FTP_OPTION_VERIFY	<p>This option specifies that file transfers should be automatically verified after the transfer has completed. If the server supports the XMD5 command, the transfer will be verified by calculating an MD5 hash of the file contents. If the server does not support the XMD5 command, but does support the XCRC command, the transfer will be verified by calculating a CRC32 checksum of the file contents. If neither the XMD5 or XCRC commands are supported, the transfer is verified by comparing the size of the file. Automatic file verification is only performed for binary mode transfers because of the end-of-line conversion that may occur when text files are uploaded or downloaded.</p>
FTP_OPTION_TRUSTEDSITE	<p>This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using either the SSL or TLS protocols.</p>
FTP_OPTION_SECURE	<p>This option specifies the client should attempt to establish a secure connection with the server. This option is the same as specifying FTP_OPTION_SECURE_IMPLICIT which immediately performs the SSL/TLS protocol negotiation when the connection is established.</p>

FTP_OPTION_SECURE_IMPLICIT	This option specifies the client should attempt to immediately establish secure SSL/TLS connection with the server. This option is typically used when connecting to a server on port 990, which is the default port number used for FTPS.
FTP_OPTION_SECURE_EXPLICIT	This option specifies the client should establish a standard connection to the server and then use the AUTH command to negotiate an explicit secure connection. This option is typically used when connecting to the server on ports other than 990.
FTP_OPTION_SECURE_SHELL	This option specifies the client should use the Secure Shell (SSH) protocol to establish the connection. This option will automatically be selected if the connection is established using port 22, the default port for SSH.
FTP_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
FTP_OPTION_TUNNEL	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established. This option also forces all connections to be outbound and enables the firewall compatibility features in the client.
FTP_OPTION_KEEPALIVE_DATA	This option specifies the client should attempt to keep the control connection active during a file transfer. Normally, when a data transfer is in progress, no additional commands are issued on the control channel until the transfer completes. Specifying this option automatically enables the FTP_OPTION_KEEPALIVE option and forces the client to continue to issue NOOP commands during the file transfer. This option only applies to FTP and FTPS connections and has no effect on connections using SFTP (SSH).
FTP_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client

	will attempt to establish a connection using IPv6 regardless if this option has been specified.
FTP_OPTION_FREETHREAD	This option specifies the handle returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the handle is synchronized across multiple threads.
FTP_OPTION_HIRES_TIMER	This option specifies the elapsed time for data transfers should be returned in milliseconds instead of seconds. This will return more accurate transfer times for smaller files being uploaded or downloaded using fast network connections.
FTP_OPTION_TLS_REUSE	This option specifies that TLS session reuse should be enabled for secure connections. This option is only supported on Windows 8.1 or Windows Server 2012 R2 and later platforms, and it should only be used when explicitly required by the server. This option is not compatible with servers built using OpenSSL 1.0.2 and earlier versions which do not provide Extended Master Secret (EMS) support as outlined in RFC7627.

lpCredentials

A pointer to a [SECURITYCREDENTIALS](#) structure. This parameter should be NULL if the connection is not secure or when client credentials are not required. Most servers do not require a client certificate to establish a secure connection. However, if the server does require a client certificate, the structure members *dwSize*, *lpzCertStore* and *lpzCertName* must be defined. Undefined structure members must be initialized to a value of zero or NULL and the *dwSize* member must be initialized to the size of the **SECURITYCREDENTIALS** structure.

Return Value

If the function succeeds, the return value is a handle to a client session. If the function fails, the return value is INVALID_CLIENT. To get extended error information, call **FtpGetLastError**.

Remarks

To prevent this function from blocking the main user interface thread, the application should create a background worker thread and establish a connection by calling **FtpConnect** in that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each client session.

If the FTP_OPTION_KEEPALIVE option is specified, a background worker thread will be created to monitor the command channel and periodically send NOOP commands to the server if no commands have been sent recently. This can prevent the server from terminating the client connection during idle periods where no commands are being issued. However, it is important to keep in mind that many servers can be configured to also limit the total amount of time a client can be connected to the server, as well as the amount of time permitted between file transfers. If the server does not respond to the NOOP command, this option will be automatically disabled for the remainder of the client session.

If the FTP_OPTION_SECURE_EXPLICIT option is specified, the client will establish a standard

connection to the server and send the AUTH TLS command to the server. If the server does not accept this command, it will then send the AUTH SSL command. If both commands are rejected by the server, an explicit SSL session cannot be established. By default, both the command and data channels will be encrypted when a secure connection is established. To change this, use the **FtpSetChannelMode** function.

The *dwOptions* argument can be used to specify the threading model that is used by the library when a connection is established. By default, the handle is initially attached to the thread that created it. From that point on, until the it is released, only the owner may call functions using that handle. The ownership of the handle may be transferred from one thread to another using the **FtpAttachThread** function.

Specifying the FTP_OPTION_FREETHREAD option enables any thread to call any function using the handle, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the handle is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same handle.

