows Server 2008 R2 and later versions of the platform. If these options are specified and the application is running on Windows XP or Windows Vista, the protocol version will be downgraded to TLS 1.0 for backwards compatibility with those platforms.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include ctools10.h

Unicode: Implemented as Unicode and ANSI versions.

Terminal Emulation Library

Emulate an ANSI or DEC VT-220 character mode display terminal.

Reference

- [Functions](#)
- [Data Structures](#)
- [Control Sequences](#)
- [Error Codes](#)

Library Information

File Name	CSNVTV10.DLL
Version	10.0.1468.2518
LibID	53152C92-4EA6-4C06-9ED3-50C79C933F01
Import Library	CSNVTV10.LIB
Dependencies	None

Overview

The Terminal Emulation library provides a comprehensive API for emulating an ANSI or DEC-VT220 terminal, with full support for all standard escape and control sequences, color mapping and other advanced features. The library functions provide both a high level interface for parsing escape sequences and updating a display, as well as lower level primitives for directly managing the virtual display, such as controlling the individual display cells, moving the cursor position and specifying display attributes.

This library can be used in conjunction with the Remote Command, Secure Shell or Telnet Protocol libraries to provide terminal emulation services for an application, or it can be used independently. For example, this library could be used to provide emulation services for a program that connects to a device using an RS-232 serial port.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). If you are using Visual C++ 6.0 it is required that you have Service Pack 6 (SP6) installed. You should install all updates for your development tools and have the current Windows SDK installed. The minimum recommended version of Visual Studio is Visual Studio 2010.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are using Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. It is recommended that you install the current service pack and all critical updates available for your version of the operating system.

This product includes both 32-bit and 64-bit libraries. Native 64-bit CPU support requires the 64-bit version of Windows 7 or later versions of the Windows operating system.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location

on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

Terminal Emulation Functions

Function	Description
NvtClearDisplay	Clear the specified display
NvtConvertDisplayPos	Convert between pixel and screen coordinates
NvtCopySelectedText	Copy the selected text to the clipboard
NvtCreateDisplay	Create a new virtual terminal emulation display
NvtDeleteChar	Delete the specified number of characters
NvtDeleteLine	Delete the current line, shifting remaining lines up
NvtDestroyDisplay	Destroy the specified virtual display
NvtEraseChar	Erase the specified number of characters
NvtEraseLine	Erase the current line
NvtGetCursorPos	Return the current cursor position
NvtGetDisplayAttributes	Return the current display attributes
NvtGetDisplayCell	Return information about the specified cell in the virtual display
NvtGetDisplayCellSize	Return the size of the display character cells
NvtGetDisplayColor	Get the current virtual display colors
NvtGetDisplayColorMap	Return the virtual display color table
NvtGetDisplayDC	Get the current virtual display device context
NvtGetDisplayEmulation	Get the current terminal emulation type
NvtGetDisplayFont	Get the current virtual display font
NvtGetDisplayInfo	Return information about the virtual display
NvtGetDisplayLine	Return a line of text from the virtual display
NvtGetDisplayMode	Get the current virtual display mode
NvtGetDisplayRect	Return the rectangle for the display window client area
NvtGetDisplayScrollPos	Get the display scroll box position
NvtGetDisplaySize	Return the current size of the virtual display
NvtGetDisplayText	Get the specified block of text from the virtual display
NvtGetDisplayWindow	Get the current virtual display window
NvtGetMappedKey	Return the escape sequence for the mapped key
NvtGetScrollRegion	Return the current scrolling region
NvtGetSelectedText	Return the currently selected text
NvtGetTextColor	Return the current text foreground or background color
NvtInitialize	Initialize the library for use by the client

NvtInsertChar	Insert the specified number of characters
NvtInsertLine	Insert a line, shifting the remaining lines down
NvtRefreshDisplay	Refresh the specified display
NvtResetDisplay	Reset the virtual display
NvtResetMappedKeys	Reset the mapped key table to default values
NvtResizeDisplay	Resize the virtual display
NvtRestoreCursor	Restore the saved cursor position and text attributes
NvtSaveCursor	Save the current cursor position and text attributes
NvtScrollDisplay	Scroll the virtual display
NvtSelectDisplayText	Select a region of the virtual display
NvtSetCursorPos	Set the current cursor position
NvtSetDisplayAttributes	Set the current display attributes
NvtSetDisplayBackColor	Set the background color for the virtual display
NvtSetDisplayBoldColor	Set the bold color for the virtual display
NvtSetDisplayCell	Set the value of a character cell in the virtual display
NvtSetDisplayColor	Set the virtual display colors
NvtSetDisplayColorMap	Set the virtual display color table
NvtSetDisplayDC	Set the current virtual display device context
NvtSetDisplayEmulation	Set the current terminal emulation type
NvtSetDisplayFocus	Set the focus on the virtual display
NvtSetDisplayFont	Set the current virtual display font
NvtSetDisplayFontName	Set the current virtual display font by name
NvtSetDisplayForeColor	Set the foreground color for the virtual display
NvtSetDisplayMode	Set the current virtual display mode
NvtSetDisplayScrollPos	Set the display scroll box position
NvtSetDisplaySize	Set the size of the virtual display
NvtSetDisplayWindow	Set the current virtual display window
NvtSetMappedKey	Set the escape sequence for the specified key
NvtSetScrollRegion	Set the current scrolling region
NvtSetTextColor	Set the current text foreground or background color
NvtTranslateMappedKey	Translate the keypress to a mapped key escape sequence
NvtUninitialize	Terminate use of the library by the application
NvtUpdateCaret	Update the display window caret
NvtUpdateDisplay	Update the window attached to the virtual display
NvtWriteDisplay	Write the specified buffer to the virtual display

NvtClearDisplay Function

```
BOOL WINAPI NvtClearDisplay(  
    HDISPLAY hDisplay,  
    UINT nMode  
);
```

The **NvtClearDisplay** function clears the specified display, erasing the text and clearing any attributes.

Parameters

hDisplay

Handle to the virtual display.

nMode

Mode which specifies how the display will be cleared. The following values may be used:

Constant	Description
NVT_CLEAR_EOS	The display is cleared from the current cursor position to the end of the display. The cursor position is not changed.
NVT_CLEAR_TOS	The display is cleared from the beginning of the display to the current cursor position. The cursor position is not changed.
NVT_CLEAR_ALL	The entire display is cleared and the cursor is repositioned to the upper left corner of the display.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it returns zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csnavt10.lib

NvtConvertDisplayPos Function

```
BOOL WINAPI NvtConvertDisplayPos(  
    HDISPLAY hDisplay,  
    INT nMethod,  
    INT xPos,  
    INT yPos,  
    LPPPOINT lppt  
);
```

The **NvtConvertDisplayPos** function converts the specified X,Y position and stores the result in the POINT structure provided by the caller.

Parameters

hDisplay

Handle to the virtual display.

nMethod

An integer value which specifies the conversion method to use. This may be one of the following values:

Constant	Description
NVT_CURSOR_TO_PIXELS	Convert cursor X,Y coordinates to the current window X,Y pixel coordinates. An error is returned if the coordinates are out of bounds for the current display.
NVT_PIXELS_TO_CURSOR	Convert window X,Y pixel coordinates to cursor X,Y coordinates. If the point is outside of the bounds of the display, it is normalized to account for mouse capture.

xPos

An integer value which specifies the X position in the virtual display. This may either be the cursor position or a pixel position, based on the value of the ***nMethod*** parameter.

yPos

An integer value which specifies the Y position in the virtual display. This may either be the cursor position or a pixel position, based on the value of the ***nMethod*** parameter.

lppt

A pointer to a POINT structure which will contain the converted coordinates.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it returns zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnavt10.lib

See Also

[NvtGetCursorPos](#), [NvtGetDisplayCellSize](#), [NvtGetDisplayScrollPos](#), [NvtGetDisplaySize](#), [NvtSetCursorPos](#), [NvtSetDisplayScrollPos](#)

NvtCopySelectedText Function

```
BOOL WINAPI NvtCopySelectedText(  
    HDISPLAY hDisplay  
);
```

The **NvtCopySelectedText** function copies any selected text to the system clipboard.

Parameters

hDisplay

Handle to the virtual display.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it returns zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csntv10.lib

See Also

[NvtGetSelectedText](#), [NvtSelectDisplayText](#)

NvtCreateDisplay Function

```
HDISPLAY WINAPI NvtCreateDisplay(  
    HWND hWnd,  
    HFONT hFont,  
    UINT nEmulation,  
    UINT nColumns,  
    UINT nRows  
);
```

The **NvtCreateDisplay** function creates a new virtual terminal emulation display using the specified window and font.

Parameters

hWnd

Handle to the window that will be used to display the virtual terminal.

hFont

Handle to the font that will be used with the virtual terminal. This parameter may be NULL, in which case a default fixed-width font will be used. If a font is specified, it must be fixed-width, otherwise the virtual cursor positioning will be incorrect in some cases.

nEmulation

Identifies the virtual terminal emulation type. The following emulation types are currently supported.

Constant	Description
NVT_EMULATION_NONE	The virtual display does not emulate any specific terminal type, and does not process escape sequences.
NVT_EMULATION_ANSI	The virtual display processes ANSI escape sequences for screen management and cursor positioning. This emulation also supports escape sequences to control the foreground and background color. The default keymap for ANSI function key escape sequences will be selected.
NVT_EMULATION_VT100	The virtual display processes DEC VT-100 escape sequences for screen management and cursor positioning. The default keymap for a DEC VT-100 terminal will be selected.
NVT_EMULATION_VT220	The virtual display processes DEC VT-220 escape sequences for screen management and cursor positioning. This emulation also supports DEC VT-320 escape sequences to control the foreground and background color. The default keymap for a DEC VT-220 terminal will be selected.

nColumns

The maximum number of columns used by the virtual display. This value must be at least 5, and no greater than 255.

nRows

The maximum number of rows used by the virtual display. This value must be at least 5, and no

greater than 127.

Return Value

If the function succeeds, the return value is a handle to the virtual display. If the function fails, the return value is `INVALID_DISPLAY`.

Remarks

The default colors for the display is a black background and white foreground. If ANSI terminal emulation is selected, bold characters will be displayed on a white background and blue foreground.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csnvtv10.lib`

NvtDeleteChar Function

```
BOOL WINAPI NvtDeleteChar(  
    HDISPLAY hDisplay,  
    INT nChars  
);
```

The **NvtDeleteChar** function deletes the specified number of characters from the display, shifting the characters that follow to the left. The characters are deleted from the current cursor position.

Parameters

hDisplay

Handle to the virtual display.

nChars

Number of characters to delete from the display.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it returns zero.

Remarks

This function does not change the current cursor position. To erase characters from the display without affecting the characters that follow, use the **NvtEraseChar** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csntv10.lib

NvtDeleteLine Function

```
BOOL WINAPI NvtDeleteLine(  
    HDISPLAY hDisplay  
);
```

The **NvtDeleteLine** function deletes the current line, shifting up the lines that follow.

Parameters

hDisplay

Handle to the virtual display.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it returns zero.

Remarks

This function does not change the current cursor position. To erase a line from the display without affecting the lines that follow, use the **NvtEraseLine** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnvtv10.lib

NvtDestroyDisplay Function

```
VOID WINAPI NvtDestroyDisplay(  
    HDISPLAY hDisplay  
);
```

The **NvtDestroyDisplay** function releases the memory allocated for the virtual display.

Parameters

hDisplay

Handle to the virtual display.

Return Value

None.

Remarks

If the display font was specified when the display was created, then it is the responsibility of the application to delete the font object using the **DeleteObject** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnavt10.lib

NvtEraseChar Function

```
BOOL WINAPI NvtEraseChar(  
    HDISPLAY hDisplay,  
    INT nChars  
);
```

The **NvtEraseChar** function erases the specified number of characters from the display, without affecting the position of the characters that follow. The characters are erased from the current cursor position.

Parameters

hDisplay

Handle to the virtual display.

nChars

Number of characters to erase from the display.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it returns zero.

Remarks

This function does not change the current cursor position. To delete characters from the display and shift the remaining characters to the left, use the **NvtDeleteChar** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csntv10.lib

[NvtClearDisplay](#), [NvtDeleteChar](#), [NvtDeleteLine](#), [NvtEraseLine](#)

NvtEraseLine Function

```
BOOL WINAPI NvtEraseLine(  
    HDISPLAY hDisplay,  
    UINT nMode  
);
```

The **NvtEraseLine** function erases the current line without affecting the lines that follow.

Parameters

hDisplay

Handle to the virtual display.

nMode

Mode which specifies how the line will be erased. The following values may be used:

Value	Description
0	The line is erased from the current cursor position to the end of the line.
1	The line is cleared from the beginning of the line to the current cursor position.
2	The entire line is cleared.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it returns zero.

Remarks

This function does not change the current cursor position. To delete a line from the display and shift the remaining lines up, use the **NvtDeleteLine** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csnvtv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

NvtGetCursorPos Function

```
BOOL WINAPI NvtGetCursorPos(  
    HDISPLAY hDisplay,  
    LPINT lpnCursorX,  
    LPINT lpnCursorY  
);
```

The **NvtGetCursorPos** function returns the current cursor column and row position on the virtual display.

Parameters

hDisplay

Handle to the virtual display.

lpnCursorX

Address of the variable that will be set to the column of the current cursor position. If this argument is a NULL pointer, the argument is ignored.

lpnCursorY

Address of the variable that will be set to the row of the current cursor position. If this argument is a NULL pointer, the argument is ignored.

Return Value

If the function succeeds, the return value is a non-zero value. If the handle to the virtual display is invalid, the function will return zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csntv10.lib

See Also

[NvtConvertDisplayPos](#), [NvtSetCursorPos](#)

NvtGetDisplayAttributes Function

```
UINT WINAPI NvtGetDisplayAttributes(  
    HDISPLAY hDisplay  
);
```

The **NvtGetDisplayAttributes** function returns the current display attributes which have been set, either explicitly by the client or as the result of an escape sequence parsed by the emulator.

Parameters

hDisplay

Handle to the virtual display.

Return Value

If the function succeeds, the return value is the current display attributes. If the function fails, the return value is NVT_ERROR.

The following table lists the valid attributes:

Constant	Description
NVT_ATTRIBUTE_NORMAL	Normal, default attributes.
NVT_ATTRIBUTE_REVERSE	Foreground and background cell colors are reversed.
NVT_ATTRIBUTE_BOLD	The character is displayed using a higher intensity color.
NVT_ATTRIBUTE_DIM	The character is displayed using a lower intensity color.
NVT_ATTRIBUTE_UNDERLINE	The character is displayed with an underline.
NVT_ATTRIBUTE_HIDDEN	The character is stored in display memory, but not shown.
NVT_ATTRIBUTE_PROTECT	The character is protected and cannot be cleared.

One or more attributes may be combined using a bitwise Or operator. Certain attributes, such as NVT_ATTRIBUTE_BOLD and NVT_ATTRIBUTE_DIM are mutually exclusive.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csntv10.lib

See Also

NvtGetDisplayCell Function

```
DWORD WINAPI NvtGetDisplayCell(  
    HDISPLAY hDisplay,  
    INT xPos,  
    INT yPos  
);
```

The **NvtGetDisplayCell** function returns information about the specified character cell in the display.

Parameters

hDisplay

Handle to the virtual display.

xPos

An integer value which specifies the X cursor position in the display.

yPos

An integer value which specifies the Y cursor position in the display.

Return Value

If the function succeeds, the return value is the cell character and attributes. If the function fails, it returns NVT_ERROR.

Remarks

The value returned by the **NvtGetDisplayCell** function is an unsigned 32-bit integer value, where the low order word specifies the ANSI character stored at that position and the high order word specifies the display attributes for that cell.

The character cell attributes may be one or more of the following values:

Constant	Description
NVT_ATTRIBUTE_NORMAL	Normal, default attributes.
NVT_ATTRIBUTE_REVERSE	Foreground and background cell colors are reversed.
NVT_ATTRIBUTE_BOLD	The character is displayed using a higher intensity color.
NVT_ATTRIBUTE_DIM	The character is displayed using a lower intensity color.
NVT_ATTRIBUTE_UNDERLINE	The character is displayed with an underline.
NVT_ATTRIBUTE_HIDDEN	The character is stored in display memory, but not shown.
NVT_ATTRIBUTE_PROTECT	The character is protected and cannot be cleared.

One or more attributes may be combined using a bitwise Or operator. Certain attributes, such as NVT_ATTRIBUTE_BOLD and NVT_ATTRIBUTE_DIM are mutually exclusive.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnvtv10.lib

NvtGetDisplayCellSize Function

```
BOOL WINAPI NvtGetDisplayCellSize(  
    HDISPLAY hDisplay,  
    LPSIZE lpCellSize  
);
```

The **NvtGetDisplayCellSize** function returns the size of a character cell in pixels.

Parameters

hDisplay

Handle to the virtual display.

lpCellSize

A pointer to a SIZE structure which will contain the size of a character cell in pixels.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it returns zero.

Remarks

The **NvtGetDisplayCellSize** function is used to determine the size of a character cell in the display. This can be useful when the application needs to determine where a display cell is physically located within the virtual display window.

To convert between display and window coordinates, use the **NvtConvertDisplayPos** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csntv10.lib

[NvtConvertDisplayPos](#), [NvtGetDisplayCell](#)

NvtGetDisplayColor Function

```
COLORREF WINAPI NvtGetDisplayColor(  
    HDISPLAY hDisplay,  
    UINT nColorIndex,  
    BOOL bForeground  
);
```

The **NvtGetDisplayColor** function returns the color used by the virtual display to display text with a specific attribute.

Parameters

hDisplay

Handle to the virtual display.

nColorIndex

The index into the virtual display color table. It may be one of the following values.

Value	Description
NVT_COLOR_NORMAL	The colors displayed for normal text. These are the default colors used with the display.
NVT_COLOR_REVERSE	The colors displayed for text with the reverse attribute set. This is only used when emulation is enabled.
NVT_COLOR_BOLD	The colors displayed for text with the bold attribute set. This is only used when emulation is enabled.
NVT_COLOR_REVERSEBOLD	The colors displayed for text with the reverse and bold attributes set. This is only used when emulation is enabled.

bForeground

A boolean flag which specifies if the color is a foreground color, used when displaying text, or a background color.

Return Value

If the function succeeds, the return value is the RGB value of the specified color. If the function fails, it returns zero.

Remarks

The default colors for the display is a black background and white foreground. Bold characters are displayed on a white background and blue foreground.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csntv10.lib

See Also

[NvtSetDisplayBackColor](#), [NvtSetDisplayBoldColor](#), [NvtSetDisplayColor](#), [NvtSetDisplayForeColor](#)

NvtGetDisplayColorMap Function

```
BOOL WINAPI NvtGetDisplayColorMap(  
    HDISPLAY hDisplay,  
    COLORREF* lpColor,  
    INT nMaxColors  
);
```

The **NvtGetDisplayColorMap** function returns the virtual display color table which determines what RGB values are used to display foreground and background text color attributes.

Parameters

hDisplay

Handle to the virtual display.

lpColor

A pointer to an array of COLORREF values which will contain the color values currently being used in the virtual display.

nMaxColors

The maximum number of colors which may be stored in the color array. The minimum value for this parameter is 1, and the maximum value is 16.

Return Value

If the function succeeds, the return value is a non-zero value. If the function fails, the return value is zero. Failure indicates that the handle to the virtual display is invalid, the pointer to the color table is NULL or the maximum number of color values is invalid.

Remarks

When the emulator processes an escape sequence that changes the current foreground or background color, the actual RGB color value is determined by looking up the value in the virtual display's color table. The **NvtGetDisplayColorMap** function is useful for determining what values are being used when a color attribute is set. The emulator currently supports a maximum of sixteen (16) color values, and the index into the table corresponds to the color as defined by the standard for ANSI terminals:

Index	Color	Default (Hex)	Default (Integer)	Default (RGB)
0	Black	0	0	RGB(0,0,0)
1	Red	000000A0h	160	RGB(160,0,0)
2	Green	0000A000h	40960	RGB(0,160,0)
3	Yellow	0000A0A0h	41120	RGB(160,160,0)
4	Blue	00A00000h	10485760	RGB(0,0,160)
5	Magenta	00A000A0h	10485920	RGB(160,0,160)
6	Cyan	00A0A000h	10526720	RGB(0,160,160)
7	White	00E0E0E0h	14737632	RGB(224,224,224)
8	Gray	00C0C0C0h	12632256	RGB(192,192,192)
9	Light Red	008080FFh	8421631	RGB(255,128,128)

10	Light Green	0090EE90h	9498256	RGB(144,238,144)
11	Light Yellow	00C0FFFFh	12648447	RGB(255,255,192)
12	Light Blue	00E6D8ADh	15128749	RGB(173,216,230)
13	Light Magenta	00FFC0FFh	16761087	RGB(255,192,255)
14	Light Cyan	00FFFFFF0h	16777184	RGB(224,255,255)
15	High White	00FFFFFFh	16777215	RGB(255,255,255)

A standard ANSI color terminal supports eight standard colors (0-7). To select a foreground color, you add 30 to the color index and pass that value as a parameter to the SGR (select graphic rendition) escape sequence. To select a background color, you add 40 to the color index. For example, to set the current foreground color to white and the background color to blue, you could send the following escape sequence:

```
ESC [ 37;44 m
```

Note that if you wanted to set the foreground color to a bold version of standard yellow, you would first set the bold attribute, and then use the index value of 3, such as:

```
ESC [ 1;33m
```

NvtGetDisplayColorMap is typically used in conjunction with the **NvtSetDisplayColorMap** function to load the current color values and then make selective changes to the actual RGB color value that is used when a color attribute is set. Note that changes to the color map will only affect new characters as they are displayed, not any previously displayed characters.

Example

The following example will load the current color table for the virtual display and change the standard white color attribute to use the same value as the high-intensity white:

```
COLORREF rgbColor[16];

if ( NvtGetDisplayColorMap(hDisplay, rgbColor, 16) )
{
    rgbColor[7] = rgbColor[15];
    NvtSetDisplayColorMap(hDisplay, rgbColor, 16);
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstoools10.h

Import Library: csnavt10.lib

Unicode: Implemented as Unicode and ANSI versions.

NvtGetDisplayDC Function

```
HDC WINAPI NvtGetDisplayDC(  
    HDISPLAY hDisplay  
);
```

The **NvtGetDisplayDC** returns the device context that has been specified for the virtual display.

Parameters

hDisplay

Handle to the virtual display.

Return Value

If the function succeeds, the return value is a handle to the device context. If the function fails, or no device context has been specified, the return value is NULL.

Remarks

Normally there is no device context explicitly set for the display. Instead, the device context is dynamically created and released when the virtual display is updated.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csntv10.lib

See Also

NvtGetDisplayEmulation Function

```
UINT WINAPI NvtGetDisplayEmulation(  
    HDISPLAY hDisplay  
);
```

The **NvtGetDisplayEmulation** function returns the current virtual terminal emulation type.

Parameters

hDisplay

Handle to the virtual display.

Return Value

If the function succeeds, the return value is the terminal emulation type and may contain one of the following values:

Value	Description
NVT_EMULATION_NONE	The virtual display does not emulate any specific terminal type, and does not process any escape sequences.
NVT_EMULATION_ANSI	The virtual display will process ANSI escape sequences. The default keymap for an ANSI console is loaded.
NVT_EMULATION_VT100	The virtual display will process DEC VT100 escape sequences. The default keymap for a VT100 terminal is loaded.
NVT_EMULATION_VT220	The virtual display will process DEC VT220 escape sequences. The default keymap for a VT220 terminal is loaded.

If the function fails, because an invalid display handle was specified, the return value will be NVT_ERROR.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csnavt10.lib

NvtGetDisplayFont Function

```
HFONT WINAPI NvtGetDisplayFont(  
    HDISPLAY hDisplay  
);
```

The **NvtGetDisplayFont** function returns the current font handle being used by the virtual display.

Parameters

hDisplay

Handle to the virtual display.

Return Value

If the function succeeds, the return value is a handle to the font. If the function fails, it returns NULL.

Remarks

The handle returned by this function should not be released, and the font object should never be directly modified by the application. Functions that return information about the font, such as **GetTextMetrics**, may be safely called.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstoools10.h

Import Library: csnavt10.lib

See Also

NvtGetDisplayInfo Function

```
BOOL WINAPI NvtGetDisplayInfo(  
    HDISPLAY hDisplay,  
    LPNVTDISPLAYINFO lpvdi  
);
```

The **NvtGetDisplayInfo** function returns information about the specified virtual display.

Parameters

hDisplay

Handle to the virtual display.

lpvdi

Pointer to a [NVTDISPLAYINFO](#) structure which contains information about the virtual display, including the display window, font, cursor and scrolling position.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it returns zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csntv10.lib

See Also

NvtGetDisplayLine Function

```
INT WINAPI NvtGetDisplayLine(  
    HDISPLAY hDisplay,  
    INT nRow,  
    LPTSTR LpszBuffer,  
    INT nMaxLength  
);
```

The **NvtGetDisplayLine** function copies a block of text from the specified virtual display into a string buffer.

Parameters

hDisplay

Handle to the virtual display.

nRow

The row in the virtual display to return the line of text from. The first row in the display is zero. If the value -1 is specified, the row where the cursor is currently located will be used.

lpszBuffer

Pointer to the buffer that the display text will be copied to, terminated with a null character character.

cbBuffer

Maximum number of characters that may be copied into the specified buffer, including the null character terminator.

Return Value

If the function succeeds, the return value is the number of characters copied into the buffer, not including the null character terminator. If the function fails, it returns zero.

Remarks

The **NvtGetDisplayLine** function allows the application to copy the contents of the display at a specific row. Note that the buffer must be large enough to accommodate the text and the null character terminator. Unlike the **NvtGetDisplayText** function, any trailing whitespace in the specified row is not copied to the buffer.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csntv10.lib

Unicode: Implemented as Unicode and ANSI versions.

NvtGetDisplayMode Function

```
UINT WINAPI NvtGetDisplayMode(  
    HDISPLAY hDisplay  
);
```

The **NvtGetDisplayMode** function returns the current virtual display modes.

Parameters

hDisplay

Handle to the virtual display.

Return Value

If the function succeeds, the return value is the display mode for the virtual display. If the function fails, it returns zero.

Remarks

The display mode is a combination of one or more flags which determines how the emulator handles automatic line wrapping, caret display, and other functions. The following values are recognized.

Constant	Description
NVT_MODE_AUTOWRAP	The emulator will automatically wrap to the next line when a character is written to the last column on the virtual display.
NVT_MODE_SHOWCARET	The emulator will display a caret when the display receives the focus.
NVT_MODE_BLOCKCARET	The emulator will display a block carat that is the height of the selected font characters. If this mode is not set, the caret is displayed as an underline.
NVT_MODE_BELL	The emulator will beep when a BEL character is processed.
NVT_MODE_CRLF	The cursor will automatically be positioned at the first column when a linefeed character is processed.
NVT_MODE_CRNL	The cursor will automatically advance to the next row when a carriage return character is processed.
NVT_MODE_APPCURSOR	The emulator cursor keys are placed in application mode. This mode changes the default key mappings used when the cursor (arrow) keys are translated. This corresponds to the application mode supported by DEC VT terminals.
NVT_MODE_APPKEYPAD	The emulator keypad keys are placed in application mode. This mode changes the default key mappings used when the keypad keys are translated. This corresponds to the application keypad mode supported by DEC VT terminals.
NVT_MODE_ORIGIN	The emulator is in origin mode. If enabled, the cursor cannot be positioned outside of the current scrolling region. Otherwise, the cursor can be positioned at any valid location on the virtual display.
NVT_MODE_COLOR	The emulator supports the use of escape sequences to change the

	foreground and background colors. This option is enabled by default if emulating an ANSI console or DEC VT220 terminal.
NVT_MODE_TABOVER	The emulator will clear the character cells between the current cursor position and the next tab stop when the HT (horizontal tab) control sequence is processed. By default this mode is disabled, and the cursor is simply positioned at the next tab stop.
NVT_MODE_HSCROLL	The emulator will display a horizontal scroll bar if the number of visible columns are less than that total number of columns in the virtual display. Disabling this mode prevents a horizontal scrollbar from being displayed, regardless of the number of visible columns. By default, this mode is enabled.
NVT_MODE_VSCROLL	The emulator will display a vertical scroll bar if the number of visible rows are less than that total number of rows in the virtual display. Disabling this mode prevents a vertical scrollbar from being displayed, regardless of the number of visible rows. By default, this mode is enabled.
NVT_MODE_NOREFRESH	The emulator will not automatically refresh the window after any change has been made to the virtual display, including changes in the cursor position or display mode. This allows the caller to make a sequence of changes, and then update the display all at one time to prevent a flicker effect.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

NvtGetDisplayRect Function

```
BOOL WINAPI NvtGetDisplayRect(  
    HDISPLAY hDisplay,  
    LPRECT lprc  
);
```

The **NvtGetDisplayRect** returns the client rectangle for the virtual display window.

Parameters

hDisplay

Handle to the virtual display.

lpRect

Pointer to a RECT structure which will contain the client rectangle values when the function returns.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it returns zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csnavt10.lib

NvtGetDisplayScrollPos Function

```
INT WINAPI NvtGetDisplayScrollPos(  
    HDISPLAY hDisplay,  
    INT nScrollBar  
);
```

The **NvtGetDisplayScrollPos** function gets the position of the scroll box for the specified scroll bar.

Parameters

hDisplay

Handle to the virtual display.

nScrollBar

Specifies the scroll bar to return the position for. This parameter can be one of the following values:

Constant	Description
SB_HORZ	Gets the position of the scroll box in the display's standard horizontal scroll bar.
SB_VERT	Gets the position of the scroll box in the display's standard vertical scroll bar.

Return Value

If the function succeeds, the return value is the position of the scroll box. If the function fails, it returns -1.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csntv10.lib

See Also

[NvtSetDisplayScrollPos](#)

NvtGetDisplaySize Function

```
BOOL WINAPI NvtGetDisplaySize(  
    HDISPLAY hDisplay,  
    LPSIZE lpSize  
);
```

The **NvtGetDisplaySize** returns the size of the virtual display in columns and rows.

Parameters

hDisplay

Handle to the virtual display.

lpRect

Pointer to a SIZE structure which will contain the size of the virtual display.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it returns zero.

Remarks

The **NvtGetDisplaySize** function returns the number of columns and rows in the virtual display. To convert this to pixels, use the **NvtGetDisplayCellSize** function to determine the size of a character cell and multiply that by the number of columns and/or rows.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnavt10.lib

NvtGetDisplayText Function

```
INT WINAPI NvtGetDisplayText(  
    HDISPLAY hDisplay,  
    INT nOffset,  
    LPTSTR lpszBuffer,  
    INT nMaxLength  
);
```

The **NvtGetDisplayText** function copies a block of text from the specified virtual display into a string buffer.

Parameters

hDisplay

Handle to the virtual display.

nOffset

Offset into the virtual display buffer. A value of -1 specifies that the current cursor position should be used as the offset.

lpszBuffer

Pointer to the buffer that the display text will be copied to, terminated with a null character character.

nMaxLength

Maximum number of characters that may be copied into the specified buffer, including the null character terminator.

Return Value

If the function succeeds, the return value is the number of characters copied into the buffer, not including the null character terminator. If the function fails, it returns zero.

Remarks

The **NvtGetDisplayText** function allows the application to copy the contents of the display at a specific location. Note that the buffer must be large enough to accommodate the text and the null character terminator. To copy an entire row of text in the display, use the **NvtGetDisplayLine** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnavt10.lib

Unicode: Implemented as Unicode and ANSI versions.

NvtGetDisplayWindow Function

```
HWND WINAPI NvtGetDisplayWindow(  
    HDISPLAY hDisplay  
);
```

The **NvtGetDisplayWindow** returns the handle to the window being used by the virtual display.

Parameters

hDisplay

Handle to the virtual display.

Return Value

If the function succeeds, the return value is a handle to the virtual display window. If the function fails, it returns NULL.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnavt10.lib

[NvtGetDisplayInfo](#)

NvtGetMappedKey Function

```
BOOL WINAPI NvtGetMappedKey(  
    HDISPLAY hDisplay,  
    UINT nMappedKey,  
    LPTSTR lpszKeyBuffer,  
    UINT cchKeyBuffer  
);
```

The **NvtGetMappedKey** function returns the escape sequence mapped to the specified key.

Parameters

hDisplay

Handle to the virtual display.

nMappedKey

The key which is an index into the display key mapping table. This defines the values returned by special (function) keys for the current emulation.

lpszKeyBuffer

Address of the buffer which will receive the escape sequence mapped to the specified key.

cchKeyBuffer

The maximum number of characters that may be copied into the key buffer string, including the terminating null character.

Return Value

If the function succeeds, the return value is non-zero and the escape sequence for the mapped key is copied into the specified buffer. If the key has not been mapped, and there is no default escape sequence defined, then the function will return zero.

Remarks

The **NvtGetMappedKey** function returns the escape sequence that has been mapped to a special key. This function can be used to determine what sequence of characters should be sent in response to a keypress (for example, what sequence should be sent to a server when the user presses the F1 function key). If a sequence has not been explicitly mapped through a call to **NvtSetMappedKey**, the default sequence for the current emulation will be returned.

Note that the current display mode, such as whether or not the emulator is in application mode or not, should be considered when determining which mapped key to use. For example, if the emulator is not in application mode and the user presses the up-arrow key, the sequence mapped to the NVT_UP key should be sent to the server. However, if the emulator is in application mode, the sequence mapped to the NVT_APPUP key should be sent instead. This is automatically handled by the **NvtTranslateMappedKey** function, so it is recommended that it be used when mapping a virtual keypress to the appropriate escape sequence.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnavt10.lib

Unicode: Implemented as Unicode and ANSI versions.

NvtGetScrollRegion Function

```
BOOL WINAPI NvtGetScrollRegion(  
    HDISPLAY hDisplay,  
    LPINT lpnTop,  
    LPINT lpnBottom  
);
```

The **NvtGetScrollRegion** function returns the top and bottom rows of the current scrolling region.

Parameters

hDisplay

Handle to the virtual display.

lpnTop

Address of the variable that will be set to the top row of the current scrolling region. If no scrolling region has been defined, the value will be 0, the first row in the virtual display. If a NULL pointer is passed as the value, this argument will be ignored.

lpnBottom

Address of the variable that will be set to the bottom row of the current scrolling region. If no scrolling region has been defined, the value will be one less than the maximum number of rows in the virtual display. If a NULL pointer is passed as the value, this argument will be ignored.

Return Value

If the function succeeds, it will return zero. If the handle to the display is invalid, the function will return zero.

Remarks

The **NvtGetScrollRegion** function allows an application to determine the top and bottom rows of the current scrolling region. By default, the scrolling region is the entire virtual display, however this may be changed through a call to **NvtSetScrollRegion** or an ANSI escape sequence. If the display is in origin mode, note that the cursor cannot be positioned outside of the current scrolling region.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csnavt10.lib

See Also

NvtGetSelectedText Function

```
INT WINAPI NvtGetSelectedText(  
    HDISPLAY hDisplay,  
    LPTSTR lpszBuffer,  
    INT nMaxLength  
);
```

The **NvtGetSelectedText** function copies the currently selected text into the specified buffer.

Parameters

hDisplay

Handle to the virtual display.

lpszBuffer

Pointer to the buffer that the selected text will be copied to, terminated with a null character character.

nMaxLength

Maximum number of characters that may be copied into the specified buffer, including the null character terminator.

Return Value

If the function succeeds, the return value is the number of characters copied into the buffer, not including the null character terminator. If the function fails, it returns zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csntv10.lib

Unicode: Implemented as Unicode and ANSI versions.

NvtGetTextColor Function

```
BOOL WINAPI NvtGetTextColor(  
    HDISPLAY hDisplay,  
    COLORREF *lprgbColor,  
    BOOL bForeground  
);
```

The **NvtGetTextColor** function returns the current foreground or background text color.

Parameters

hDisplay

Handle to the virtual display.

lprgbColor

A pointer to a COLORREF variable which will contain the current foreground or background text color.

bForeground

A boolean value which determines if the foreground or background color is returned. A value of TRUE indicates that the foreground color should be returned, otherwise the background color is returned.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. Failure indicates that the handle to the display is invalid, the display does not support text color attributes, or the pointer to the color value is NULL.

Remarks

This function is used to return the current foreground or background color, as determined by the text attribute. The RGB color value for a color attribute is determined by the virtual display's color table.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csntv10.lib

See Also

[NvtGetDisplayColorMap](#), [NvtSetDisplayColorMap](#), [NvtSetTextColor](#)

NvtInitialize Function

```
BOOL WINAPI NvtInitialize(  
    LPCTSTR lpszLicenseKey,  
    LPINITDATA lpData  
);
```

The **NvtInitialize** function initializes the library and validates the specified license key at runtime.

Parameters

lpszLicenseKey

Pointer to a string that specifies the runtime license key to be validated. If this parameter is NULL, the library will validate the development license installed on the local system.

lpData

Pointer to an INITDATA data structure. This parameter may be NULL if the initialization data for the library is not required.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **NvtGetLastError**. All other client functions will fail until a license key has been successfully validated.

Remarks

This must be the first function that an application calls before using any of the other functions in the library. When a NULL license key is specified, the library will only function on the development system. Before redistributing the application to an end-user, you must insure that this function is called with a valid license key.

If the *lpData* argument is specified, it must point to an INITDATA structure which has been initialized by setting the *dwSize* member to the size of the structure. All other structure members should be set to zero. If the function is successful, then the INITDATA structure will be filled with identifying information about the library.

Although it is only required that **NvtInitialize** be called once for the current process, it may be called multiple times; however, each call must be matched by a corresponding call to **NvtUninitialize**.

This function dynamically loads other system libraries and allocates thread local storage. If you are calling the functions in this library from within another DLL, it is important that you do not call the **NvtInitialize** or **NvtUninitialize** functions from the **DllMain** function because it can result in deadlocks or access violation errors. If the DLL is linked with the C runtime library (CRT), it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csntv10.lib

NvtInsertChar Function

```
BOOL WINAPI NvtInsertChar(  
    HDISPLAY hDisplay,  
    INT nChars  
);
```

The **NvtInsertChar** function inserts one or more space characters at the current cursor position.

Parameters

hDisplay

Handle to the virtual display.

nChars

Number of space characters to insert at the current cursor position.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it returns zero.

Remarks

This function does not change the cursor position. Inserting space characters may cause the virtual display to scroll.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csntv10.lib

NvtInsertLine Function