Example

```
// Connect to a server using a standard (non-secure) connection on
// the default port. The username and password are not encrypted.

hClient = FtpConnect(lpszRemoteHost,
                    FTP_PORT_DEFAULT,
                    lpszUserName,
                    lpszPassword,
                    FTP_TIMEOUT,
                    FTP_OPTION_DEFAULT,
                    NULL);

// Connect to a server using the default port and then initiate a
// secure connection using the AUTH TLS command

hClient = FtpConnect(lpszRemoteHost,
                    FTP_PORT_DEFAULT,
                    lpszUserName,
                    lpszPassword,
                    FTP_TIMEOUT,
                    FTP_OPTION_PASSIVE | FTP_OPTION_SECURE_EXPLICIT,
                    NULL);

// Connect to a server on port 990 and immediately initiate a
// secure connection as soon as the connection is established

hClient = FtpConnect(lpszRemoteHost,
                    FTP_PORT_SECURE,
                    lpszUserName,
                    lpszPassword,
                    FTP_TIMEOUT,
                    FTP_OPTION_PASSIVE | FTP_OPTION_SECURE_IMPLICIT,
                    NULL);

// Connect to a server on port 22 using the Secure Shell (SFTP)
// protocol to transfer files

hClient = FtpConnect(lpszRemoteHost,
```

```
FTP_PORT_SSH,  
lpszUserName,  
lpszPassword,  
FTP_TIMEOUT,  
FTP_OPTION_SECURE_SHELL,  
NULL);
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csftpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

FtpConnectUrl Function

```
HCLIENT WINAPI FtpConnectUrl(  
    LPCTSTR lpszURL,  
    UINT nTimeout,  
    DWORD dwOptions  
);
```

The **FtpConnectUrl** function establishes a connection with the specified server using a URL.

Parameters

lpszURL

A pointer to a string which specifies the URL for the server. The URL must follow the conventions for the File Transfer Protocol and may specify either a standard or secure connection, alternate port number, username, password and optional working directory.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
FTP_OPTION_PASSIVE	This option specifies the client should attempt to establish the data connection with the server. When the client uploads or downloads a file, normally the server establishes a second connection back to the client which is used to transfer the file data. However, if the local system is behind a firewall or a NAT router, the server may not be able to create the data connection and the transfer will fail. By specifying this option, it forces the client to establish an outbound data connection with the server. It is recommended that applications use passive mode whenever possible.
FTP_OPTION_FIREWALL	This option specifies the client should always use the host IP address to establish the data connection with the server, not the address returned by the server in response to the PASV command. This option may be necessary if the server is behind a router that performs Network Address Translation (NAT) and it returns an unreachable IP address for the data connection. If this option is specified, it will also enable passive mode data transfers.
FTP_OPTION_NOAUTH	This option specifies the server does not require authentication, or that it requires an alternate authentication method. When this option is used, the client connection is flagged as authenticated as

	<p>soon as the connection to the server has been established. Note that using this option to bypass authentication may result in subsequent errors when attempting to retrieve a directory listing or transfer a file. It is recommended that you consult the technical reference documentation for the server to determine its specific authentication requirements.</p>
FTP_OPTION_KEEPALIVE	<p>This option specifies the client should attempt to keep the connection with the server active for an extended period of time. It is important to note that regardless of this option, the server may still choose to disconnect client sessions that are holding the command channel open but are not performing file transfers.</p>
FTP_OPTION_NOAUTHRSA	<p>This option specifies that RSA authentication should not be used with SSH-1 connections. This option is ignored with SSH-2 connections and should only be specified if required by the server. This option has no effect on standard or secure connections using SSL.</p>
FTP_OPTION_NOPWDNUL	<p>This option specifies the user password cannot be terminated with a null character. This option is ignored with SSH-2 connections and should only be specified if required by the server. This option has no effect on standard or secure connections using SSL.</p>
FTP_OPTION_NOREKEY	<p>This option specifies the client should never attempt a repeat key exchange with the server. Some SSH servers do not support rekeying the session, and this can cause the client to become non-responsive or abort the connection after being connected for an hour. This option has no effect on standard or secure connections using SSL.</p>
FTP_OPTION_COMPATSID	<p>This compatibility option changes how the session ID is handled during public key authentication with older SSH servers. This option should only be specified when connecting to servers that use OpenSSH 2.2.0 or earlier versions. This option has no effect on standard or secure connections using SSL.</p>
FTP_OPTION_COMPATHMAC	<p>This compatibility option changes how the HMAC authentication codes are generated. This option should only be specified when connecting to servers that use OpenSSH 2.2.0 or earlier versions. This option has no effect on standard or secure connections using SSL.</p>

FTP_OPTION_VIRTUALHOST	This option specifies the server supports virtual hosting, where multiple domains are hosted by a server using the same external IP address. If this option is enabled, the client will send the HOST command to the server upon establishing a connection.
FTP_OPTION_VERIFY	This option specifies that file transfers should be automatically verified after the transfer has completed. If the server supports the XMD5 command, the transfer will be verified by calculating an MD5 hash of the file contents. If the server does not support the XMD5 command, but does support the XCRC command, the transfer will be verified by calculating a CRC32 checksum of the file contents. If neither the XMD5 or XCRC commands are supported, the transfer is verified by comparing the size of the file. Automatic file verification is only performed for binary mode transfers because of the end-of-line conversion that may occur when text files are uploaded or downloaded.
FTP_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using either the SSL or TLS protocols.
FTP_OPTION_SECURE	This option specifies the client should attempt to establish a secure connection with the server. This option is the same as specifying FTP_OPTION_SECURE_IMPLICIT which immediately performs the SSL/TLS protocol negotiation when the connection is established.
FTP_OPTION_SECURE_IMPLICIT	This option specifies the client should attempt to immediately establish secure SSL/TLS connection with the server. This option is typically used when connecting to a server on port 990, which is the default port number used for FTPS.
FTP_OPTION_SECURE_EXPLICIT	This option specifies the client should establish a standard connection to the server and then use the AUTH command to negotiate an explicit secure connection. This option is typically used when connecting to the server on ports other than 990.
FTP_OPTION_SECURE_SHELL	This option specifies the client should use the Secure Shell (SSH) protocol to establish the connection. This option will automatically be selected if the connection is established using port 22, the default port for SSH.
FTP_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility

	with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
FTP_OPTION_TUNNEL	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established. This option also forces all connections to be outbound and enables the firewall compatibility features in the client.
FTP_OPTION_KEEPALIVE_DATA	This option specifies the client should attempt to keep the control connection active during a file transfer. Normally, when a data transfer is in progress, no additional commands are issued on the control channel until the transfer completes. Specifying this option automatically enables the FTP_OPTION_KEEPALIVE option and forces the client to continue to issue NOOP commands during the file transfer. This option only applies to FTP and FTPS connections and has no effect on connections using SFTP (SSH).
FTP_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
FTP_OPTION_FREETHREAD	This option specifies the handle returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the handle is synchronized across multiple threads.
FTP_OPTION_HIRES_TIMER	This option specifies the elapsed time for data transfers should be returned in milliseconds instead of seconds. This will return more accurate transfer times for smaller files being uploaded or downloaded using fast network connections.
FTP_OPTION_TLS_REUSE	This option specifies that TLS session reuse should be enabled for secure connections. This option is only supported on Windows 8.1 or Windows Server 2012 R2 and later platforms, and it should only be used when explicitly required by the server. This

option is not compatible with servers built using OpenSSL 1.0.2 and earlier versions which do not provide Extended Master Secret (EMS) support as outlined in RFC7627.
--

Return Value

If the function succeeds, the return value is a handle to a client session. If the function fails, the return value is `INVALID_CLIENT`. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpConnectUrl** function is a high-level function that uses an FTP URL to establish a connection with a server. Unlike the other connection related functions such as **FtpConnect**, this function does more than simply connect to the server. It will also authenticate the client session, change the current working directory and set the default file transfer mode. By default, this function will always place the client in passive mode, ensuring the broadest compatibility with most servers.

The URL must be complete, and specify either a standard or secure FTP scheme:

```
[ftp|ftps|sftp]://[username : password] @[remotehost] [:remoteport] /  
[path / ...] [filename]
```

If no user name and password is provided, then the client session will be authenticated as an anonymous user. If a path is specified as part of the URL, the function will attempt to change the current working directory. The paths in an FTP URL are relative to the home directory of the user account and are not absolute paths starting at the root directory on the server. If a file name is also specified in the URL, it will be ignored and only the file path will be used. The URL scheme will always determine if the connection is secure, not the option. In other words, if the "ftp" scheme is used and the `FTP_OPTION_SECURE` option is specified, that option will be ignored. To establish a secure connection, either the "ftps" or "sftp" scheme must be specified.

The **FtpConnectUrl** function is designed to provide a simpler, more convenient interface to establishing a connection with a server. However, complex connections such as those using a proxy server or a secure connection which uses a client certificate will require the program to use the lower-level connection functions. If you only need to upload or download a file using a URL, then refer to the **FtpUploadFile** and **FtpDownloadFile** functions.

The *dwOptions* argument can be used to specify the threading model that is used by the library when a connection is established. By default, the handle is initially attached to the thread that created it. From that point on, until the it is released, only the owner may call functions using that handle. The ownership of the handle may be transferred from one thread to another using the **FtpAttachThread** function.

Specifying the `FTP_OPTION_FREETHREAD` option enables any thread to call any function using the handle, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the handle is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same handle.

Example

```
HCLIENT hClient;  
LPCTSTR lpszURL = _T("ftp://ftp.sockettools.com/pub/");  
  
// Connect to the site specified by the URL
```

```
hClient = FtpConnectUrl(lpszURL, FTP_TIMEOUT, FTP_OPTION_DEFAULT);

if (hClient == INVALID_CLIENT)
{
    TCHAR szError[128];

    // Display a message box that describes the error
    FtpGetErrorString(FtpGetLastError(), szError, 128);
    MessageBox(NULL, szError, NULL, MB_ICONEXCLAMATION|MB_TASKMODAL);
    return;
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csftpv10.lib

FtpCreateDirectory Function

```
INT WINAPI FtpCreateDirectory(  
    HCLIENT hClient,  
    LPCTSTR lpszDirectory  
);
```

The **FtpCreateDirectory** function creates the specified directory on the server.