```
BOOL WINAPI NvtInsertLine(  
    HDISPLAY hDisplay  
);
```

The **NvtInsertLine** function inserts an empty line at the current row, shifting the remaining lines down.

Parameters

hDisplay

Handle to the virtual display.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it returns zero.

Remarks

This function does not change the cursor position. Inserting a line may cause the virtual display to scroll.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

NvtRefreshDisplay Function

```
BOOL WINAPI NvtRefreshDisplay(  
    HDISPLAY hDisplay,  
    BOOL bUpdate  
);
```

The **NvtRefreshDisplay** function refreshes the specified virtual display, updating the current scroll position and caret.

Parameters

hDisplay

Handle to the virtual display.

bUpdate

Boolean flags which specifies if the display window is to be updated. If set, the window client area is invalidated and the virtual display is redrawn.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it returns zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnvtv10.lib

NvtResetDisplay Function

```
BOOL WINAPI NvtResetDisplay(  
    HDISPLAY hDisplay,  
    HWND hWnd,  
    HFONT hFont,  
    UINT nColumns,  
    UINT nRows  
);
```

The **NvtResetDisplay** resets the virtual terminal display, using the new window, font, columns and rows. This function should be used when the virtual display must be attached to a different window, or the number of rows or columns must be changed.

Parameters

hDisplay

Handle to the virtual display.

hWnd

Handle to the window that will be used to display the virtual terminal. This parameter may be NULL, in which case the current window will be used.

hFont

Handle to the font that will be used with the virtual terminal. This parameter may be NULL, in which case the current font will be used. If a font is specified, it must be fixed-width, otherwise the virtual cursor positioning will be incorrect in some cases.

nColumns

The maximum number of columns used by the virtual display. A value of zero specifies that the same number of columns should be used. If a non-zero value is specified, it must be at least 5, and no greater than 255.

nRows

The maximum number of rows used by the virtual display. A value of zero specifies that the same number of columns should be used. If a non-zero value is specified, it must be at least 5, and no greater than 127.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero.

Remarks

This function will clear the display and reset the current text attributes.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csntv10.lib

NvtResetMappedKeys Function

```
BOOL WINAPI NvtResetMappedKeys(  
    HDISPLAY hDisplay  
);
```

The **NvtResetMappedKeys** function resets all mapped function keys to their default values, based on the current emulation.

Parameters

hDisplay

Handle to the virtual display.

Return Value

If the function succeeds, the return value is non-zero. If the handle to the display is invalid, the function will return zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csntv10.lib

NvtResizeDisplay Function

```
BOOL WINAPI NvtResizeDisplay(  
    HDISPLAY hDisplay,  
    INT cxClient,  
    INT cyClient  
);
```

The **NvtResizeDisplay** function resizes the virtual display to the specified width and height.

Parameters

hDisplay

Handle to the virtual display.

cxClient

New width of the display window in pixels. If this value is zero, the width of the virtual display remains unchanged.

cyClient

New height of the display window in pixels. If this value is zero, the height of the virtual display remains unchanged.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it returns zero.

Remarks

This function resizes the virtual display and updates the scrolling information. Typically this function is called when the display window receives a WM_SIZE message, causing the virtual display to match the size of the window's client area.

This function will not change the size of the display window. To change the size of the display window, use the **SetWindowPos** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csntv10.lib

Unicode: Implemented as Unicode and ANSI versions.

NvtRestoreCursor Function

```
BOOL WINAPI NvtRestoreCursor(  
    HDISPLAY hDisplay  
);
```

The **NvtRestoreCursor** function restores the cursor position and text attributes to their previous values.

Parameters

hDisplay

Handle to the virtual display.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it returns zero.

Remarks

Use the **NvtSaveCursor** function to save the current cursor position and text attributes. This function may only be called once for each time that the cursor position is saved.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csntv10.lib

NvtSaveCursor Function

```
BOOL WINAPI NvtSaveCursor(  
    HDISPLAY hDisplay  
);
```

The **NvtSaveCursor** function saves the current cursor position and text attributes.

Parameters

hDisplay

Handle to the virtual display.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it returns zero.

Remarks

Use the **NvtRestoreCursor** function to restore the cursor position and text attributes to their previous values.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csntv10.lib

See Also

NvtScrollDisplay Function

```
BOOL WINAPI NvtScrollDisplay(  
    HDISPLAY hDisplay,  
    BOOL bScrollUp  
);
```

The **NvtScrollDisplay** function scrolls the virtual display up or down and updates the scroll box position if necessary.

Parameters

hDisplay

Handle to the virtual display.

bScrollUp

Boolean flag which specifies if the virtual display is scrolled up or down.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it returns zero.

Remarks

This function does not change the current cursor position. The **NvtRefreshDisplay** function should be called to update the window attached to the virtual display.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnavt10.lib

See Also

[NvtGetDisplayScrollPos](#), [NvtRefreshDisplay](#), [NvtSetDisplayScrollPos](#)

NvtSelectDisplayText Function

```
BOOL WINAPI NvtSelectDisplayText(  
    HDISPLAY hDisplay,  
    LPRECT lprc,  
    DWORD dwOptions  
);
```

The **NvtSelectDisplayText** function selects or unselects a region of the virtual display.

Parameters

hDisplay

Handle to the virtual display.

lprc

A pointer to a region of the display to select. The coordinates must be in display cursor coordinates, not pixels. If this parameter is NULL, any selected text in the display is unselected.

dwOptions

One or more options which specifies how the region will be selected. These options may be combined using a bitwise Or operator. The following values may be used:

Constant	Description
NVT_SELECT_DEFAULT	The default selection option. If there is a region of the display already selected, it will be cleared and the new region is selected.
NVT_SELECT_CLIPBOARD	Copy the selected text to the clipboard. If this option is not specified, the selected text is buffered and may be copied at a later point.
NVT_SELECT_NOREFRESH	The display is not refreshed when the region is selected. This is useful if the application is going to be selecting multiple regions of the display, or combining more than one region, in order to minimize output to the window.
NVT_SELECT_NOBUFFER	Do not buffer the text in the selected region of the display. The display will show any text as being selected, but it will not be available to be copied by the application. This can be useful if the application is going to select multiple regions and combine them.
NVT_SELECT_COMBINE	If there is already a region of the display that has been selected, the new region is combined with the previous region, selecting all of the text.
NVT_SELECT_UNSELECT	Unselect the specified region of the display.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it returns zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnavt10.lib

See Also

NvtSetCursorPos Function

```
BOOL WINAPI NvtSetCursorPos(  
    HDISPLAY hDisplay,  
    INT nCursorX,  
    INT nCursorY  
);
```

The **NvtSetCursorPos** function sets the current cursor column and row position on the virtual display.

Parameters

hDisplay

Handle to the virtual display.

nCursorX

New cursor column position. If this value is greater than the maximum number of columns, the current position is set to the last column on the display. The first column on the display is zero.

nCursorY

New cursor row position. If this value is greater than the maximum number of rows, the current position is set to the last row on the display. The first row on the display is zero.

Return Value

If the function succeeds, the return value is non-zero. If the handle to the virtual display is invalid, the function will return zero.

Remarks

The **NvtSetCursorPos** function sets the current cursor position on the virtual display. If the display is in origin mode (a scrolling region has been set), then the cursor row position is bound by the current region.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csnvtv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

NvtSetDisplayAttributes Function

```
UINT WINAPI NvtSetDisplayAttributes(  
    HDISPLAY hDisplay,  
    UINT nAttributes  
);
```

The **NvtSetDisplayAttributes** function sets the current display attributes.

Parameters

hDisplay

Handle to the virtual display.

nAttributes

An unsigned integer value which specifies the new display attributes. This may be one or more of the following values:

Constant	Description
NVT_ATTRIBUTE_NORMAL	Normal, default attributes.
NVT_ATTRIBUTE_REVERSE	Foreground and background cell colors are reversed.
NVT_ATTRIBUTE_BOLD	The character is displayed using a higher intensity color.
NVT_ATTRIBUTE_DIM	The character is displayed using a lower intensity color.
NVT_ATTRIBUTE_UNDERLINE	The character is displayed with an underline.
NVT_ATTRIBUTE_HIDDEN	The character is stored in display memory, but not shown.
NVT_ATTRIBUTE_PROTECT	The character is protected and cannot be cleared.

Return Value

If the function succeeds, the return value is the previous display attributes. If the function fails, the return value is NVT_ERROR.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csntv10.lib

See Also

NvtSetDisplayBackColor Function

```
BOOL WINAPI NvtSetDisplayBackColor(  
    HDISPLAY hDisplay,  
    COLORREF rgbBackground  
);
```

The **NvtSetDisplayBackColor** sets the background color used by the virtual display.

Parameters

hDisplay

Handle to the virtual display.

rgbBackground

The background color specified as a 32-bit RGB value.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it returns zero.

Remarks

This function sets the background color for normal, reverse, bold and reverse-bold text attributes. To set the background color for a specific attribute, use the **NvtSetDisplayColor** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csntv10.lib

See Also

[NvtGetDisplayColor](#), [NvtSetDisplayBoldColor](#), [NvtSetDisplayColor](#), [NvtSetDisplayForeColor](#)

NvtSetDisplayBoldColor Function

```
BOOL WINAPI NvtSetDisplayBoldColor(  
    HDISPLAY hDisplay,  
    COLORREF rgbBold  
);
```

The **NvtSetDisplayBoldColor** sets the color used by the virtual display to display text with the bold attribute enabled.

Parameters

hDisplay

Handle to the virtual display.

rgbBold

The bold attribute color specified as a 32-bit RGB value.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it returns zero.

Remarks

This function sets the foreground color for the bold and reverse-bold text attributes. To set the color for a specific attribute, use the **NvtSetDisplayColor** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnavt10.lib

See Also

NvtSetDisplayCell Function

```
DWORD WINAPI NvtSetDisplayCell(  
    HDISPLAY hDisplay,  
    INT xPos,  
    INT yPos,  
    DWORD dwCell  
);
```

The **NvtSetDisplayCell** function sets the value of the specified cell in the virtual display.

Parameters

hDisplay

Handle to the virtual display.

xPos

An integer value which specifies the cell column in the virtual display. A value of -1 specifies that the current cursor position should be used.

yPos

An integer value which specifies the cell row in the virtual display. A value of -1 specifies that the current cursor position should be used.

dwCell

An unsigned integer which specifies the new value for the cell in the virtual display. The low order word of this value should contain the character to be displayed at that location. The high order word should specify the attributes for that cell.

Return Value

If the function succeeds, the return value is the previous cell value. If the function fails, it returns 0xFFFFFFFF. The previous cell value is the same value returned by the **NvtGetDisplayCell** function.

Remarks

The **NvtSetDisplayCell** function is used to modify a specific character cell in the virtual display, changing both the character and the attributes for that cell. Unlike the higher level functions such as **NvtWriteDisplay** which process character strings and escape sequences, the **NvtGetDisplayCell** and **NvtSetDisplayCell** functions allow direct, low-level access to the virtual display in memory. After one or more cells are modified using this function, you should call the **NvtRefreshDisplay** function to redraw the virtual display.

The character cell attributes may be one or more of the following values:

Constant	Description
NVT_ATTRIBUTE_NORMAL	Normal, default attributes.
NVT_ATTRIBUTE_REVERSE	Foreground and background cell colors are reversed.
NVT_ATTRIBUTE_BOLD	The character is displayed using a higher intensity color.
NVT_ATTRIBUTE_DIM	The character is displayed using a lower intensity color.
NVT_ATTRIBUTE_UNDERLINE	The character is displayed with an underline.
NVT_ATTRIBUTE_HIDDEN	The character is stored in display memory, but not

	shown.
NVT_ATTRIBUTE_PROTECT	The character is protected and cannot be cleared.

One or more attributes may be combined using a bitwise Or operator. Certain attributes, such as NVT_ATTRIBUTE_BOLD and NVT_ATTRIBUTE_DIM are mutually exclusive.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnvtv10.lib

See Also

[NvtGetDisplayAttributes](#), [NvtGetDisplayCell](#), [NvtRefreshDisplay](#), [NvtSetDisplayAttributes](#), [NvtWriteDisplay](#)

NvtSetDisplayColor Function

```
BOOL WINAPI NvtSetDisplayColor(  
    HDISPLAY hDisplay,  
    UINT nColorIndex,  
    COLORREF dwColor,  
    BOOL bForeground  
);
```

The **NvtSetDisplayColor** function sets the colors used by the virtual display. Each display has a color table which specifies the foreground and background colors used when displaying text with a specific attribute.

Parameters

hDisplay

Handle to the virtual display.

nColorIndex

The index into the virtual display color table. It may be one of the following values.

Constant	Description
NVT_COLOR_NORMAL	The colors displayed for normal text. These are the default colors used with the display.
NVT_COLOR_REVERSE	The colors displayed for text with the reverse attribute set. This is only used when emulation is enabled.
NVT_COLOR_BOLD	The colors displayed for text with the bold attribute set. This is only used when emulation is enabled.
NVT_COLOR_REVERSEBOLD	The colors displayed for text with the reverse and bold attributes set. This is only used when emulation is enabled.

dwColor

The RGB color value that will be used.

bForeground

A boolean flag which specifies if the color is a foreground color, used when displaying text, or a background color.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it returns zero.

Remarks

The default colors for the display is a black background and white foreground. Bold characters are displayed on a white background and blue foreground.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csntvt10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[NvtGetDisplayColor](#), [NvtSetDisplayBackColor](#), [NvtSetDisplayBoldColor](#), [NvtSetDisplayForeColor](#)

NvtSetDisplayColorMap Function

```
BOOL WINAPI NvtSetDisplayColorMap(  
    HDISPLAY hDisplay,  
    COLORREF *lpColor,  
    INT nColors  
);
```

The **NvtSetDisplayColorMap** function modifies the virtual display color table which determines what RGB values are used to display foreground and background text color attributes.

Parameters

hDisplay

Handle to the virtual display.

lpColor

A pointer to an array of COLORREF values which specifies the values to be used by the emulator when setting a color attribute. If this value is NULL, the default color table will be loaded.

nColors

The number of colors which are stored in the array. The minimum value for this parameter is 1, and the maximum value is 16.

Return Value

If the function succeeds, the return value is a non-zero value. If the function fails, the return value is zero. Failure indicates that the handle to the virtual display is invalid or the number of color values is invalid.

Remarks

When the emulator processes an escape sequence that changes the current foreground or background color, the actual RGB color value is determined by looking up the value in the virtual display's color table. The **NvtSetDisplayColorMap** function is useful for changing what values are being used when a color attribute is set. The emulator currently supports a maximum of sixteen (16) color values, and the index into the table corresponds to the color as defined by the standard for ANSI terminals:

Index	Color	Default (Hex)	Default (Integer)	Default (RGB)
0	Black	0	0	RGB(0,0,0)
1	Red	000000A0h	160	RGB(160,0,0)
2	Green	0000A000h	40960	RGB(0,160,0)
3	Yellow	0000A0A0h	41120	RGB(160,160,0)
4	Blue	00A00000h	10485760	RGB(0,0,160)
5	Magenta	00A000A0h	10485920	RGB(160,0,160)
6	Cyan	00A0A000h	10526720	RGB(0,160,160)
7	White	00E0E0E0h	14737632	RGB(224,224,224)
8	Gray	00C0C0C0h	12632256	RGB(192,192,192)

9	Light Red	008080FFh	8421631	RGB(255,128,128)
10	Light Green	0090EE90h	9498256	RGB(144,238,144)
11	Light Yellow	00C0FFFFh	12648447	RGB(255,255,192)
12	Light Blue	00E6D8ADh	15128749	RGB(173,216,230)
13	Light Magenta	00FFC0FFh	16761087	RGB(255,192,255)
14	Light Cyan	00FFFFE0h	16777184	RGB(224,255,255)
15	High White	00FFFFFFh	16777215	RGB(255,255,255)

A standard ANSI color terminal supports eight standard colors (0-7). To select a foreground color, you add 30 to the color index and pass that value as a parameter to the SGR (select graphic rendition) escape sequence. To select a background color, you add 40 to the color index. For example, to set the current foreground color to white and the background color to blue, you could send the following escape sequence:

```
ESC [ 37;44 m
```

Note that if you wanted to set the foreground color to a bold version of standard yellow, you would first set the bold attribute, and then use the index value of 3, such as:

```
ESC [ 1;33m
```

The **NvtSetDisplayColorMap** function is used to modify the actual color displayed by the emulator. For example, if the emulator processes an escape sequence which sets the current foreground color to white, the actual color displayed could be changed to light green. Passing a NULL pointer as the second parameter restores the original color map back to the default values. Note that changes to the color map will only affect new characters as they are displayed, not any previously displayed characters.

Example

The following example will load the current color table for the virtual display and change the standard white color attribute to use the same value as the high-intensity white:

```
COLORREF rgbColor[16];

if ( NvtGetDisplayColorMap(hDisplay, rgbColor, 16) )
{
    rgbColor[7] = rgbColor[15];
    NvtSetDisplayColorMap(hDisplay, rgbColor, 16);
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnvtv10.lib

See Also

[NvtGetDisplayColor](#), [NvtGetDisplayColorMap](#), [NvtGetTextColor](#), [NvtSetDisplayColor](#), [NvtSetTextColor](#)

NvtSetDisplayDC Function

```
BOOL WINAPI NvtSetDisplayDC(  
    HDISPLAY hDisplay,  
    HDC hDC  
);
```

The **NvtSetDisplayDC** function sets the device context to be used by the virtual display when updating the window.

Parameters

hDisplay

Handle to the virtual display.

hDC

Handle to the device context. This parameter may be NULL, any device context that is currently associated with the virtual display will be removed. Note that the application still has the responsibility for deleting the device context, otherwise a handle leak will occur.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it returns zero.

Remarks

It is not required that the device context be explicitly set by the application. By default, the library will use a device context created using the window attached to the virtual display. If a device context is specified by the application, it must be released when it is no longer needed.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csntv10.lib

NvtSetDisplayEmulation Function

```
BOOL WINAPI NvtSetDisplayEmulation(  
    HDISPLAY hDisplay,  
    UINT nEmulation  
);
```

The **NvtSetDisplayEmulation** function specifies the type of terminal emulation to be performed by the virtual display.

Parameters

hDisplay

Handle to the virtual display.

nEmulation

Identifies the virtual terminal emulation type. The following emulation types are currently supported.

Value	Description
NVT_EMULATION_NONE	The virtual display does not emulate any specific terminal type, and does not process any escape sequences.
NVT_EMULATION_ANSI	The virtual display will process ANSI escape sequences. The default keymap for an ANSI console is loaded.
NVT_EMULATION_VT100	The virtual display will process DEC VT100 escape sequences. The default keymap for a VT100 terminal is loaded.
NVT_EMULATION_VT220	The virtual display will process DEC VT220 escape sequences. The default keymap for a VT220 terminal is loaded.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it returns zero.

Remarks

Changing the emulation type will not affect the current display.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnavt10.lib

See Also

NvtSetDisplayFocus Function

```
BOOL WINAPI NvtSetDisplayFocus(  
    HDISPLAY hDisplay,  
    BOOL bFocus  
);
```

The **NvtSetDisplayFocus** function sets or removes the focus from the virtual display. This function should be called when the display window receives or loses focus.

Parameters

hDisplay

Handle to the virtual display.

bFocus

A boolean flag which specifies that the display should receive or lose focus.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it returns zero.

Remarks

When the virtual display receives focus, it updates the current cursor position and displays the caret. When the display loses focus, the caret is hidden. This function should be called in response to the display window receiving the WM_SETFOCUS and WM_KILLFOCUS messages.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csntv10.lib

See Also

[NvtUpdateCaret](#)

NvtSetDisplayFont Function

```
BOOL WINAPI NvtSetDisplayFont(  
    HDISPLAY hDisplay,  
    HFONT hFont  
);
```

The **NvtSetDisplayFont** sets the font that will be used when updating the display. The specified font must be fixed-width, otherwise the virtual cursor positioning will be incorrect in some cases.

Parameters

hDisplay

Handle to the virtual display.

hFont

Handle to the font that will be used with the virtual terminal. This parameter may be NULL, in which case a default fixed-width font will be used.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it returns zero.

Remarks

If the previous font was a default font created by the library as the result of a NULL font handle being passed to a function, it will be released. However, if the previous font was created by the application, the **DeleteObject** function must be called to release it.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csntv10.lib

See Also

[NvtGetDisplayFont](#), [NvtSetDisplayFontName](#)

NvtSetDisplayFontName Function

```
BOOL WINAPI NvtSetDisplayFontName(  
    HDISPLAY hDisplay,  
    LPTSTR lpszFontName,  
    INT nFontSize  
);
```

The **NvtSetDisplayFontName** function sets the font that is to be used when updating the display. This function always attempts to load a font which is fixed-width and uses the OEM character set.

Parameters

hDisplay

Handle to the virtual display.

lpszFontName

A pointer to a string which specifies the name of the font that will be loaded. If a NULL pointer or an empty string is passed as the value, the default **Terminal** font will be used.

nFontSize

The point size of the font that will be loaded. If this value is zero, a default point size will be used.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it returns zero.

Remarks

The **NvtGetDisplayFont** function will return the handle to the font created by this function. However, this handle should not be released using the **DeleteObject** function. Font handles created by calling this function or passing a NULL handle to the **NvtSetDisplayFont** function will be automatically released by the library when the font is changed or the virtual display is destroyed.

If the previous display font was created using the **CreateFont** or **CreateFontIndirect** functions and then set using **NvtSetDisplayFont**, the font handle must be released by calling the **DeleteObject** function after this function has been called.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csnavt10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[NvtGetDisplayFont](#), [NvtSetDisplayFont](#)

NvtSetDisplayForeColor Function

```
BOOL WINAPI NvtSetDisplayForeColor(  
    HDISPLAY hDisplay,  
    COLORREF rgbForeground  
);
```

The **NvtSetDisplayForeColor** sets the foreground color used by the virtual display.

Parameters

hDisplay

Handle to the virtual display.

rgbForeground

The foreground color specified as a 32-bit RGB value.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it returns zero.

Remarks

This function sets the foreground color for the normal and reverse text attributes. To set the foreground color for a specific attribute, use the **NvtSetDisplayColor** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csntv10.lib

NvtSetDisplayMode Function

```
BOOL WINAPI NvtSetDisplayMode(  
    HDISPLAY hDisplay,  
    UINT nMode,  
    BOOL bEnable  
);
```

The **NvtSetDisplayMode** function sets one or more display modes for the specified virtual display.

Parameters

hDisplay

Handle to the virtual display.

nMode

The virtual display mode bitmask. This value is a combination of one or more flags which determines how the emulator handles automatic line wrapping, caret display, and other functions. The following values may be specified.

Constant	Description
NVT_MODE_AUTOWRAP	The emulator will automatically wrap to the next line when a character is written to the last column on the virtual display.
NVT_MODE_SHOWCARET	The emulator will display a caret when the display receives the focus.
NVT_MODE_BLOCKCARET	The emulator will display a block caret that is the height of the selected font characters. If this mode is not set, the caret is displayed as an underline.
NVT_MODE_BELL	The emulator will beep when a BEL character is processed.
NVT_MODE_CRLF	The cursor will automatically be positioned at the first column when a linefeed character is processed.
NVT_MODE_CRNL	The cursor will automatically advance to the next row when a carriage return character is processed.
NVT_MODE_APPCURSOR	The emulator cursor keys are placed in application mode. This mode changes the default key mappings used when the cursor (arrow) keys are translated. This corresponds to the application mode supported by DEC VT terminals.
NVT_MODE_APPKEYPAD	The emulator keypad keys are placed in application mode. This mode changes the default key mappings used when the keypad keys are translated. This corresponds to the application keypad mode supported by DEC VT terminals.
NVT_MODE_ORIGIN	The emulator is in origin mode. If enabled, the cursor cannot be positioned outside of the current scrolling region. Otherwise, the cursor can be positioned at any valid location on the virtual display.
NVT_MODE_COLOR	The emulator supports the use of escape sequences to

	change the foreground and background colors. This option is enabled by default if emulating an ANSI console or DEC VT220 terminal.
NVT_MODE_TABOVER	The emulator will clear the character cells between the current cursor position and the next tab stop when the HT (horizontal tab) control sequence is processed. By default this mode is disabled, and the cursor is simply positioned at the next tab stop.
NVT_MODE_HSCROLL	The emulator will display a horizontal scroll bar if the number of visible columns are less than the total number of columns in the virtual display. Disabling this mode prevents a horizontal scroll bar from being displayed, regardless of the number of visible columns. By default, this mode is enabled.
NVT_MODE_VSCROLL	The emulator will display a vertical scroll bar if the number of visible rows are less than the total number of rows in the virtual display. Disabling this mode prevents a vertical scroll bar from being displayed, regardless of the number of visible rows. By default, this mode is enabled.
NVT_MODE_NOREFRESH	The emulator will not automatically refresh the window after any change has been made to the virtual display, including changes in the cursor position or display mode. This allows the caller to make a sequence of changes, and then update the display all at one time to prevent a flicker effect.

bEnable

This boolean flag specifies if the specified mode is to be enabled or disabled.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it returns zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnavt10.lib

See Also

NvtSetDisplayScrollPos Function

```
BOOL WINAPI NvtSetDisplayScrollPos(  
    HDISPLAY hDisplay,  
    INT nScrollBar,  
    INT nScrollPos  
);
```

The **NvtSetDisplayScrollPos** function sets the position of the scroll box for the specified scroll bar and redraws the scroll bar to reflect the new position of the scroll box.

Parameters

hDisplay

Handle to the virtual display.

nScrollBar

Specifies the scroll bar to be set. This parameter can be one of the following values:

Value	Description
SB_HORZ	Sets the position of the scroll box in the display's standard horizontal scroll bar.
SB_VERT	Sets the position of the scroll box in the display's standard vertical scroll bar.

nScrollPos

Specifies the new row or column of the scroll box. The position must be within the scrolling range.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it returns zero.

Remarks

This function should always be used to change the scroll box position. The **NvtSetDisplayScrollPos** function will result in unpredictable behavior if used on the virtual display window.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csnavt10.lib

See Also

NvtSetDisplaySize Function

```
BOOL WINAPI NvtSetDisplaySize(  
    HDISPLAY hDisplay,  
    LPSIZE lpSize  
);
```

The **NvtSetDisplaySize** sets the size of the virtual display.

Parameters

hDisplay

Handle to the virtual display.

lpRect

Pointer to a SIZE structure which specifies the new size of the virtual display. The width should be specified in columns and the height should be specified in rows.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it returns zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csntv10.lib

NvtSetDisplayWindow Function

```
BOOL WINAPI NvtSetDisplayWindow(  
    HDISPLAY hDisplay,  
    HWND hWnd  
);
```

The **NvtSetDisplayWindow** function sets the window used by the virtual display.

Parameters

hDisplay

Handle to the virtual display.

hWnd

Handle to the window that will be used by the virtual display. This parameter cannot be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it returns zero.

Remarks

This function will clear the display and reset the current text attributes.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csntv10.lib

See Also

NvtSetMappedKey Function

```
BOOL WINAPI NvtSetMappedKey(  
    HDISPLAY hDisplay,  
    UINT nMappedKey,  
    LPCTSTR LpszKeyBuffer  
);
```

The **NvtSetMappedKey** function maps an escape sequence to the specified key.

Parameters

hDisplay

Handle to the virtual display.

nMappedKey

The key which is an index into the display key mapping table. This defines the values returned by special (function) keys for the current emulation.

lpszKeyBuffer

Pointer to a string which defines the sequence of characters that are to be mapped to the specified key. Passing an empty string or NULL pointer will delete the current sequence mapped to the key and restore the default value, if one has been defined.

Return Value

If the function succeeds, the return value is non-zero and the escape sequence is mapped to the specified key. If the key value is invalid or could not be mapped, then the function will return zero.

Remarks

The **NvtSetMappedKey** function maps an escape sequence to a special key. This function can be used to specify what sequence of characters should be sent in response to a keypress (for example, what sequence should be sent to a server when the user presses the F1 function key). There are a number of default sequences that are mapped to the function and cursor keys, based on the current emulation. Calling this function will override the default sequence for a key, if one has been defined.

The following special keys are defined:

Value	Constant	Description	Value	Constant	Description
0	NVT_F1	F1 function key	26	NVT_UP	Cursor up key
1	NVT_F2	F2 function key	27	NVT_DOWN	Cursor down key
2	NVT_F3	F3 function key	28	NVT_LEFT	Cursor left key
3	NVT_F4	F4 function key	29	NVT_RIGHT	Cursor right key
4	NVT_F5	F5 function key	30	NVT_INSERT	Insert key
5	NVT_F6	F6 function key	31	NVT_DELETE	Delete key
6	NVT_F7	F7 function key	32	NVT_HOME	Home key
7	NVT_F8	F8 function key	33	NVT_END	End key
8	NVT_F9	F9 function key	34	NVT_PGUP	Page up key
9	NVT_F10	F10 function key	35	NVT_PGDN	Page down key
10	NVT_F11	F11 function key	36	NVT_APPUP	Up arrow key
11	NVT_F12	F12 function key	37	NVT_APPDOWN	Down arrow key
12	NVT_SF1	Shift F1 function key	38	NVT_APPLEFT	Left arrow key
13	NVT_SF2	Shift F2 function key	39	NVT_APPRIGHT	Right arrow key

14	NVT_SF3	Shift F3 function key	40	NVT_APPENTER	Keypad enter key
15	NVT_SF4	Shift F4 function key	41	NVT_KEYPAD0	Numeric keypad 0
16	NVT_SF5	Shift F5 function key	42	NVT_KEYPAD1	Numeric keypad 1
17	NVT_SF6	Shift F6 function key	43	NVT_KEYPAD2	Numeric keypad 2
18	NVT_SF7	Shift F7 function key	44	NVT_KEYPAD3	Numeric keypad 3
19	NVT_SF8	Shift F8 function key	45	NVT_KEYPAD4	Numeric keypad 4
20	NVT_SF9	Shift F9 function key	46	NVT_KEYPAD5	Numeric keypad 5
21	NVT_SF10	Shift F10 function key	47	NVT_KEYPAD6	Numeric keypad 6
22	NVT_SF11	Shift F11 function key	48	NVT_KEYPAD7	Numeric keypad 7
23	NVT_SF12	Shift F12 function key	49	NVT_KEYPAD8	Numeric keypad 8
24	NVT_ENTER	Enter key	50	NVT_KEYPAD9	Numeric keypad 9
25	NVT_ERASE	Backspace key			

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csntv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[NvtGetDisplayMode](#), [NvtGetMappedKey](#), [NvtResetMappedKeys](#), [NvtSetDisplayMode](#), [NvtTranslateMappedKey](#)

NvtSetScrollRegion Function

```
BOOL WINAPI NvtSetScrollRegion(  
    HDISPLAY hDisplay,  
    INT nTop,  
    INT nBottom  
);
```

The **NvtSetScrollRegion** function sets the top and bottom rows of the current scrolling region.

Parameters

hDisplay

Handle to the virtual display.

nTop

The top row of the current scrolling region. If this value is greater than the bottom scrolling region row or the total number of rows in the display, it will be silently adjusted.

nBottom

The bottom row of the current scrolling region. If this value is less than zero or the top scrolling region row, it will be silently adjusted.

Return Value

If the function succeeds, it will return zero. If the handle to the display is invalid, the function will return zero.

Remarks

The **NvtSetScrollRegion** function allows an application to set the current scrolling region for the virtual display. This specifies the region (between the top and bottom rows) in which text will normally scroll. If the display is in origin mode, the cursor cannot be positioned outside of the scrolling region.

The minimum scrolling region that may be defined is two rows. If a scrolling region is specified that is less than two rows, the function will fail and the current scrolling region will remain unchanged. Specifying values of -1 for both arguments will reset the scrolling region to the default values (the full display).

The DEC STBM escape sequence is used to set or clear the scrolling region of the virtual display.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnavt10.lib

See Also

NvtSetTextColor Function

```
BOOL WINAPI NvtSetTextColor(  
    HDISPLAY hDisplay,  
    COLORREF rgbColor,  
    BOOL bForeground  
);
```

The **NvtSetTextColor** function changes the current foreground or background text color.

Parameters

hDisplay

Handle to the virtual display.

rgbColor

A color value which specifies the current foreground or background text color. The RGB macro can be used to specify the red, green and blue values for the color.

bForeground

A boolean value which determines if the foreground or background color is changed. A value of TRUE indicates that the foreground color should be changed, otherwise the background color is changed.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. Failure indicates that the handle to the display is invalid or that the current display does not support color text attributes.

Remarks

This function is used to change the current foreground or background color, as determined by the text attribute. Note that changing the current foreground or background text color does not affect the virtual display color table. To change how color attributes are mapped to an RGB color value, use the **NvtSetDisplayColorMap** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csntv10.lib

See Also

NvtTranslateMappedKey Function

```
BOOL WINAPI NvtTranslateMappedKey(  
    HDISPLAY hDisplay,  
    UINT nKey,  
    UINT nFlags,  
    UINT * lpnMappedKey,  
    LPTSTR lpszKeyBuffer,  
    UINT cchBuffer  
);
```

The **NvtTranslateMappedKey** function translates a virtual key press to an escape sequence based on the current terminal emulation that has been selected.

Parameters

hDisplay

Handle to the virtual display.

nKey

The virtual key code for the specified key.

nFlags

The scan code, key-transition code, previous key state, and context code for the specified key.

lpnMappedKey

A pointer to an unsigned integer which will contain the index into the keymap table when the function returns. This is the same value used with the **NvtGetMappedKey** and **NvtSetMappedKey** function. If the index into the keymap is not required, this parameter can be NULL.

lpszKeyBuffer

Address of the buffer to receive the escape sequence mapped to the specified key. If the mapped key string is not required, this parameter can be NULL.

cchBuffer

The maximum number of characters that can be copied into the key buffer, including the terminating null character. If the *lpszKeyBuffer* parameter is NULL, this value must be zero.

Return Value

If the virtual key can be mapped to an escape sequence, the function will return a non-zero value. If the key is not mapped, or one of the arguments is invalid, the function will return zero.

Remarks

The **NvtTranslateMappedKey** function allows an application to map a virtual key code to an escape sequence that is appropriate for the type of terminal that is being emulated. For example, it will return the escape sequence for the F1 function key when passed the VK_F1 key value. This function should be called when the WM_KEYDOWN message is processed by an application so that it may send the correct sequence to the server.

This function should only be called in response to a keyboard message such as WM_KEYDOWN. To determine if a specific key has been mapped to an escape sequence, use the **NvtGetMappedKey** function.

Example

```

case WM_KEYDOWN:
    /*
     * If the Num Lock key is pressed, then set the terminal into application
     * keypad mode. This will change how the NvtTranslateMappedKey function will
     * translate the keypad keys.
     *
     * Note that the terminal may also be placed into application keypad mode
     * if emulating a DEC VT terminal and the DECNMK escape sequence is sent
     * by the host.
     */
    if (wParam == VK_NUMLOCK)
        NvtSetDisplayMode(hDisplay, NVT_MODE_APPKEYPAD, !
(GetKeyState(VK_NUMLOCK) & 1));
    else
    {
        BOOL bMapped;
        UINT nMappedKey;
        TCHAR szKey[128];

        bMapped = NvtTranslateMappedKey(hDisplay, wParam, HIWORD(lParam),
&nMappedKey, szKey, 128);

        if (bMapped)
            TelnetWrite(hClient, szKey, lstrlen(szKey));
    }
    break;

```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnavt10.lib

Unicode: Implemented as Unicode and ANSI versions.

NvtUninitialize Function

```
VOID WINAPI NvtUninitialize();
```

The **NvtUninitialize** function terminates the use of the library.

Parameters

There are no parameters.

Return Value

None.

Remarks

An application is required to perform a successful **NvtInitialize** call before it can call any of the other library functions. When it has completed the use of library, the application must call **NvtUninitialize** to allow the library to free any resources allocated on behalf of the process.

There must be a call to **NvtUninitialize** for every successful call to **NvtInitialize** made by a process. In a multithreaded environment, operations for all threads in the client are terminated.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnavt10.lib

See Also

[NvtDestroyDisplay](#), [NvtUninitialize](#)

NvtUpdateCaret Function

```
BOOL WINAPI NvtUpdateCaret(  
    HDISPLAY hDisplay  
);
```

The **NvtUpdateCaret** function updates the position of the caret in the display window to the current cursor position.

Parameters

hDisplay

Handle to the virtual display.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it returns zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnavt10.lib

See Also

[NvtSetCursorPos](#), [NvtSetDisplayMode](#), [NvtUpdateDisplay](#)

NvtUpdateDisplay Function

```
BOOL WINAPI NvtUpdateDisplay(  
    HDISPLAY hDisplay  
);
```

The **NvtUpdateDisplay** function updates the window attached to the virtual display.

Parameters

hDisplay

Handle to the virtual display.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it returns zero.

Remarks

This function should be called when the display window receives a WM_PAINT message. If the **NvtSetDisplayDC** function has not been called to explicitly set the display device context, this function will acquire one for the display window. In this case, the application should not create a device context for the window or call the **BeginPaint** and **EndPaint** functions.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csntv10.lib

See Also

NvtWriteDisplay Function

```
BOOL WINAPI NvtWriteDisplay(  
    HDISPLAY hDisplay,  
    LPBYTE lpBuffer,  
    INT cbBuffer  
);
```

The **NvtWriteDisplay** function writes the contents of the specified buffer to the virtual display.

Parameters

hDisplay

Handle to the virtual display.

lpBuffer

Pointer to the buffer which contains the data to be written to the virtual display.

cbBuffer

Number of bytes to write to the display.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it returns zero.

Remarks

This function writes the data at the current cursor location. Control characters are recognized by this function and processed accordingly. If ANSI emulation is enabled, embedded escape sequences will also be parsed and processed.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csntv10.lib

Terminal Emulation Data Structures

- INITDATA
- NVTDISPLAYINFO

Copyright © 2023 Catalyst Development Corporation. All rights reserved.

INITDATA Structure

This structure contains information about the SocketTools library when the initialization function returns.

```
typedef struct _INITDATA
{
    DWORD        dwSize;
    DWORD        dwVersionMajor;
    DWORD        dwVersionMinor;
    DWORD        dwVersionBuild;
    DWORD        dwOptions;
    DWORD_PTR    dwReserved1;
    DWORD_PTR    dwReserved2;
    TCHAR        szDescription[128];
} INITDATA, *LPINITDATA;
```

Members

dwSize

Size of this structure. This structure member must be set to the size of the structure prior to calling the initialization function. Failure to do so will cause the function to fail.

dwVersionMajor

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the major version number for the library.

dwVersionMinor

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the minor version number for the library.

dwVersionBuild

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the build number for the library.

dwOptions

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

dwReserved1

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

dwReserved2

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

szDescription

A null terminated string which describes the library.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Unicode: Implemented as Unicode and ANSI versions.