Parameters

hClient

Handle to the client session.

lpszDirectory

Points to a string that specifies the name of the directory. The file pathing and name conventions must be that of the server.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

This function uses the MKD command to create the directory. The user must have the appropriate permission to create the specified directory.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

FtpCreateSecurityCredentials Function

```
BOOL WINAPI FtpCreateSecurityCredentials(  
    DWORD dwProtocol,  
    DWORD dwOptions,  
    LPCTSTR lpszUserName,  
    LPCTSTR lpszPassword,  
    LPCTSTR lpszCertStore,  
    LPCTSTR lpszCertName,  
    LPVOID lpvReserved,  
    LPSECURITYCREDENTIALS* lppCredentials  
);
```

The **FtpCreateSecurityCredentials** function creates a **SECURITYCREDENTIALS** structure.

Parameters

dwProtocol

A bitmask of supported security protocols. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_SSL	Either SSL 2.0 or SSL 3.0 should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, TLS will be excluded from the list of supported protocols. Both SSL 2.0 and 3.0 have been deprecated and will never be used unless explicitly specified. It is not recommended that you enable either of these protocols for secure connections because it will cause most servers to reject your connection request, even if a version of TLS is also specified.
SECURITY_PROTOCOL_TLS	Either the TLS 1.0, 1.1 or 1.2 protocol should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers that reject any attempt to use the older SSL protocol and require that only TLS be used.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol should be used when establishing a secure connection. This version is

	supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This is the recommended version of TLS to use with secure connections.
SECURITY_PROTOCOL_SSH	Either version 1.0 or 2.0 of the Secure Shell protocol should be used when establishing the connection. The correct protocol is automatically selected based on the version of the protocol that is supported by the server.
SECURITY_PROTOCOL_SSH1	The Secure Shell 1.0 protocol should be used when establishing the connection. This is an older version of the protocol which should not be used unless explicitly required by the server. Most modern SSH server support version 2.0 of the protocol.
SECURITY_PROTOCOL_SSH2	The Secure Shell 2.0 protocol should be used when establishing the connection. This is the default version of the protocol that is supported by most SSH servers.

dwOptions

A value which specifies one or options. This value should always be zero for connections using SSH. This member is constructed by using a bitwise operator with any of the following values:

Constant	Description
CREDENTIAL_STORE_CURRENT_USER	The library will attempt to open a store for the current user using the certificate store name provided in this structure. If no options are specified, then this is the default behavior.
CREDENTIAL_STORE_LOCAL_MACHINE	The library will attempt to open a local

	machine store using the certificate store name provided in this structure. If this option is specified, the library will always search for a local machine store before searching for the store by that name for the current user.
CREDENTIAL_STORE_FILENAME	The certificate store name is a file that contains the certificate and private key that will be used.

lpszUserName

A pointer to a string which specifies the certificate owner's username. A value of NULL specifies that no username is required. Currently this parameter is not used and any value specified will be ignored.

lpszPassword

A pointer to a string which specifies the certificate owner's password. A value of NULL specifies that no password is required. This parameter is only used if a PKCS12 (PFX) certificate file is specified and that certificate has been secured with a password. This value will be ignored the current user or local machine certificate store is specified.

lpszCertStore

A pointer to a string which specifies the name of the certificate store to open. A certificate store is a collection of certificates and their private keys, typically organized by how they are used. If this value is NULL or points to an empty string, the default certificate store "MY" will be used.

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as VeriSign and Thawte act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. This corresponds to the "Personal" store that is displayed by the certificate manager utility and is the default store used by the library.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as VeriSign and Thawte are installed as part of the operating system and periodically updated by Microsoft.

lpszCertName

A pointer to a null terminated string which specifies the name of the certificate to use. The function will first search the certificate store for a certificate with a matching "friendly name"; this is a name for the certificate that is assigned by the user. Note that the name must match completely, but the comparison is not case sensitive. If no matching certificate is found, the function will then attempt to find a certificate that has a matching common name (also called the certificate subject). This comparison is less stringent, and the first partial match will be returned. If this second search fails, the function will return an error indicating that the certificate could not be found.

lpvReserved

Pointer reserved for future use. Set it to NULL when using this function.

lppCredentials

Pointer to an [LPSECURITYCREDENTIALS](#) pointer. The memory for the credentials structure will be allocated by this function and must be released by calling the **FtpDeleteSecurityCredentials** function when it is no longer needed. The pointer value must be set to NULL before the function is called. It is important to note that this is a pointer to a pointer variable, not a pointer to the SECURITYCREDENTIALS structure itself.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **FtpGetLastError**.

Remarks

The structure that is created by this function may be used as client credentials when establishing a secure connection. This is particularly useful for programming languages other than C/C++ which may not support C structures or pointers. The pointer to the SECURITYCREDENTIALS structure can be declared as an unsigned integer variable which is passed by reference to this function, and then passed by value to the **FtpAsyncConnect** or **FtpConnect** functions.

Example

```
LPSECURITYCREDENTIALS lpSecCred = NULL;
FtpCreateSecurityCredentials(SEcurity_PROTOCOL_DEFAULT,
                             CREDENTIAL_STORE_CURRENT_USER,
                             NULL,
                             NULL,
                             strCertStore,
                             strCertName,
                             NULL,
                             &lpSecCred);
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cstools10.h

Import Library: csWSKV10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

FtpDeleteFile Function

```
INT WINAPI FtpDeleteFile(  
    HCLIENT hClient,  
    LPCTSTR lpszFileName  
);
```

The **FtpDeleteFile** function deletes the specified file from the server.

Parameters

hClient

Handle to the client session.

lpszFileName

Points to a string that specifies the name of the remote file to delete. The file pathing and name conventions must be that of the server.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The current user must have the appropriate permission to delete the file, or an error will be returned by the server.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

FtpDeleteSecurityCredentials Function

```
VOID WINAPI FtpDeleteSecurityCredentials(  
    LPSECURITYCREDENTIALS *LppCredentials  
);
```

The **FtpDeleteSecurityCredentials** function deletes an existing **SECURITYCREDENTIALS** structure.

Parameters

lppCredentials

Pointer to an **LPSECURITYCREDENTIALS** pointer. On exit from the function, the pointer will be NULL.

Return Value

None.

Example

```
if (lpSecCred)  
    FtpDeleteSecurityCredentials(&lpSecCred);  
FtpUninitialize();
```

Remarks

This function can be used to release the memory allocated to the client or server credentials after a secure connection has been terminated.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

FtpDisableEvents Function

```
INT WINAPI FtpDisableEvents(  
    HCLIENT hClient  
);
```

The **FtpDisableEvents** function disables the event notification mechanism, preventing subsequent event notification messages from being posted to the application's message queue.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpDisableEvents** function is used to disable event message posting for the specified client session. Although this will immediately prevent any new events from being generated, it is possible that messages could be waiting in the message queue. Therefore, an application must be prepared to handle client event messages after this function has been called.

This function is automatically called if the client has event notification enabled, and the **FtpDisconnect** function is called. The same issues regarding outstanding event messages also applies in this situation, requiring that the application handle event messages that may reference a client handle that is no longer valid.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

FtpDisableTrace Function

```
BOOL WINAPI FtpDisableTrace();
```

The **FtpDisableTrace** function disables the logging of socket function calls to the trace log.

Parameters

None.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, a value of zero is returned.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csftpv10.lib

See Also

[FtpEnableTrace](#)

FtpDisconnect Function

```
INT WINAPI FtpDisconnect(  
    HCLIENT hClient  
);
```

The **FtpDisconnect** function terminates the connection with the server, closing the socket and releasing the memory allocated for the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

FtpDownloadFile Function

```
BOOL WINAPI FtpDownloadFile(  
    LPCTSTR lpszLocalFile,  
    LPCTSTR lpszFileURL,  
    UINT nTimeout  
    DWORD dwOptions  
    LPFTPTRANSFERSTATUS lpStatus  
    FTPEVENTPROC lpEventProc  
    DWORD_PTR dwParam  
);
```

The **FtpDownloadFile** function downloads the specified file from the server to the local system.

Parameters

lpszLocalFile

A pointer to a string that specifies the file on the local system that will be created, overwritten or appended to. The file pathing and name conventions must be that of the local host.

lpszFileURL

A pointer to a string that specifies the complete URL of the file to be downloaded. The URL must follow the conventions for the File Transfer Protocol and may specify either a standard or secure connection, alternate port number, username, password and optional working directory.

nTimeout

The number of seconds that the client will wait for a response before failing the operation. A value of zero specifies that the default timeout period of sixty seconds will be used.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
FTP_OPTION_PASSIVE	This option specifies the client should attempt to establish the data connection with the server. When the client uploads or downloads a file, normally the server establishes a second connection back to the client which is used to transfer the file data. However, if the local system is behind a firewall or a NAT router, the server may not be able to create the data connection and the transfer will fail. By specifying this option, it forces the client to establish an outbound data connection with the server. It is recommended that applications use passive mode whenever possible.
FTP_OPTION_FIREWALL	This option specifies the client should always use the host IP address to establish the data connection with the server, not the address returned by the server in response to the PASV command. This option may be necessary if the server is behind a router that performs Network Address Translation (NAT) and it returns an unreachable IP address for the data

	connection. If this option is specified, it will also enable passive mode data transfers.
FTP_OPTION_SECURE	This option specifies the client should attempt to establish a secure connection with the server. Note that the server must support secure connections using either the SSL or TLS protocol.
FTP_OPTION_SECURE_EXPLICIT	This option specifies the client should use the AUTH command to negotiate an explicit secure connection. Some servers may only require this when connecting to the server on ports other than 990.

lpStatus

A pointer to an FTPTRANSFERSTATUS structure which contains information about the status of the current file transfer. If this information is not required, a NULL pointer may be specified as the parameter.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **FtpEventProc** callback function. If this parameter is NULL, the callback for the specified event is disabled.

dwParam

A user-defined integer value that is passed to the callback function.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpDownloadFile** function provides a convenient way for an application to download a file in a single function call. Based on the connection information specified in the URL, it will connect to the server, authenticate the session, change the current working directory if necessary and then download the file to the local system. The URL must be complete, and specify either a standard or secure FTP scheme:

```
[ftp|ftps|sftp]://[username : password] @[remotehost] [:remoteport] /
[path / ...] [filename] [;type=a|i]
```

If no user name and password is provided, then the client session will be authenticated as an anonymous user. If a path is specified as part of the URL, the function will attempt to change the current working directory. Note that the path in an FTP URL is relative to the home directory of the user account and is not an absolute path starting at the root directory on the server. The URL scheme will always determine if the connection is secure, not the option. In other words, if the "ftp" scheme is used and the FTP_OPTION_SECURE option is specified, that option will be ignored. To establish a secure connection, either the "ftps" or "sftp" scheme must be specified.

The optional "type" value at the end of the file name determines if the file should be downloaded as a text or binary file. A value of "a" specifies that the file should be downloaded as a text file. A value of "i" specifies that the file should be downloaded as a binary file. If the type is not explicitly specified, the file will be downloaded as a binary file.

The *lpStatus* parameter can be used by the application to determine the final status of the transfer, including the total number of bytes copied, the amount of time elapsed and other

information related to the transfer process. If this information isn't needed, then this parameter may be specified as NULL.

The *lpEventProc* parameter specifies a pointer to a function which will be periodically called during the file transfer process. This can be used to check the status of the transfer by calling **FtpGetTransferStatus** and then update the program's user interface. For example, the callback function could calculate the percentage for how much of the file has been transferred and then update a progress bar control. The *dwParam* parameter is used in conjunction with the event handler and specifies a user-defined value that is passed to the callback function. One common use in a C++ program is to pass the *this* pointer as the value, and then cast it back to an object pointer inside the callback function. If no event handler is required, then a NULL pointer can be specified as the value for *lpEventProc* and the *dwParam* parameter will be ignored.

The **FtpDownloadFile** function is designed to provide a simpler interface for downloading a file. However, complex connections such as those using a proxy server or a secure connection which uses a client certificate will require the program to establish the connection using **FtpConnect** and then use **FtpGetFile** to download the file.

Example

```
FTPTRANSFERSTATUS ftpStatus;
LPCTSTR lpszLocalFile = _T("c:\\temp\\database.mdb");
LPCTSTR lpszFileURL = _T("ftp://ftp.example.com/updates/database.mdb");
BOOL bResult;

// Download the file using the specified URL
bResult = FtpDownloadFile(lpszLocalFile,
                          lpszFileURL,
                          FTP_OPTION_PASSIVE,
                          &ftpStatus,
                          NULL, 0);

if (!bResult)
{
    TCHAR szError[128];

    // Display a message box that describes the error
    FtpGetErrorString(FtpGetLastError(), szError, 128);
    MessageBox(NULL, szError, NULL, MB_ICONEXCLAMATION|MB_TASKMODAL);
    return;
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

FtpDownloadFileEx Function

```
BOOL WINAPI FtpDownloadFileEx(  
    LPCTSTR lpszLocalFile,  
    LPCTSTR lpszFileURL,  
    UINT nTimeout  
    DWORD dwOptions  
    LPFTPTRANSFERSTATUSEX lpStatus  
    FTPEVENTPROC lpEventProc  
    DWORD_PTR dwParam  
);
```

The **FtpDownloadFileEx** function downloads the specified file from the server to the local system. This version of the function is designed to support files that are larger than 4GB.

Parameters

lpszLocalFile

A pointer to a string that specifies the file on the local system that will be created, overwritten or appended to. The file pathing and name conventions must be that of the local host.

lpszFileURL

A pointer to a string that specifies the complete URL of the file to be downloaded. The URL must follow the conventions for the File Transfer Protocol and may specify either a standard or secure connection, alternate port number, username, password and optional working directory.

nTimeout

The number of seconds that the client will wait for a response before failing the operation. A value of zero specifies that the default timeout period of sixty seconds will be used.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
FTP_OPTION_PASSIVE	This option specifies the client should attempt to establish the data connection with the server. When the client uploads or downloads a file, normally the server establishes a second connection back to the client which is used to transfer the file data. However, if the local system is behind a firewall or a NAT router, the server may not be able to create the data connection and the transfer will fail. By specifying this option, it forces the client to establish an outbound data connection with the server. It is recommended that applications use passive mode whenever possible.
FTP_OPTION_FIREWALL	This option specifies the client should always use the host IP address to establish the data connection with the server, not the address returned by the server in response to the PASV command. This option may be necessary if the server is behind a router that performs Network Address Translation (NAT) and it

	returns an unreachable IP address for the data connection. If this option is specified, it will also enable passive mode data transfers.
FTP_OPTION_SECURE	This option specifies the client should attempt to establish a secure connection with the server. Note that the server must support secure connections using either the SSL or TLS protocol.
FTP_OPTION_SECURE_EXPLICIT	This option specifies the client should use the AUTH command to negotiate an explicit secure connection. Some servers may only require this when connecting to the server on ports other than 990.

lpStatus

A pointer to an FTPTRANSFERSTATUSEX structure which contains information about the status of the current file transfer. If this information is not required, a NULL pointer may be specified as the parameter.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **FtpEventProc** callback function. If this parameter is NULL, the callback for the specified event is disabled.