NVTDISPLAYINFO Structure

This structure is used by the [NvtGetDisplayInfo](#) function to return information about the specified virtual terminal display. No member of this structure should be modified directly by the application.

```
typedef struct _NVTDISPLAYINFO {
    HWND    hWnd;
    HFONT   hFont;
    INT     xPos;
    INT     yPos;
    INT     cxClient;
    INT     cyClient;
    INT     cxChar;
    INT     cyChar;
    INT     nScrollCol;
    INT     nScrollRow;
    INT     nMaxScrollCol;
    INT     nMaxScrollRow;
} NVTDISPLAYINFO, *LPNVTDISPLAYINFO;
```

Members

hWnd

The handle to the terminal emulation display window.

hFont

The handle to the current font.

xPos

The current display x coordinate.

yPos

The current display y coordinate.

cxClient

The width of the client window in pixels.

cyClient

The height of the client window in pixels.

cxChar

The width of the current font in pixels.

cyChar

The height of the current font in pixels.

nScrollCol

The current horizontal scrolling column.

nScrollRow

The current vertical scrolling row.

nMaxScrollCol

The maximum horizontal scrolling column.

nMaxScrollRow

The maximum vertical scrolling row.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

	1		Blue
	2		Green
	3		Cyan
	4		Red
	5		Magenta
<ESC>[= <i>n</i> K	6		Brown
	7		White
	8		Gray
	9		Light blue
	10		Light green
	11		Light cyan
	12		Light red
	13		Light magenta
	14		Yellow
	15		High White

Control Character Sequences

<CTL>G	Ring audible bell, if enabled
<CTL>H	Move cursor one character backwards
<CTL>I	Move cursor forward to next tabstop
<CTL>J	Move cursor down to next line
<CTL>M	Move cursor to beginning of line
<CTL>N	Select G1 character set
<CTL>O	Select G0 character set
<CTL>Z	Abort current escape sequence
	Erase and move cursor one character backwards

Text Message Library

Send text messages to a mobile communications device using a gateway service.

Reference

- [Functions](#)
- [Data Structures](#)
- [Error Codes](#)

Library Information

File Name	CSTXTV10.DLL
Version	10.0.1468.2518
LibID	224FEFCC-A572-4432-81E0-FC25C4ED00AA
Import Library	CSTXTV10.LIB
Dependencies	None

Overview

Short Message Service (SMS) is a text messaging service used by mobile communication devices to exchange brief text messages. Most service providers also provide gateway servers that can be used to send messages to a wireless device on their network using standard email protocols. The Text Message API provides functions that can be used to determine the provider associated with a specific telephone number and send a text message to the device using the provider's mail gateway.

This library has been designed to assist developers in sending text message notifications as part of their application. For example, it can be used to enable your software to automatically send notifications when a specific event occurs, such as an error condition. This library is not designed to be used with software that will send out a large number of text messages to many users, and there are limitations on the number of messages that may be sent to different phone numbers over a short period of time. Because many recipients must pay a fee for each text message they receive, text messages should only be sent to those who explicitly request them.

Note: This library only supports service providers in North America and cannot be used to send text messages to mobile devices that use providers outside of the United States and Canada. Some service providers may prevent messages from being sent through their gateway to a user that does not have unlimited text messaging as part of their service agreement.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). If you are using Visual C++ 6.0 it is required that you have Service Pack 6 (SP6) installed. You should install all updates for your development tools and have the current Windows SDK installed. The minimum recommended version of Visual Studio is Visual Studio 2010.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are using Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. It is recommended that you install the current service pack and all critical updates available for your version of the operating system.

This product includes both 32-bit and 64-bit libraries. Native 64-bit CPU support requires the 64-bit version of Windows 7 or later versions of the Windows operating system.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

Text Message Functions

Function	Description
SmsDisableTrace	Disable logging of network function calls
SmsEnableTrace	Enable logging of network function calls to a text file
SmsEnumProviders	Enumerate the available wireless service providers
SmsGetErrorString	Return a description for the specified error code
SmsGetFirstProvider	Return information about the first supported wireless service provider
SmsGetGateway	Return information about the gateway server for the specified phone number
SmsGetNextProvider	Return information about the next supported wireless service provider
SmsGetProvider	Return information about the wireless service provider for the specified phone number
SmsGetLastError	Return the last error code
SmsInitialize	Initialize the library and validate the specified license key at runtime
SmsSendMessage	Send a text message to the specified mobile device
SmsSetLastError	Set the last error code
SmsUninitialize	Terminate use of the library by the application

SmsDisableTrace Function

```
BOOL WINAPI SmsDisableTrace();
```

The **SmsDisableTrace** function disables the logging of network function calls.

Parameters

None.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cstxtv10.lib

See Also

[SmsEnableTrace](#)

SmsEnableTrace Function

```
BOOL WINAPI SmsEnableTrace(  
    LPCTSTR lpszTraceFile,  
    DWORD dwTraceFlags  
);
```

The **SmsEnableTrace** function enables the logging of network function calls to a text file.

Parameters

lpszTraceFile

A pointer to a string which specifies the name of the trace log file. If this parameter is NULL or an empty string, the default file name **cstrace.log** is used. The file is stored in the directory specified by the TEMP environment variable, if it is defined; otherwise, the current working directory is used.

dwTraceFlags

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
TRACE_INFO	All function calls are written to the trace file. This is the default value.
TRACE_ERROR	Only those function calls which fail are recorded in the trace file.
TRACE_WARNING	Only those function calls which fail or return values which indicate a warning are recorded in the trace file.
TRACE_HEXDUMP	All functions calls are written to the trace file, plus all the data that is sent or received is displayed, in both ASCII and hexadecimal format.
TRACE_PROCESS	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for multithreaded applications that are using worker threads.

Return Value

If the function succeeds, the return value is non-zero. A return value of zero indicates an error. Failure typically indicates that the tracing library **cstrcv10.dll** cannot be loaded on the local system.

Remarks

When trace logging is enabled, the file is opened, appended to and closed for each socket function call. This makes it possible for an application to append its own logging information, however care should be taken to ensure that the file is closed before the next network operation is performed. To limit the size of the log files, enable and disable logging only around those sections of code that you wish to trace.

Note that the TRACE_HEXDUMP trace level generates very large log files since it includes all of the data exchanged between your application and the server.

Trace function logging is managed on a per-thread basis, not for each client handle. This means that all SocketTools libraries and components share the same settings in the current thread. If you

are using multiple SocketTools libraries or components in your application, you only need to enable logging once.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstxtv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[SmsDisableTrace](#)

SmsEnumProviders Function

```
INT WINAPI SmsEnumProviders(  
    LPSMSPROVIDER lpProviders,  
    INT nMaxProviders,  
    DWORD dwReserved  
);
```

The **SmsEnumProviders** function enumerates the supported wireless service providers and populates an array of **SMSPROVIDER** structures.

Parameters

lpProviders

A pointer to an array of **SMSPROVIDER** structures that will be populated with information about each service provider. If this parameter is NULL, the function will return the number of service providers that are known.

nMaxProviders

An integer value which specifies the maximum number of service providers that may be enumerated by this function. If this parameter is zero, the function will return the number of service providers that are known. If the *lpProviders* parameter is NULL, this value should be zero.

dwReserved

A reserved parameter. This value should always be zero.

Return Value

If the function succeeds, the return value is the number of known service providers. If the function fails, the return value is **SMS_ERROR**. To get extended error information, call **SmsGetLastError**. If the *lpProviders* parameter is not NULL and the *nMaxProviders* parameter indicates the array is not large enough to store all of the provider information, this function will fail with an error indicating that the buffer is too small.

Remarks

The **SmsEnumProviders** function is used to enumerate all of the supported service providers, populating an array of **SMSPROVIDER** structures that contains information about each provider, such as their name, domain, region of the country they service and the maximum message size they will accept. Typically this would be used to update a user interface control such as a listbox or drop-down combobox, enabling a user to select a preferred service provider.

Because some programming languages may not support arrays of structures in the same way that C/C++ does, the **SmsGetFirstProvider** and **SmsGetNextProvider** functions offer an alternative way to easily enumerate the available service providers.

To obtain information about a single service provider, use the **SmsGetProvider** function.

Example

```
SMSPROVIDER smsProviders[MAXPROVIDERS];  
INT nProviders;  
  
nProviders = SmsEnumProviders(smsProviders, MAXPROVIDERS, 0);  
if (nProviders == SMS_ERROR)  
{  
    DWORD dwError = SmsGetLastError();
```

```
    _tprintf(_T("An error has occurred, error code %d\n"),
(INT)LOWORD(dwError));
}
else
{
    for (INT nIndex = 0; nIndex < nProviders; nIndex++)
        _tprintf(_T("%s\n"), smsProviders[nIndex].szName);

    _tprintf(_T("%d providers returned\n"), nProviders);
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstxtv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[SmsGetFirstProvider](#), [SmsGetGateway](#), [SmsGetNextProvider](#), [SmsGetProvider](#), [SMSPROVIDER](#)

SmsGetErrorString Function

```
INT WINAPI SmsGetErrorString(  
    DWORD dwErrorCode,  
    LPTSTR lpszDescription,  
    INT cbDescription  
);
```

The **SmsGetErrorString** function is used to return a description of a specific error code. Typically this is used in conjunction with the **SmsGetLastError** function for use with warning dialogs or as diagnostic messages.

Parameters

dwErrorCode

The last-error code for which a description is returned.

lpszDescription

A pointer to the buffer that will contain a description of the specified error code. This buffer should be at least 128 characters in length.

cbDescription

The maximum number of characters that may be copied into the description buffer.

Return Value

If the function succeeds, the return value is the length of the description string. If the function fails, the return value is zero, meaning that no description exists for the specified error code. Typically this indicates that the error code passed to the function is invalid.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `cstxtv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

See Also

[SmsGetLastError](#), [SmsSetLastError](#)

SmsGetFirstProvider Function

```
BOOL WINAPI SmsGetFirstProvider(  
    LPSMSPROVIDER lpProvider,  
    LPDWORD lpdwToken,  
);
```

The **SmsGetFirstProvider** function returns information about the first supported wireless service provider.

Parameters

lpProvider

A pointer to an [SMSPROVIDER](#) structure that will contain information about the service provider. This parameter cannot be NULL.

lpdwToken

A pointer to an unsigned integer value that is used when enumerating the service providers. The value will be initialized by this function and the modified by subsequent calls to the **SmsGetNextProvider** function. This parameter cannot be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **SmsGetLastError**.

Remarks

The **SmsGetFirstProvider** function is used in conjunction with **SmsGetNextProvider** to enumerate all of the supported wireless providers available to the client. These two functions can be used as an alternative to the **SmsEnumProviders** function, which may not be easily used with some programming languages because it populates an array of data structures rather than a single structure. The data that is returned is identical, the only difference is the method by which the service providers are enumerated.

The *lpdwToken* parameter is used to maintain context between multiple calls to the **SmsGetNextProvider** function. It should be treated as an opaque value and never modified directly by the application.

Example

```
SMSPROVIDER smsProvider;  
DWORD dwToken;  
BOOL bResult;  
  
bResult = SmsGetFirstProvider(&smsProvider, &dwToken);  
while (bResult)  
{  
    pListBox->AddString(smsProvider.szName);  
    bResult = SmsGetNextProvider(&smsProvider, &dwToken);  
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstxtv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[SmsEnumProviders](#), [SmsGetGateway](#), [SmsGetNextProvider](#), [SMSPROVIDER](#)

SmsGetGateway Function

```
INT WINAPI SmsGetGateway(  
    LPCTSTR lpszPhoneNumber,  
    LPCTSTR lpszProvider,  
    LPSMSGATEWAY lpGateway  
);
```

The **SmsGetGateway** function returns text message service information for a phone number.

Parameters

lpszPhoneNumber

A pointer to a string which specifies the telephone number that you wish to obtain information about. Any whitespace, punctuation or other non-numeric characters in the string will be ignored. This parameter cannot be NULL.

lpszProvider

A pointer to a string which specifies the preferred service provider for this telephone number. If the preferred service provider is unknown, this parameter can be NULL and the default provider will be selected.

lpGateway

A pointer to an [SMSGATEWAY](#) structure that will contain information about the text message gateway when the function returns. This includes information such as the name of the provider, the server that will accept text messages for this phone number, and the recipient address that should be used. This parameter cannot be NULL.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is SMS_ERROR. To get extended error information, call **SmsGetLastError**.

Remarks

The **SmsGetGateway** function returns information about the service provider and mail gateway for a specific phone number, and can be used to determine if a given phone number is assigned to a mobile device capable of receiving text messages. This is done by sending an query to a server that will check the phone number against a database of known providers and the phone numbers that have been allocated for wireless devices. If the phone number is valid, information will be returned about the provider that is responsible for that number along with information about its text message gateway service.

If the *lpszProvider* parameter is not NULL, this will identify a preferred provider for the phone number specified. In the United States and Canada, most wireless common carriers are required to provide wireless number portability (WNP) which allows a customer to continue to use their current phone number even if they switch to another service provider. This can result in a situation where a specific phone number is shown as allocated to one provider, but in actuality that user has switched to a different provider. For example, a user may have originally purchased a phone and service with AT&T and then later switched to Verizon, but decided to keep their phone number. In this case, if Verizon was not specified as the preferred provider, the library would attempt to send the message to the AT&T gateway, since that was the original provider who allocated the phone number.

For most applications, the correct way to handle the situation in which a user may have switched to a different service provider is to allow them to select an alternate service provider in your user

interface. For example, you could display a drop-down list of available service providers, populated using the **SmsEnumProviders** function. If they select a preferred provider, then you would pass that value to this function. If they do not, then specify a NULL pointer and the default provider will be selected.

This function sends an HTTP query to the server **api.sockettools.com** to obtain information about the phone number and wireless service provider. This requires that the local system can establish a standard network connection over port 80. If the client cannot connect to the server, the function will fail and an appropriate error will be returned. The server imposes a limit on the maximum number of connections that can be established and the maximum number of requests that can be issued per minute. If this function is called multiple times over a short period, the library may also force the application to block briefly. Server responses are cached per session, so calling this function multiple times using the same phone number will not increase the request count.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstxtv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[SmsEnumProviders](#), [SmsGetProvider](#), [SMSGATEWAY](#)

SmsGetLastError Function

```
DWORD WINAPI SmsGetLastError();
```

Parameters

None.

Return Value

The return value is the last error code value for the current thread. Functions set this value by calling the **SmsSetLastError** function. The Return Value section of each reference page notes the conditions under which the function sets the last error code.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. You should call the **SmsGetLastError** function immediately when a function's return value indicates that an error has occurred. That is because some functions call **SmsSetLastError(0)** when they succeed, clearing the error code set by the most recently failed function.

Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CHANNEL or SMS_ERROR. Those functions which call **SmsSetLastError** when they succeed are noted on the function reference page.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstxtv10.lib

SmsGetNextProvider Function

```
BOOL WINAPI SmsGetNextProvider(  
    LPSMSPROVIDER lpProvider,  
    LPDWORD lpdwToken,  
);
```

The **SmsGetNextProvider** function returns information about the next supported wireless service provider.

Parameters

lpProvider

A pointer to an [SMSPROVIDER](#) structure that will contain information about the service provider. This parameter cannot be NULL.

lpdwToken

A pointer to an unsigned integer value that is used when enumerating the service providers. The value will be initialized by the **SmsGetFirstProvider** function and the modified by subsequent calls to this function. This parameter cannot be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the last service provider has been enumerated or the function fails, the return value is zero. To get extended error information, call **SmsGetLastError**.

Remarks

The **SmsGetNextProvider** function is used in conjunction with **SmsGetFirstProvider** to enumerate all of the supported wireless providers available to the client. These two functions can be used as an alternative to the **SmsEnumProviders** function, which may not be easily used with some programming languages because it populates an array of data structures rather than a single structure. The data that is returned is identical, the only difference is the method by which the service providers are enumerated.

The *lpdwToken* parameter is used to maintain context between multiple calls to this function. It should be treated as an opaque value and never modified directly by the application.

Example

```
SMSPROVIDER smsProvider;  
DWORD dwToken;  
BOOL bResult;  
  
bResult = SmsGetFirstProvider(&smsProvider, &dwToken);  
while (bResult)  
{  
    pListBox->AddString(smsProvider.szName);  
    bResult = SmsGetNextProvider(&smsProvider, &dwToken);  
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstxtv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[SmsEnumProviders](#), [SmsGetGateway](#), [SmsGetNextProvider](#), [SMSPROVIDER](#)

SmsGetProvider Function

```
INT WINAPI SmsGetProvider(  
    LPCTSTR lpszPhoneNumber,  
    LPSMSPROVIDER lpProvider  
);
```

The **SmsGetProvider** function returns information about the service provider for the specified phone number.

Parameters

lpszPhoneNumber

A pointer to a string which specifies the telephone number that you wish to obtain information about. Any whitespace, punctuation or other non-numeric characters in the string will be ignored. This parameter cannot be NULL.

lpProvider

A pointer to an [SMSPROVIDER](#) structure that will contain information about the service provider for the specified phone number.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is SMS_ERROR. To get extended error information, call **SmsGetLastError**.

Remarks

The **SmsGetProvider** function returns information about the service provider associated with a phone number. This is done by sending an query to a server that will check the phone number against a database of known providers and the phone numbers that have been allocated for wireless devices. If the phone number is valid, information will be returned about the provider that is responsible for that number.

Because most wireless carriers in the United States and Canada must provide for wireless number portability, there is the possibility that the provider information returned may no longer correspond to the telephone number. It is recommended that you provide your end-user with the ability to specify an alternate preferred provider to use when sending the text message. For more information, refer to the **SmsGetGateway** function.

This function sends an HTTP query to the server **api.sockettools.com** to obtain information about the wireless service provider. This requires that the local system can establish a standard network connection over port 80. If the client cannot connect to the server, the function will fail and an appropriate error will be returned. The server imposes a limit on the maximum number of connections that can be established and the maximum number of requests that can be issued per minute. If this function is called multiple times over a short period, the library may also force the application to block briefly. Server responses are cached per session, so calling this function multiple times using the same phone number will not increase the request count.

For a list of all supported wireless service providers, use the **SmsEnumProviders** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstxtv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[SmsEnumProviders](#), [SmsGetGateway](#), [SMS PROVIDER](#)

SmsInitialize Function

```
BOOL WINAPI SmsInitialize(  
    LPCTSTR lpszLicenseKey,  
    LPINITDATA lpData  
);
```

The **SmsInitialize** function initializes the library and validates the specified license key at runtime.

Parameters

lpszLicenseKey

Pointer to a string that specifies the runtime license key to be validated. If this parameter is NULL, the library will validate the development license installed on the local system.

lpData

Pointer to an INITDATA data structure. This parameter may be NULL if the initialization data for the library is not required.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **SmsGetLastError**. All other client functions will fail until a license key has been successfully validated.

Remarks

This must be the first function that an application calls before using any of the other functions in the library. When a NULL license key is specified, the library will only function on the development system. Before redistributing the application to an end-user, you must insure that this function is called with a valid license key.

If the *lpData* argument is specified, it must point to an INITDATA structure which has been initialized by setting the *dwSize* member to the size of the structure. All other structure members should be set to zero. If the function is successful, then the INITDATA structure will be filled with identifying information about the library.

Although it is only required that **SmsInitialize** be called once for the current process, it may be called multiple times; however, each call must be matched by a corresponding call to **SmsUninitialize**.

This function dynamically loads other system libraries and allocates thread local storage. If you are calling the functions in this library from within another DLL, it is important that you do not call the **SmsInitialize** or **SmsUninitialize** functions from the **DllMain** function because it can result in deadlocks or access violation errors. If the DLL is linked with the C runtime library (CRT), it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstxtv10.lib

Unicode: Implemented as Unicode and ANSI versions.

SmsSendMessage Function

```
INT WINAPI SmsSendMessage(  
    LPSSERVICE lpService,  
    LPSMSMESSAGE lpMessage,  
    DWORD dwReserved,  
);
```

The **SmsSendMessage** function sends a text message to the specified mobile device.

Parameters

lpService

A pointer to an [SMSERVICE](#) structure that identifies the messaging service that will be used to send the text message. The default service sends the message through the mail server gateway for the wireless service provider associated with the recipient's phone number. This parameter cannot be NULL.

lpMessage

A pointer to an [SMSMESSAGE](#) structure that contains information about the message to be sent, including the sender, the recipient and the text message itself. This parameter cannot be NULL.

dwReserved

A reserved parameter. This value should always be zero.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is SMS_ERROR. To get extended error information, call **SmsGetLastError**.

Remarks

The **SmsSendMessage** function is used to send a text message to a mobile device. This API is designed to support multiple methods of sending text messages, with the default method sending the message through a server gateway established by the wireless service provider.

SMS_SERVICE_SMTP

This message service sends the message through the wireless service provider's mail gateway using the SMTP protocol. However, it is important to note that many of these gateways will not accept messages from a client that is connected to them using a residential Internet service provider. If the application is being run on a system that uses a residential provider, that service provider may also block outbound connections to all mail servers other than their own. These anti-spam measures typically require that most end-user applications specify a relay mail server rather than submitting the message directly to the wireless provider's gateway.

Because most wireless carriers in the United States and Canada must provide for wireless number portability, there is the possibility that the provider information returned may no longer correspond to the telephone number. It is recommended that you provide your end-user with the ability to specify an alternate preferred provider to use when sending the text message. For more information, refer to the **SmsGetGateway** function.

This service also sends an HTTP query to the server **api.sockettools.com** to obtain information about the phone number and wireless service provider. This requires that the local system can establish a standard network connection over port 80. If the client cannot connect to the server, the function will fail and an appropriate error will be returned. The server imposes a limit on the

maximum number of connections that can be established and the maximum number of requests that can be issued per minute. If this function is called multiple times over a short period, the library may also force the application to block briefly. Server responses are cached per session, so calling this function multiple times using the same phone number will not increase the request count.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstxtv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[SmsGetGateway](#), [SmsGetProvider](#), [SMSMESSAGE](#), [SMSSERVICE](#)

SmsSetLastError Function

```
VOID WINAPI SmsSetLastError(  
    DWORD dwErrorCode  
);
```

The **SmsSetLastError** function sets the error code for the current thread. This function is typically used to clear the last error by passing a value of zero as the parameter.

Parameters

dwErrorCode

Specifies the error code for the current thread.

Return Value

None.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or SMS_ERROR. Those functions which call **SmsSetLastError** when they succeed are noted on the function reference page.

Applications can retrieve the value saved by this function by using the **SmsGetLastError** function. The use of **SmsGetLastError** is optional; an application can call the function to determine the specific reason for a function failure.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cstxtv10.lib

See Also

[SmsGetErrorString](#), [SmsGetLastError](#)

SmsUninitialize Function

```
VOID WINAPI SmsUninitialize();
```

The **SmsUninitialize** function terminates the use of the library.

Parameters

There are no parameters.

Return Value

None.

Remarks

An application is required to perform a successful **SmsInitialize** call before it can call any of the other the library functions. When it has completed the use of library, the application must call **SmsUninitialize** to allow the library to free any resources allocated on behalf of the process. Any pending blocking or asynchronous calls in this process are canceled without posting any notification messages, and all sockets that were opened by the process are closed.

There must be a call to **SmsUninitialize** for every successful call to **SmsInitialize** made by a process. In a multithreaded environment, operations for all threads in the client are terminated.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstxtv10.lib

    DWORD        dwVersionBuild;
    DWORD        dwOptions;
    DWORD_PTR    dwReserved1;
    DWORD_PTR    dwReserved2;
    TCHAR        szDescription[128];
} INITDATA, *LPINITDATA;
```

Members

dwSize

Size of this structure. This structure member must be set to the size of the structure prior to calling the initialization function. Failure to do so will cause the function to fail.

dwVersionMajor

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the major version number for the library.

dwVersionMinor

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the minor version number for the library.

dwVersionBuild

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the build number for the library.

dwOptions

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

dwReserved1

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

dwReserved2

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

szDescription

A null terminated string which describes the library.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Unicode: Implemented as Unicode and ANSI versions.

MSGGATEWAY Structure

This structure contains information about a text message gateway server and the recipient.

```
typedef struct _MSGGATEWAY
{
    INT      nGatewayId;
    INT      nCountryCode;
    INT      nAreaCode;
    INT      nExchange;
    INT      nMessageLength;
    DWORD    dwReserved;
    TCHAR    szProvider[SMS_MAXPROVIDERNAMELEN];
    TCHAR    szDomain[SMS_MAXDOMAINNAMELEN];
    TCHAR    szServer[SMS_MAXMAILSERVERLEN];
    TCHAR    szAddress[SMS_MAXMAILADDRESSLEN];
} SMSCHANNEL, *LPSMSCHANNEL;
```

Members

nGatewayId

An integer value which identifies the gateway record. This value is used internally and an application should not depend on the value not changing over time for a specific telephone number. As new area codes are introduced, the provider database will be updated to reflect these changes and that can result in a change to the gateway ID associated with a specific telephone number.

nCountryCode

An integer value which specifies the ITU country calling code associated with the service provider. Currently this value will always be 1, which is the country code used by North American service providers. If the service provider database is expanded to include additional countries in the future, this value will identify the country of origin.

nAreaCode

An integer value which specifies the Numbering Plan Area (NPA) code, commonly known as the area code. For the United States and Canada, area codes are assigned by the North American Numbering Plan Administration (NANPA). In North America, the area code is digits 1-3 for a 10-digit telephone number. This value, along with the exchange, is used to determine which company provides wireless service for a specific telephone number.

nExchange

An integer value which specifies the exchange area. In North America, the exchange is digits 4-6 for a 10-digit telephone number. This value, along with the area code, is used to determine which company provides wireless service for a specific telephone number.

nMessageLength

An integer value which specifies the maximum number of characters that the service provider will accept for a single text message. If the message exceeds this number of characters, the service provider may reject the message, or it may split the message into multiple messages.

dwReserved

A value reserved for internal use.

szProvider

A pointer to a string which identifies the name of the service provider that is associated with the specified telephone number. Note that this value may not represent the actual company that is

providing the wireless service.

szDomain

A pointer to a string which identifies the gateway domain name used by the service provider to accept text messages for their customer. This domain name is used to determine the actual name of the gateway mail server that is responsible for accepting messages.

szServer

A pointer to a string which identifies the host name or IP address of the mail server used to accept text messages for the specified service provider. In some cases, a provider may have multiple gateway servers and this value will represent the preferred mail server for the domain.

szAddress

A pointer to a string which contains the complete email address that should be used when sending the text message through the gateway mail server. Different service providers can have slightly different rules about how the address is formatted, but it typically is a combination of the telephone number and the gateway domain name.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Unicode: Implemented as Unicode and ANSI versions.

SMSMESSAGE Structure

This structure provides information about a text message.

```
typedef struct _SMSMESSAGE
{
    DWORD dwFormat;
    DWORD dwLength;
    DWORD dwFlags;
    DWORD dwReserved;
    LPCTSTR lpszProvider;
    LPCTSTR lpszPhoneNumber;
    LPCTSTR lpszSender;
    LPCTSTR lpszMessage;
} SMSMESSAGE, *LPSMSMESSAGE;
```

Members

dwFormat

An integer value which specifies the format of the message message. This member is included for future use where a service provider supports multiple message formats based on different versions of the protocol. The default value for this member is SMS_FORMAT_TEXT.

dwLength

An integer value which specifies the length of the message. If this member is zero, the length will be automatically calculated based on the length of the *lpszMessage* text that is terminated by a null character. If this value is larger than the actual length of the message text, it will be ignored.

dwFlags

An integer value which specifies one or more message options.

Constant	Description
SMS_MESSAGE_DEFAULT	The default value used with standard text messages.
SMS_MESSAGE_URGENT	The text message should be flagged as urgent. For messages that are sent through a mail gateway, this will set the header to indicate that it is a high priority message. Note that service providers handle urgent messages differently and some may ignore the message priority.

dwReserved

Reserved for future use. This value should always be zero.

lpszProvider

A pointer to a null terminated string which specifies the name of the preferred wireless service provider responsible for handling the message. If this member is NULL or an empty string, the default provider assigned to the recipient's phone number will be used. This structure member is only used with SMS_SERVICE_SMTP messages and is ignored for other message services.

lpszPhoneNumber

A pointer to a null terminated string which specifies the recipient's phone number. This can be a standard E.164 formatted number or an unformatted number. Any extraneous whitespace, punctuation or other non-numeric characters in the string will be ignored. This structure member cannot be NULL.

lpszSender

A pointer to a null terminated string which identifies the sender of the message. For SMS_SERVICE_SMTP messages, this string should be a valid email address. For other services, this string may specify a phone number or shortcode. This structure member cannot be NULL.

lpszMessage

A pointer to a null terminated string that contains the message to be sent to the recipient. In most cases, a message should not exceed 160 characters in length, although some service providers may accept longer messages. If a message exceeds the maximum number of characters accepted by a service provider, the message may be ignored or it may be split into multiple messages.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Unicode: Implemented as Unicode and ANSI versions.

See Also

[SmsSendMessage](#), [SMSSERVICE](#)

SMSPROVIDER Structure

This structure contains information about a wireless service provider.

```
typedef struct _SMSPROVIDER
{
    INT        nProviderId;
    INT        nCountryCode;
    INT        nRegionCode;
    INT        nMessageLength;
    DWORD      dwFlags;
    DWORD      dwReserved;
    TCHAR      szGuid[SMS_MAXPROVIDERGUIDLEN];
    TCHAR      szName[SMS_MAXPROVIDERNAMELEN];
    TCHAR      szCompany[SMS_MAXCOMPANYNAMELEN];
    TCHAR      szDomain[SMS_MAXDOMAINNAMELEN];
} SMSPROVIDER, *LPSMSPROVIDER;
```

Members

nProviderId

An integer value which identifies the provider record. This value is used internally and an application should not depend on the value not changing over time for a specific service provider. To uniquely identify a provider, use the *szGuid* member of the structure, which is guaranteed not to change as providers are added and removed from the database.

nCountryCode

An integer value which specifies the ITU country calling code associated with the service provider. Currently this value will always be 1, which is the country code used by North American service providers. If the service provider database is expanded to include additional countries in the future, this value will identify the country of origin.

nRegionCode

An integer value which identifies the region that the service provider covers. In North America, each region consists of multiple states and/or provinces. If a provider services multiple regions, this will identify the primary region where they provide coverage.

Constant	Description
SMS_REGION_NATIONAL 0	All regions. This region code is used for service providers that have national coverage and do not exclusively provide service within one or more specific geographical regions.
SMS_REGION_NORTH_EAST_ATLANTIC 1	Northeastern Atlantic region which includes Connecticut, Maine, Massachusetts, New Hampshire, New Brunswick, Newfoundland, Nova Scotia, Rhode Island and Vermont.
SMS_REGION_MIDDLE_ATLANTIC 2	Middle Atlantic region which includes New Jersey, New York, Delaware, District of Columbia, Maryland, Pennsylvania, Quebec, Virginia and West Virginia.
SMS_REGION_EAST_NORTH_CENTRAL 3	Northeastern central region which includes Illinois, Indiana, Michigan, Ohio and

	Wisconsin.
SMS_REGION_SOUTH_ATLANTIC 4	Southern Atlantic region which includes Florida, Georgia, North Carolina and South Carolina.
SMS_REGION_EAST_SOUTH_CENTRAL 5	Southeastern central region which includes Alabama, Kentucky, Mississippi and Tennessee.
SMS_REGION_WEST_NORTH_CENTRAL 6	Northwestern central region which includes Iowa, Kansas, Manitoba, Minnesota, Missouri, Nebraska, North Dakota, Ontario and South Dakota.
SMS_REGION_WEST_SOUTH_CENTRAL 7	Southwestern central region which includes Arkansas, Louisiana, Oklahoma and Texas.
SMS_REGION_MOUNTAIN 8	Mountain region which includes Alberta, Arizona, Colorado, Idaho, Montana, Nevada, New Mexico, Northwest Territories, Saskatchewan, Utah and Wyoming.
SMS_REGION_PACIFIC 9	Pacific region which includes Alaska, British Columbia, California, Hawaii, Oregon, Washington and Yukon.

nMessageLength

An integer value which specifies the maximum number of characters that the service provider will accept for a single text message. If the message exceeds this number of characters, the service provider may reject the message, or it may split the message into multiple messages.

dwFlags

An unsigned integer value which specifies one or more flags that provides additional information about the service provider. This value is constructed by using a bitwise operator with any of the following constants:

Constant	Description
SMS_PROVIDER_DEFAULT 0	A standard service provider. Typically this means that customers have a service contract for their mobile device and pay monthly access and service charges.
SMS_PROVIDER_PREPAID 1	A service provider that offers pre-paid calling cards or fixed month-to-month payments that do not require long-term service contracts.

dwReserved

A value reserved for internal use.

szGuid

A pointer to a string which uniquely identifies the service provider. The string is in a standard format used for globally unique identifiers (GUIDs) and is guaranteed to not change for the service provider it has been assigned to.

szName

A pointer to a string which specifies the name of service provider. Note that this value may not represent the actual company that is providing the wireless service.

szCompany

A pointer to a string which specifies the name of the company associated with the service provider. This may be the same as name of the service provider itself or it may be the name of a parent company that owns the service provider.

szDomain

A pointer to a string which identifies the gateway domain name used by the service provider to accept text messages for their customer. This domain name is used to determine the actual name of the gateway mail server that is responsible for accepting messages.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Unicode: Implemented as Unicode and ANSI versions.

SMSSERVICE Structure

This structure provides information about the service used to send a text message.

```
typedef struct _SMSSERVICE
{
    DWORD dwServiceType;
    DWORD dwAuthType;
    DWORD dwVersion;
    DWORD dwTimeout;
    DWORD dwOptions;
    DWORD dwReserved;
    LPCTSTR lpszResource;
    LPCTSTR lpszAccount;
    LPCTSTR lpszUserName;
    LPCTSTR lpszPassword;
} SMSSERVICE, *LPSMSSERVICE;
```

Members

dwServiceType

An integer value which identifies the type of service that will be used to send the message. This member can be one of the following values:

Constant	Description
SMS_SERVICE_SMTP	The text message will be sent through the mail gateway for the specified service provider. This service uses SMTP to submit the message for delivery, either directly to the server provider's mail gateway server or through a relay server. This is the default service type.

dwAuthType

An integer value which identifies the type of authentication used with the service. This member can be one of the following values:

Constant	Description
SMS_AUTH_DEFAULT	The default authentication method for this service type should be used. Most applications should use this value unless a service type provides multiple authentication methods.
SMS_AUTH_USERNAME	The service requires authentication using a username and password. This value can be used with an SMTP service that requires user authentication and is typically needed when using a mail server relay. For the SMS_SERVICE_SMTP service, this is the default authentication method.

dwVersion

An integer value which identifies the interface version for the service being used. This member is included for future use where a service may support multiple versions of their interface and should normally be set to the value SMS_VERSION_DEFAULT.

dwTimeout

An integer value which specifies the amount of time in seconds that a function will wait for a

response from the service. If this value is zero, a default timeout period of 20 seconds will be used. If the service does not respond within this time period, the function will fail.

dwOptions

An integer value which specifies one or more options.

Constant	Description
SMS_OPTION_NONE	No additional options for the service.
SMS_OPTION_SECURE	This option specifies that SSL/TLS will be used to establish a secure, encrypted connection with the service. For some services, it may be required to connect to them securely and this option will be enabled automatically.

dwReserved

Reserved for future use. This value should always be zero.

lpszResource

A pointer to a null terminated string that specifies a resource for the service. Typically this will be either a fully qualified domain name or a URL. For gateways using SMTP, this string should identify the mail server. An alternate port number can also be specified by appending it to the hostname, separated by a colon. For example, **smtp.company.com:587** would connect to the server on port 587. If you are specifying an IPv6 address with an alternate port number, the address must be enclosed in brackets. For services where a domain name or resource URL is not required, this member will be ignored and can be NULL.

lpszAccount

A pointer to a null terminated string that specifies an account name or identifier. Some service providers may require a unique account name or a token (application ID) in conjunction with other credentials. This member is not used with mail gateways and ignored if the service type is SMS_SERVICE_SMTP. If no account name is required for session authentication, this member can be NULL.

lpszUserName

A pointer to a null terminated string that specifies a user name to authenticate the session. If the authentication type is SMS_AUTH_USERNAME this member must specify a valid user name. If no authentication is required, this member may be NULL. Note that some service providers may use terminology other than "username" with their documentation; this member will always specify the first of a pair of authentication tokens.

lpszPassword

A pointer to a null terminated string that specifies the password used to authenticate the session. If the authentication type is SMS_AUTH_USERNAME this member must specify a valid password. If no authentication is required, this member may be NULL. Note that some service providers may use terminology other than "password" with their documentation; this member will always specify the second of a pair of authentication tokens.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Unicode: Implemented as Unicode and ANSI versions.

Time Protocol Library

Query a time server for the current time and synchronize the local system clock with that value.

Reference

- [Functions](#)
- [Data Structures](#)
- [Error Codes](#)

Library Information

File Name	CSTIMV10.DLL
Version	10.0.1468.2518
LibID	7E65DD9F-5799-42FA-A72D-EC0B714E3021
Import Library	CSTIMV10.LIB
Dependencies	None
Standards	RFC 868

Overview

The Time Protocol library provides an interface for synchronizing the local system's time and date with that of a server. The time values returned are in Coordinated Universal Time and be adjusted for the local host's timezone. The library enables developers to query a server for the current time and then update the system clock if desired.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). If you are using Visual C++ 6.0 it is required that you have Service Pack 6 (SP6) installed. You should install all updates for your development tools and have the current Windows SDK installed. The minimum recommended version of Visual Studio is Visual Studio 2010.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are using Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. It is recommended that you install the current service pack and all critical updates available for your version of the operating system.

This product includes both 32-bit and 64-bit libraries. Native 64-bit CPU support requires the 64-bit version of Windows 7 or later versions of the Windows operating system.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

Time Protocol Functions

Function	Description
ConvertNetworkTime	Convert network time to system time
ConvertSystemTime	Convert system time to network time
GetNetworkTime	Return the current network time from the server
QueryNetworkTime	Query the server for the network time
ReadNetworkTime	Read the network time returned by the server
TimeDisableTrace	Disable logging of socket function calls to the trace log
TimeEnableTrace	Enable logging of socket function calls to a file
TimeGetErrorString	Return a description for the specified error code
TimeGetLastError	Return the last error code
TimeInitialize	Initialize the library and validate the specified license key at runtime
TimeSetLastError	Set the last error code
TimeUninitialize	Terminate use of the library by the application
UpdateLocalTime	Update the local system time with the network time

ConvertNetworkTime Function

```
BOOL WINAPI ConvertNetworkTime(  
    DWORD dwNetworkTime,  
    LPSYSTEMTIME lpSystemTime,  
    BOOL bLocalTime  
);
```

The **ConvertNetworkTime** function converts the specified network time, adjusting for the local timezone if required. The network time is a 32-bit number, represented as the number of seconds since midnight, 1 January 1900 UTC.

Parameters

dwNetworkTime

The network time to be converted.

lpSystemTime

A pointer to a [SYSTEMTIME](#) structure which will be modified for the specified network time.

bLocalTime

A boolean flag that is used to specify if the network time should be adjusted for the local timezone.

Return Value

If the network time could be converted, the function returns a non-zero value. If the network time cannot be converted, or the pointer to the SYSTEMTIME structure is invalid, the function will return zero.

Remarks

The network time value can represent a date and time up to the year 2036.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cstimv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[ConvertSystemTime](#)

ConvertSystemTime Function

```
DWORD WINAPI ConvertSystemTime(  
    LPSYSTEMTIME lpSystemTime  
);
```

The **ConvertSystemTime** function converts the specified system time to network time. The network time value is a 32-bit number, represented as the number of seconds since midnight, 1 January 1900 UTC.

Parameters

lpSystemTime

A pointer to a [SYSTEMTIME](#) structure which will be modified for the specified network time.

Return Value

If the system time could be converted, the function returns the number of seconds since midnight, 1 January 1900 UTC. If the pointer to the [SYSTEMTIME](#) structure is invalid, or the structure contains invalid data, the function will return zero.

Remarks

The network time value can represent a date and time up to the year 2036.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `cstimv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

See Also

[ConvertNetworkTime](#), [UpdateLocalTime](#)

GetNetworkTime Function

```
DWORD WINAPI GetNetworkTime(  
    LPCTSTR lpszRemoteHost,  
    UINT nRemotePort,  
    UINT nTimeout  
);
```

The **GetNetworkTime** function returns the network time from the specified host. The network time is a 32-bit number, represented as the number of seconds since midnight, 1 January 1900 UTC.

Parameters

lpszRemoteHost

A pointer to the name of the server. The host must be running a time server that complies with the specifications outlined in RFC 868.

nRemotePort

The port the time server is running on. A value of zero indicates that the default port number for the service should be used.

nTimeout

The number of seconds that the function will wait for a response from the server.

Return Value

If the function succeeds, it returns the number of seconds since midnight, 1 January 1900 UTC. If the function was unable to obtain the time from the specified host, it returns zero.

Remarks

The **GetNetworkTime** function will cause the calling thread to block until the time is returned by the server, or the operation times out. For applications which require asynchronous operation, the **QueryNetworkTime** function should be used instead.

The network time value can represent a date and time up to the year 2036. It is important to note that the network time value is not the same as the UNIX time value that is used the standard C library time functions.

In the United States, the National Institute of Standards and Technology (NIST) hosts a number of public servers which can be used to obtain the current time. The following table lists the current host names and addresses:

Server Name	IP Address	Location
time-a.nist.gov	129.6.15.28	Gaithersburg, Maryland
time-b.nist.gov	129.6.15.29	Gaithersburg, Maryland
time-nw.nist.gov	131.107.13.100	Redmond, Washington
time-a.timefreq.bldrdoc.gov	132.163.4.101	Boulder, Colorado
time-b.timefreq.bldrdoc.gov	132.163.4.102	Boulder, Colorado
time-c.timefreq.bldrdoc.gov	132.163.4.103	Boulder, Colorado

Time servers are also commonly maintained by Internet service providers and universities. If you are unable to obtain the time from a server, contact the system administrator to determine if they

have the standard time service available on port 37.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstimv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[ConvertNetworkTime](#), [QueryNetworkTime](#), [ReadNetworkTime](#), [TimeInitialize](#)

QueryNetworkTime Function

```
HCLIENT WINAPI QueryNetworkTime(  
    LPCTSTR LpszRemoteHost,  
    UINT nRemotePort,  
    HWND hEventWnd,  
    UINT uEventMsg  
);
```

The **QueryNetworkTime** function connects to the specified server and issues a request for the current network time. The handle is passed as a parameter to the **ReadNetworkTime** function to read the value returned by the server.

Parameters

LpszRemoteHost

A pointer to the name of the server. The host must be running a time server that complies with the specifications outlined in RFC 868.

nRemotePort

The port the time server is running on. A value of zero indicates that the default port number for the service (37) should be used.

hEventWnd

A handle to the window that will receive the notification that the network time has been returned by the server.

uEventMsg

The notification message that will be sent to the window, indicating that the client has received the network time from the server.

Return Value

If the function succeeds, it returns a handle which can be used with the obtain the network time. If the function fails, it returns INVALID_CLIENT. To get extended error information, call **TimeGetLastError**.

Remarks

When a message is posted to the notification window, the low word of the *lParam* parameter contains the event identifier. The high word of *lParam* contains the low word of the error code, if an error has occurred. The *wParam* parameter contains the client handle. One or more of the following event identifiers may be sent:

Constant	Description
TIME_EVENT_QUERY	The connection to the server has completed and the request for the time has been sent. The client should wait for the response from the server.
TIME_EVENT_REPLY	The server has replied to the request for the time. The client should call the ReadNetworkTime function to read the value returned by the server.
TIME_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.

TIME_EVENT_CANCEL

The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cstimv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[ConvertNetworkTime](#), [GetNetworkTime](#), [ReadNetworkTime](#), [UpdateLocalTime](#)

ReadNetworkTime Function

```
DWORD WINAPI ReadNetworkTime(  
    HCLIENT hClient  
);
```

The **ReadNetworkTime** function returns the network time from the specified host.

Parameters

hClient

The client handle.

Return Value

If the function succeeds, it returns the number of seconds since midnight, 1 January 1900 UTC. If the function was unable to read the time from the specified host, it returns zero.

Remarks

The **ReadNetworkTime** function reads the time value returned by the server using the handle returned by the **QueryNetworkTime** function. The network time value can represent a date and time up to the year 2036.

To convert the time value to a SYSTEMTIME structure, use the **ConvertNetworkTime** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cstimv10.lib

See Also

[ConvertNetworkTime](#), [QueryNetworkTime](#)

TimeAttachThread Function

```
DWORD WINAPI TimeAttachThread(  
    HCLIENT hClient  
    DWORD dwThreadId  
);
```

The **TimeAttachThread** function attaches the specified client handle to another thread.

Parameters

hClient

Handle to the client session.

dwThreadId

The ID of the thread that will become the new owner of the handle. A value of zero specifies that the current thread should become the owner of the client handle.

Return Value

If the function succeeds, the return value is the thread ID of the previous owner. If the function fails, the return value is `TIME_ERROR`. To get extended error information, call **TimeGetLastError**.

Remarks

When a client handle is created, it is associated with the current thread that created it. Normally, if another thread attempts to perform an operation using that handle, an error is returned since it does not own the handle. This is used to ensure that other threads cannot interfere with an operation being performed by the owner thread. In some cases, it may be desirable for one thread in a client application to create the client handle, and then pass that handle to another worker thread. The **TimeAttachThread** function can be used to change the ownership of the handle to the new worker thread. By preserving the return value from the function, the original owner of the handle can be restored before the worker thread terminates.

This function should be called by the new thread immediately after it has been created, and if the new thread does not release the handle itself, the ownership of the handle should be restored to the parent thread before it terminates. Under no circumstances should **TimeAttachThread** be used to forcibly release a handle allocated by another thread while a blocking operation is in progress. To cancel an operation, use the **TimeCancel** function and then release the handle after the blocking function exits and control is returned to the current thread.

Note that the *dwThreadId* parameter is presumed to be a valid thread ID and no checks are performed to ensure that the thread actually exists. Specifying an invalid thread ID will orphan the handle until the **TimeUninitialize** function is called.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `cstimv10.lib`

See Also

[QueryNetworkTime](#), [ReadNetworkTime](#), [TimeInitialize](#), [TimeUninitialize](#)

TimeDisableEvents Function

```
INT WINAPI TimeDisableEvents(  
    HCLIENT hClient  
);
```

The **TimeDisableEvents** function disables all event notification, including event callbacks. Any pending events are deleted.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is TIME_ERROR. To get extended error information, call **TimeGetLastError**.

Remarks

This function affects both event notification and event callbacks. Any outstanding events in the message queue should be ignored by the client application.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstimv10.lib

See Also

[TimeEnableEvents](#), [TimeFreezeEvents](#), [TimeRegisterEvent](#)

TimeDisableTrace Function

```
BOOL WINAPI TimeDisableTrace();
```

The **TimeDisableTrace** function disables the logging of socket function calls to the trace log.

Parameters

None.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cstimv10.lib

See Also

TimeEnableEvents Function

```
INT WINAPI TimeEnableEvents(  
    HCLIENT hClient,  
    HWND hEventWnd,  
    UINT uEventMsg  
);
```

The **TimeEnableEvents** function enables event notifications using Windows messages.

This function has been deprecated and is retained for backwards compatibility. Applications should use the **TimeRegisterEvent** function to register an event handler which is invoked when an event occurs.

Parameters

hClient

Handle to the client session.

hEventWnd

Handle to the event notification window. This window receives a user-defined message which specifies the event that has occurred. If this value is NULL, event notification is disabled.

uEventMsg

An unsigned integer which specifies the user-defined message that is sent when an event occurs. This parameter's value must be greater than the value of WM_USER.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is TIME_ERROR. To get extended error information, call **TimeGetLastError**.

Remarks

When a message is posted to the notification window, the low word of the *lParam* parameter contains the event identifier. The high word of *lParam* contains the low word of the error code, if an error has occurred. The *wParam* parameter contains the client handle. One or more of the following event identifiers may be sent:

Constant	Description
TIME_EVENT_CONNECT	The connection to the server has completed. The high word of the <i>lParam</i> parameter should be checked, since this notification message will be posted if an error has occurred.
TIME_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
TIME_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
TIME_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.

TIME_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
TIME_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.

To cancel asynchronous notification and return the client to a blocking mode, use the **TimeDisableEvents** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cstimv10.lib

TimeEnableTrace Function

```
BOOL WINAPI TimeEnableTrace(  
    LPCTSTR lpszTraceFile,  
    DWORD dwTraceFlags  
);
```

The **TimeEnableTrace** function enables the logging of socket function calls to a file.

Parameters

lpszTraceFile

A pointer to a string which specifies the name of the trace log file. If this parameter is NULL or an empty string, the default file name **cstrace.log** is used. The file is stored in the directory specified by the TEMP environment variable, if it is defined; otherwise, the current working directory is used.

dwTraceFlags

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
TRACE_INFO	All function calls are written to the trace file. This is the default value.
TRACE_ERROR	Only those function calls which fail are recorded in the trace file.
TRACE_WARNING	Only those function calls which fail or return values which indicate a warning are recorded in the trace file.
TRACE_HEXDUMP	All functions calls are written to the trace file, plus all the data that is sent or received is displayed, in both ASCII and hexadecimal format.
TRACE_PROCESS	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for multithreaded applications that are using worker threads.

Return Value

If the function succeeds, the return value is non-zero. A return value of zero indicates an error. Failure typically indicates that the tracing library **cstrcv10.dll** cannot be loaded on the local system.

Remarks

When trace logging is enabled, the file is opened, appended to and closed for each socket function call. This makes it possible for an application to append its own logging information, however care should be taken to ensure that the file is closed before the next network operation is performed. To limit the size of the log files, enable and disable logging only around those sections of code that you wish to trace.

Note that the TRACE_HEXDUMP trace level generates very large log files since it includes all of the data exchanged between your application and the server.

Trace function logging is managed on a per-thread basis, not for each client handle. This means that all SocketTools libraries and components share the same settings in the current thread. If you

are using multiple SocketTools libraries or components in your application, you only need to enable logging once.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstimv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[TimeDisableTrace](#)

TimeEventProc Function

```
VOID CALLBACK TimeEventProc(  
    HCLIENT hClient,  
    UINT nEventId,  
    DWORD dwError,  
    DWORD_PTR dwParam  
);
```

The **TimeEventProc** function is an application-defined callback function that processes events generated by the calling process.

Parameters

hClient

The handle to the client session.

nEvent

An unsigned integer which specifies which event occurred. For a complete list of events, refer to the **TimeRegisterEvent** function.

dwError

An unsigned integer which specifies any error that occurred. If no error occurred, then this parameter will be zero.

dwParam

A user-defined integer value which was specified when the event callback was registered.

Return Value

None.

Remarks

An application must register this callback function by passing its address to the **TimeRegisterEvent** function. The **TimeEventProc** function is a placeholder for the application-defined function name.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cstimv10.lib

See Also

[TimeDisableEvents](#), [TimeEnableEvents](#), [TimeFreezeEvents](#), [TimeRegisterEvent](#)

TimeFreezeEvents Function

```
INT WINAPI TimeFreezeEvents(  
    HCLIENT hClient,  
    BOOL bFreeze  
);
```

The **TimeFreezeEvents** function is used to suspend and resume event handling by the client.

Parameters

hClient

Handle to the client session.

bFreeze

A non-zero value specifies that event handling should be suspended by the client. A zero value specifies that event handling should be resumed.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is `TIME_ERROR`. To get extended error information, call **TimeGetLastError**.

Remarks

This function should be used when the application does not want to process events, such as when a modal dialog is being displayed. When events are suspended, all client events are queued. If events are re-enabled at a later point, those queued events will be sent to the application for processing. Note that only one of each event will be generated. For example, if the client has suspended event handling, and four read events occur, once event handling is resumed only one of those read events will be posted to the client. This prevents the application from being flooded by a potentially large number of queued events.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `cstimv10.lib`

TimeGetErrorString Function

```
INT WINAPI TimeGetErrorString(  
    DWORD dwErrorCode,  
    LPTSTR lpszDescription,  
    INT cbDescription  
);
```

The **TimeGetErrorString** function is used to return a description of a specific error code. Typically this is used in conjunction with the **TimeGetLastError** function for use with warning dialogs or as diagnostic messages.

Parameters

dwErrorCode

The last-error code for which a description is returned.

lpszDescription

A pointer to the buffer that will contain a description of the specified error code. This buffer should be at least 128 characters in length.

cbDescription

The maximum number of characters that may be copied into the description buffer.

Return Value

If the function succeeds, the return value is the length of the description string. If the function fails, the return value is 0, meaning that no description exists for the specified error code. Typically this indicates that the error code passed to the function is invalid.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `cstimv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

See Also

[TimeGetLastError](#), [TimeSetLastError](#)

TimeGetLastError Function

```
DWORD WINAPI TimeGetLastError();
```

Parameters

None.

Return Value

The return value is the last error code value for the current thread. Functions set this value by calling the **TimeSetLastError** function. The Return Value section of each reference page notes the conditions under which the function sets the last error code.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. You should call the **TimeGetLastError** function immediately when a function's return value indicates that an error has occurred. That is because some functions call **TimeSetLastError(0)** when they succeed, clearing the error code set by the most recently failed function.

Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or TIME_ERROR. Those functions which call **TimeSetLastError** when they succeed are noted on the function reference page.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cstimv10.lib

See Also

[TimeGetErrorString](#), [TimeSetLastError](#)

TimeGetStatus Function

```
INT WINAPI TimeGetStatus(  
    HCLIENT hClient  
);
```

The **TimeGetStatus** function returns the current status of the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the client status code. If the function fails, the return value is TIME_ERROR. To get extended error information, call **TimeGetLastError**.

Remarks

The **TimeGetStatus** function returns a numeric code which identifies the current state of the client session. The following values may be returned:

Value	Constant	Description
1	TIME_STATUS_IDLE	The client is current idle and not sending or receiving data.
2	TIME_STATUS_CONNECT	The client is establishing a connection with the server.
3	TIME_STATUS_READ	The client is reading data from the server.
4	TIME_STATUS_WRITE	The client is writing data to the server.
5	TIME_STATUS_DISCONNECT	The client is disconnecting from the server.

In a multithreaded application, any thread in the current process may call this function to obtain status information for the specified client session.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstimv10.lib

See Also

[QueryNetworkTime](#), [ReadNetworkTime](#)

TimeInitialize Function

```
BOOL WINAPI TimeInitialize(  
    LPCTSTR lpszLicenseKey,  
    LPINITDATA lpData  
);
```

The **TimeInitialize** function initializes the library and validates the specified license key at runtime.

Parameters

lpszLicenseKey

Pointer to a string that specifies the runtime license key to be validated. If this parameter is NULL, the library will validate the development license installed on the local system.

lpData

Pointer to an INITDATA data structure. This parameter may be NULL if the initialization data for the library is not required.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **TimeGetLastError**. All other client functions will fail until a license key has been successfully validated.

Remarks

This must be the first function that an application calls before using any of the other functions in the library. When a NULL license key is specified, the library will only function on the development system. Before redistributing the application to an end-user, you must insure that this function is called with a valid license key.

If the *lpData* argument is specified, it must point to an INITDATA structure which has been initialized by setting the *dwSize* member to the size of the structure. All other structure members should be set to zero. If the function is successful, then the INITDATA structure will be filled with identifying information about the library.

Although it is only required that **TimeInitialize** be called once for the current process, it may be called multiple times; however, each call must be matched by a corresponding call to **TimeUninitialize**.

This function dynamically loads other system libraries and allocates thread local storage. If you are calling the functions in this library from within another DLL, it is important that you do not call the **TimeInitialize** or **TimeUninitialize** functions from the **DllMain** function because it can result in deadlocks or access violation errors. If the DLL is linked with the C runtime library (CRT), it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cstimv10.lib

Unicode: Implemented as Unicode and ANSI versions.

TimeRegisterEvent Function

```
INT WINAPI TimeRegisterEvent(  
    HCLIENT hClient,  
    UINT nEventId,  
    INETEVENTPROC LpfnEvent,  
    DWORD_PTR dwParam  
);
```

The **TimeRegisterEvent** function registers a callback function for the specified event.

Parameters

hClient

Handle to client session.

nEventId

An unsigned integer which specifies which event should be registered with the specified callback function. One or more of the following values may be used:

Constant	Description
TIME_EVENT_CONNECT	The connection to the server has completed.
TIME_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
TIME_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
TIME_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
TIME_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
TIME_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.

lpfnEvent

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **TimeEventProc** callback function. If this parameter is NULL, the callback for the specified event is disabled.

dwParam

A user-defined integer value that is passed to the callback function. If the application targets the

x86 (32-bit) platform, this parameter must be a 32-bit unsigned integer. If the application targets the x64 (64-bit) platform, this parameter must be a 64-bit unsigned integer.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is `TIME_ERROR`. To get extended error information, call **TimeGetLastError**.

Remarks

The **TimeRegisterEvent** function associates a callback function with a specific event. The event handler is an **TimeEventProc** function that is invoked when the event occurs. Arguments are passed to the function to identify the client session, the event type and the user-defined value specified when the event handler is registered. If the event occurs because of an error condition, the error code will be provided to the handler.

The callback function specified by the *lpEventProc* parameter must be declared using the `__stdcall` calling convention. This ensures the arguments passed to the event handler are pushed on to the stack in the correct order. Failure to use the correct calling convention will corrupt the stack and cause the application to terminate abnormally.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `cstimv10.lib`

See Also

[TimeDisableEvents](#), [TimeEnableEvents](#), [TimeEventProc](#), [TimeFreezeEvents](#)

TimeSetLastError Function

```
VOID WINAPI TimeSetLastError(  
    DWORD dwErrorCode  
);
```

The **TimeSetLastError** function sets the error code for the current thread. This function is typically used to clear the last error by passing a value of zero as the parameter.

Parameters

dwErrorCode

Specifies the error code for the current thread.

Return Value

None.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or TIME_ERROR. Those functions which call **TimeSetLastError** when they succeed are noted on the function reference page.

Applications can retrieve the value saved by this function by using the **TimeGetLastError** function. The use of **TimeGetLastError** is optional; an application can call the function to determine the specific reason for a function failure.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cstimv10.lib

See Also

[TimeGetErrorString](#), [TimeGetLastError](#)

TimeUninitialize Function

```
VOID WINAPI TimeUninitialize();
```

The **TimeUninitialize** function terminates the use of the library.

Parameters

There are no parameters.

Return Value

None.

Remarks

An application is required to perform a successful **TimeInitialize** call before it can call any of the other the library functions. When it has completed the use of library, the application must call **TimeUninitialize** to allow the library to free any resources allocated on behalf of the process. Any pending blocking or asynchronous calls in this process are canceled without posting any notification messages, and all sockets that were opened by the process are closed.

There must be a call to **TimeUninitialize** for every successful call to **TimeInitialize** made by a process. In a multithreaded environment, operations for all threads in the client are terminated.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstimv10.lib

See Also

[TimeInitialize](#)

UpdateLocalTime Function

```
BOOL WINAPI UpdateLocalTime(  
    DWORD dwNetworkTime  
);
```

The **UpdateLocalTime** function sets the local system clock to the specified date and time.

Parameters

dwNetworkTime

The date and time the system clock should be set to, represented as the number of seconds since midnight, 1 January 1900.

Return Value

If the function is able to update the local time, it returns a non-zero value. If the specified time is invalid, or the user does not have the access rights to change the system clock, the function returns zero.

Remarks

The network time value can represent a date and time up to the year 2036.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cstimv10.lib

Time Protocol Data Structures

- INITDATA
- SYSTEMTIME

Copyright © 2023 Catalyst Development Corporation. All rights reserved.

INITDATA Structure

This structure contains information about the SocketTools library when the initialization function returns.

```
typedef struct _INITDATA
{
    DWORD        dwSize;
    DWORD        dwVersionMajor;
    DWORD        dwVersionMinor;
    DWORD        dwVersionBuild;
    DWORD        dwOptions;
    DWORD_PTR    dwReserved1;
    DWORD_PTR    dwReserved2;
    TCHAR        szDescription[128];
} INITDATA, *LPINITDATA;
```

Members

dwSize

Size of this structure. This structure member must be set to the size of the structure prior to calling the initialization function. Failure to do so will cause the function to fail.

dwVersionMajor

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the major version number for the library.

dwVersionMinor

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the minor version number for the library.

dwVersionBuild

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the build number for the library.

dwOptions

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

dwReserved1

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

dwReserved2

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

szDescription

A null terminated string which describes the library.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Unicode: Implemented as Unicode and ANSI versions.

SYSTEMTIME Structure

The **SYSTEMTIME** structure represents a date and time using individual members for the month, day, year, weekday, hour, minute, second, and millisecond.

```
typedef struct _SYSTEMTIME
{
    WORD wYear;
    WORD wMonth;
    WORD wDayOfWeek;
    WORD wDay;
    WORD wHour;
    WORD wMinute;
    WORD wSecond;
    WORD wMilliseconds;
} SYSTEMTIME, *LPSYSTEMTIME;
```

Members

wYear

Specifies the current year. The year value must be greater than 1601.

wMonth

Specifies the current month. January is 1, February is 2 and so on.

wDayOfWeek

Specifies the current day of the week. Sunday is 0, Monday is 1 and so on.

wDay

Specifies the current day of the month

wHour

Specifies the current hour.

wMinute

Specifies the current minute

wSecond

Specifies the current second.

wMilliseconds

Specifies the current millisecond.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include windows.h.

Web Services Library

The Web Services library provides data storage and location services for applications.

Reference

- [Functions](#)
- [Constants](#)
- [Data Structures](#)
- [Error Codes](#)

Library Information

File Name	CSWEBV10.DLL
Version	10.0.1468.2518
LibID	62AB4693-FFA1-4A6F-BC44-FDC113EB2C68
Import Library	CSWEBV10.LIB
Dependencies	None

Overview

The Web Services library enables an application to store and manage data remotely, and return information about the current physical location of the client. These functions use secure services provided by SocketTools API servers and do not require third-party APIs or accounts with other cloud service providers.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). If you are using Visual C++ 6.0 it is required that you have Service Pack 6 (SP6) installed. You should install all updates for your development tools and have the current Windows SDK installed. The minimum recommended version of Visual Studio is Visual Studio 2010.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are using Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. It is recommended that you install the current service pack and all critical updates available for your version of the operating system.

This product includes both 32-bit and 64-bit libraries. Native 64-bit CPU support requires the 64-bit version of Windows 7 or later versions of the Windows operating system.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

Web Services Functions

Function	Description
WebCancelTransfer	Cancel a storage operation that is currently in progress
WebCloseStorage	Close a storage container and release resources allocated for the client session
WebCompareFile	Compare the contents of a stored object with a local file
WebCompareObject	Compare the contents of a stored object with a memory buffer
WebCompareText	Compare the contents of a stored object with a string
WebCopyObject	Copy a storage object to a new location and optionally rename the object label
WebDeleteObject	Delete an existing storage object
WebDownloadFile	Download the contents of a stored object to a local file
WebDownloadFileEx	Download the contents of a stored object with progress notifications
WebDisableTrace	Disable logging of function calls to the trace log
WebEnableTrace	Enable logging of function calls to a file
WebEnumApplications	Enumerate all registered storage applications
WebEnumObjects	Enumerate all storage objects that match the specified label or content type
WebGetAccountId	Return the current web services account identifier
WebGetErrorString	Return a description for the specified error code
WebGetFile	Download the contents of a storage object and copy to a local file
WebGetFileEx	Download the contents of a storage object and return information about the object
WebGetFirstApplication	Return information about the first registered storage application
WebGetFirstObject	Return information about the first object that matches search criteria
WebGetLastError	Return the last error code
WebGetLocation	Return the current physical location of the local computer system
WebGetNextApplication	Return information about the next registered storage application
WebGetNextObject	Return information about the next object that matches search criteria
WebGetObject	Download the contents of a storage object to a buffer
WebGetObjectEx	Download the contents of a storage object to buffer and return information about the object
WebGetObjectInformation	Retrieve the metadata for the specified storage object
WebGetObjectSize	Return the size of the specified storage object
WebGetStorageId	Return the returns the storage container ID
WebGetStorageQuota	Return quota limits assigned to your storage account
WebGetStorageTimeout	Get the number of seconds until a storage operation times out
WebGetTextObject	Download the contents of a text object into a string buffer
WebGetTransferStatus	Return status information about the progress of a data transfer
WebInitialize	Initialize the library and validate the specified license key at runtime
WebMoveObject	Move a storage object to a new location and optionally rename the object label
WebOpenStorage	Open a storage container and return a handle for the client session
WebPutFile	Upload the contents of a local file to a new storage object

WebPutFileEx	Upload the contents of a local file and return information about the new object
WebPutObject	Upload the contents of a memory buffer to a new storage object
WebPutObjectEx	Upload the contents of a memory buffer and return information about the new object
WebPutTextObject	Create or replace a text object with the contents of a string buffer
WebRegisterAppId	Register a new application identifier used to store and retrieve data
WebRegisterEvent	Register an event handler to receive notifications for the session
WebRenameObject	Change the label associated with a storage object
WebResetStorage	Resets the application storage container and deletes all stored objects
WebResetStorageEx	Resets the specified storage container for an application and deletes all stored objects
WebSetLastError	Set the last error code
WebSetStorageTimeout	Set the number of seconds until a storage operation times out
WebUninitialize	Terminates the use of the library
WebUnregisterAppId	Unregister the application identifier and delete all associated storage objects
WebUploadFile	Upload the contents of a local file, creating or overwriting a stored object
WebUploadFileEx	Upload the contents of a local file with progress notifications
WebValidateAppId	Validate the specified application identifier
WebValidateLabel	Check the specified string to ensure it is a valid object label

WebCancelTransfer Function

```
BOOL WINAPI WebCancelTransfer(  
    HSTORAGE hStorage  
);
```

The **WebCancelTransfer** function cancels the current data transfer in progress.

Parameters

hStorage

A handle to the storage container.

Return Value

If the function succeeds, the return value is a non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebCancelTransfer** function will cancel the current data transfer and abort the connection to the storage server. This function will fail if an active data transfer (either an upload or download) is not in progress.

This would typically be used within an event handler to cancel an operation as the contents of an object are being read or written. There is no mechanism to resume a canceled data transfer and this function should only be used when absolutely necessary.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

WebCloseStorage Function

```
BOOL WINAPI WebCloseStorage(  
    HSTORAGE hStorage  
);
```

The **WebCloseStorage** function closes the storage container.

Parameters

hStorage

A handle to the storage container.

Return Value

If the function succeeds, the return value is a non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebCloseStorage** function must be called after all operations using the storage container have completed. The access token granted to the application will be released and the memory allocated for the session cache will be freed. Failure to call this function can result in a memory leak.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswebv10.lib

See Also

[WebOpenStorage](#)

WebCompareFile Function

```
BOOL WINAPI WebCompareFile(  
    HSTORAGE hStorage,  
    LPCTSTR lpszObjectLabel,  
    LPCTSTR lpszLocalFile  
);
```

The **WebCompareFile** function compares the contents of a stored object with a local file.

Parameters

hStorage

A handle to the storage container.

lpszObjectLabel

A pointer to a null terminated string which specifies the label of the object to be compared.

lpszLocalFile

A pointer to a null terminated string that specifies the name of the local file. If a path is not specified, the file will be created in the current working directory.

Return Value

If the function succeeds, the return value is a non-zero and the contents of the file matches the stored object. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebCompareFile** function performs a binary comparison of the contents of a local file with a stored object on the server. The contents of the file must be identical to the contents of the stored object or the function will fail.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstoools10.h

Import Library: cswebv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[WebCompareObject](#), [WebCompareText](#), [WebGetObjectInformation](#)

WebCompareObject Function

```
BOOL WINAPI WebCompareObject(  
    HSTORAGE hStorage,  
    LPCTSTR lpszObjectLabel,  
    LPCVOID lpvBuffer,  
    DWORD dwLength  
);
```

The **WebCompareObject** function compares the contents of a stored object with the data provided by the caller.

Parameters

hStorage

A handle to the storage container.

lpszObjectLabel

A pointer to a null terminated string which specifies the label of the object to be compared.

lpvBuffer

A pointer to a buffer that contains the data to be compared against the storage object.

dwLength

An unsigned integer which specifies the length of the data buffer to be compared.

Return Value

If the function succeeds, the return value is a non-zero and the data matches the contents of the stored object. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebCompareObject** function performs a binary comparison of the data in the specified buffer with the contents of the storage object on the server. The *dwLength* parameter must match the size of the stored object exactly, or this function will fail. Partial comparisons are not supported by this function.

If you wish to compare the contents of a text object, it is recommended that you use **WebCompareText**. This function ensures that Unicode text is compared correctly.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswebv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[WebCompareFile](#), [WebCompareText](#), [WebGetObjectInformation](#)

WebCompareText Function

```
BOOL WINAPI WebCompareText(  
    HSTORAGE hStorage,  
    LPCTSTR lpszObjectLabel,  
    LPCTSTR lpszObjectText,  
    INT cchObjectText  
);
```

The **WebCompareText** function compares the contents of a stored object with the string provided by the caller.

Parameters

hStorage

A handle to the storage container.

lpszObjectLabel

A pointer to a null terminated string which specifies the label of the object to be compared.

lpszObjectText

A pointer to a null terminated string which contains the text to be compared with the stored object.

cchObjectText

The number of characters in the *lpszObjectText* string to be compared. This value may be -1, in which case the string length will be determined by counting the number of characters up to the terminating null.

Return Value

If the function succeeds, the return value is a non-zero and the data matches the contents of the stored object. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebCompareText** function performs a text comparison of the characters in the string with the contents of the storage object on the server. The string length must match the amount of text in the stored object exactly, or this function will fail. Partial comparisons are not supported by this function.

The Unicode version of this function will automatically convert the UTF-16 string to UTF-8 encoding in the same way the **WebPutTextObject** function does.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cswebv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

WebCopyObject Function

```
BOOL WINAPI WebCopyObject(  
    HSTORAGE hStorage,  
    LPCTSTR lpszOldLabel,  
    LPCTSTR lpszNewLabel,  
    DWORD dwStorageType,  
    LPWEB_STORAGE_OBJECT lpObject  
);
```

The **WebCopyObject** function creates a copy of an existing storage object using a new label.

Parameters

hStorage

A handle to the storage container.

lpszOldLabel

A pointer to a null terminated string which specifies the label of the existing storage object to be copied. This parameter must specify a valid object label and cannot be a NULL pointer or an empty string.

lpszNewLabel

A pointer to a null terminated string which specifies the name of the new storage object that will be created. This parameter may be NULL or point to an empty string, in which case the label name is not changed. In this case, the *dwStorageType* parameter cannot be WEB_STORAGE_DEFAULT.

dwStorageType

An integer value that identifies the storage container type. One of the following values should be specified:

Constant	Description
WEB_STORAGE_DEFAULT (0)	The default storage type. If this value is specified, the new object will be created using the same storage type as the original storage object.
WEB_STORAGE_GLOBAL (1)	Global storage. Objects stored using this storage type are available to all users. Any changes made to objects using this storage type will affect all users of the application. Unless there is a specific need to limit access to the objects stored by the application to specific domains, local machines or users, it is recommended that you use this storage type when creating new objects.
WEB_STORAGE_DOMAIN (2)	Local domain storage. Objects stored using this storage type are only available to users in the same local domain, as defined by the domain name or workgroup name assigned to the local system. If the domain or workgroup name changes, objects previously stored using this storage type will not be available to the application.
WEB_STORAGE_MACHINE (3)	Local machine storage. Objects stored using this storage type are only available to users on the same local

	machine. The local machine is identified by unique characteristics of the system, including the boot volume GUID. Objects previously stored using this storage type will not be available on that system if the boot disk is reformatted.
WEB_STORAGE_USER (4)	Current user storage. Objects stored using this storage type are only available to the current user logged in on the local machine. The user identifier is based on the Windows user SID that is assigned when the user account is created. If the user account is deleted, the objects previously stored using this storage type will not be available to the application.

lpObject

A pointer to a [WEB_STORAGE_OBJECT](#) structure that will contain information about the new storage object. If this information is not required, this parameter may be a NULL pointer.

Return Value

If the function succeeds, the return value is a non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebCopyObject** function is used to create a copy of an existing storage object. It may be used to duplicate an object with a different label, or it may be used to copy the object to a new storage container type. For example, it can copy an object originally created using WEB_STORAGE_USER to a new object stored using WEB_STORAGE_MACHINE.

Copied objects are assigned their own unique ID and are not linked to one another. Any subsequent changes made to the original object will not affect the copied object. Attempting to copy an object to itself or another existing object will result in an error.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cswebv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[WebDeleteObject](#), [WebMoveObject](#), [WebRenameObject](#)

WebDeleteObject Function

```
BOOL WINAPI WebDeleteObject(  
    HSTORAGE hStorage,  
    LPCTSTR lpszObjectLabel  
);
```

The **WebDeleteObject** function deletes an object from the storage container.

Parameters

hStorage

A handle to the storage container.

lpszObjectLabel

A pointer to a null terminated string which specifies the label of the object to be deleted.

Return Value

If the function succeeds, the return value is a non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebDeleteObject** function permanently deletes the storage object and its associated data from the server. Deleted objects cannot be recovered by the application. To remove all objects stored in the container, use the **WebResetStorage** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cswebv10.lib

Unicode: Implemented as Unicode and ANSI versions.

WebDisableTrace Function

```
BOOL WINAPI WebDisableTrace();
```

The **WebDisableTrace** function disables the logging of socket function calls to the trace log.

Parameters

None.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, a value of zero is returned.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswebv10.lib

[WebEnableTrace](#)

WebDownloadFile Function

```
BOOL WINAPI WebDownloadFile(  
    LPCTSTR lpzLocalFile,  
    LPCTSTR lpzObjectLabel,  
    LPWEB_STORAGE_OBJECT lpObject  
);
```

The **WebDownloadFile** function downloads the contents of a storage object and copies it to a local file.

Parameters

lpzObjectLabel

A pointer to a null terminated string that specifies the label of the object that should be retrieved from the server. This parameter cannot be NULL or an empty string. Refer to the **WebValidateLabel** function for more information about object labels.

lpzLocalFile

A pointer to a null terminated string that specifies the name of the local file that will be created or overwritten with the contents of the storage object. If a path is not specified, the file will be created in the current working directory.

lpObject

A pointer to a [WEB_STORAGE_OBJECT](#) structure that will contain additional information about the object that has been downloaded. This parameter may be NULL if the information is not required.

Return Value

If the function succeeds, the return value is a non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebDownloadFile** function downloads the contents of the storage object and stores it in a local file. The object must have been previously created in the storage container `WEB_STORAGE_GLOBAL` using the application ID **SocketTools.Storage.Default**. This is the same default container used by the **WebUploadFile** function.

Unlike the **WebGetFile** and **WebGetFileEx** functions, it is not required that you open a storage container using the **WebOpenStorage** function prior to calling **WebDownloadFile**.

Additional metadata about the object will be returned in the `WEB_STORAGE_OBJECT` structure provided by the caller, such as the date and time the object was created, the content type and the SHA-256 hash of the object contents.

The **WebDownloadFileEx** function provides similar functionality with a more complex interface that supports custom application IDs, additional options and the ability to provide a callback function that is invoked during the download process.