dwParam

A user-defined integer value that is passed to the callback function.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpDownloadFileEx** function provides a convenient way for an application to download a file in a single function call. Based on the connection information specified in the URL, it will connect to the server, authenticate the session, change the current working directory if necessary and then download the file to the local system. The URL must be complete, and specify either a standard or secure FTP scheme:

```
[ftp|ftps|sftp]://[username : password] @] remotehost [:remoteport] /
[path / ...] [filename] [;type=a|i]
```

If no user name and password is provided, then the client session will be authenticated as an anonymous user. If a path is specified as part of the URL, the function will attempt to change the current working directory. Note that the path in an FTP URL is relative to the home directory of the user account and is not an absolute path starting at the root directory on the server. The URL scheme will always determine if the connection is secure, not the option. In other words, if the "ftp" scheme is used and the FTP_OPTION_SECURE option is specified, that option will be ignored. To establish a secure connection, either the "ftps" or "sftp" scheme must be specified.

The optional "type" value at the end of the file name determines if the file should be downloaded as a text or binary file. A value of "a" specifies that the file should be downloaded as a text file. A value of "i" specifies that the file should be downloaded as a binary file. If the type is not explicitly specified, the file will be downloaded as a binary file.

The *lpStatus* parameter can be used by the application to determine the final status of the

transfer, including the total number of bytes copied, the amount of time elapsed and other information related to the transfer process. If this information isn't needed, then this parameter may be specified as NULL.

The *lpEventProc* parameter specifies a pointer to a function which will be periodically called during the file transfer process. This can be used to check the status of the transfer by calling **FtpGetTransferStatusEx** and then update the program's user interface. For example, the callback function could calculate the percentage for how much of the file has been transferred and then update a progress bar control. The *dwParam* parameter is used in conjunction with the event handler and specifies a user-defined value that is passed to the callback function. One common use in a C++ program is to pass the *this* pointer as the value, and then cast it back to an object pointer inside the callback function. If no event handler is required, then a NULL pointer can be specified as the value for *lpEventProc* and the *dwParam* parameter will be ignored.

The **FtpDownloadFileEx** function is designed to provide a simpler interface for downloading a file. However, complex connections such as those using a proxy server or a secure connection which uses a client certificate will require the program to establish the connection using **FtpConnect** and then use **FtpGetFileEx** to download the file.

Example

```
FTPTRANSFERSTATUSEX ftpStatus;
LPCTSTR lpszLocalFile = _T("c:\\temp\\database.mdb");
LPCTSTR lpszFileURL = _T("ftp://ftp.example.com/updates/database.mdb");
BOOL bResult;

// Download the file using the specified URL
bResult = FtpDownloadFileEx(lpszLocalFile,
                           lpszFileURL,
                           FTP_OPTION_PASSIVE,
                           &ftpStatus,
                           NULL, 0);

if (!bResult)
{
    TCHAR szError[128];

    // Display a message box that describes the error
    FtpGetErrorString(FtpGetLastError(), szError, 128);
    MessageBox(NULL, szError, NULL, MB_ICONEXCLAMATION|MB_TASKMODAL);
    return;
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csftpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

FtpEnableEvents Function

```
INT WINAPI FtpEnableEvents(  
    HCLIENT hClient,  
    HWND hEventWnd,  
    UINT uEventMsg  
);
```

The **FtpEnableEvents** function enables event notifications using Windows messages.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Applications should use the **FtpRegisterEvent** function to register an event handler which is invoked when an event occurs.

Parameters

hClient

Handle to the client session.

hEventWnd

Handle to the window which will receive the client notification messages. This parameter must specify a valid window handle. If a NULL handle is specified, event notification will be disabled.

uEventMsg

The message that is received when a client event occurs. This value must be greater than 1024.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpEnableEvents** function is used to request that notification messages be posted to the specified window whenever a client event occurs. This allows an application to monitor the status of different client operations, such as a file transfer.

The *wParam* argument will contain the client handle, the low word of the *lParam* argument will contain the event ID, and the high word will contain any error code. If no error has occurred, the high word will always have a value of zero. The following events may be generated:

Constant	Description
FTP_EVENT_CONNECT	The control connection to the server has completed. The high word of the <i>lParam</i> parameter should be checked, since this notification message will be posted if an error has occurred.
FTP_EVENT_DISCONNECT	The server has closed the control connection to the client. The client should read any remaining data and disconnect.
FTP_EVENT_OPENFILE	The data connection to the server has completed. The high word of the <i>lParam</i> parameter should be checked, since this notification message will be posted if an error has occurred.
FTP_EVENT_CLOSEFILE	The server has closed the data connection to the client. The client

	should read any remaining data and close the data channel.
FTP_EVENT_READFILE	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
FTP_EVENT_WRITEFILE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
FTP_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
FTP_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.
FTP_EVENT_COMMAND	A command has been issued by the client and the server response has been received and processed. This event can be used to log the result codes and messages returned by the server in response to actions taken by the client.
FTP_EVENT_PROGRESS	The client is in the process of sending or receiving a file on the data channel. This event is called periodically during a transfer so that the client can update any user interface components such as a status control or progress bar.
FTP_EVENT_GETFILE	This event is generated when a file download has completed. If multiple files are being downloaded, this event will be generated for each file.
FTP_EVENT_PUTFILE	This event is generated when a file upload has completed. If multiple files are being uploaded, this event will be generated for each file.

It is not required that the client be placed in asynchronous mode in order to receive command and progress event notifications. To disable event notification, call the **FtpDisableEvents** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csftpv10.lib

FtpEnableFeature Function