Example

```
WEB_STORAGE_OBJECT webObject;  
  
// Download the object from global storage to a local file  
if (WebDownloadFile(lpzLocalFile, lpzObjectLabel, &webObject))  
{
```

```
// The object was downloaded, display the metadata
_tprintf(_T("Object:  %s\n"), webObject.szObjectId);
_tprintf(_T("Label:   %s\n"), webObject.szLabel);
_tprintf(_T("Size:    %lu\n"), webObject.dwObjectSize);
_tprintf(_T("Digest:  %s\n"), webObject.szDigest);
_tprintf(_T("Content: %s\n"), webObject.szContent);
}
else
{
    // The object could not be downloaded, display the error
    TCHAR szError[128];

    WebGetErrorString(WebGetLastError(), szError, 128);
    _tprintf(_T("Unable to download \"%s\" (%s)\n"), lpszObjectLabel, szError);
}
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswebv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[WebDownloadFileEx](#), [WebGetFile](#), [WebUploadFile](#), [WebValidateLabel](#)

WebDownloadFileEx Function

```
BOOL WINAPI WebDownloadFileEx(  
    LPCTSTR lpszLocalFile,  
    LPCTSTR lpszObjectLabel,  
    LPCTSTR lpszAppId,  
    DWORD dwStorageType,  
    DWORD dwReserved,  
    DWORD dwTimeout,  
    LPWEB_STORAGE_OBJECT LpObject,  
    WEBEVENTPROC LpEventProc,  
    DWORD_PTR dwParam  
);
```

The **WebDownloadFileEx** function downloads the contents of a storage object and copies it to a local file.

Parameters

lpszLocalFile

A pointer to a null terminated string that specifies the name of the local file that will be created or overwritten with the contents of the storage object. If a path is not specified, the file will be created in the current working directory.

lpszObjectLabel

A pointer to a null terminated string that specifies the label of the object that should be retrieved from the server.

lpszAppId

A pointer to null terminated string which specifies the application ID for the storage container. The application ID is a string that uniquely identifies the application and can only contain letters, numbers, the period and the underscore character. If this parameter is NULL or an empty string, the default identifier **SocketTools.Storage.Default** will be used.

dwStorageType

An integer value that identifies the storage container type. One of the following values should be specified:

Constant	Description
WEB_STORAGE_GLOBAL (1)	Global storage. Objects stored using this storage type are available to all users. Any changes made to objects using this storage type will affect all users of the application. Unless there is a specific need to limit access to the objects stored by the application to specific domains, local machines or users, it is recommended that you use this storage type when creating new objects.
WEB_STORAGE_DOMAIN (2)	Local domain storage. Objects stored using this storage type are only available to users in the same local domain, as defined by the domain name or workgroup name assigned to the local system. If the domain or workgroup name changes, objects previously stored using this storage type will not be available to the application.

WEB_STORAGE_MACHINE (3)	Local machine storage. Objects stored using this storage type are only available to users on the same local machine. The local machine is identified by unique characteristics of the system, including the boot volume GUID. Objects previously stored using this storage type will not be available on that system if the boot disk is reformatted.
WEB_STORAGE_USER (4)	Current user storage. Objects stored using this storage type are only available to the current user logged in on the local machine. The user identifier is based on the Windows user SID that is assigned when the user account is created. If the user account is deleted, the objects previously stored using this storage type will not be available to the application.

dwReserved

An unsigned integer value that is reserved for future use. This value should always be zero.

dwTimeout

An unsigned integer value that specifies a timeout period in seconds. If this value is zero, a default timeout period will be used.

lpObject

A pointer to a [WEB_STORAGE_OBJECT](#) structure that will contain additional information about the object that has been downloaded. This parameter may be NULL if the information is not required.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **WebEventProc** callback function. If this parameter is NULL, no callback function will be invoked during the data transfer.

dwParam

A user-defined integer value that is passed to the callback function specified by *lpEventProc*. If the application targets the x86 (32-bit) platform, this parameter must be a 32-bit unsigned integer. If the application targets the x64 (64-bit) platform, this parameter must be a 64-bit unsigned integer.

Return Value

If the function succeeds, the return value is a non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebDownloadFileEx** function downloads the contents of the storage object and stores it in a local file. The **WebDownloadFile** function provides a simpler interface that defaults to downloading an object from the global storage container.

Unlike the **WebGetFile** and **WebGetFileEx** functions, it is not required that you open a storage container using the **WebOpenStorage** function prior to calling **WebDownloadFileEx**.

Additional metadata about the object will be returned in the [WEB_STORAGE_OBJECT](#) structure provided by the caller, such as the date and time the object was created, the content type and the SHA-256 hash of the object contents.

If you are downloading a large object and want your application to receive progress updates during the data transfer, provide a pointer to a callback function as the *lpEventProc* parameter. That function will receive event notifications as the data is being downloaded.

Example

```
WEB_STORAGE_OBJECT webObject;

// Download the object from global storage to a local file
if (WebDownloadFileEx(lpszLocalFile,
                    lpszObjectLabel,
                    lpszAppId,
                    WEB_STORAGE_GLOBAL,
                    0,
                    &webObject,
                    NULL, 0))
{
    // The object was downloaded, display the metadata
    _tprintf(_T("Object:  %s\n"), webObject.szObjectId);
    _tprintf(_T("Label:   %s\n"), webObject.szLabel);
    _tprintf(_T("Size:    %lu\n"), webObject.dwObjectSize);
    _tprintf(_T("Digest:  %s\n"), webObject.szDigest);
    _tprintf(_T("Content: %s\n"), webObject.szContent);
}
else
{
    // The object could not be retrieved, display the error
    TCHAR szError[128];

    WebGetErrorString(WebGetLastError(), szError, 128);
    _tprintf(_T("Unable to retrieve \"%s\" (%s)\n"), lpszObjectLabel, szError);
}
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswebv10.lib

Unicode: Implemented as Unicode and ANSI versions.

WebEnableTrace Function

```
BOOL WINAPI WebEnableTrace(  
    LPCTSTR lpszTraceFile,  
    DWORD dwTraceFlags  
);
```

The **WebEnableTrace** function enables the logging of socket function calls to a file.

Parameters

lpszTraceFile

A pointer to a string which specifies the name of the trace log file. If this parameter is NULL or an empty string, the default file name **cstrace.log** is used. The file is stored in the directory specified by the TEMP environment variable, if it is defined; otherwise, the current working directory is used.

dwTraceFlags

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
TRACE_INFO	All function calls are written to the trace file. This is the default value.
TRACE_ERROR	Only those function calls which fail are recorded in the trace file.
TRACE_WARNING	Only those function calls which fail or return values which indicate a warning are recorded in the trace file.
TRACE_HEXDUMP	All functions calls are written to the trace file, plus all the data that is sent or received is displayed, in both ASCII and hexadecimal format.
TRACE_PROCESS	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for multithreaded applications that are using worker threads.

Return Value

If the function succeeds, the return value is non-zero. A return value of zero indicates an error. Failure typically indicates that the tracing library **cstrcv10.dll** cannot be loaded on the local system.

Remarks

When trace logging is enabled, the file is opened, appended to and closed for each socket function call. This makes it possible for an application to append its own logging information, however care should be taken to ensure that the file is closed before the next network operation is performed. To limit the size of the log files, enable and disable logging only around those sections of code that you wish to trace.

Note that the TRACE_HEXDUMP trace level generates very large log files since it includes all of the data exchanged between your application and the server.

Trace function logging is managed on a per-thread basis, not for each client handle. This means that all SocketTools libraries and components share the same settings in the current thread. If you

are using multiple SocketTools libraries or components in your application, you only need to enable logging once.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswebv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[WebDisableTrace](#)

WebEnumApplications Function

```
BOOL WINAPI WebEnumApplications(  
    LPWEB_STORAGE_APPLICATION LpApplications,  
    LPDWORD LpdwRegistered  
);
```

The **WebEnumApplications** function enumerates all registered applications associated with the storage account.

Parameters

hStorage

lpApplications

A pointer to an array of [WEB_STORAGE_APPLICATION](#) structures that will contain information about the enumerated application IDs. If this parameter is NULL, then no information is returned.

lpdwRegistered

A pointer to an unsigned integer that will contain the number of registered applications enumerated by this function. If the *lpApplications* parameter points to an array of [WEB_STORAGE_APPLICATION](#) structures, this parameter must be initialized to the maximum size of the array being passed to the function. If the *lpApplications* parameter is NULL, this value must be initialized to zero and when the function returns it will contain the number of registered applications.

Return Value

If the function succeeds, the return value is a non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebEnumApplications** function can be used to enumerate the application IDs registered with the storage account using the **WebRegisterAppId** function.

This function can be used in two ways. If the *lpApplications* parameter is NULL and the value passed by reference in the *lpdwRegistered* parameter is initialized to zero, the function will return the number of registered applications in *lpdwRegistered*. This can be used to dynamically determine the size of the *lpApplications* array instead of declaring a fixed-size array in your application.

If the *lpApplications* parameter is not NULL, then the value referenced by *lpdwRegistered* must be initialized to the maximum size of the array that *lpApplications* points to. It is important to note that if either parameter is not initialized correctly, it can result in memory corruption and/or an unhandled exception.

The **WebGetFirstApplication** and **WebGetNextApplication** functions can be used to iterate through all registered application IDs without requiring you to preallocate memory for an array. This can be more efficient if a large number of application IDs have been registered.

Example

```
DWORD dwAppCount = 0;  
  
if (WebEnumApplications(NULL, &dwAppCount ))  
{
```

```

LPWEB_STORAGE_APPLICATION lpAppArray = NULL;
DWORD dwIndex;

// Return if there are no registered applications
if (dwAppCount == 0)
    return;

// Allocate memory for an array of WEB_STORAGE_APPLICATION structures
lpAppArray = (LPWEB_STORAGE_APPLICATION)LocalAlloc(LPTR,
sizeof(WEB_STORAGE_APPLICATION) * dwAppCount);

if (lpAppArray == NULL)
    return; // Exhausted virtual memory?

// Enumerate the registered application IDs
if (!WebEnumApplications(lpAppArray, &dwAppCount))
    return;

// Print information about each application
for (dwIndex = 0; dwIndex < dwAppCount ; dwIndex++)
{
    _tprintf(_T("AppId: %s\n"), lpAppArray[dwIndex].szAppId);
    _tprintf(_T("Key: %s\n"), lpAppArray[dwIndex].szApiKey);
    _tprintf(_T("LUID: %s\n"), lpAppArray[dwIndex].szLuid);
    _tprintf(_T("Tokens: %lu\n"), lpAppArray[dwIndex].dwTokens);

    if (dwAppCount > 1 && dwIndex < dwAppCount - 1)
        _tprintf(_T("\n"));
}

LocalFree((HLOCAL)lpAppArray);
}

```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswebv10.lib

Unicode: Implemented as Unicode and ANSI versions.

WebEnumObjects Function

```
BOOL WINAPI WebEnumObjects(  
    HSTORAGE hStorage,  
    LPCTSTR lpszMatchLabel,  
    LPCTSTR lpszContentType,  
    DWORD dwReserved,  
    LPWEB_STORAGE_OBJECT lpObjects,  
    LPDWORD lpdwObjects  
);
```

The **WebEnumObjects** function enumerates all storage objects that match the specified label or content type.

Parameters

hStorage

A handle to the storage container.

lpszMatchLabel

A pointer to a null terminated string which specifies the value to match against the object labels in the container. The string may contain wildcard characters similar to those use with the Windows filesystem. A "?" character matches any single character, and "*" matches any number of characters in the label. If this value is a NULL pointer or an empty string, all objects in the container will be matched.

lpszContentType

A pointer to a null terminated string which specifies the content type of the objects to be enumerated. If this value is a NULL pointer or an empty string, the content type is ignored and all matching objects are returned.

dwReserved

An unsigned integer value that is reserved for future use. This value must be zero.

lpObjects

A pointer to an array of [WEB_STORAGE_OBJECT](#) structures that will contain information about the enumerated objects. If this parameter is NULL, then no object information is returned.

lpdwObjects

A pointer to an unsigned integer that will contain the number of objects enumerated by this function. If the *lpObjects* parameter points to an array of [WEB_STORAGE_OBJECT](#) structures, this parameter must be initialized to the maximum size of the array being passed to the function. If the *lpObjects* parameter is NULL, this value must be initialized to zero, and when the function returns it will contain the number of matching objects.

Return Value

If the function succeeds, the return value is a non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebEnumObjects** function can be used to enumerate the number of objects that match a given label, content type or both. If a content type is specified, it must be a valid MIME media content type designated using the type/subtype nomenclature. For example, "text/plain" or "image/jpeg". An invalid MIME type will cause the function to fail.

This function can be used in two ways. If the *lpObjects* parameter is NULL and the value passed by reference in the *lpdwObjects* parameter is initialized to zero, the function will return the number of matching objects in *lpdwObjects*. This can be used to dynamically determine the size of the *lpObjects* array instead of declaring a fixed-size array in your application.

If the *lpObjects* parameter is not NULL, then the value referenced by *lpdwObjects* must be initialized to the maximum size of the array that *lpObjects* points to. It is important to note that if either parameter is not initialized correctly, it can result in memory corruption and/or an unhandled exception.

The **WebGetFirstObject** and **WebGetNextObject** functions can be used to iterate through all matching storage objects without requiring you to preallocate memory for an array. Using **WebGetFirstObject** and **WebGetNextObject** is more efficient when the container contains a large number of objects that match the specified label and/or content type.

Example

```
DWORD dwObjects = 0;

if (WebEnumObjects(hStorage, _T("*.pdf"), NULL, 0, NULL, &dwObjects))
{
    LPWEB_STORAGE_OBJECT lpObjects = NULL;
    DWORD dwIndex;

    // Return if there are no matching objects in the container
    if (dwObjects == 0)
        return;

    // Allocate memory for an array of WEB_STORAGE_OBJECT structures
    lpObjects = (LPWEB_STORAGE_OBJECT)LocalAlloc(LPTR,
sizeof(WEB_STORAGE_OBJECT) * dwObjects);

    if (lpObjects == NULL)
        return; // Exhausted virtual memory?

    // Enumerate the matching objects
    if (!WebEnumObjects(hStorage, NULL, NULL, 0, lpObjects, &dwObjects))
        return;

    // Print information about each object
    for (dwIndex = 0; dwIndex < dwObjects; dwIndex++)
    {
        _tprintf(_T("Object: %s\n"), lpObjects[dwIndex].szObjectId);
        _tprintf(_T("Label: %s\n"), lpObjects[dwIndex].szLabel);
        _tprintf(_T("Size: %lu\n"), lpObjects[dwIndex].dwObjectSize);
        _tprintf(_T("Digest: %s\n"), lpObjects[dwIndex].szDigest);
        _tprintf(_T("Content: %s\n"), lpObjects[dwIndex].szContent);

        if (dwObjects > 1 && dwIndex < dwObjects - 1)
            _tprintf(_T("\n"));
    }

    LocalFree((HLOCAL)lpObjects);
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswebv10.lib

Unicode: Implemented as Unicode and ANSI versions.

WebEventProc Function

```
VOID CALLBACK WebEventProc(  
    HSTORAGE hStorage,  
    UINT nEventId,  
    DWORD dwError,  
    DWORD_PTR dwParam  
);
```

The **WebEventProc** function is an application-defined callback function that processes events generated by the client.

Parameters

hStorage

A handle to the storage container.

nEventId

An unsigned integer which specifies which event occurred. For a complete list of events, refer to the **WebRegisterEvent** function.

dwError

An unsigned integer which specifies any error that occurred. If no error occurred, then this parameter will be zero.

dwParam

A user-defined integer value which was specified when the event callback was registered. If the application targets the x86 (32-bit) platform, this parameter must be a 32-bit unsigned integer. If the application targets the x64 (64-bit) platform, this parameter must be a 64-bit unsigned integer.

Return Value

None.

Remarks

An application must register this callback function by passing its address to the **WebRegisterEvent** function. The **WebEventProc** function is a placeholder for the application-defined function name.

To obtain information about the current status of the read or write operation, call the **WebGetTransferStatus** function. An event handler can cancel the current operation by calling the **WebCancelTransfer** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cswebv10.lib

Unicode: Implemented as Unicode and ANSI versions.

WebGetAccountId Function

```
BOOL WINAPI WebGetAccountId(  
    LPCTSTR lpszAccountId,  
    INT nMaxLength  
);
```

The **WebGetAccountId** function returns the web services account ID associated with the current session.

Parameters

lpszAccountId

A pointer to a null-terminated string that will contain the account ID when the function returns. This parameter cannot be NULL and must be at least 35 characters in length.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the *lpszAccountId* string parameter, including the terminating null character.

Return Value

If the function succeeds, the return value is a non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The account ID is a string that uniquely identifies the web services account that is associated with the session. The account ID corresponds with your product serial number and runtime license key, but it is not identical to either of those values.

If you are using an evaluation license, the account ID is temporary and only valid during the evaluation period. After the evaluation period has expired, the account ID is revoked and objects stored using this ID will be deleted. It is not recommended that you store critical application data using an evaluation license.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cswebv10.lib

Unicode: Implemented as Unicode and ANSI versions.

WebGetErrorString Function

```
INT WINAPI WebGetErrorString(  
    DWORD dwErrorCode,  
    LPTSTR lpszDescription,  
    INT cbDescription  
);
```

The **WebGetErrorString** function is used to return a description of a specific error code. Typically this is used in conjunction with the **WebGetLastError** function for use with warning dialogs or as diagnostic messages.

Parameters

dwErrorCode

The error code for which a description is returned.

lpszDescription

A pointer to the buffer that will contain a description of the specified error code. This buffer should be at least 128 characters in length.

cbDescription

The maximum number of characters that may be copied into the description buffer.

Return Value

If the function succeeds, the return value is the length of the description string. If the function fails, the return value is zero, meaning that no description exists for the specified error code. Typically this indicates that the error code passed to the function is invalid.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `cswebv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

See Also

WebGetFile Function

```
BOOL WINAPI WebGetFile(  
    HSTORAGE hStorage,  
    LPCTSTR lpszLocalFile,  
    LPCTSTR lpszObjectLabel  
);
```

The **WebGetFile** function downloads the contents of a storage object and copies it to a local file.

Parameters

hStorage

A handle to the storage container.

lpszLocalFile

A pointer to a null terminated string that specifies the name of the local file that will be created or overwritten with the contents of the storage object. If a path is not specified, the file will be created in the current working directory.

lpszObjectLabel

A pointer to a null terminated string that specifies the label of the object that should be retrieved from the server.

Return Value

If the function succeeds, the return value is a non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebGetFile** function downloads the contents of the storage object and stores it in a local file. For information about the stored object that has been downloaded, use the **WebGetFileEx** function.

If you are downloading a large object and want your application to receive progress updates during the data transfer, use the **WebRegisterEvent** function and provide a pointer to a callback function that will receive event notifications.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstoools10.h

Import Library: cswebv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[WebDownloadFile](#), [WebGetFileEx](#), [WebGetObject](#), [WebPutFile](#), [WebPutObject](#), [WebRegisterEvent](#), [WebUploadFile](#)

WebGetFileEx Function

```
BOOL WINAPI WebGetFileEx(  
    HSTORAGE hStorage,  
    LPCTSTR lpszLocalFile,  
    LPCTSTR lpszObjectLabel,  
    DWORD dwReserved,  
    LPWEB_STORAGE_OBJECT lpObject  
);
```

The **WebGetFileEx** function downloads the contents of a storage object and copies it to a local file.

Parameters

hStorage

A handle to the storage container.

lpszLocalFile

A pointer to a null terminated string that specifies the name of the local file that will be created or overwritten with the contents of the storage object. If a path is not specified, the file will be created in the current working directory.

lpszObjectLabel

A pointer to a null terminated string that specifies the label of the object that should be retrieved from the server.

dwReserved

An unsigned integer value that is reserved for future use. This value should always be zero.

lpObject

A pointer to a [WEB_STORAGE_OBJECT](#) structure that will contain additional information about the object. This parameter may be NULL if the information is not required.

Return Value

If the function succeeds, the return value is a non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebGetFileEx** function downloads the contents of the storage object and stores it in a local file. Additional metadata about the object will be returned in the [WEB_STORAGE_OBJECT](#) structure provided by the caller, such as the date and time the object was created, the content type and the SHA-256 hash of the object contents.

If you are downloading a large object and want your application to receive progress updates during the data transfer, use the **WebRegisterEvent** function and provide a pointer to a callback function that will receive event notifications.

The **WebDownloadFile** and **WebDownloadFileEx** functions provide similar functionality, but do not require a handle to an open storage container.

Example

```
WEB_STORAGE_OBJECT webObject;  
  
// Download the object and store the contents in a local file  
if (WebGetFileEx(hStorage, lpszLocalFile, lpszObjectLabel, 0, &webObject))
```

```

{
    // The object was downloaded, display the metadata
    _tprintf(_T("Object:  %s\n"), webObject.szObjectId);
    _tprintf(_T("Label:   %s\n"), webObject.szLabel);
    _tprintf(_T("Size:    %I64u\n"), webObject.dwObjectSize);
    _tprintf(_T("Digest:  %s\n"), webObject.szDigest);
    _tprintf(_T("Content: %s\n"), webObject.szContent);
}
else
{
    // The object could not be retrieved, display the error
    TCHAR szError[128];

    WebGetErrorString(WebGetLastError(), szError, 128);
    _tprintf(_T("Unable to retrieve \"%s\" (%s)\n"), lpszObjectLabel, szError);
}

```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswebv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[WebRegisterEvent](#), [WebUploadFile](#)

WebGetLastError Function

```
DWORD WINAPI WebGetLastError();
```

Parameters

None.

Return Value

The return value is the last error code value for the current thread. Functions set this value by calling the **WebSetLastError** function. The Return Value section of each reference page notes the conditions under which the function sets the last error code.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. You should call the **WebGetLastError** function immediately when a function's return value indicates that an error has occurred. That is because some functions call **WebSetLastError(0)** when they succeed, clearing the error code set by the most recently failed function.

Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or WEB_ERROR. Those functions which call **WebSetLastError** when they succeed are noted on the function reference page.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cswebv10.lib

See Also

[WebGetErrorString](#), [WebSetLastError](#)

WebGetFirstApplication Function

```
BOOL WINAPI WebGetFirstApplication(  
    LPWEB_STORAGE_APPLICATION LpAppInfo,  
    LPDWORD LpdwContext,  
);
```

The **WebGetFirstApplication** function returns information about the first registered application for the current storage account.

Parameters

lpAppInfo

A pointer to a [WEB_STORAGE_APPLICATION](#) structure that will contain information about the registered application when the function returns. This parameter cannot be NULL.

lpdwContext

A pointer to an unsigned integer that is used with subsequent calls to the **WebGetNextApplication** function. This parameter cannot be NULL.

Return Value

If the function succeeds, the return value is a non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebGetFirstApplication** function returns information about the first registered application. It is used in conjunction with the **WebGetNextApplication** function to enumerate all of the registered application IDs associated with your storage account.

This function provides an alternative to the **WebEnumApplications** function, which populates an array of [WEB_STORAGE_APPLICATION](#) structures. In some cases, iterating through each AppID in a loop may be preferred to preallocating memory for an array to store every registered application. Using **WebGetFirstApplication** and **WebGetNextApplication** is more efficient when you have registered a large number of application IDs.

You cannot intermix calls between **WebGetFirstApplication** and **WebEnumApplications**. The **WebEnumApplications** function will reset the internal application ID cache for the client session and subsequent calls to **WebGetNextApplication** will fail. The cached application ID information used by this function is shared by the entire process. Attempting to enumerate all registered application IDs in multiple threads at the same time can yield unexpected results. It is recommended that multi-threaded clients use a critical section to ensure that only a single thread is enumerating the AppIDs at any one time.

Example

```
WEB_STORAGE_APPLICATION webApp;  
DWORD dwContext = 0;  
  
if (WebGetFirstApplication(&webApp, &dwContext))  
{  
    do  
    {  
        // Print information for each registered application  
        _tprintf(_T("AppId: %s\n"), webApp.szAppId);  
        _tprintf(_T("Key: %s\n"), webApp.szApiKey);  
        _tprintf(_T("LUID: %s\n"), webApp.szLuid);  
    }  
}
```

```
        _tprintf(_T("Tokens: %lu\n"), webApp.dwTokens);
        _tprintf(_T("\n"));
    }
    while (WebGetNextApplication(&webApp, &dwContext));
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cswebv10.lib

Unicode: Implemented as Unicode and ANSI versions.

WebGetFirstObject Function

```
BOOL WINAPI WebGetFirstObject(  
    HSTORAGE hStorage,  
    LPCTSTR lpszMatchLabel,  
    LPCTSTR lpszContentType,  
    DWORD dwReserved,  
    LPWEB_STORAGE_OBJECT lpObject  
);
```

The **WebGetFirstObject** function returns information about the first storage object that matches the specified label or content type.

Parameters

hStorage

A handle to the storage container.

lpszMatchLabel

A pointer to a null terminated string which specifies the value to match against the object labels in the container. The string may contain wildcard characters similar to those use with the Windows filesystem. A "?" character matches any single character, and "*" matches any number of characters in the label. If this value is a NULL pointer or an empty string, all objects in the container will be matched.

lpszContentType

A pointer to a null terminated string which specifies the content type of the objects to be enumerated. If this value is a NULL pointer or an empty string, the content type is ignored and all matching objects are returned. If a content type is specified, it must be a valid MIME media content type designated using the **type/subtype** nomenclature.

dwReserved

An unsigned integer value that is reserved for future use. This value must be zero.

lpObject

A pointer to a [WEB_STORAGE_OBJECT](#) structure that will contain information about the storage object when the function returns. This parameter cannot be NULL.

Return Value

If the function succeeds, the return value is a non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebGetFirstObject** function returns information about the first object that matches a given label, content type or both. It is used in conjunction with the **WebGetNextObject** function to enumerate all of the matching objects in the storage container.

This function provides an alternative to the **WebEnumObjects** function, which populates an array of [WEB_STORAGE_OBJECT](#) structures. In some cases, iterating over each object in a loop may be preferred to preallocating memory for an array to store every matching object. Using **WebGetFirstObject** and **WebGetNextObject** is more efficient when the container contains a large number of objects that match the specified label and/or content type.

You cannot intermix calls between **WebGetFirstObject** and **WebEnumObjects**. The **WebEnumObjects** function will reset the internal object cache for the client session and

subsequent calls to **WebGetNextObject** will fail.

Example

```
WEB_STORAGE_OBJECT webObject;

if (WebGetFirstObject(hStorage, _T("*.pdf"), NULL, 0, &webObject))
{
    do
    {
        // Print information about each object
        _tprintf(_T("Object: %s\n"), webObject.szObjectId);
        _tprintf(_T("Label: %s\n"), webObject.szLabel);
        _tprintf(_T("Size: %lu\n"), webObject.dwObjectSize);
        _tprintf(_T("Digest: %s\n"), webObject.szDigest);
        _tprintf(_T("Content: %s\n"), webObject.szContent);
        _tprintf(_T("\n"));
    }
    while (WebGetNextObject(hStorage, &webObject));
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cswebv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[WebEnumObjects](#), [WebGetNextObject](#)

WebGetLocation Function

```
BOOL WINAPI WebGetLocation(  
    LPWEB_LOCATION lpLocation  
);
```

The **WebGetLocation** function returns the current physical location of the local computer system.

Parameters

lpLocation

A pointer to a [WEB_LOCATION](#) structure that will contain information about the location when the function returns. The structure members will be automatically initialized to zero and zero-length strings when the function is called. This parameter cannot be a NULL pointer.

Return Value

If the function succeeds, the return value is a non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebGetLocation** function is used to obtain physical location information associated with the with the external IP address of the local system. The accuracy of this information can vary depending on the location, with the most detailed information being available for North America. The country and time zone information for all locations is generally accurate. However, as the location information becomes more precise, details such as city names, postal codes and specific geographic locations (e.g.: longitude and latitude) may have reduced accuracy.

This location information should not be used by programs that require extremely accurate map coordinates, such as navigation applications. The location information in North America should be generally accurate within a 25 mile (40km) radius. However, given the nature of how IP address location works, there is no guarantee that location information for any specific IP address or network will be accurate.

Software that is designed to protect the privacy of users, such as those which route all Internet traffic through proxy servers or VPNs, can significantly impact the accuracy of this information. In this case, the data returned in this structure may reflect the location of the network or proxy server, and not the location of the person using your application. It is recommended that you always request permission from the user before acquiring their location, have them confirm that the location is correct and provide a mechanism for them to update that information.

Example

```
WEB_LOCATION webLocation;  
  
// Return information about the location of the local system  
if (WebGetLocation(&webLocation))  
{  
    _tprintf(_T("Location ID: %s\n"), webLocation.szLocationId);  
    _tprintf(_T("IP address: %s\n"), webLocation.szIPAddress);  
    _tprintf(_T("ASN: %u\n"), webLocation.nAutonomousSystemNumber);  
    _tprintf(_T("Organization: %s\n"), webLocation.szOrganization);  
    _tprintf(_T("Region Name: %s\n"), webLocation.szRegionName);  
    _tprintf(_T("Region Code: %03u\n"), webLocation.nRegionCode);  
    _tprintf(_T("Country Name: %s\n"), webLocation.szCountryName);  
    _tprintf(_T("Country Code: %03u\n"), webLocation.nCountryCode);  
    _tprintf(_T("Subdivision: %s\n"), webLocation.szSubdivision);  
}
```

```

    _tprintf(_T("City Name: %s\n"), webLocation.szCityName);
    _tprintf(_T("Postal Code: %s\n"), webLocation.szPostalCode);
    _tprintf(_T("Timezone: %s (%ld)\n"), webLocation.szTimezone,
webLocation.nTimezoneOffset);
    _tprintf(_T("Local Time: %04d-%02d-%02d %02d:%02d:%02d %s\n"),
        webLocation.stLocalTime.wYear,
        webLocation.stLocalTime.wMonth,
        webLocation.stLocalTime.wDay,
        webLocation.stLocalTime.wHour,
        webLocation.stLocalTime.wMinute,
        webLocation.stLocalTime.wSecond,
        webLocation.szTzShortName);
    _tprintf(_T("Coordinates: %s\n"), webLocation.szCoordinates);
    _tprintf(_T("Latitude: %.4f\n"), webLocation.dLatitude);
    _tprintf(_T("Longitude: %.4f\n"), webLocation.dLongitude);
}
else
{
    _tprintf(_T("Unable to determine the current location\n"));
}

```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswebv10.lib

Unicode: Implemented as Unicode and ANSI versions.

WebGetNextApplication Function

```
BOOL WINAPI WebGetNextApplication(  
    LPWEB_STORAGE_APPLICATION LpAppInfo,  
    LPDWORD LpdwContext,  
);
```

The **WebGetNextApplication** function returns information about the next registered application for the current storage account.

Parameters

lpAppInfo

A pointer to a [WEB_STORAGE_APPLICATION](#) structure that will contain information about the registered application when the function returns. This parameter cannot be NULL.

lpdwContext

A pointer to an unsigned integer that is used with subsequent calls to the **WebGetNextApplication** function. The value of this parameter is initialized by calling the **WebGetFirstApplication** function. This parameter cannot be NULL.

Return Value

If the function succeeds, the return value is a non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebGetNextApplication** function returns information about the next registered application after initially calling the **WebGetFirstApplication** function. It is used to enumerate all of the registered application IDs associated with your storage account.

This function provides an alternative to the **WebEnumApplications** function, which populates an array of [WEB_STORAGE_APPLICATION](#) structures. In some cases, iterating through each AppID in a loop may be preferred to preallocating memory for an array to store every registered application. Using **WebGetFirstApplication** and **WebGetNextApplication** is more efficient when you have registered a large number of application IDs.

You cannot intermix calls between **WebGetNextApplication** and **WebEnumApplications**. The **WebEnumApplications** function will reset the internal application ID cache for the client session and subsequent calls to **WebGetNextApplication** will fail. The cached application ID information used by this function is shared by the entire process. Attempting to enumerate all registered application IDs in multiple threads at the same time can yield unexpected results. It is recommended that multi-threaded clients use a critical section to ensure that only a single thread is enumerating the AppIDs at any one time.

Example

```
WEB_STORAGE_APPLICATION webApp;  
DWORD dwContext = 0;  
  
if (WebGetFirstApplication(&webApp, &dwContext))  
{  
    do  
    {  
        // Print information for each registered application  
        _tprintf(_T("AppId: %s\n"), webApp.szAppId);  
        _tprintf(_T("Key: %s\n"), webApp.szApiKey);  
    }  
}
```

```
        _tprintf(_T("LUID: %s\n"), webApp.szLuid);
        _tprintf(_T("Tokens: %lu\n"), webApp.dwTokens);
        _tprintf(_T("\n"));
    }
    while (WebGetNextApplication(&webApp, &dwContext));
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstoools10.h

Import Library: cswebv10.lib

WebGetNextObject Function

```
BOOL WINAPI WebGetNextObject(  
    HSTORAGE hStorage,  
    LPWEB_STORAGE_OBJECT lpObject  
);
```

The **WebGetNextObject** function returns information about the next storage object that matches the specified label or content type.

Parameters

hStorage

A handle to the storage container.

lpObject

A pointer to a [WEB_STORAGE_OBJECT](#) structure that will contain information about the storage object when the function returns. This parameter cannot be NULL.

Return Value

If the function succeeds, the return value is a non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebGetNextObject** function returns information about the next object that matches the label and/or content type that was specified by the **WebGetFirstObject** function call. This function may only be called after **WebGetFirstObject** has been called, otherwise it will fail.

When all matching objects have been returned to the caller, this function will return zero (FALSE) and the **WebGetLastError** function will return NO_ERROR. Any other error code indicates an underlying problem with the request, such as an invalid parameter passed to the function.

You cannot intermix calls between **WebGetNextObject** and **WebEnumObjects**. The **WebEnumObjects** function will reset the internal object cache for the client session and subsequent calls to **WebGetNextObject** will fail.

Example

```
WEB_STORAGE_OBJECT webObject;  
  
if (WebGetFirstObject(hStorage, _T("*.pdf"), NULL, 0, &webObject))  
{  
    do  
    {  
        // Print information about each object  
        _tprintf(_T("Object: %s\n"), webObject.szObjectId);  
        _tprintf(_T("Label: %s\n"), webObject.szLabel);  
        _tprintf(_T("Size: %lu\n"), webObject.dwObjectSize);  
        _tprintf(_T("Digest: %s\n"), webObject.szDigest);  
        _tprintf(_T("Content: %s\n"), webObject.szContent);  
        _tprintf(_T("\n"));  
    }  
    while (WebGetNextObject(hStorage, &webObject));  
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswebv10.lib

Unicode: Implemented as Unicode and ANSI versions.

WebGetObject Function

```
BOOL WINAPI WebGetObject(  
    HSTORAGE hStorage,  
    LPCTSTR lpszObjectLabel,  
    LPVOID lpvBuffer,  
    DWORD lpdwLength  
);
```

The **WebGetObject** function retrieves the contents of a storage object and copies it to the memory buffer that is provided.

Parameters

hStorage

A handle to the storage container.

lpszObjectLabel

A pointer to a null terminated string that specifies the label of the object that should be retrieved from the server.

lpvBuffer

A pointer to a byte buffer which will contain the data transferred from the server, or a pointer to a global memory handle which will reference the data when the function returns.

lpdwLength

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the *lpvBuffer* parameter. If the *lpvBuffer* parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the actual length of the file that was downloaded.

Return Value

If the function succeeds, the return value is a non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebGetObject** function is used to retrieve a stored object from the server and copy it into a local buffer. The function may be used in one of two ways, depending on the needs of the application. The first method is to pre-allocate a buffer large enough to store the contents of the object. In this case, the *lpvBuffer* parameter will point to the buffer that was allocated and the value that the *lpdwLength* parameter points to should be initialized to the size of that buffer.

The second method that can be used is have the *lpvBuffer* parameter point to a global memory handle which will contain the file data when the function returns. In this case, the value that the *lpdwLength* parameter points to must be initialized to zero. It is important to note that the memory handle returned by the function must be freed by the application, otherwise a memory leak will occur. See the example code below.

Example

```
HGLOBAL hgb1Buffer = (HGLOBAL)NULL;  
DWORD dwLength = 0;
```

```
// Return the file data into block of global memory allocated by  
// the GlobalAlloc function; the handle to this memory will be
```

```
// returned in the hglobalBuffer parameter
if (WebGetObject(hStorage, lpzObjectLabel, &hglobalBuffer, &dwLength))
{
    // Lock the global memory handle, returning a pointer to the
    // resource data
    LPBYTE lpBuffer = (LPBYTE)GlobalLock(hglobalBuffer);

    // After the data has been used, the handle must be unlocked
    // and freed, otherwise a memory leak will occur
    GlobalUnlock(hglobalBuffer);
    GlobalFree(hglobalBuffer);
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cswebv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[WebGetFile](#), [WebGetObjectEx](#), [WebPutFile](#), [WebPutObject](#)

WebGetObjectEx Function

```
BOOL WINAPI WebGetObjectEx(  
    HSTORAGE hStorage,  
    LPCTSTR lpszObjectLabel,  
    DWORD dwReserved,  
    LPVOID lpvBuffer,  
    LPDWORD lpdwLength,  
    LPWEB_STORAGE_OBJECT lpObject,  
);
```

The **WebGetObjectEx** function retrieves the contents of a storage object and copies it to the memory buffer that is provided. Additional information about the object is returned to the caller.

Parameters

hStorage

A handle to the storage container.

lpszObjectLabel

A pointer to a null terminated string that specifies the label of the object that should be retrieved from the server.

dwReserved

An unsigned integer that is reserved for future use. This value should always be zero.

lpvBuffer

A pointer to a byte buffer which will contain the data transferred from the server, or a pointer to a global memory handle which will reference the data when the function returns.

lpdwLength

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the *lpvBuffer* parameter. If the *lpvBuffer* parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the actual length of the file that was downloaded.

lpObject

A pointer to a [WEB_STORAGE_OBJECT](#) structure that will contain additional information about the object. This parameter may be NULL if the information is not required.

Return Value

If the function succeeds, the return value is a non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebGetObjectEx** function is used to retrieve a stored object from the server and copy it into a local buffer. The function may be used in one of two ways, depending on the needs of the application. The first method is to pre-allocate a buffer large enough to store the contents of the object. In this case, the *lpvBuffer* parameter will point to the buffer that was allocated and the value that the *lpdwLength* parameter points to should be initialized to the size of that buffer.

The second method that can be used is have the *lpvBuffer* parameter point to a global memory handle which will contain the file data when the function returns. In this case, the value that the *lpdwLength* parameter points to must be initialized to zero. It is important to note that the

memory handle returned by the function must be freed by the application, otherwise a memory leak will occur. See the example code below.

If you wish to retrieve the contents of a text object and store it in a null terminated string buffer, use the **WebGetTextObject** function. If you wish to download the contents of a stored file, use the **WebGetFileEx** function.

Additional metadata about the object will be returned in the WEB_STORAGE_OBJECT structure provided by the caller, such as the date and time the object was created, the content type and the SHA-256 hash of the object contents.

Example

```
HGLOBAL hgblBuffer = (HGLOBAL)NULL;
DWORD dwLength = 0;
WEB_STORAGE_OBJECT webObject;

// Return the file data into block of global memory allocated by
// the GlobalAlloc function; the handle to this memory will be
// returned in the hgblBuffer parameter
if (WebGetObjectEx(hStorage, lpszObjectLabel, 0, &hgblBuffer, &dwLength,
&webObject))
{
    // Lock the global memory handle, returning a pointer to the
    // resource data
    LPBYTE lpBuffer = (LPBYTE)GlobalLock(hgblBuffer);

    // After the data has been used, the handle must be unlocked
    // and freed, otherwise a memory leak will occur
    GlobalUnlock(hgblBuffer);
    GlobalFree(hgblBuffer);
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cswebv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[WebGetFileEx](#), [WebGetObject](#), [WebGetTextObject](#), [WebPutFileEx](#), [WebPutObjectEx](#)

WebGetObjectInformation Function

```
BOOL WINAPI WebGetObjectInformation(  
    HSTORAGE hStorage,  
    LPCTSTR lpszObjectLabel,  
    DWORD dwReserved,  
    LPWEB_STORAGE_OBJECT lpObject  
);
```

The **WebGetObjectInformation** function retrieves the metadata for a storage object.

Parameters

hStorage

A handle to the storage container.

lpszObjectLabel

A pointer to a null terminated string that specifies the label of the storage object.

dwReserved

An unsigned integer that is reserved for future use. This value should always be zero.

lpObject

A pointer to a [WEB_STORAGE_OBJECT](#) structure that will contain additional information about the object. This parameter cannot be a NULL pointer.

Return Value

If the function succeeds, the return value is a non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebGetObjectInformation** function is used to retrieve the metadata for a stored object on the server, such as the date and time the object was created, the content type and the SHA-256 hash of the object contents. This function can also be used as a simple method to determine if the specified object exists without the overhead of requesting the server attempt to retrieve the contents of an object.

Although storage object labels are similar to Windows file names, they are case-sensitive. When requesting information about an object, your application must specify the label name exactly as it was created. The object label cannot contain wildcard characters.

If you are only interested in obtaining the size of a stored object, you can use the **WebGetObjectSize** function.

To obtain information about how much storage your applications are using and the total number of stored objects, use the **WebGetStorageQuota** function.

Example

```
WEB_STORAGE_OBJECT webObject;  
  
// Get information about the object  
if (WebGetObjectInformation(hStorage, lpszObjectLabel, 0, &webObject))  
{  
    // The object exists, display the metadata  
    _tprintf(_T("Object:  %s\n"), webObject.szObjectId);  
    _tprintf(_T("Label:   %s\n"), webObject.szLabel);  
}
```

```
    _tprintf(_T("Size:    %lu\n"), webObject.dwObjectSize);
    _tprintf(_T("Digest:  %s\n"), webObject.szDigest);
    _tprintf(_T("Content: %s\n"), webObject.szContent);
}
else
{
    // The object does not exist, display the error
    TCHAR szError[128];

    WebGetErrorString(WebGetLastError(), szError, 128);
    _tprintf(_T("Unable to get information on \"%s\" (%s)\n"), lpszObjectLabel,
szError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstoools10.h

Import Library: cswebv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[WebGetFile](#), [WebGetObject](#), [WebGetObjectSize](#), [WebGetStorageQuota](#), [WebPutFile](#),
[WebPutObject](#)

WebGetObjectSize Function

```
BOOL WINAPI WebGetObjectSize(  
    HSTORAGE hStorage,  
    LPCTSTR lpszObjectLabel,  
    LPDWORD lpdwObjectSize  
);
```

The **WebGetObjectSize** function returns the size of the stored object.

Parameters

hStorage

A handle to the storage container.

lpszObjectLabel

A pointer to a null terminated string that specifies the label of the storage object. This parameter cannot be a NULL pointer.

lpdwObjectSize

A pointer to an unsigned integer value that will contain the size of the object. If this parameter is NULL, the parameter is ignored and the function only checks for the existence of an object that matches the specified label.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebGetObjectSize** function is used to retrieve the size of a stored object on the server. This function can also be used as a simple method to determine if the specified object exists. An object size of zero means the object exists, but currently has no data associated with it.

If the *lpdwObjectSize* parameter is not NULL, its value is initialized to zero when the function is called, and updated with the object size when the function returns.

Although storage object labels are similar to Windows file names, they are case-sensitive. When requesting the size of an object, your application must specify the label name exactly as it was created. The object label cannot contain wildcard characters.

The **WebGetObjectInformation** function can be used to obtain the metadata associated with the storage object, including the size, content type, creation date and a SHA-256 digest of the data.

To obtain information about how much storage your applications are using and the total number of stored objects, use the **WebGetStorageQuota** function.

Example

```
// Check if the object exists  
DWORD dwObjectSize;  
  
if (WebGetObjectSize(hStorage, lpszObjectLabel, &dwObjectSize))  
{  
    // The object exists, display the size in bytes  
    _tprintf(_T("The size of \"%s\" is %lu bytes\n"), lpszObjectLabel,  
dwObjectSize);  
}
```

```
else
{
    // The object size could not be determined, display the error
    TCHAR szError[128];

    WebGetErrorString(WebGetLastError(), szError, 128);
    _tprintf(_T("Unable to get the size of \"%s\" (%s)\n"), lpszObjectLabel,
szError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cswebv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[WebGetObject](#), [WebGetObjectInformation](#), [WebGetStorageQuota](#), [WebPutObject](#)

WebGetStorageId Function

```
BOOL WINAPI WebGetStorageId(  
    HSTORAGE hStorage,  
    LPCTSTR lpszStorageId,  
    INT nMaxLength  
);
```

The **WebGetStorageId** function returns the storage container ID.

Parameters

hStorage

A handle to the storage container.

lpszStorageId

A pointer to a null-terminated string that will contain the storage ID when the function returns. This parameter cannot be NULL and must be at least 35 characters in length.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the *lpszStorageId* string parameter, including the terminating null character.

Return Value

If the function succeeds, the return value is a non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The storage ID is a string that identifies the storage container that was opened with the **WebOpenStorage** function. The storage ID is associated with your development license and is guaranteed to be a unique value.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cswebv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[WebGetAccountId](#), [WebOpenStorage](#)

WebGetStorageQuota Function

```
BOOL WINAPI WebGetStorageQuota(  
    LPWEB_STORAGE_QUOTA lpQuota  
);
```

The **WebGetStorageQuota** function returns quota limits assigned to your storage account.

Parameters

lpQuota

A pointer to a [WEB_STORAGE_QUOTA](#) structure that will contain information the quota limits for your account when the function returns. This parameter cannot be NULL.

Return Value

If the function succeeds, the return value is a non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebGetStorageQuota** function can be used to determine how much storage space is available to your application. The *ulBytesFree* structure member will tell you how many bytes of storage you have available, and the *dwObjectSize* member will tell you the maximum size of any individual storage object. In addition to the bytes allocated for storage, there is also a limit on the total number of objects that your application may create which is specified by the *dwObjectLimit* member.

Accounts that are created with an evaluation license have much lower quota limits than a standard account and should be used for testing purposes only. After the evaluation period has ended, all objects stored using the evaluation license will be deleted.

Example

```
WEB_STORAGE_QUOTA appQuota;  
  
// Initialize the library  
if (WebInitialize(CSTOOLS10_LICENSE_KEY, NULL) == FALSE)  
{  
    _tprintf(_T("Unable to initialize the SocketTools library\n"));  
    return;  
}  
  
// Display storage account usage and limits  
if (WebGetStorageQuota(&appQuota))  
{  
    _tprintf(_T("Objects Used:   %lu\n"), appQuota.dwObjects);  
    _tprintf(_T("Object Limit:  %lu\n"), appQuota.dwObjectLimit);  
    _tprintf(_T("Object Size:   %lu\n"), appQuota.dwObjectSize);  
    _tprintf(_T("Bytes Used:    %I64u\n"), appQuota.ulBytesUsed);  
    _tprintf(_T("Bytes Free:    %I64u\n"), appQuota.ulBytesFree);  
    _tprintf(_T("Storage Limit: %I64u\n"), appQuota.ulStorageLimit);  
}  
else  
{  
    // Unable to get the quota information for this account  
    TCHAR szError[128];  
  
    WebGetErrorString(WebGetLastError(), szError, 128);
```

```
    _tprintf(_T("Unable to get the account quota (%s)\n"), szError);  
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswebv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[WebGetObjectInformation](#), [WebGetObjectSize](#), [WEB_STORAGE_QUOTA](#)

WebGetStorageTimeout Function

```
DWORD WINAPI WebGetStorageTimeout(  
    HSTORAGE hStorage  
);
```

The **WebGetStorageTimeout** function returns the number of seconds the client will wait for a response from the storage server. Once the specified number of seconds has elapsed, the function will fail and return to the caller.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the timeout period in seconds. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The default timeout period is 10 seconds.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswebv10.lib

See Also

[WebOpenStorage](#), [WebSetStorageTimeout](#)

WebGetTextObject Function

```
BOOL WINAPI WebGetTextObject(  
    HSTORAGE hStorage,  
    LPCTSTR lpszObjectLabel,  
    LPTSTR lpszBuffer,  
    INT nMaxLength,  
    LPWEB_STORAGE_OBJECT lpObject,  
);
```

The **WebGetTextObject** function retrieves the contents of a text storage object and copies it to the string buffer that is provided. Additional information about the object is returned to the caller.

Parameters

hStorage

A handle to the storage container.

lpszObjectLabel

A pointer to a null terminated string that specifies the label of the text object that should be retrieved from the server.

lpszBuffer

A pointer to a string buffer which will contain the text stored in the object. The string must be large enough to store the terminating null character.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer. This value must be large enough to store the complete text and the terminating null character.

lpObject

A pointer to a [WEB_STORAGE_OBJECT](#) structure that will contain additional information about the object. This parameter may be NULL if the information is not required.

Return Value

If the function succeeds, the return value is a non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebGetTextObject** function is used to retrieve the text from a stored object and copy it into a string buffer. The string buffer must be pre-allocated and large enough to contain the entire text and a terminating null character.

If you use the **WebGetObjectSize** function to determine the size of the object so your application can dynamically allocate memory for the string buffer, be sure to allocate a string buffer that is larger than the reported size. The size of the stored text object may differ slightly from what is returned in the string, depending on how the text has been encoded.

Text objects that are created or updated using the Unicode version of **WebPutTextObject** function will always be converted and stored as UTF-8 encoded text. If your application uses the ANSI version of this function to retrieve that text, it will be UTF-8 encoded and your application will need to convert it back to UTF-16 encoded text, if needed. The Unicode version of this function will perform the conversion automatically.

This function should never be used to retrieve data from an object that does not contain text. If

the **WebPutObject** function was previously used to store UTF-16 encoded text, you must use **WebGetObject** to retrieve that data. This function only recognizes UTF-8 encoded text and considers UTF-16 encoded text to be binary data.

Additional metadata about the object will be returned in the [WEB_STORAGE_OBJECT](#) structure provided by the caller, such as the date and time the object was created, the content type and the SHA-256 hash of the object contents.

Example

```
LPTSTR lpszBuffer = (LPTSTR)NULL;
INT nMaxLength = 8192;
WEB_STORAGE_OBJECT webObject;

lpszBuffer = (LPTSTR)LocalAlloc(LPTR, nMaxLength);
if (lpszBuffer == NULL)
{
    // Unable to allocate memory for the string
    _ftprintf(stderr, _T("Unable to allocate %d bytes of memory\n"),
nMaxLength);
    return;
}

if (WebGetTextObject(hStorage, lpszObjectLabel, lpszBuffer, nMaxLength,
&webObject))
{
    // Output the text contained in the object
    _fputts(lpszBuffer, stdout);
}
else
{
    DWORD dwError = WebGetLastError();
    TCHAR szError[128];

    WebGetErrorString(dwError, szError, 128);
    _ftprintf(stderr, _T("Unable to get \"%s\": %s\n"), lpszObjectLabel,
szError);
}

// Free memory allocated for the text when no longer needed
LocalFree((HLOCAL)lpszBuffer);
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstoools10.h

Import Library: cswebv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[WebPutTextObject](#)

WebGetTransferStatus Function

```
BOOL WINAPI WebGetTransferStatus(  
    HSTORAGE hStorage,  
    LPWEB_STORAGE_TRANSFER lpStatus  
);
```

The **WebGetTransferStatus** function returns information about the current data transfer in progress.

Parameters

hStorage

Handle to the storage container.

lpStatus

A pointer to a [WEB_STORAGE_TRANSFER](#) structure which contains information about the status of the current data transfer.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebGetTransferStatus** function returns information about the current data transfer, including the average number of bytes transferred per second and the estimated amount of time until the transfer completes. If there is no data currently being transferred, this function will return the status of the last successful data transfer.

In a multithreaded application, any thread in the current process may call this function to obtain status information for the specified storage session.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `cswebv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

See Also

[WebCancelTransfer](#), [WebRegisterEvent](#)

WebInitialize Function

```
BOOL WINAPI WebInitialize(  
    LPCTSTR lpszLicenseKey,  
    LPINITDATA lpData  
);
```

The **WebInitialize** function initializes the library and validates the specified license key at runtime.

Parameters

lpszLicenseKey

Pointer to a string that specifies the runtime license key to be validated. If this parameter is NULL, the library will validate the development license installed on the local system.

lpData

Pointer to an INITDATA data structure. This parameter may be NULL if the initialization data for the library is not required.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**. All other client functions will fail until a license key has been successfully validated.

Remarks

This must be the first function that an application calls before using any of the other functions in the library. When a NULL license key is specified, the library will only function on the development system. Before redistributing the application to an end-user, you must insure that this function is called with a valid license key.

If the *lpData* argument is specified, it must point to an INITDATA structure which has been initialized by setting the *dwSize* member to the size of the structure. All other structure members should be set to zero. If the function is successful, then the INITDATA structure will be filled with identifying information about the library.

Although it is only required that **WebInitialize** be called once for the current process, it may be called multiple times; however, each call must be matched by a corresponding call to **WebUninitialize**.

This function dynamically loads other system libraries and allocates thread local storage. If you are calling the functions in this library from within another DLL, it is important that you do not call the **WebInitialize** or **WebUninitialize** functions from the **DllMain** function because it can result in deadlocks or access violation errors. If the DLL is linked with the C runtime library (CRT), it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cswebv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

WebMoveObject Function

```
BOOL WINAPI WebMoveObject(  
    HSTORAGE hStorage,  
    LPCTSTR lpszOldLabel,  
    LPCTSTR lpszNewLabel,  
    DWORD dwStorageType,  
    LPWEB_STORAGE_OBJECT lpObject  
);
```

The **WebMoveObject** function moves an existing object to a different storage container.

Parameters

hStorage

A handle to the storage container.

lpszOldLabel

A pointer to a null terminated string which specifies the name of the existing storage object to be moved. This parameter must specify a valid object label and cannot be a NULL pointer or an empty string.

lpszNewLabel

A pointer to a null terminated string which specifies a new label for the storage object being moved. This parameter may be NULL or point to an empty string, in which case the label name is not changed.

dwStorageType

An integer value that identifies the storage container type. One of the following values should be specified:

Constant	Description
WEB_STORAGE_GLOBAL (1)	Global storage. Objects stored using this storage type are available to all users. Any changes made to objects using this storage type will affect all users of the application. Unless there is a specific need to limit access to the objects stored by the application to specific domains, local machines or users, it is recommended that you use this storage type when creating new objects.
WEB_STORAGE_DOMAIN (2)	Local domain storage. Objects stored using this storage type are only available to users in the same local domain, as defined by the domain name or workgroup name assigned to the local system. If the domain or workgroup name changes, objects previously stored using this storage type will not be available to the application.
WEB_STORAGE_MACHINE (3)	Local machine storage. Objects stored using this storage type are only available to users on the same local machine. The local machine is identified by unique characteristics of the system, including the boot volume GUID. Objects previously stored using this storage type will not be available on that system if the boot disk is reformatted.

WEB_STORAGE_USER
(4)

Current user storage. Objects stored using this storage type are only available to the current user logged in on the local machine. The user identifier is based on the Windows user SID that is assigned when the user account is created. If the user account is deleted, the objects previously stored using this storage type will not be available to the application.

lpObject

A pointer to a [WEB_STORAGE_OBJECT](#) structure that will contain information about the new storage object. If this information is not required, this parameter may be a NULL pointer.

Return Value

If the function succeeds, the return value is a non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebMoveObject** function is used to move an existing storage object to a new container. For example, it can move an object originally created using WEB_STORAGE_USER to the WEB_STORAGE_MACHINE container. The *dwStorageType* parameter must specify a valid storage container type and cannot be WEB_STORAGE_DEFAULT.

If the *dwStorageType* parameter specifies the same container that the object is currently in, and the *lpszNewLabel* parameter specifies a new label name, this function will simply rename the existing object and is effectively the same as calling the **WebRenameObject** function.

To duplicate an existing storage object, use the **WebCopyObject** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cswebv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[WebCopyObject](#), [WebDeleteObject](#), [WebRenameObject](#)

WebOpenStorage Function

```
HSTORAGE WINAPI WebOpenStorage(  
    LPCTSTR lpszAppId,  
    DWORD dwStorageType
```

The **WebOpenStorage** function establishes a connection with the server and opens the storage container associated with the specified storage type.

Parameters

lpszAppId

A pointer to null terminated string which specifies the application ID for the storage container. The application ID is a string that uniquely identifies the application and can only contain letters, numbers, the period and the underscore character. If this parameter is NULL or an empty string, the default identifier **SocketTools.Storage.Default** will be used.

dwStorageType

An integer value that identifies the storage container type. One of the following values should be specified:

Constant	Description
WEB_STORAGE_GLOBAL (1)	Global storage. Objects stored using this storage type are available to all users. Any changes made to objects using this storage type will affect all users of the application. Unless there is a specific need to limit access to the objects stored by the application to specific domains, local machines or users, it is recommended that you use this storage type when creating new objects.
WEB_STORAGE_DOMAIN (2)	Local domain storage. Objects stored using this storage type are only available to users in the same local domain, as defined by the domain name or workgroup name assigned to the local system. If the domain or workgroup name changes, objects previously stored using this storage type will not be available to the application.
WEB_STORAGE_MACHINE (3)	Local machine storage. Objects stored using this storage type are only available to users on the same local machine. The local machine is identified by unique characteristics of the system, including the boot volume GUID. Objects previously stored using this storage type will not be available on that system if the boot disk is reformatted.
WEB_STORAGE_USER (4)	Current user storage. Objects stored using this storage type are only available to the current user logged in on the local machine. The user identifier is based on the Windows user SID that is assigned when the user account is created. If the user account is deleted, the objects previously stored using this storage type will not be available to the application.

Return Value

If the function succeeds, the return value is a handle to the storage container. If the function fails, the return value is `INVALID_HANDLE`. To get extended error information, call **WebGetLastError**.

Remarks

The **WebOpenStorage** function opens the specified storage container and requests an access token for the application. This is the first function that must be called prior to accessing any stored objects.

The application ID is a string that uniquely identifies the application requesting the access and must have been previously registered with the server by calling the **WebRegisterAppId** function. If the *lpszAppId* parameter is `NULL` or an empty string, the function will use a default internal ID that is allocated for each storage account. You can use this default ID if you wish to share data between all of the applications you create.

The storage type specifies the type of container that objects will be stored in. In most cases, we recommend using `WEB_STORAGE_GLOBAL` which means that stored objects will be accessible to all users of your application. However, you can limit access to the stored objects based on the local domain, local machine ID or the current user SID.

If you specify anything other than global storage, objects can be orphaned if the system configuration changes. For example, if `WEB_STORAGE_MACHINE` is specified, the objects that are stored there can only be accessed from that computer system. If the system is reconfigured (for example, the boot volume formatted and Windows is reinstalled) the unique identifier for that system will change and the previous objects that were stored by your application can no longer be accessed.

It is advisable to store critical application data and configuration information using `WEB_STORAGE_GLOBAL` and use other non-global storage containers for configuration information that is unique to that system and/or user which is not critical and can be easily recreated.

Example

```
HSTORAGE hStorage = INVALID_HANDLE;
LPCTSTR lpszAppId = _T("MyCompany.WebTest.1");
LPCTSTR lpszLocalFile = _T("TestDocument.pdf");
LPCTSTR lpszObjectLabel = _T("TestDocument.pdf");
WEB_STORAGE_OBJECT webObject = { 0, };
BOOL bSuccess = FALSE;

// Register the application ID which identifies the application
if (!WebRegisterAppId(lpszAppId))
{
    tprintf(_T("Unable to register the application ID"));
    _exit(0);
}

// Open the application storage container
hStorage = WebOpenStorage(lpszAppId, WEB_STORAGE_GLOBAL);

if (hStorage == INVALID_HANDLE)
{
    tprintf(_T("Unable to open global storage for this application"));
    _exit(0);
}
```

```

// Upload a local file to the storage server and return information
// about the stored object when it completes
bSuccess = WebPutFileEx(hStorage,
                        lpszLocalFile,
                        lpszObjectLabel,
                        NULL,
                        WEB_OBJECT_DEFAULT,
                        0,
                        &webObject);

if (bSuccess)
{
    // Print information about the object that was created
    _tprintf(_T("Object: %s\n"), webObject.szObjectId);
    _tprintf(_T("Label: %s\n"), webObject.szLabel);
    _tprintf(_T("Size: %lu\n"), webObject.dwObjectSize);
    _tprintf(_T("Digest: %s\n"), webObject.szDigest);
    _tprintf(_T("Content: %s\n"), webObject.szContent);
}
else
{
    // The upload failed, display error information
    DWORD dwError = WebGetLastError();
    TCHAR szError[128];

    WebGetErrorString(dwError, szError, 128);
    _tprintf(_T("WebPutFileEx failed, error 0x%08lX (%s)\n"), dwError, szError);
}

// Release the handle allocated for this storage session
WebCloseStorage(hStorage);

```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswebv10.lib

Unicode: Implemented as Unicode and ANSI versions.

WebPutFile Function

```
BOOL WINAPI WebPutFile(  
    HSTORAGE hStorage,  
    LPCTSTR lpszLocalFile,  
    LPCTSTR lpszObjectLabel  
);
```

The **WebPutFile** function uploads the contents of a local file to a storage container.

Parameters

hStorage

A handle to the storage container.

lpszLocalFile

A pointer to a null terminated string that specifies the name of the local file that will be uploaded. If a path is not specified, the file will be read from the current working directory. The current user must have read access to the file, and an error will be returned if the function cannot obtain an exclusive lock on the file during the upload process.

lpszObjectLabel

A pointer to a null terminated string that specifies the label of the storage object that will be created or replaced. This parameter cannot be NULL or a zero-length string. The function will fail if the label contains any illegal characters.

Return Value

If the function succeeds, the return value is a non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebPutFile** function uploads the contents of a local file to the storage container specified by the *hStorage* handle. If an object with this name already exists, its data will be replaced with the contents of the file. The object will be created using the default attributes that permit read and write access, and will automatically determine the content type based on the type of file being uploaded.

If the label identifies an object that already exists in the container, and that object was created with the WEB_OBJECT_READONLY attribute, this function will fail. To replace a read-only object, the application must first move, rename or delete the existing object.

If you want to specify the object content type, its attributes, or obtain additional information about the storage object that was created, use the **WebPutFileEx** function.

The **WebValidateLabel** function can be used to ensure a label is valid prior to calling this function. Refer to that function for more information about the difference between Windows file names and object labels.

If you are uploading a large file and want your application to receive progress updates during the data transfer, use the **WebRegisterEvent** function and provide a pointer to a callback function that will receive event notifications.

Example

```
// Upload a local file to the storage container  
if (WebPutFile(hStorage, lpszLocalFile, lpszObjectLabel)
```

```
{
    // The file was uploaded successfully
    _tprintf(_T("The file was stored as \"%s\"\n"), lpszObjectLabel);
}
else
{
    // The file could not be uploaded, display the error
    TCHAR szError[128];

    WebGetErrorString(WebGetLastError(), szError, 128);
    _tprintf(_T("Unable to store \"%s\" (%s)\n"), lpszLocalFile, szError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cswebv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[WebValidateLabel](#)

WebPutFileEx Function

```
BOOL WINAPI WebPutFileEx(  
    HSTORAGE hStorage,  
    LPCTSTR lpszLocalFile,  
    LPCTSTR lpszObjectLabel,  
    LPCTSTR lpszContentType,  
    DWORD dwAttributes,  
    DWORD dwReserved,  
    LPWEB_STORAGE_OBJECT LpObject  
);
```

The **WebPutFileEx** function uploads the contents of a local file to a storage container and returns information about the new object.

Parameters

hStorage

A handle to the storage container.

lpszLocalFile

A pointer to a null terminated string that specifies the name of the local file that will be uploaded. If a path is not specified, the file will be read from the current working directory. The current user must have read access to the file, and an error will be returned if the function cannot obtain an exclusive lock on the file during the upload process.

lpszObjectLabel

A pointer to a null terminated string that specifies the label of the storage object that will be created or replaced. This parameter cannot be NULL or a zero-length string. The function will fail if the label contains any illegal characters.

lpszContentType

A pointer to a null terminated string that identifies the contents of the file being uploaded. If this parameter is a NULL pointer, or specifies a zero-length string, the function will attempt to automatically determine the content type based on the file name extension and the contents of the file.

dwAttributes

An unsigned integer that specifies the attributes associated with the storage object. This value can be a combination of one or more of the following bitflags using a bitwise OR operation:

Value	Constant	Description
0	WEB_OBJECT_DEFAULT	Default object attributes. This value is used to indicate the object can be modified, or that the attributes for a previously existing object should not be changed.
1	WEB_OBJECT_NORMAL	A normal object that that can be read and modified by the application. This is the default attribute for new objects that are created by the application.
2	WEB_OBJECT_READONLY	A read-only object that can only be read by the application. Attempts to modify or replace the contents of the object will fail. Read-only objects

		can be deleted.
4	WEB_OBJECT_HIDDEN	A hidden object. Objects with this attribute are not returned when enumerated using the WebEnumObjects function. The object can only be accessed directly when specifying its label.

dwReserved

An unsigned integer value that is reserved for future use. This value should always be zero.

lpObject

A pointer to a [WEB_STORAGE_OBJECT](#) structure that will contain additional information about the object. This parameter may be NULL if the information is not required.

Return Value

If the function succeeds, the return value is a non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebPutFileEx** function uploads the contents of a local file to the storage container specified by the *hStorage* handle. The caller is responsible for specifying the object's content type and the attributes for the object being created.

If a content type is provided, it must specify a valid MIME media type and subtype. For example, normal text files have a content type of **text/plain** while an XML-formatted text file would have a content type of **text/xml**. Files that contain unstructured binary data are typically identified as **application/octet-stream**.

If the label identifies an object that already exists in the container, and that object was created with the WEB_OBJECT_READONLY attribute, this function will fail. To replace a read-only object, the application must first move, rename or delete the existing object.

The **WebValidateLabel** function can be used to ensure a label is valid prior to calling this function. Refer to that function for more information about the difference between Windows file names and object labels

If you are uploading a large file and want your application to receive progress updates during the data transfer, use the **WebRegisterEvent** function and provide a pointer to a callback function that will receive event notifications.

The **WebUploadFile** and **WebUploadFileEx** functions provide similar functionality, but do not require a handle to an open storage container.

Example

```
WEB_STORAGE_OBJECT webObject;

// Upload a local file to the storage container, automatically
// determining the content type with normal read/write access
if (WebPutFileEx(hStorage, lpzLocalFile, lpzObjectLabel, NULL,
WEB_OBJECT_NORMAL, 0, &webObject))
{
    // The file was uploaded, display the object metadata
    _tprintf(_T("Object:  %s\n"), webObject.szObjectId);
    _tprintf(_T("Label:   %s\n"), webObject.szLabel);
    _tprintf(_T("Size:    %lu\n"), webObject.dwObjectSize);
    _tprintf(_T("Digest:  %s\n"), webObject.szDigest);
}
```

```
    _tprintf(_T("Content: %s\n"), webObject.szContent);
}
else
{
    // The file could not be uploaded, display the error
    TCHAR szError[128];

    WebGetErrorString(WebGetLastError(), szError, 128);
    _tprintf(_T("Unable to store \"%s\" (%s)\n"), lpszLocalFile, szError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswebv10.lib

Unicode: Implemented as Unicode and ANSI versions.

WebPutObject Function

```
BOOL WINAPI WebPutObject(  
    HSTORAGE hStorage,  
    LPCTSTR lpszObjectLabel,  
    LPCVOID lpvBuffer,  
    DWORD dwLength  
);
```

The **WebPutObject** function creates a new storage object or overwrites an existing object with the contents of the buffer provided.

Parameters

hStorage

A handle to the storage container.

lpszObjectLabel

A pointer to a null terminated string that specifies the label of the storage object that will be created or replaced. This parameter cannot be NULL or a zero-length string. The function will fail if the label contains any illegal characters.

lpvBuffer

A pointer to a buffer that contains the data to be stored. If this parameter is NULL, the *dwLength* parameter must have a value of zero and a storage object will be created which has no data associated with it.

dwLength

An unsigned integer value that specifies the number of bytes that will be copied from the *lpvBuffer* parameter and stored in the object. If the *lpvBuffer* parameter is NULL, this value must be zero or the function will fail.

Return Value

If the function succeeds, the return value is a non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebPutObject** function stores the contents of a buffer to the storage container specified by the *hStorage* handle. If an object with this name already exists, its data will be replaced with the contents of the file. The object will be created using the default attributes that permit read and write access, and it will automatically determine the content type based on the data being stored.

Although storage object labels are similar to Windows file names, they are case-sensitive. When requesting information about an object, your application must specify the label name exactly as it was created using this function. The object label cannot contain wildcard characters.

If the label identifies an object that already exists in the container, and that object was created with the WEB_OBJECT_READONLY attribute, this function will fail. To replace a read-only object, the application must first move, rename or delete the existing object.

If you want to specify the object content type, its attributes, or obtain additional information about the storage object that was created, use the **WebPutObjectEx** function.

If you want to upload the contents of a file, the **WebPutFile** function simplifies this process. The example code below demonstrates how the Windows API can be used to read from a local file and store the contents using **WebPutObject**.

If you are storing a large amount of data and want your application to receive progress updates during the data transfer, use the **WebRegisterEvent** function and provide a pointer to a callback function that will receive event notifications.

Example

```
HANDLE hFile = INVALID_HANDLE_VALUE;
LPBYTE lpContents = NULL;
DWORD dwLength = 0;
BOOL bFileRead = FALSE;

// Open a file on the local system and read the contents
// into a buffer that will be stored on the server
hFile = CreateFile(lpszLocalFile,
                  GENERIC_READ,
                  0,
                  NULL,
                  OPEN_EXISTING,
                  FILE_ATTRIBUTE_NORMAL,
                  NULL);

if (hFile == INVALID_HANDLE_VALUE)
{
    // Unable to open the file
    return;
}

// Get the size of the file and allocate a buffer large
// enough to store the contents of the file
dwLength = GetFileSize(hFile, NULL);
lpContents = (LPBYTE)LocalAlloc(LPTR, dwLength + 1);

if (lpContents == NULL)
{
    // Memory allocation failed
    return;
}

bFileRead = ReadFile(hFile, lpContents, dwLength, &dwLength, NULL);
CloseHandle(hFile);

if (!bFileRead)
{
    // Unable to read the contents of the file
    return;
}

// Store the contents of the buffer
if (WebPutObject(hStorage, lpszObjectLabel, lpContents, dwLength))
{
    _tprintf(_T("WebPutObject stored %lu bytes\n"), dwLength);
}
else
{
    // The object could not be created
    TCHAR szError[128];

    WebGetErrorString(WebGetLastError(), szError, 128);
    _tprintf(_T("Unable to create \"%s\" (%s)\n"), lpszObjectLabel, szError);
}
```

```
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswebv10.lib

Unicode: Implemented as Unicode and ANSI versions.

WebPutObjectEx Function

```
BOOL WINAPI WebPutObjectEx(  
    HSTORAGE hStorage,  
    LPCTSTR lpszObjectLabel,  
    LPCTSTR lpszContentType,  
    DWORD dwAttributes,  
    DWORD dwReserved,  
    LPCVOID lpvBuffer,  
    DWORD dwLength,  
    LPWEB_STORAGE_OBJECT lpObject  
);
```

The **WebPutObjectEx** function stores the contents of buffer to a container and returns information about the new object.

Parameters

hStorage

A handle to the storage container.

lpszObjectLabel

A pointer to a null terminated string that specifies the label of the storage object that will be created or replaced. This parameter cannot be NULL or a zero-length string. The function will fail if the label contains any illegal characters.

lpszContentType

A pointer to a null terminated string that identifies the contents of the buffer being stored. If this parameter is a NULL pointer, or specifies a zero-length string, the function will attempt to automatically determine the content type based on the object label and the contents of the buffer.

dwAttributes

An unsigned integer that specifies the attributes associated with the storage object. This value can be a combination of one or more of the following bitflags using a bitwise OR operation:

Value	Constant	Description
0	WEB_OBJECT_DEFAULT	Default object attributes. This value is used to indicate the object can be modified, or that the attributes for a previously existing object should not be changed.
1	WEB_OBJECT_NORMAL	A normal object that that can be read and modified by the application. This is the default attribute for new objects that are created by the application.
2	WEB_OBJECT_READONLY	A read-only object that can only be read by the application. Attempts to modify or replace the contents of the object will fail. Read-only objects can be deleted.
4	WEB_OBJECT_HIDDEN	A hidden object. Objects with this attribute are not returned when enumerated using the WebEnumObjects function. The object can only

	be accessed directly when specifying its label.
--	---

dwReserved

An unsigned integer value that is reserved for future use. This value should always be zero.

lpvBuffer

A pointer to a buffer that contains the data to be stored. If this parameter is NULL, the **dwLength** parameter must have a value of zero and a storage object will be created which has no data associated with it.

dwLength

An unsigned integer value that specifies the number of bytes that will be copied from the **lpvBuffer** parameter and stored in the object. If the **lpvBuffer** parameter is NULL, this value must be zero or the function will fail.

lpObject

A pointer to a [WEB_STORAGE_OBJECT](#) structure that will contain additional information about the object that was created or replaced. This parameter may be NULL if the information is not required.

Return Value

If the function succeeds, the return value is a non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebPutObjectEx** function uploads the contents of a buffer to the storage container specified by the **hStorage** handle. The caller is responsible for specifying the object's content type and the attributes for the object being created.

Although storage object labels are similar to Windows file names, they are case-sensitive. When requesting information about an object, your application must specify the label name exactly as it was created using this function. The object label cannot contain wildcard characters.

If a content type is provided, it must specify a valid MIME media type and subtype. For example, typical text data has a content type of **text/plain** while XML-formatted text would have a content type of **text/xml**. Data which contains unstructured binary data is typically identified as **application/octet-stream**.

If the label identifies an object that already exists in the container, and that object was created with the **WEB_OBJECT_READONLY** attribute, this function will fail. To replace a read-only object, the application must explicitly move, rename or delete the existing object.

If you wish to store the contents of a null terminated string, you can use the **WebPutTextObject** function. If you want to upload the contents of a file, the **WebPutFileEx** function simplifies this process. The example code below demonstrates how the Windows API can be used to read from a local file and store the contents using **WebPutObjectEx**.

If you are storing a large amount of data and want your application to receive progress updates during the data transfer, use the **WebRegisterEvent** function and provide a pointer to a callback function that will receive event notifications.

Example

```
HANDLE hFile = INVALID_HANDLE_VALUE;  
LPBYTE lpContents = NULL;  
DWORD dwLength = 0;  
BOOL bFileRead = FALSE;
```

```

WEB_STORAGE_OBJECT webObject;

// Open a file on the local system and read the contents
// into a buffer that will be stored on the server
hFile = CreateFile(lpszLocalFile,
                  GENERIC_READ,
                  0,
                  NULL,
                  OPEN_EXISTING,
                  FILE_ATTRIBUTE_NORMAL,
                  NULL);

if (hFile == INVALID_HANDLE_VALUE)
{
    // Unable to open the file
    return;
}

// Get the size of the file and allocate a buffer large
// enough to store the contents of the file
dwLength = GetFileSize(hFile, NULL);
lpContents = (LPBYTE)LocalAlloc(LPTR, dwLength + 1);

if (lpContents == NULL)
{
    // Memory allocation failed
    return;
}

bFileRead = ReadFile(hFile, lpContents, dwLength, &dwLength, NULL);
CloseHandle(hFile);

if (!bFileRead)
{
    // Unable to read the contents of the file
    return;
}

// Store the contents of the buffer, identifying it as an unstructured
// stream of bytes, and the object is created with read/write access
if (WebPutObjectEx(hStorage,
                  lpszObjectLabel,
                  _T("application/octet-stream"),
                  WEB_OBJECT_NORMAL,
                  0,
                  lpContents,
                  dwLength,
                  &webObject))
{
    // The object was created or replaced, display the metadata
    _tprintf(_T("Object:  %s\n"), webObject.szObjectId);
    _tprintf(_T("Label:   %s\n"), webObject.szLabel);
    _tprintf(_T("Size:    %lu\n"), webObject.dwObjectSize);
    _tprintf(_T("Digest:  %s\n"), webObject.szDigest);
    _tprintf(_T("Content: %s\n"), webObject.szContent);
}
else
{
    // The object could not be created

```

```
TCHAR szError[128];

WebGetErrorString(WebGetLastError(), szError, 128);
_tprintf(_T("Unable to create \"%s\" (%s)\n"), lpszObjectLabel, szError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cswebv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[WebPutFileEx](#), [WebPutObject](#), [WebPutTextObject](#), [WebRegisterEvent](#)

WebPutTextObject Function

```
BOOL WINAPI WebPutTextObject(  
    HSTORAGE hStorage,  
    LPCTSTR lpszObjectLabel,  
    LPCTSTR lpszObjectText,  
    INT cchObjectText,  
    LPWEB_STORAGE_OBJECT lpObject,  
);
```

The **WebPutTextObject** function creates or replaces a text object with the contents of a string buffer. Additional information about the object is returned to the caller.

Parameters

hStorage

A handle to the storage container.

lpszObjectLabel

A pointer to a null terminated string that specifies the label of the text object that should be created or updated.

lpszObjectText

A pointer to a string which contains the text that should be uploaded to the storage server. This parameter may be NULL, in which case the object is created but no data is stored.

cchObjectText

The number of characters that are stored in the *lpszObjectText* string. If this value is -1, the size of the string will be determined automatically by counting the number of characters up to the terminating null character. If the *lpszObjectText* parameter is NULL, this value must be zero.

lpObject

A pointer to a [WEB_STORAGE_OBJECT](#) structure that will contain additional information about the object. This parameter may be NULL if the information is not required.

Return Value

If the function succeeds, the return value is a non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebPutTextObject** function is used to store the contents of a string as a text object. The string should be terminated with a null character and cannot contain embedded nulls. If the Unicode version of this function is called, the contents of the string will be normalized prior to being converted to UTF-8 using canonical composition, where decomposed characters are combined to create their canonical precomposed equivalent.

The size of the text object that is created can be different from the length of the string buffer passed to this function, depending on how the text has been encoded and stored. This will almost always be the case when the Unicode version of this function is called because the UTF-16 string will be converted and stored as UTF-8 encoded text. This encoding will typically increase the size of the stored object unless the string only contains ASCII characters.

This function should only be used to store textual data in a null terminated string, and should never be used to store binary data. If you wish to create or update an object which contains binary data, use the **WebPutObjectEx** function instead. If you want to upload the contents of a file, the

WebPutFileEx function simplifies this process.

Additional metadata about the object will be returned in the [WEB_STORAGE_OBJECT](#) structure provided by the caller, such as the date and time the object was created, the content type and the SHA-256 hash of the object contents.

Example

```
LPCTSTR lpszObjectLabel = _T("LoremIpsum");
LPCTSTR lpszObjectText = _T("Lorem ipsum dolor sit amet, consectetur adipiscing elit.");
WEB_STORAGE_OBJECT webObject;

if (WebPutTextObject(hStorage, lpszObjectLabel, lpszObjectText, -1, &webObject))
{
    // The object was created or replaced, display the metadata
    _tprintf(_T("Object:  %s\n"), webObject.szObjectId);
    _tprintf(_T("Label:   %s\n"), webObject.szLabel);
    _tprintf(_T("Size:    %lu\n"), webObject.dwObjectSize);
    _tprintf(_T("Digest:  %s\n"), webObject.szDigest);
    _tprintf(_T("Content: %s\n"), webObject.szContent);
}
else
{
    DWORD dwError = WebGetLastError();
    TCHAR szError[128];

    WebGetErrorString(dwError, szError, 128);
    _ftprintf(stderr, _T("Unable to store \"%s\": %s\n"), lpszObjectLabel, szError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cswebv10.lib

Unicode: Implemented as Unicode and ANSI versions.

WebRegisterAppId Function

```
BOOL WINAPI WebRegisterAppId(  
    LPCTSTR LpszAppId  
);
```

The **WebRegisterAppId** function registers a unique application identifier with the server.

Parameters

lpszAppId

A pointer to a null terminated string which identifies the application requesting access. This parameter cannot be NULL or point to a zero-length string. If the application ID contains illegal characters, the function will fail. See the remarks below on the recommended method for identifying your application.

Return Value

If the function succeeds, the return value is a non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebRegisterAppId** function registers an application ID with the server which uniquely identifies the application that is requesting access to the storage container. The ID must only consist of ASCII letters, numbers, the period and underscore character. Whitespace characters and non-ASCII Unicode characters are not permitted. The maximum length of an application ID string is 64 characters, including the terminating null character.

It is recommended that you use a standard format for the application ID that consists of your company name, application name and optionally a version number. For example:

- MyCompany.MyApplication
- MyCompany.MyApplication.1

It is important to note that with these two example IDs, although they are similar, they reference two different applications. Objects stored using the first ID will not be accessible using the second ID. If you want to store objects that should be shared between all versions of the application, it is recommended that you use the first form, without the version number. If you want to store objects that should only be accessible to a specific version of your application, then it is recommended that you use the second form that includes the version number.

It is safe to call this function with an application ID that was previously registered. If the provided application ID has already been registered, this function will succeed. You can choose to call this function every time your application starts to ensure the application has been registered correctly.

If you no longer wish to use an application ID you have previously registered, you can call the **WebUnregisterAppId** function. Exercise caution when unregistering an application. This will cause all objects stored using that ID to be deleted by the storage server. Once an application ID has been unregistered, the operation is permanent. Calling **WebUnregisterAppId** and then **WebRegisterAppId** again using the same ID will force the system to create new access tokens for your application. You will not be able to regain access to the objects that were previously stored using that ID.

The application ID is intended to be an application defined human-readable string that uniquely identifies your application. If you want to obtain the internal storage ID associated with your

application, use the **WebGetStorageId** function. The storage ID is a fixed-length string of letters and numbers guaranteed to be unique across all applications that you register.

It is not required for your application to create a unique application ID. Each storage account has a default internal application ID named **SocketTools.Storage.Default**. This default ID is used if a NULL pointer or an empty string is specified to functions like **WebOpenStorage**. It is intended to identify storage available to all applications that you create.

To enumerate the application IDs that you have created, use the **WebGetFirstApplication** and **WebGetNextApplication** functions.

Example

```
HSTORAGE hStorage = INVALID_HANDLE;
LPCTSTR lpszAppId = _T("MyCompany.WebTest.1");
LPCTSTR lpszLocalFile = _T("TestDocument.pdf");
LPCTSTR lpszObjectLabel = _T("TestDocument.pdf");
WEB_STORAGE_OBJECT webObject = { 0, };
BOOL bSuccess = FALSE;

// Register the application ID which identifies the application
if (!WebRegisterAppId(lpszAppId))
{
    tprintf(_T("Unable to register the application ID"));
    _exit(0);
}

// Open the application storage container
hStorage = WebOpenStorage(lpszAppId, WEB_STORAGE_GLOBAL);

if (hStorage == INVALID_HANDLE)
{
    tprintf(_T("Unable to open global storage for this application"));
    _exit(0);
}

// Upload a local file to the storage server and return information
// about the stored object when it completes
bSuccess = WebPutFileEx(hStorage,
                        lpszLocalFile,
                        lpszObjectLabel,
                        NULL,
                        WEB_OBJECT_DEFAULT,
                        0,
                        &webObject);

if (bSuccess)
{
    // Print information about the object that was created
    _tprintf(_T("Object: %s\n"), webObject.szObjectId);
    _tprintf(_T("Label: %s\n"), webObject.szLabel);
    _tprintf(_T("Size: %I64u\n"), webObject.dwObjectSize);
    _tprintf(_T("Digest: %s\n"), webObject.szDigest);
    _tprintf(_T("Content: %s\n"), webObject.szContent);
}
else
{
    // The upload failed, display error information
    DWORD dwError = WebGetLastError();
}
```

```
TCHAR szError[128];

WebGetErrorString(dwError, szError, 128);
_tprintf(_T("WebPutFileEx failed, error 0x%08lX (%s)\n"), dwError, szError);
}

// Release the handle allocated for this storage session
WebCloseStorage(hStorage);
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswebv10.lib

Unicode: Implemented as Unicode and ANSI versions.

WebRegisterEvent Function

```
INT WINAPI WebRegisterEvent(  
    HSTORAGE hStorage,  
    UINT nEventId,  
    WEBEVENTPROC LpEventProc,  
    DWORD_PTR dwParam  
);
```

The **WebRegisterEvent** function registers an event handler for the specified event.

Parameters

hStorage

A handle to the storage container.

nEventId

An unsigned integer which specifies which event should be registered with the specified callback function. This parameter cannot be zero. The following values may be used:

Constant	Description
WEB_EVENT_CONNECT (1)	The connection to the storage server has been established and the session has been authenticated. This is the first event that occurs when initiating an operation to create or retrieve a storage object.
WEB_EVENT_DISCONNECT (2)	The connection to the storage server has been closed and the session is terminating. This is the last event that occurs after completing an operation to create or retrieve a storage object.
WEB_EVENT_READ (4)	The contents of an object is being read from the storage container. This event occurs only once after the operation has been initiated by the application. This event can also be generated if there is an error during the process of retrieving the object contents from the container.
WEB_EVENT_WRITE (8)	The contents of an object is being written to the storage container. This event occurs only once after the operation has been initiated by the application. This event can also be generated if there is an error during the process of submitting the object contents to the container.
WEB_EVENT_TIMEOUT (16)	The operation has exceeded the specified timeout period. The application may attempt to retry the operation or report an error to the user. This event typically indicates a connectivity problem with the storage server.
WEB_EVENT_CANCEL (32)	The operation has been canceled. This event occurs after the application calls WebCancelTransfer while an object is being stored or retrieved.
WEB_EVENT_PROGRESS (64)	A storage operation is in progress. This event periodically occurs as the contents of a storage object is being read or written from the container. To retrieve information about the status of the operation, the application should register a

handler for this event and call the WebGetTransferStatus function from within that handler.
--

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **WebEventProc** callback function. If this parameter is NULL, the callback for the specified event is disabled.

dwParam

A user-defined integer value that is passed to the callback function specified by *lpEventProc*. If the application targets the x86 (32-bit) platform, this parameter must be a 32-bit unsigned integer. If the application targets the x64 (64-bit) platform, this parameter must be a 64-bit unsigned integer.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebRegisterEvent** function associates a callback function with a specific event. The event handler is a **WebEventProc** function that is invoked when the event occurs. Arguments are passed to the function to identify the storage handle, the event type and the user-defined value specified when the event handler is registered. If the event occurs because of an error condition, the error code will be provided to the handler.

Events are only generated as the result of a call to the **WebGetFile**, **WebGetFileEx**, **WebPutFile** and **WebPutFileEx** functions. Other storage functions will not generate event notifications.

This function is typically used to register an event handler that is invoked while the contents of a storage object is being transferred. The **WEB_EVENT_PROGRESS** event will only be generated periodically during the transfer to ensure the application is not flooded with event notifications. It is guaranteed that at least one **WEB_EVENT_PROGRESS** notification will occur at the beginning of the transfer, and one at the end of the transfer when it has completed.

The callback function specified by the *lpEventProc* parameter must be declared using the **__stdcall** calling convention. This ensures the arguments passed to the event handler are pushed on to the stack in the correct order. Failure to use the correct calling convention will corrupt the stack and cause the application to terminate abnormally.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `cswebv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

WebRenameObject Function

```
BOOL WINAPI WebRenameObject(  
    HSTORAGE hStorage,  
    LPCTSTR lpszOldLabel,  
    LPCTSTR lpszNewLabel  
);
```

The **WebRenameObject** function changes the label associated with the storage object.

Parameters

hStorage

A handle to the storage container.

lpszOldLabel

A pointer to a null terminated string which specifies the name of the existing storage object to be renamed. This parameter must specify a valid object label and cannot be a NULL pointer or an empty string.

lpszNewLabel

A pointer to a null terminated string which specifies a new label for the storage object being moved. This parameter may not be NULL or point to an empty string.

Return Value

If the function succeeds, the return value is a non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebRenameObject** function is used to change the label for an existing storage object. Although storage object labels are similar to Windows file names, they are case-sensitive. When renaming an object, your application must specify the original label name exactly as it was created. The object label cannot contain wildcard characters.

To duplicate an existing storage object, use the **WebCopyObject** function. If you need to move the object to a different storage container, use the **WebMoveObject** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswebv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[WebCopyObject](#), [WebDeleteObject](#), [WebMoveObject](#)

WebResetStorage Function

```
BOOL WINAPI WebResetStorage(  
    HSTORAGE hStorage  
);
```

The **WebResetStorage** function resets the application storage container and deletes all stored objects.

Parameters

hStorage

A handle to the storage container.

Return Value

If the function succeeds, the return value is a non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The storage container contains information for each of the objects that have been stored using the handle returned by the **WebOpenStorage** function. Each of these objects are associated with both the application ID and the storage type that was specified by the caller. This function instructs the server to reset the container back to its initial state, deleting all of the objects that were stored in it.

Exercise caution when using this function. The reset operation is immediate and the objects that are stored in the container are permanently deleted. They cannot be recovered by your application.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswebv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[WebDeleteObject](#), [WebOpenStorage](#), [WebRegisterAppId](#), [WebUnregisterAppId](#)

WebResetStorageEx Function

```
BOOL WINAPI WebResetStorageEx(  
    HSTORAGE hStorage,  
    DWORD dwStorageType,  
    LPVOID LpReserved,  
    LPDWORD LpdwObjects  
);
```

The **WebResetStorageEx** function resets the specified storage container and deletes all stored objects.

Parameters

hStorage

A handle to the storage container.

dwStorageType

An integer value that identifies the storage container type. One of the following values should be specified:

Constant	Description
WEB_STORAGE_GLOBAL (1)	Global storage. Objects stored using this storage type are available to all users. Any changes made to objects using this storage type will affect all users of the application. Unless there is a specific need to limit access to the objects stored by the application to specific domains, local machines or users, it is recommended that you use this storage type when creating new objects.
WEB_STORAGE_DOMAIN (2)	Local domain storage. Objects stored using this storage type are only available to users in the same local domain, as defined by the domain name or workgroup name assigned to the local system. If the domain or workgroup name changes, objects previously stored using this storage type will not be available to the application.
WEB_STORAGE_MACHINE (3)	Local machine storage. Objects stored using this storage type are only available to users on the same local machine. The local machine is identified by unique characteristics of the system, including the boot volume GUID. Objects previously stored using this storage type will not be available on that system if the boot disk is reformatted.
WEB_STORAGE_USER (4)	Current user storage. Objects stored using this storage type are only available to the current user logged in on the local machine. The user identifier is based on the Windows user SID that is assigned when the user account is created. If the user account is deleted, the objects previously stored using this storage type will not be available to the application.

LpReserved

A reserved parameter that should always be NULL. If your project targets the x64 platform, this must be a 64-bit pointer with a value of zero. If this parameter is not a NULL pointer, the function will fail.

lpdwObjects

A pointer to an unsigned integer value which will contain the number of objects that were deleted when the contents of the container were expunged.

Return Value

If the function succeeds, the return value is a non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The storage container contains information for each of the objects that have been stored using the handle returned by the **WebOpenStorage** function. Each of these objects are associated with both the application ID and the storage type that was specified by the caller. This function instructs the server to reset the container back to its initial state, deleting all of the objects that were stored in it.

Exercise caution when using this function. The reset operation is immediate and the objects that are stored in the container are permanently deleted. They cannot be recovered by your application.

Unlike the **WebResetStorage** function which deletes all of the objects in the container opened using **WebOpenStorage**, this function enables you reset the contents of a different container without explicitly opening it. For example, if you used **WebOpenStorage** to open the WEB_STORAGE_GLOBAL container, you could call this version of the function using that handle, but specifying the WEB_STORAGE_USER container to remove all of the objects created by the current user without affecting the stored objects in the global container.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswebv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

WebSetLastError Function

```
VOID WINAPI WebSetLastError(  
    DWORD dwErrorCode  
);
```

The **WebSetLastError** function sets the last error code for the current thread. This function is typically used to clear the last error by specifying a value of zero as the parameter.

Parameters

dwErrorCode

Specifies the last error code for the current thread.

Return Value

None.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or WEB_ERROR. Those functions which call **WebSetLastError** when they succeed are noted on the function reference page.

Applications can retrieve the value saved by this function by using the **WebGetLastError** function. The use of **WebGetLastError** is optional; an application can call the function to determine the specific reason for a function failure.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cswebv10.lib

See Also

[WebGetErrorString](#), [WebGetLastError](#)

WebSetStorageTimeout Function

```
INT WINAPI WebSetStorageTimeout(  
    HSTORAGE hStorage,  
    INT nSeconds  
);
```

The **WebSetStorageTimeout** function sets the number of seconds the client will wait for a response from the storage server. Once the specified number of seconds has elapsed, the function will fail and return to the caller.

Parameters

hClient

Handle to the client session.

nSeconds

The number of seconds to wait for a storage operation to complete.

Return Value

If the function succeeds, the return value is the previous timeout period set for this storage handle. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The default timeout period is 10 seconds. The minimum timeout period is 5 seconds, and the maximum timeout period is 60 seconds. Values outside of this range will be normalized internally and will not cause the function to fail.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswebv10.lib

See Also

[WebGetStorageTimeout](#), [WebOpenStorage](#)

WebUninitialize Function

```
VOID WINAPI WebUninitialize();
```

The **WebUninitialize** function terminates the use of the library.

Parameters

There are no parameters.

Return Value

None.

Remarks

An application is required to perform a successful **WebInitialize** call before it can call any of the other library functions. When it has completed the use of library, the application must call **WebUninitialize** to allow the library to free any resources allocated on behalf of the process. Any pending blocking or asynchronous calls in this process are canceled without posting any notification messages, and all sockets that were opened by the process are closed.

There must be a call to **WebUninitialize** for every successful call to **WebInitialize** made by a process. In a multithreaded environment, operations for all threads in the client are terminated.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswebv10.lib

See Also

[WebCloseStorage](#), [WebInitialize](#), [WebOpenStorage](#), [WebRegisterAppId](#)

WebUnregisterAppId Function

```
BOOL WINAPI WebUnregisterAppId(  
    LPCTSTR lpszAppId  
);
```

The **WebUnregisterAppId** function unregisters the application identifier and deletes all associated storage objects.

Parameters

lpszAppId

A pointer to a null terminated string which specifies the application ID to be deleted. This parameter cannot be NULL or point to a zero-length string. If the application ID contains illegal characters, the function will fail.

Return Value

If the function succeeds, the return value is a non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebUnregisterAppId** function deletes the internal storage identifier associated with the application ID and revokes all access tokens that were granted for the application. This operation is immediate and permanent.

Exercise caution when using this function. This will permanently delete all objects that were stored for the specified application. Calling **WebUnregisterAppId** and then **WebRegisterAppId** again using the same ID will force the system to create new access tokens for your application. You will not be able to regain access to the objects that were previously stored using that ID.

This function cannot be used to unregister the default storage application identifier **SocketTools.Storage.Default**. If this ID is specified, the function will fail with an error indicating that the ID is invalid.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswebv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[WebOpenStorage](#), [WebRegisterAppId](#), [WebResetStorage](#), [WebValidateAppId](#)

WebUploadFile Function

```
BOOL WINAPI WebUploadFile(  
    LPCTSTR lpszLocalFile,  
    LPCTSTR lpszObjectLabel,  
    LPWEB_STORAGE_OBJECT lpObject  
);
```

The **WebUploadFile** function uploads the contents of a local file and creates or overwrites a storage object.

Parameters

lpszLocalFile

A pointer to a null terminated string that specifies the name of the local file that will be created or overwritten with the contents of the storage object. If a path is not specified, the file will be created in the current working directory.

lpszObjectLabel

A pointer to a null terminated string that specifies the label of the object that should be retrieved from the server. This parameter cannot be NULL or an empty string. Refer to the **WebValidateLabel** function for more information about object labels.

lpObject

A pointer to a [WEB_STORAGE_OBJECT](#) structure that will contain additional information about the object that has been downloaded. This parameter may be NULL if the information is not required.

Return Value

If the function succeeds, the return value is a non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebUploadFile** function uploads the contents of a local file and either creates a new storage object, or replaces an object if one already exists with the same label. The object will be created in the storage container `WEB_STORAGE_GLOBAL` using the application ID

SocketTools.Storage.Default. This is the same default container used by the **WebDownloadFile** function.

If the label identifies an object that already exists in the container, and that object was created with the `WEB_OBJECT_READONLY` attribute, this function will fail. To replace a read-only object, the application must explicitly move, rename or delete the existing object.

Unlike the **WebPutFile** and **WebPutFileEx** functions, it is not required that you open a storage container using the **WebOpenStorage** function prior to calling **WebUploadFile**.

Additional metadata about the object will be returned in the `WEB_STORAGE_OBJECT` structure provided by the caller, such as the date and time the object was created, the content type and the SHA-256 hash of the object contents.

The **WebUploadFileEx** function provides similar functionality with a more complex interface that supports custom application IDs, additional options and the ability to provide a callback function that is invoked during the upload process.

Example

```

WEB_STORAGE_OBJECT webObject;

// Upload a local file to the global storage container
if (WebUploadFile(lpszLocalFile, lpszObjectLabel, &webObject))
{
    // The object was uploaded, display the metadata
    _tprintf(_T("Object:  %s\n"), webObject.szObjectId);
    _tprintf(_T("Label:   %s\n"), webObject.szLabel);
    _tprintf(_T("Size:    %lu\n"), webObject.dwObjectSize);
    _tprintf(_T("Digest:  %s\n"), webObject.szDigest);
    _tprintf(_T("Content: %s\n"), webObject.szContent);
}
else
{
    // The object could not be uploaded, display the error
    TCHAR szError[128];

    WebGetErrorString(WebGetLastError(), szError, 128);
    _tprintf(_T("Unable to upload \"%s\" (%s)\n"), lpszLocalFile, szError);
}

```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswebv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[WebDownloadFile](#), [WebGetFile](#), [WebPutFile](#), [WebUploadFileEx](#), [WebValidateLabel](#)

WebUploadFileEx Function

```
BOOL WINAPI WebUploadFileEx(  
    LPCTSTR lpszLocalFile,  
    LPCTSTR lpszObjectLabel,  
    LPCTSTR lpszAppId,  
    DWORD dwStorageType,  
    DWORD dwAttributes,  
    DWORD dwReserved,  
    DWORD dwTimeout,  
    LPWEB_STORAGE_OBJECT lpObject,  
    WEBEVENTPROC lpEventProc,  
    DWORD_PTR dwParam  
);
```

The **WebUploadFileEx** function uploads the contents of a local file and creates or overwrites a storage object.

Parameters

lpszLocalFile

A pointer to a null terminated string that specifies the name of the local file that will be created or overwritten with the contents of the storage object. If a path is not specified, the file will be created in the current working directory.

lpszObjectLabel

A pointer to a null terminated string that specifies the label of the object that should be retrieved from the server.

lpszAppId

A pointer to null terminated string which specifies the application ID for the storage container. The application ID is a string that uniquely identifies the application and can only contain letters, numbers, the period and the underscore character. If this parameter is NULL or an empty string, the default identifier **SocketTools.Storage.Default** will be used.

dwStorageType

An integer value that identifies the storage container type. One of the following values should be specified:

Constant	Description
WEB_STORAGE_GLOBAL (1)	Global storage. Objects stored using this storage type are available to all users. Any changes made to objects using this storage type will affect all users of the application. Unless there is a specific need to limit access to the objects stored by the application to specific domains, local machines or users, it is recommended that you use this storage type when creating new objects.
WEB_STORAGE_DOMAIN (2)	Local domain storage. Objects stored using this storage type are only available to users in the same local domain, as defined by the domain name or workgroup name assigned to the local system. If the domain or workgroup name changes, objects previously stored using this storage type will not be available to the application.

WEB_STORAGE_MACHINE (3)	Local machine storage. Objects stored using this storage type are only available to users on the same local machine. The local machine is identified by unique characteristics of the system, including the boot volume GUID. Objects previously stored using this storage type will not be available on that system if the boot disk is reformatted.
WEB_STORAGE_USER (4)	Current user storage. Objects stored using this storage type are only available to the current user logged in on the local machine. The user identifier is based on the Windows user SID that is assigned when the user account is created. If the user account is deleted, the objects previously stored using this storage type will not be available to the application.

dwAttributes

An unsigned integer that specifies the attributes associated with the storage object. This value can be a combination of one or more of the following bitflags using a bitwise OR operation:

Value	Constant	Description
0	WEB_OBJECT_DEFAULT	Default object attributes. This value is used to indicate the object can be modified, or that the attributes for a previously existing object should not be changed.
1	WEB_OBJECT_NORMAL	A normal object that that can be read and modified by the application. This is the default attribute for new objects that are created by the application.
2	WEB_OBJECT_READONLY	A read-only object that can only be read by the application. Attempts to modify or replace the contents of the object will fail. Read-only objects can be deleted.
4	WEB_OBJECT_HIDDEN	A hidden object. Objects with this attribute are not returned when enumerated using the WebEnumObjects function. The object can only be accessed directly when specifying its label.

dwReserved

An unsigned integer value that is reserved for future use. This value should always be zero.

dwTimeout

An unsigned integer value that specifies a timeout period in seconds. If this value is zero, a default timeout period will be used.

lpObject

A pointer to a [WEB_STORAGE_OBJECT](#) structure that will contain additional information about the object that has been downloaded. This parameter may be NULL if the information is not required.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **WebEventProc** callback function. If this parameter is NULL, no callback function will be invoked during the data transfer.

dwParam

A user-defined integer value that is passed to the callback function specified by *lpEventProc*. If the application targets the x86 (32-bit) platform, this parameter must be a 32-bit unsigned integer. If the application targets the x64 (64-bit) platform, this parameter must be a 64-bit unsigned integer.

Return Value

If the function succeeds, the return value is a non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebUploadFileEx** function uploads the contents of a local file and either creates a new storage object, or replaces an object if one already exists with the same label. The **WebUploadFile** function provides a simpler interface that defaults to uploading an object to the global storage container.

If the label identifies an object that already exists in the container, and that object was created with the `WEB_OBJECT_READONLY` attribute, this function will fail. To replace a read-only object, the application must explicitly move, rename or delete the existing object.

Unlike the **WebPutFile** and **WebPutFileEx** functions, it is not required that you open a storage container using the **WebOpenStorage** function prior to calling **WebUploadFileEx**.

Additional metadata about the object will be returned in the `WEB_STORAGE_OBJECT` structure provided by the caller, such as the date and time the object was created, the content type and the SHA-256 hash of the object contents.

If you are uploading a large file and want your application to receive progress updates during the data transfer, provide a pointer to a callback function as the *lpEventProc* parameter. That function will receive event notifications as the data is being uploaded.

Example

```
WEB_STORAGE_OBJECT webObject;

// Upload a local file to the global storage container
if (WebUploadFileEx(lpszLocalFile,
                   lpszObjectLabel,
                   lpszAppId,
                   WEB_STORAGE_GLOBAL,
                   WEB_OBJECT_DEFAULT,
                   0,
                   &webObject,
                   NULL, 0))
{
    // The object was uploaded, display the metadata
    _tprintf(_T("Object:  %s\n"), webObject.szObjectId);
    _tprintf(_T("Label:   %s\n"), webObject.szLabel);
    _tprintf(_T("Size:    %lu\n"), webObject.dwObjectSize);
    _tprintf(_T("Digest:  %s\n"), webObject.szDigest);
    _tprintf(_T("Content: %s\n"), webObject.szContent);
}
else
{
    // The object could not be uploaded, display the error
    TCHAR szError[128];
```

```
WebGetErrorString(WebGetLastError(), szError, 128);  
_tprintf(_T("Unable to upload \"%s\" (%s)\n"), lpszLocalFile, szError);  
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswebv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[WebDownloadFile](#), [WebGetFileEx](#), [WebPutFileEx](#), [WebUploadFile](#)

WebValidateAppId Function

```
BOOL WINAPI WebValidateAppId(  
    LPCTSTR LpszAppId  
);
```

The **WebValidateAppId** function validates the specified application identifier.

Parameters

lpszAppId

A pointer to a null terminated string which specifies the application ID to be validated. This parameter cannot be NULL or point to a zero-length string. If the application ID contains illegal characters, the function will fail.

Return Value

If the function succeeds, the return value is a non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebValidateAppId** function is used to determine if the specified application identifier is valid and has been previously registered using the **WebRegisterAppId** function. The ID must only consist of ASCII letters, numbers, the period and underscore character. Whitespace characters and non-ASCII Unicode characters are not permitted. The maximum length of an application ID string is 64 characters, including the terminating null character.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cswebv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[WebRegisterAppId](#), [WebUnregisterAppId](#)

WebValidateLabel Function

```
BOOL WINAPI WebValidateLabel(  
    LPCTSTR lpszObjectLabel  
);
```

The **WebValidateLabel** function validates the specified object label.

Parameters

lpszObjectLabel

A pointer to a null terminated string which specifies the object label to be validated. This parameter cannot be NULL or point to a zero-length string.

Return Value

If the function succeeds, the return value is a non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

Object labels are similar to Windows file names, except they are case-sensitive. The maximum length of a label string is 512 characters, including the terminating null character. Leading and trailing whitespace (spaces, tabs, linebreaks, etc.) are ignored in label names.

Illegal characters include ASCII and Unicode control characters 1 through 31, single quotes (39), double quotes (34), less than symbol (60), greater than symbol (62), pipe (124), asterisk (42) and question mark (63). A null character (0) specifies the end of the label and any subsequent characters are ignored. It is not possible to embed null characters in the label name.

Label names may contain forward slash (47) characters and backslash (92) characters, however it is important to note that objects are not stored in a hierarchical structure. An application can create its own folder-like structure to the labels it creates, but this structure is not imposed or enforced by the library.

If the application is built to use Unicode, labels can contain Unicode characters which are internally encoded as UTF-8. This is important to consider if you have an project built using a multi-byte (ANSI) character set and it needs to access an object that was created using Unicode characters. In that case, the ANSI application must be prepared to handle UTF-8 encoded names and display them appropriately.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstoools10.h

Import Library: cswebv10.lib

Unicode: Implemented as Unicode and ANSI versions.

Web Services Data Structures

- INITDATA
- SYSTEMTIME
- WEB_LOCATION
- WEB_STORAGE_APPLICATION
- WEB_STORAGE_QUOTA
- WEB_STORAGE_OBJECT
- WEB_STORAGE_TRANSFER

INITDATA Structure

This structure contains information about the SocketTools library when the initialization function returns.

```
typedef struct _INITDATA
{
    DWORD        dwSize;
    DWORD        dwVersionMajor;
    DWORD        dwVersionMinor;
    DWORD        dwVersionBuild;
    DWORD        dwOptions;
    DWORD_PTR    dwReserved1;
    DWORD_PTR    dwReserved2;
    TCHAR        szDescription[128];
} INITDATA, *LPINITDATA;
```

Members

dwSize

Size of this structure. This structure member must be set to the size of the structure prior to calling the initialization function. Failure to do so will cause the function to fail.

dwVersionMajor

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the major version number for the library.

dwVersionMinor

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the minor version number for the library.

dwVersionBuild

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the build number for the library.

dwOptions

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

dwReserved1

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

dwReserved2

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

szDescription

A null terminated string which describes the library.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Unicode: Implemented as Unicode and ANSI versions.

SYSTEMTIME Structure

The **SYSTEMTIME** structure represents a date and time using individual members for the month, day, year, weekday, hour, minute, second, and millisecond.

```
typedef struct _SYSTEMTIME
{
    WORD wYear;
    WORD wMonth;
    WORD wDayOfWeek;
    WORD wDay;
    WORD wHour;
    WORD wMinute;
    WORD wSecond;
    WORD wMilliseconds;
} SYSTEMTIME, *LPSYSTEMTIME;
```

Members

wYear

Specifies the current year. The year value must be greater than 1601.

wMonth

Specifies the current month. January is 1, February is 2 and so on.

wDayOfWeek

Specifies the current day of the week. Sunday is 0, Monday is 1 and so on.

wDay

Specifies the current day of the month

wHour

Specifies the current hour.

wMinute

Specifies the current minute

wSecond

Specifies the current second.

wMilliseconds

Specifies the current millisecond.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include windows.h.

WEB_LOCATION Structure

The **WEB_LOCATION** structure contains information about the current location of the local computer system.

```
typedef struct _WEB_LOCATION
{
    TCHAR    szLocationId[40];
    TCHAR    szIPAddress[46];
    UINT     nAutonomousSystemNumber;
    TCHAR    szOrganization[64];
    TCHAR    szRegionName[64];
    UINT     nRegionCode;
    TCHAR    szCountryName[64];
    TCHAR    szCountryAlpha2[4];
    TCHAR    szCountryAlpha3[4];
    UINT     nCountryCode;
    TCHAR    szSubdivision[64];
    TCHAR    szSubdivisionCode[4];
    TCHAR    szCityName[64];
    TCHAR    szPostalCode[32];
    TCHAR    szCoordinates[32];
    TCHAR    szTimezone[64];
    TCHAR    szTzShortName[16];
    LONG     nTimezoneOffset;
    DOUBLE   dLatitude;
    DOUBLE   dLongitude;
    SYSTEMTIME stLocalTime;
} WEB_LOCATION, *LPWEB_LOCATION;
```

Members

szLocationId

A null-terminated string which contains a string of hexadecimal characters which uniquely identifies the location for this computer system. This value is used internally by the location service, and may also be used by the application for its own purposes. If this value changes in subsequent queries, it indicates the external IP address for the local system has changed.

lpszIPAddress

A null-terminated string which contains the external IP address for the local system. If the system has been assigned multiple IP addresses, it reflects the address of the interface that was used to establish a connection with the SocketTools server. If the connection is made through a Virtual Private Network (VPN) it will use that assigned IP address. If a connection is made through a proxy server, the IP address may be the address of the proxy rather than the local host, depending on how the connection is made.

nAutonomousSystemNumber

An unsigned integer value which is used to uniquely identify a global network (autonomous system) that is connected to the Internet. This number is assigned by regional registries and used by large networks, such as Internet Service Providers, for exchanging routing information with one another. This value can be used to determine the ownership of a particular network.

szOrganization

A null-terminated string which identifies the organization associated with the local system's external IP address. For residential end-users this is typically the name of their Internet Service

provider, however it may also identify a private company such as Microsoft, Google or Amazon. Because of the nature of how this information is updated, the organization names can change over time due to acquisitions or changes of ownership. If the owner of the network cannot be determined, this member may contain an empty string.

szRegionName

A null-terminated string which identifies the region in which the external IP address is located. This refers to a broad geographical area, such as "North America" or "Southeast Asia" and uses the conventions for supranational regions as defined by UN M49 codes. These names will always be in English, regardless of the current system locale.

nRegionCode

An unsigned integer value which identifies the geographical region in which the external IP address is located. This value corresponds to the name returned in the ***szRegionName*** structure member. The numeric values use the UN M49 standard established by the United Nations Statistics Division.

szCountryName

A null-terminated string which contains the full name of the country in which the external IP address is located. These names will always be in English, regardless of the current system locale.

szCountryAlpha2

A null-terminated string which contains the ISO 3166-1 alpha-2 code for the country the external IP address is located in. This is a two-letter country code established by the International Organization for Standardization (ISO). For example, the code for the United States is "US".

szCountryAlpha3

A null-terminated string which contains the ISO 3166-1 alpha-3 code for the country the external IP address is located in. This is a three-letter country code established by the International Organization for Standardization (ISO). For example, the code for the United States is "USA".

nCountryCode

An unsigned integer value which identifies the country where the external IP address is located. These codes can be up to three digits (usually displayed with leading zeros as necessary) and correspond to the country codes assigned by the United Nations. For example, the code for the United States is 840. It is important to note that these are not international dialing codes and should not be used with telephony applications.

szSubdivision

A null-terminated string which identifies the geopolitical subdivision within a country where the external IP address is located. In the United States, this will contain the full name of the state or commonwealth. In Canada, this will contain the name of the province or territory. These names will always be in English, regardless of the current system locale.

szSubdivisionCode

A null-terminated string which is either a two- or three-letter code which identifies a geopolitical subdivision within the country where the external IP address is located. These codes are defined by the ISO 3166-2 standard. For example, the code for the state of California in the United States is "CA". For specificity, these subdivision codes are often combined with the ISO 3166-1 alpha-2 or alpha-3 code for the country the subdivision is located within. Using the previous example of California, ISO alpha-2 code and subdivision code would be combined as "US-CA".

szCityName

A null-terminated string which identifies the city in which the external IP address is located. These names will always be in English, regardless of the current system locale. If the city name cannot be determined, this member may contain an empty string.

szPostalCode

A null-terminated string which contains the postal code associated with the area where the IP address is located. In the United States, this is a 5-digit numeric code. In Canada, this will contain the forward sortation area (the first three characters of the six character postal code). Local delivery portions of a postal code (such as the ZIP+4 code in the United States, or the local delivery unit in Canada) are not included. This information will be most accurate within the geographic region of North America. Postal codes are locale specific, and this structure member may contain an empty string if the postal code for the location cannot be determined.

szCoordinates

A null-terminated string which specifies the location expressed using the Universal Transverse Mercator (UTM) coordinate system with the WGS-84 ellipsoid. UTM coordinates are commonly used with the Global Positioning System (GPS) and are comprised of three parts: the zone, the easting (the eastward-measured distance or *x*-coordinate) and the northing (the northward-measured distance or *y*-coordinate). An example of a string value returned in this structure member would be "14S 702089E 3646476N".

szTimezone

A null-terminated string which specifies the full time zone name in which the external IP address is located. These names are defined by the Internet Assigned Numbers Authority (IANA) and have values like "America/Los_Angeles" and "Europe/London". These time zones may also be defined as "Etc/GMT+10" if there is not a regional name associated with the time zone.

szTzShortName

A null-terminated string which specifies the abbreviated time zone code in which the external IP address is located. If daylight savings time is used within the time zone, then this value can change based on whether or not daylight savings is in effect. For example, if the IP address is located within the Pacific time zone in the United States, this will return "PDT" when daylight savings is in effect and "PST" when it is not. If a short time zone code cannot be determined, a value such as "UTC+9" may be returned, indicating the number of hours ahead or behind UTC.

nTimezoneOffset

A signed integer which specifies the number of seconds east or west of the prime meridian (UTC). A positive value indicates a time zone that is east of the prime meridian and a negative value indicates a time zone that is west of the prime meridian. For example, the Pacific time zone in the western United States during daylight savings time would have a value of -25200 (7 hours).

dLatitude

A floating point value which specifies the latitude of the location in decimal format. A positive value indicates a location that is north of the equator, while a negative value is a location that is south of the equator.

dLongitude

A floating point value which specifies the longitude of the location in decimal format. A positive value indicates a location that is east of the prime meridian, while a negative value is a location that is west of the prime meridian.

stLocalTime

A [SYSTEMTIME](#) structure that contains information about the current date and time at the location, adjusted for its time zone and whether or not it's in daylight savings time.

Remarks

Use the **WebGetLocation** function to populate this structure with information about the physical location of the local computer system.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cstools10.h`

See Also

[WebGetLocation](#)

WEB_STORAGE_APPLICATION Structure

The **WEB_STORAGE_APPLICATION** structure contains information about a registered application.

```
typedef struct _WEB_STORAGE_APPLICATION
{
    TCHAR        szAppId[64];
    TCHAR        szApiKey[64];
    TCHAR        szLuid[64];
    DWORD        dwTokens;
    DWORD        dwReserved;
    SYSTEMTIME   stCreated;
    SYSTEMTIME   stUpdated;
} WEB_STORAGE_APPLICATION, *LPWEB_STORAGE_APPLICATION;
```

Members

szAppId

A null-terminated string which contains the application ID that was registered using the **WebRegisterAppId** function.

szApiKey

A null-terminated string which contains the API key value that is used internally by the storage services. The AppID is effectively the human readable alias for this key value used to identify the stored objects for the application. This value is guaranteed to be unique across all applications registered with the storage service.

szLuid

A null-terminated string which specifies a locally unique value associated with the registered application. This value is used internally by the storage service and guaranteed to be unique to the storage account that has registered the application. Note that there are no functions that currently accept the application LUID as parameter, but you may choose to use this value in your own application for other purposes.

dwTokens

An unsigned integer value which specifies the number of access tokens associated with the registered application. Typically there is only one access token associated with a given AppID at any one time, although it is possible that the API may allocate additional access tokens under some circumstances.

dwReserved

An unsigned integer value that is reserved for future use. This value will always be zero.

stCreated

A SYSTEMTIME structure that specifies the date and time the AppID was registered. This value is represented using Coordinated Universal Time (UTC) and is not adjusted for the local time zone.

stUpdated

A SYSTEMTIME structure that specifies the date and time the AppID object was last updated. This value is represented using Coordinated Universal Time (UTC) and is not adjusted for the local time zone. When a storage object is first created, this value will be the same as the object creation time.

Remarks

This structure is used in conjunction with the **WebEnumApplications** function which is used to

enumerate all of the registered applications for the storage account. It is also used with the **WebGetFirstApplication** and **WebGetNextApplication** functions which provide an alternative method for enumerating registered applications.

To adjust the creation and update times to account for the local time zone, use the **SystemTimeToTzSpecificLocalTime** function. If you prefer to use FILETIME values, use the **SystemTimeToFileTime** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include ctools10.h

Unicode: Implemented as Unicode and ANSI versions.

WEB_STORAGE_OBJECT Structure

The **WEB_STORAGE_OBJECT** structure contains information about an individual storage object.

```
typedef struct _WEB_STORAGE_OBJECT
{
    TCHAR        szObjectId[64];
    TCHAR        szLabel[512];
    TCHAR        szDigest[128];
    TCHAR        szContent[128];
    DWORD        dwAttributes;
    DWORD        dwObjectSize;
    SYSTEMTIME   stCreated;
    SYSTEMTIME   stModified;
} WEB_STORAGE_OBJECT, *LPWEB_STORAGE_OBJECT;
```

Members

szObjectId

A null-terminated string which contains the unique identifier associated with this object. Object IDs are guaranteed to be unique for each storage object that is created by the application. The maximum length of an object ID is 64 characters, including the terminating null character.

szLabel

A null-terminated string which contains the label assigned to the object by the application. Object labels are case-sensitive and must be unique for each object. An application uses labels to reference an object with a human-recognizable name, rather than referencing them by their object ID. The maximum length of an object label is 512 characters, including the terminating null character.

szDigest

A null-terminated string which specifies the digest of the object contents, computed using an SHA-256 hash. The maximum length of the *szDigest* string is 128 characters, including the terminating null character. However, the digest value is always represented as a string of hexadecimal numbers that is exactly 64 characters long. It is important to note that even a zero-length object will have a digest, which is the standard SHA-256 NULL hash value.

szContent

A null-terminated string which specifies the MIME content type for the storage object. The content type is determined by the object label and evaluating the contents of the object. It is also possible for the application to explicitly specify the content type of the object when it is created.

dwAttributes

An unsigned integer value that specifies the attributes for the storage object. The object attributes are comprised of one or more bitflags:

Value	Constant	Description
0	WEB_OBJECT_DEFAULT	Default object attributes. This value is used to indicate the object can be modified, or that the attributes for a previously existing object should not be changed.
1	WEB_OBJECT_NORMAL	A normal object that that can be read and modified by the application. This is the default

		attribute for new objects that are created by the application.
2	WEB_OBJECT_READONLY	A read-only object that can only be read by the application. Attempts to modify or replace the contents of the object will fail. Read-only objects can be deleted.
4	WEB_OBJECT_HIDDEN	A hidden object. Objects with this attribute are not returned when enumerated using the WebEnumObjects function. The object can only be accessed directly when specifying its label.

dwObjectSize

An unsigned integer value that specifies the size of the storage object in bytes. The maximum size of an individual object is determined by the storage quota limits established for the account.

stCreated

A SYSTEMTIME structure that specifies the date and time the storage object was created. This value is represented using Coordinated Universal Time (UTC) and is not adjusted for the local time zone.

stModified

A SYSTEMTIME structure that specifies the date and time the storage object was last modified. This value is represented using Coordinated Universal Time (UTC) and is not adjusted for the local time zone. When a storage object is first created, this value will be the same as the object creation time.

Remarks

The object content type will always be in the format **type/subtype** where the type specifies a common media type (e.g.: text, audio, video, etc.) and subtype specifies the specific content. The most common content type for text files is **text/plain**. If the content type is unknown, the default content type is **application/octet-stream**.

Text objects may also optionally include the character encoding as part of the content type. For example, if an object contains UTF-8 encoded text, the content type may be returned as **text/plain; charset=utf-8**. If your application is parsing the content types, you must check if a character encoding was also included in the value. Text objects that do not specify an encoding either contain ASCII or text which uses the system code page. Unicode text will always be stored using UTF-8 encoding.

To adjust the object creation and modification times to account for the local time zone, use the **SystemTimeToTzSpecificLocalTime** function. If you prefer to use FILETIME values, use the **SystemTimeToFileTime** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cstoools10.h

Unicode: Implemented as Unicode and ANSI versions.

WEB_STORAGE_QUOTA Structure

The **WEB_STORAGE_QUOTA** structure contains information about the current storage account data usage and limits. This structure is used with the **WebGetStorageQuota** function.

```
typedef struct _WEB_STORAGE_QUOTA
{
    DWORD        dwObjects;
    DWORD        dwObjectLimit;
    DWORD        dwObjectSize;
    ULONGLONG    ulBytesUsed;
    ULONGLONG    ulBytesFree;
    ULONGLONG    ulStorageLimit;
} WEB_STORAGE_QUOTA, *LPWEB_STORAGE_QUOTA;
```

Members

dwObjects

An unsigned integer value which specifies the number of storage objects allocated for the account. This value may not exceed the total number of objects specified by the *dwObjectLimit* member.

dwObjectLimit

An unsigned integer value which specifies the maximum number of storage objects that may be created. In addition to the limit on the total amount of storage that may be used, there is a limit on the total number of objects that may be created by all applications.

dwObjectSize

An unsigned integer value which specifies the maximum size of an individual storage object. In addition to a limit on the total amount of storage used and the number of objects created, each object stored by the application cannot exceed this size.

ulBytesUsed

An unsigned 64-bit integer value which specifies the total number of bytes of data allocated for all storage objects. This value may not exceed the total number of bytes of storage available, which is specified by the *ulStorageLimit* member.

ulBytesFree

An unsigned 64-bit integer value which specifies the number of bytes available for the storage of new objects. This value reflects the total amount of available storage across all applications registered with the development account. If this value is zero, your storage account has reached its storage limit.

ulStorageLimit

An unsigned 64-bit integer value which specifies the maximum number of bytes of data storage available. This limit applies to all applications registered with the development account.

Remarks

Storage quota limits are assigned for each SocketTools development account. The **WebGetStorageQuota** function will populate this structure with information about the limits on your account. Accounts that are created with an evaluation license have much lower quota limits than a standard account and should be used for testing purposes only. After the evaluation period has ended, all objects stored using the evaluation license will be deleted.

These values do not represent limits on storage usage by a specific application. Quotas limits

apply to all applications that are registered with the development account, which is identified with the runtime license key passed to the **WebInitialize** function.

If your storage quota has been exceeded, either because the total number of objects or the total bytes of storage has reached their limit, your applications will be unable to create new objects. Your application can continue to access existing objects, regardless of your current quota limits.

To free storage space, use the **WebDeleteObject** function to delete individual storage objects that are no longer needed by your application, or use the **WebResetStorage** function to delete all objects in a container.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cstools10.h`

See Also

[WebGetStorageQuota](#)

WEB_STORAGE_TRANSFER Structure

This structure is used by the **WebGetTransferStatus** function to return information about a data transfer in progress.

```
typedef struct _WEB_STORAGE_TRANSFER
{
    TCHAR        szObjectLabel[512];
    DWORD        dwStorageType;
    DWORD        dwBytesTotal;
    DWORD        dwBytesCopied;
    DWORD        dwBytesPerSecond;
    DWORD        dwTimeElapsed;
    DWORD        dwTimeEstimated;
} WEB_STORAGE_TRANSFER, *LPWEB_STORAGE_TRANSFER
```

Members

szObjectLabel

A null-terminated string that specifies the label for the object that is being retrieved, created or replaced.

dwStorageType

An integer value that identifies the storage container type. This will be one of the following values:

Constant	Description
WEB_STORAGE_GLOBAL (1)	Global storage. Objects stored using this storage type are available to all users. Any changes made to objects using this storage type will affect all users of the application. Unless there is a specific need to limit access to the objects stored by the application to specific domains, local machines or users, it is recommended that you use this storage type when creating new objects.
WEB_STORAGE_DOMAIN (2)	Local domain storage. Objects stored using this storage type are only available to users in the same local domain, as defined by the domain name or workgroup name assigned to the local system. If the domain or workgroup name changes, objects previously stored using this storage type will not be available to the application.
WEB_STORAGE_MACHINE (3)	Local machine storage. Objects stored using this storage type are only available to users on the same local machine. The local machine is identified by unique characteristics of the system, including the boot volume GUID. Objects previously stored using this storage type will not be available on that system if the boot disk is reformatted.
WEB_STORAGE_USER (4)	Current user storage. Objects stored using this storage type are only available to the current user logged in on the local machine. The user identifier is based on the Windows user SID that is assigned when the user account

	is created. If the user account is deleted, the objects previously stored using this storage type will not be available to the application.
--	---

dwBytesTotal

An unsigned integer which specifies the total number of bytes that will be transferred. If the object is being downloaded to the local host, this is the size of the stored object. If the data is being uploaded from the local host to be stored on the server, it is the size of the buffer or local file.

dwBytesCopied

An unsigned integer which specifies the total number of bytes that have been copied.

dwBytesPerSecond

The average number of bytes that have been copied per second.

dwTimeElapsed

The number of seconds that have elapsed since the file transfer started.

dwTimeEstimated

The estimated number of seconds until the data transfer is completed. This is based on the average number of bytes transferred per second.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Whois Protocol Library

Request registration information for an Internet domain name.

Reference

- [Functions](#)
- [Data Structures](#)
- [Error Codes](#)

Library Information

File Name	CSWHOV10.DLL
Version	10.0.1468.2518
LibID	A1E831CF-F84F-48B1-9710-D012B50AB6D5
Import Library	CSWHOV10.LIB
Dependencies	None
Standards	RFC 954

Overview

The Whois protocol library provides an interface for requesting registration information for an Internet domain name. When a domain name is registered, the organization that registers the domain must provide certain contact information along with technical information such as the primary name servers for that domain. The library provides an API for requesting that information and returning it to the program so that it can be displayed or processed. This library would be most commonly used to query the Whois server at **whois.internic.net** to obtain information about a specific Internet domain name or an administrative contact at that domain.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). If you are using Visual C++ 6.0 it is required that you have Service Pack 6 (SP6) installed. You should install all updates for your development tools and have the current Windows SDK installed. The minimum recommended version of Visual Studio is Visual Studio 2010.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are using Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. It is recommended that you install the current service pack and all critical updates available for your version of the operating system.

This product includes both 32-bit and 64-bit libraries. Native 64-bit CPU support requires the 64-bit version of Windows 7 or later versions of the Windows operating system.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

Whois Protocol Functions

Function	Description
WhoisAsyncConnect	Connect asynchronously to the specified server
WhoisAttachThread	Attach the specified client handle to another thread
WhoisCancel	Cancel the current blocking operation
WhoisConnect	Connect to the specified server
WhoisDisableEvents	Disable asynchronous event notification
WhoisDisableTrace	Disable logging of socket function calls to the trace log
WhoisDisconnect	Disconnect from the current server
WhoisEnableEvents	Enable asynchronous event notification
WhoisEnableTrace	Enable logging of socket function calls to a file
WhoisEventProc	Callback function that processes events generated by the client
WhoisFreezeEvents	Suspend or resume event handling by the calling process
WhoisGetErrorString	Return a description for the specified error code
WhoisGetLastError	Return the last error code
WhoisGetStatus	Return the current client status.
WhoisGetTimeout	Return the number of seconds until an operation times out
WhoisInitialize	Initialize the library and validate the specified license key at runtime
WhoisIsBlocking	Determine if the client is blocked, waiting for information
WhoisIsConnected	Determine if the client is connected to the server
WhoisIsReadable	Determine if there is data available to be read from the server
WhoisRead	Read data returned by the server
WhoisRegisterEvent	Register an event callback function
WhoisSearch	Search for the specified record
WhoisSetLastError	Set the last error code
WhoisSetTimeout	Set the number of seconds until an operation times out
WhoisUninitialize	Terminate use of the library by the application

WhoisAsyncConnect Function

```
HCLIENT WINAPI WhoisAsyncConnect(  
    LPCTSTR LpszRemoteHost,  
    UINT nRemotePort,  
    UINT nTimeout,  
    DWORD dwReserved,  
    HWND hEventWnd,  
    UINT uEventMsg  
);
```

The **WhoisAsyncConnect** function is used to establish a connection with the server.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

The application should create a background worker thread and establish a connection by calling **WhoisConnect** within that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each client session.

Parameters

LpszRemoteHost

A pointer to the name of the server to connect to; this may be a fully-qualified domain name or an IP address.

nRemotePort

The port number the server is listening on; a value of zero specifies that the default port number should be used.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwReserved

A reserved parameter. This value should always be zero.

hEventWnd

The handle to the event notification window. This window receives messages which notify the client of various asynchronous network events that occur. If this parameter is NULL, then a synchronous (blocking) connection will be established with the server.

uEventMsg

The message identifier that is used when an asynchronous network event occurs. This value should be greater than WM_USER as defined in the Windows header files. If the *hEventWnd* parameter is NULL, this parameter should be specified as WM_NULL.

Return Value

If the function succeeds, the return value is a handle to a client session. If the function fails, the return value is INVALID_CLIENT. To get extended error information, call **WhoisGetLastError**.

Remarks

When a message is posted to the notification window, the low word of the *lParam* parameter contains the event identifier. The high word of *lParam* contains the low word of the error code, if

an error has occurred. The *wParam* parameter contains the client handle. One or more of the following event identifiers may be sent:

Constant	Description
WHOIS_EVENT_CONNECT	The connection to the server has completed. The high word of the <i>lParam</i> parameter should be checked, since this notification message will be posted if an error has occurred.
WHOIS_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
WHOIS_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
WHOIS_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
WHOIS_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
WHOIS_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.

To cancel asynchronous notification and return the client to a blocking mode, use the **WhoisDisableEvents** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswhov10.lib

Unicode: Implemented as Unicode and ANSI versions.

WhoisAttachThread Function

```
DWORD WINAPI WhoisAttachThread(  
    HCLIENT hClient  
    DWORD dwThreadId  
);
```

The **WhoisAttachThread** function attaches the specified client handle to another thread.

Parameters

hClient

Handle to the client session.

dwThreadId

The ID of the thread that will become the new owner of the handle. A value of zero specifies that the current thread should become the owner of the client handle.

Return Value

If the function succeeds, the return value is the thread ID of the previous owner. If the function fails, the return value is `WHOIS_ERROR`. To get extended error information, call

WhoisGetLastError.

Remarks

When a client handle is created, it is associated with the current thread that created it. Normally, if another thread attempts to perform an operation using that handle, an error is returned since it does not own the handle. This is used to ensure that other threads cannot interfere with an operation being performed by the owner thread. In some cases, it may be desirable for one thread in a client application to create the client handle, and then pass that handle to another worker thread. The **WhoisAttachThread** function can be used to change the ownership of the handle to the new worker thread. By preserving the return value from the function, the original owner of the handle can be restored before the worker thread terminates.

This function should be called by the new thread immediately after it has been created, and if the new thread does not release the handle itself, the ownership of the handle should be restored to the parent thread before it terminates. Under no circumstances should **WhoisAttachThread** be used to forcibly release a handle allocated by another thread while a blocking operation is in progress. To cancel an operation, use the **WhoisCancel** function and then release the handle after the blocking function exits and control is returned to the current thread.

Note that the *dwThreadId* parameter is presumed to be a valid thread ID and no checks are performed to ensure that the thread actually exists. Specifying an invalid thread ID will orphan the handle until the **WhoisUninitialize** function is called.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `cswhov10.lib`

See Also

[WhoisCancel](#), [WhoisAsyncConnect](#), [WhoisConnect](#), [WhoisDisconnect](#), [WhoisUninitialize](#)

WhoisCancel Function

```
INT WINAPI WhoisCancel(  
    HCLIENT hClient  
);
```

The **WhoisCancel** function cancels any outstanding blocking operation in the client, causing the blocking function to fail. The application may then retry the operation or terminate the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is WHOIS_ERROR. To get extended error information, call **WhoisGetLastError**.

Remarks

When the **WhoisCancel** function is called, the blocking function will not immediately fail. An internal flag is set which causes the blocking operation to exit with an error. This means that the application cannot cancel an operation and immediately perform some other operation. Instead it must allow the calling stack to unwind, returning back to the blocking operation before making any further function calls.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswhov10.lib

[WhoisIsBlocking](#)

WhoisConnect Function

```
HCLIENT WINAPI WhoisConnect(  
    LPCTSTR lpszRemoteHost,  
    UINT nRemotePort,  
    UINT nTimeout,  
    DWORD dwReserved  
);
```

The **WhoisConnect** function is used to establish a connection with the server.

Parameters

lpszRemoteHost

A pointer to the name of the server to connect to; this may be a fully-qualified domain name or an IP address.

nRemotePort

The port number the server is listening on; a value of zero specifies that the default port number should be used.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwReserved

A reserved parameter. This value should always be zero.

Return Value

If the function succeeds, the return value is a handle to a client session. If the function fails, the return value is `INVALID_CLIENT`. To get extended error information, call **WhoisGetLastError**.

Remarks

To prevent this function from blocking the main user interface thread, the application should create a background worker thread and establish a connection by calling **WhoisConnect** in that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each client session.

Requirements

If the function succeeds, the return value is a handle to a client session. If the function fails, the return value is `INVALID_CLIENT`. To get extended error information, call **WhoisGetLastError**.

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `cswhov10.lib`

Unicode: Implemented as Unicode and ANSI versions.

WhoisDisableEvents Function

```
INT WINAPI WhoisDisableEvents(  
    HCLIENT hClient  
);
```

The **WhoisDisableEvents** function disables the event notification mechanism, preventing subsequent event notification messages from being posted to the application's message queue.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is WHOIS_ERROR. To get extended error information, call **WhoisGetLastError**.

Remarks

This function affects both event notification and event callbacks. Any outstanding events in the message queue should be ignored by the client application.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswhov10.lib

See Also

[WhoisEnableEvents](#), [WhoisFreezeEvents](#), [WhoisRegisterEvent](#)

WhoisDisableTrace Function

```
BOOL WINAPI WhoisDisableTrace();
```

The **WhoisDisableTrace** function disables the logging of socket function calls to the trace log file.

Parameters

None.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswhov10.lib

See Also

[WhoisEnableTrace](#)

WhoisDisconnect Function

```
INT WINAPI WhoisDisconnect(  
    HCLIENT hClient  
);
```

The **WhoisDisconnect** function terminates the connection with the server, closing the socket and releasing the memory allocated for the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is WHOIS_ERROR. To get extended error information, call **WhoisGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cswhov10.lib

WhoisEnableEvents Function

```
INT WINAPI WhoisEnableEvents(  
    HCLIENT hClient,  
    HWND hEventWnd,  
    UINT uEventMsg  
);
```

The **WhoisEnableEvents** function enables event notifications using Windows messages.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Applications should use the **WhoisRegisterEvent** function to register an event handler which is invoked when an event occurs.

Parameters

hClient

Handle to the client session.

hEventWnd

Handle to the event notification window. This window receives a user-defined message which specifies the event that has occurred. If this value is NULL, event notification is disabled.

uEventMsg

An unsigned integer which specifies the user-defined message that is sent when an event occurs. This parameter's value must be greater than the value of WM_USER.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is WHOIS_ERROR. To get extended error information, call **WhoisGetLastError**.

Remarks

When a message is posted to the notification window, the low word of the *lParam* parameter contains the event identifier. The high word of *lParam* contains the low word of the error code, if an error has occurred. The *wParam* parameter contains the client handle. One or more of the following event identifiers may be sent:

Constant	Description
WHOIS_EVENT_CONNECT	The connection to the server has completed. The high word of the <i>lParam</i> parameter should be checked, since this notification message will be posted if an error has occurred.
WHOIS_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
WHOIS_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
WHOIS_EVENT_WRITE	The client can now write data. This notification is sent after a

	connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
WHOIS_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
WHOIS_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.

To cancel asynchronous notification and return the client to a blocking mode, use the **WhoisDisableEvents** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cswhov10.lib

See Also

[WhoisDisableEvents](#), [WhoisFreezeEvents](#), [WhoisRegisterEvent](#)

WhoisEnableTrace Function

```
BOOL WINAPI WhoisEnableTrace(  
    LPCTSTR lpszTraceFile,  
    DWORD dwTraceFlags  
);
```

The **WhoisEnableTrace** function enables the logging of socket function calls to a file.

Parameters

lpszTraceFile

A pointer to a string which specifies the name of the trace log file. If this parameter is NULL or an empty string, the default file name **cstrace.log** is used. The file is stored in the directory specified by the TEMP environment variable, if it is defined; otherwise, the current working directory is used.

dwTraceFlags

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
TRACE_INFO	All function calls are written to the trace file. This is the default value.
TRACE_ERROR	Only those function calls which fail are recorded in the trace file.
TRACE_WARNING	Only those function calls which fail or return values which indicate a warning are recorded in the trace file.
TRACE_HEXDUMP	All functions calls are written to the trace file, plus all the data that is sent or received is displayed, in both ASCII and hexadecimal format.
TRACE_PROCESS	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for multithreaded applications that are using worker threads.

Return Value

If the function succeeds, the return value is non-zero. A return value of zero indicates an error. Failure typically indicates that the tracing library **cstrcv10.dll** cannot be loaded on the local system.

Remarks

When trace logging is enabled, the file is opened, appended to and closed for each socket function call. This makes it possible for an application to append its own logging information, however care should be taken to ensure that the file is closed before the next network operation is performed. To limit the size of the log files, enable and disable logging only around those sections of code that you wish to trace.

Note that the TRACE_HEXDUMP trace level generates very large log files since it includes all of the data exchanged between your application and the server.

Trace function logging is managed on a per-thread basis, not for each client handle. This means that all SocketTools libraries and components share the same settings in the current thread. If you

are using multiple SocketTools libraries or components in your application, you only need to enable logging once.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswhov10.lib

Unicode: Implemented as Unicode and ANSI versions.

[WhoisDisableTrace](#)

WhoisEventProc Function

```
VOID CALLBACK WhoisEventProc(  
    HCLIENT hClient,  
    UINT nEventId,  
    DWORD dwError,  
    DWORD_PTR dwParam  
);
```

The **WhoisEventProc** function is an application-defined callback function that processes events generated by the calling process.

Parameters

hClient

The handle to the client session.

nEvent

An unsigned integer which specifies which event occurred. For a complete list of events, refer to the **WhoisRegisterEvent** function.

dwError

An unsigned integer which specifies any error that occurred. If no error occurred, then this parameter will be zero.

dwParam

A user-defined integer value which was specified when the event callback was registered.

Return Value

None.

Remarks

An application must register this callback function by passing its address to the **WhoisRegisterEvent** function. The **WhoisEventProc** function is a placeholder for the application-defined function name.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cswhov10.lib

See Also

[WhoisDisableEvents](#), [WhoisEnableEvents](#), [WhoisFreezeEvents](#), [WhoisRegisterEvent](#)

WhoisFreezeEvents Function

```
INT WINAPI WhoisFreezeEvents(  
    HCLIENT hClient,  
    BOOL bFreeze  
);
```

The **WhoisFreezeEvents** function is used to suspend and resume event handling by the client.

Parameters

hClient

Handle to the client session.

bFreeze

A non-zero value specifies that event handling should be suspended by the client. A zero value specifies that event handling should be resumed.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is WHOIS_ERROR. To get extended error information, call **WhoisGetLastError**.

Remarks

This function should be used when the application does not want to process events, such as when a modal dialog is being displayed. When events are suspended, all client events are queued. If events are re-enabled at a later point, those queued events will be sent to the application for processing. Note that only one of each event will be generated. For example, if the client has suspended event handling, and four read events occur, once event handling is resumed only one of those read events will be posted to the client. This prevents the application from being flooded by a potentially large number of queued events.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswhov10.lib

See Also

[WhoisDisableEvents](#), [WhoisEnableEvents](#), [WhoisRegisterEvent](#)

WhoisGetErrorString Function

```
INT WINAPI WhoisGetErrorString(  
    DWORD dwErrorCode,  
    LPTSTR lpszDescription,  
    INT cbDescription  
);
```

The **WhoisGetErrorString** function is used to return a description of a specific error code. Typically this is used in conjunction with the **WhoisGetLastError** function for use with warning dialogs or as diagnostic messages.

Parameters

dwErrorCode

The last-error code for which a description is returned.

lpszDescription

A pointer to the buffer that will contain a description of the specified error code. This buffer should be at least 128 characters in length.

cbDescription

The maximum number of characters that may be copied into the description buffer.

Return Value

If the function succeeds, the return value is the length of the description string. If the function fails, the return value is 0, meaning that no description exists for the specified error code. Typically this indicates that the error code passed to the function is invalid.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `cswhov10.lib`

Unicode: Implemented as Unicode and ANSI versions.

See Also

[WhoisGetLastError](#), [WhoisSetLastError](#)

WhoisGetLastError Function

```
DWORD WINAPI WhoisGetLastError();
```

Parameters

None.

Return Value

The return value is the last error code value for the current thread. Functions set this value by calling the **WhoisSetLastError** function. The Return Value section of each reference page notes the conditions under which the function sets the last error code.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. You should call the **WhoisGetLastError** function immediately when a function's return value indicates that an error has occurred. That is because some functions call **WhoisSetLastError(0)** when they succeed, clearing the error code set by the most recently failed function.

Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or WHOIS_ERROR. Those functions which call **WhoisSetLastError** when they succeed are noted on the function reference page.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswhov10.lib

See Also

[WhoisGetErrorString](#), [WhoisSetLastError](#)

WhoisGetStatus Function

```
INT WINAPI WhoisGetStatus(  
    HCLIENT hClient  
);
```

The **WhoisGetStatus** function returns the current status of the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the client status code. If the function fails, the return value is WHOIS_ERROR. To get extended error information, call **WhoisGetLastError**.

Remarks

The **WhoisGetStatus** function returns a numeric code which identifies the current state of the client session. The following values may be returned:

Value	Constant	Description
1	WHOIS_STATUS_IDLE	The client is current idle and not sending or receiving data.
2	WHOIS_STATUS_CONNECT	The client is establishing a connection with the server.
3	WHOIS_STATUS_READ	The client is reading data from the server.
4	WHOIS_STATUS_WRITE	The client is writing data to the server.
5	WHOIS_STATUS_DISCONNECT	The client is disconnecting from the server.

In a multithreaded application, any thread in the current process may call this function to obtain status information for the specified client session.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswhov10.lib

[WhoisIsBlocking](#), [WhoisIsConnected](#), [WhoisIsReadable](#)

WhoisGetTimeout Function

```
INT WINAPI WhoisGetTimeout(  
    HCLIENT hClient  
);
```

The **WhoisGetTimeout** function returns the number of seconds the client will wait for a response from the server. Once the specified number of seconds has elapsed, the function will fail and return to the caller.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the timeout period in seconds. If the function fails, the return value is WHOIS_ERROR. To get extended error information, call **WhoisGetLastError**.

Remarks

The timeout value is only used with blocking client connections. A value of zero indicates that the default timeout period of 20 seconds should be used.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cswhov10.lib

See Also

[WhoisSetTimeout](#)

WhoisInitialize Function

```
BOOL WINAPI WhoisInitialize(  
    LPCTSTR lpszLicenseKey,  
    LPINITDATA lpData  
);
```

The **WhoisInitialize** function initializes the library and validates the specified license key at runtime.

Parameters

lpszLicenseKey

Pointer to a string that specifies the runtime license key to be validated. If this parameter is NULL, the library will validate the development license installed on the local system.

lpData

Pointer to an INITDATA data structure. This parameter may be NULL if the initialization data for the library is not required.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WhoisGetLastError**. All other client functions will fail until a license key has been successfully validated.

Remarks

This must be the first function that an application calls before using any of the other functions in the library. When a NULL license key is specified, the library will only function on the development system. Before redistributing the application to an end-user, you must insure that this function is called with a valid license key.

If the *lpData* argument is specified, it must point to an INITDATA structure which has been initialized by setting the *dwSize* member to the size of the structure. All other structure members should be set to zero. If the function is successful, then the INITDATA structure will be filled with identifying information about the library.

Although it is only required that **WhoisInitialize** be called once for the current process, it may be called multiple times; however, each call must be matched by a corresponding call to **WhoisUninitialize**.

This function dynamically loads other system libraries and allocates thread local storage. If you are calling the functions in this library from within another DLL, it is important that you do not call the **WhoisInitialize** or **WhoisUninitialize** functions from the **DllMain** function because it can result in deadlocks or access violation errors. If the DLL is linked with the C runtime library (CRT), it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswhov10.lib

Unicode: Implemented as Unicode and ANSI versions.

WhoisIsBlocking Function

```
BOOL WINAPI WhoisIsBlocking(  
    HCLIENT hClient  
);
```

The **WhoisIsBlocking** function is used to determine if the client is currently performing a blocking operation.

Parameters

hClient

Handle to the client session.

Return Value

If the client is performing a blocking operation, the function returns TRUE. If the client is not performing a blocking operation, or the client handle is invalid, the function returns FALSE.

Remarks

Because a blocking operation can allow the application to be re-entered (for example, by pressing a button while the operation is being performed), it is possible that another blocking function may be called while it is in progress. Since only one thread of execution may perform a blocking operation at any one time, an error would occur. The **WhoisIsBlocking** function can be used to determine if the client is already blocked, and if so, take some other action (such as warning the user that they must wait for the operation to complete).

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswhov10.lib

WhoisIsConnected Function

```
BOOL WINAPI WhoisIsConnected(  
    HCLIENT hClient  
);
```

The **WhoisIsConnected** function is used to determine if the client is currently connected to a server.

Parameters

hClient

Handle to the client session.

Return Value

If the client is connected to a server, the function returns a non-zero value. If the client is not connected, or the client handle is invalid, the function returns zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cswhov10.lib

[WhoisGetStatus](#), [WhoisIsBlocking](#), [WhoisIsReadable](#)

WhoisIsReadable Function

```
BOOL WINAPI WhoisIsReadable(  
    HCLIENT hClient,  
    INT nTimeout,  
    LPDWORD lpdwAvail  
);
```

The **WhoisIsReadable** function is used to determine if data is available to be read from the server.

Parameters

hClient

Handle to the client session.

nTimeout

Timeout for server response, in seconds. A value of zero specifies that the connection should be polled without blocking the current thread.

lpdwAvail

A pointer to an unsigned integer which will contain the number of bytes available to read. This parameter may be NULL if this information is not required.

Return Value

If the client can read data from the server within the timeout period, the function returns a non-zero value. If the client cannot read any data, the function returns zero.

Remarks

On some platforms, this value will not exceed the size of the receive buffer (typically 64K bytes). Because of differences between TCP/IP stack implementations, it is not recommended that your application exclusively depend on this value to determine the exact number of bytes available. Instead, it should be used as a general indicator that there is data available to be read.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswhov10.lib

See Also

WhoisRead Function

```
INT WINAPI WhoisRead(  
    HCLIENT hClient,  
    LPBYTE lpBuffer,  
    INT cbBuffer  
);
```

The **WhoisRead** function reads the specified number of bytes from the client socket and copies them into the buffer. The data may be of any type, and is not terminated with a null character.

Parameters

hClient

Handle to the client session.

lpBuffer

Pointer to the buffer in which the data will be copied.

cbBuffer

The maximum number of bytes to read and copy into the specified buffer. This value must be greater than zero.

Return Value

If the function succeeds, the return value is the number of bytes actually read. A return value of zero indicates that the server has closed the connection and there is no more data available to be read. If the function fails, the return value is WHOIS_ERROR. To get extended error information, call **WhoisGetLastError**.

Remarks

When **WhoisRead** is called and the client is in non-blocking mode, it is possible that the function will fail because there is no available data to read at that time. This should not be considered a fatal error. Instead, the application should simply wait to receive the next asynchronous notification that data is available.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswhov10.lib

WhoisRegisterEvent Function

```
INT WINAPI WhoisRegisterEvent(  
    HCLIENT hClient,  
    UINT nEventId,  
    INETEVENTPROC LpfnEvent,  
    DWORD_PTR dwParam  
);
```

The **WhoisRegisterEvent** function registers a callback function for the specified event.

Parameters

hClient

Handle to client session.

nEventId

An unsigned integer which specifies which event should be registered with the specified callback function. One or more of the following values may be used:

Constant	Description
WHOIS_EVENT_CONNECT	The connection to the server has completed.
WHOIS_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
WHOIS_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
WHOIS_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
WHOIS_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
WHOIS_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.

lpfnEvent

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **WhoisEventProc** callback function. If this parameter is NULL, the callback for the specified event is disabled.

dwParam

A user-defined integer value that is passed to the callback function. If the application targets the x86 (32-bit) platform, this parameter must be a 32-bit unsigned integer. If the application targets the x64 (64-bit) platform, this parameter must be a 64-bit unsigned integer.

Remarks

The **WhoisRegisterEvent** function associates a callback function with a specific event. The event handler is an **WhoisEventProc** function that is invoked when the event occurs. Arguments are passed to the function to identify the client session, the event type and the user-defined value specified when the event handler is registered. If the event occurs because of an error condition, the error code will be provided to the handler.

The callback function specified by the *lpEventProc* parameter must be declared using the **__stdcall** calling convention. This ensures the arguments passed to the event handler are pushed on to the stack in the correct order. Failure to use the correct calling convention will corrupt the stack and cause the application to terminate abnormally.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is WHOIS_ERROR. To get extended error information, call **WhoisGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswhov10.lib

WhoisSearch Function

```
INT WINAPI WhoisSearch(  
    HCLIENT hClient,  
    LPCTSTR lpszKeyword,  
    UINT nSearchType  
);
```

The **WhoisSearch** function submits the specified keyword to the server.

Parameters

hClient

Handle to the client session.

lpszKeyword

Points to a string which specifies the query keyword. It may be a handle, name or mailbox.

nSearchType

The type of search being performed. One of the following values may be used:

Constant	Description
WHOIS_SEARCH_ANY	Search for any record that matches the specified keyword.
WHOIS_SEARCH_HANDLE	Search only for handles that match the specified keyword.
WHOIS_SEARCH_MAILBOX	Search only for mailboxes that match the specified keyword.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is WHOIS_ERROR. To get extended error information, call **WhoisGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswhov10.lib

Unicode: Implemented as Unicode and ANSI versions.

WhoisSetLastError Function

```
VOID WINAPI WhoisSetLastError(  
    DWORD dwErrorCode  
);
```

The **WhoisSetLastError** function sets the error code for the current thread. This function is typically used to clear the last error by passing a value of zero as the parameter.

Parameters

dwErrorCode

Specifies the error code for the current thread.

Return Value

None.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or WHOIS_ERROR. Those functions which call **WhoisSetLastError** when they succeed are noted on the function reference page.

Applications can retrieve the value saved by this function by using the **WhoisGetLastError** function. The use of **WhoisGetLastError** is optional; an application can call the function to determine the specific reason for a function failure.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswhov10.lib

[WhoisGetErrorString](#), [WhoisGetLastError](#)

WhoisSetTimeout Function

```
INT WINAPI WhoisSetTimeout(  
    HCLIENT hClient,  
    UINT nTimeout  
);
```

The **WhoisSetTimeout** function sets the number of seconds the client will wait for a response from the server. Once the specified number of seconds has elapsed, the function will fail and return to the caller.

Parameters

hClient

Handle to the client session.

nTimeout

The number of seconds to wait for a blocking operation to complete.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is WHOIS_ERROR. To get extended error information, call **WhoisGetLastError**.

Remarks

The timeout value is only used with blocking client connections.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cswhov10.lib

See Also

[WhoisGetTimeout](#)

WhoisUninitialize Function

```
VOID WINAPI WhoisUninitialize();
```

The **WhoisUninitialize** function terminates the use of the library.

Parameters

There are no parameters.

Return Value

None.

Remarks

An application is required to perform a successful **WhoisInitialize** call before it can call any of the other the library functions. When it has completed the use of library, the application must call **WhoisUninitialize** to allow the library to free any resources allocated on behalf of the process. Any pending blocking or asynchronous calls in this process are canceled without posting any notification messages, and all sockets that were opened by the process are closed.

There must be a call to **WhoisUninitialize** for every successful call to **WhoisInitialize** made by a process. In a multithreaded environment, operations for all threads in the client are terminated.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswhov10.lib

Whois Protocol Data Structures

- INITDATA

INITDATA Structure

This structure contains information about the SocketTools library when the initialization function returns.

```
typedef struct _INITDATA
{
    DWORD        dwSize;
    DWORD        dwVersionMajor;
    DWORD        dwVersionMinor;
    DWORD        dwVersionBuild;
    DWORD        dwOptions;
    DWORD_PTR    dwReserved1;
    DWORD_PTR    dwReserved2;
    TCHAR        szDescription[128];
} INITDATA, *LPINITDATA;
```

Members

dwSize

Size of this structure. This structure member must be set to the size of the structure prior to calling the initialization function. Failure to do so will cause the function to fail.

dwVersionMajor

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the major version number for the library.

dwVersionMinor

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the minor version number for the library.

dwVersionBuild

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the build number for the library.

dwOptions

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

dwReserved1

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

dwReserved2

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

szDescription

A null terminated string which describes the library.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Unicode: Implemented as Unicode and ANSI versions.