```
BOOL WINAPI FtpEnableFeature(  
    HCLIENT hClient,  
    DWORD dwFeature,  
    BOOL bEnable  
);
```

The **FtpEnableFeature** function enables or disables a specific server feature available to the client.

Parameters

hClient

Handle to the client session.

dwFeature

An unsigned integer which specifies the feature to be enabled to disabled for the current client session. Refer to the documentation for the **FtpGetFeatures** function for a list of available features.

bEnable

A boolean flag which specifies if the feature should be enabled or disabled. If the value is non-zero, the library will attempt to use that feature on the server. If the value is zero, the feature is disabled. If an application calls a function which requires a specific feature and that feature is disabled, the function will fail with an error indicating the feature is not supported.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it will return a value of zero. To get extended error information, call the **FtpGetLastError** function.

Remarks

The **FtpEnableFeature** function is used to enable or disable a specific feature for the current session. When a client connection is first established, features are enabled based on the server type and the server's response to the FEAT command. However, as the client issues commands to the server, if the server reports that the command is unrecognized that feature will automatically be disabled in the client. An application can use the **FtpEnableFeature** function to control what commands will be sent to the server, or re-enable a command that was previously disabled.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftpv10.lib

FtpEnableTrace Function

```
BOOL WINAPI FtpEnableTrace(  
    LPCTSTR lpszTraceFile,  
    DWORD dwTraceFlags  
);
```

The **FtpEnableTrace** function enables the logging of socket function calls to a file.

Parameters

lpszTraceFile

A pointer to a string which specifies the name of the trace log file. If this parameter is NULL or an empty string, the default file name **cstrace.log** is used. The file is stored in the directory specified by the TEMP environment variable, if it is defined; otherwise, the current working directory is used.

dwTraceFlags

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
TRACE_INFO	All function calls are written to the trace file. This is the default value.
TRACE_ERROR	Only those function calls which fail are recorded in the trace file.
TRACE_WARNING	Only those function calls which fail or return values which indicate a warning are recorded in the trace file.
TRACE_HEXDUMP	All functions calls are written to the trace file, plus all the data that is sent or received is displayed, in both ASCII and hexadecimal format.
TRACE_PROCESS	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for multithreaded applications that are using worker threads.

Return Value

If the function succeeds, the return value is non-zero. A return value of zero indicates an error. Failure typically indicates that the tracing library **cstrcv10.dll** cannot be loaded on the local system.

Remarks

When trace logging is enabled, the file is opened, appended to and closed for each socket function call. This makes it possible for an application to append its own logging information, however care should be taken to ensure that the file is closed before the next network operation is performed. To limit the size of the log files, enable and disable logging only around those sections of code that you wish to trace.

Note that the TRACE_HEXDUMP trace level generates very large log files since it includes all of the data exchanged between your application and the server.

Trace function logging is managed on a per-thread basis, not for each client handle. This means that all SocketTools libraries and components share the same settings in the current thread. If you

are using multiple SocketTools libraries or components in your application, you only need to enable logging once.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csftpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

FtpEndOfFile Function

```
BOOL WINAPI FtpEndOfFile(  
    HCLIENT hClient  
);
```

The **FtpEndOfFile** function is used to determine if the end-of-file has been reached while reading the contents of a remote file.

Parameters

hClient

Handle to the client session.

Return Value

If the end-of-file has been reached, the function returns a non-zero value. If the client handle is invalid, or the end-of-file has not been reached, the function returns zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csftpv10.lib

FtpEnumFiles Function

```
INT WINAPI FtpEnumFiles(  
    HCLIENT hClient,  
    LPCTSTR lpszDirectory,  
    LPCTSTR lpszFileMask,  
    DWORD dwOptions,  
    LPFTPFILESTATUS lpFileList,  
    INT nMaxFiles  
);
```

The **FtpEnumFilesEx** function populates an array of structures that contain information about the files in a directory.

Parameters

hClient

Handle to the client session.

lpszDirectory

A pointer to a string that specifies the name of a directory on the server. If this parameter is NULL or points to an empty string, the function will return the files in the current working directory. This string cannot contain wildcard characters and must specify a valid directory name that exists on the server.

lpszFileMask

A pointer to a string that specifies a wildcard file mask that is used to return a subset of files in the directory. If this parameter is NULL or an empty string then all of the files in the directory will be returned.

dwOptions

An unsigned integer value that specifies one or more options. This parameter can be a combination of one or more of the following values:

Constant	Description
FTP_ENUM_DEFAULT	The function will return both regular files and subdirectories.
FTP_ENUM_FILE	The function will return only regular files.
FTP_ENUM_DIRECTORY	The function will return only subdirectories.
FTP_ENUM_FULLPATH	The function will return the full path of the file or subdirectory.

lpFileList

A pointer to an array of [FTPFILESTATUS](#) structures which contains information about each of the files in the specified directory. This parameter cannot be NULL, and the array must be large enough to store the number of files specified by the *nMaxFiles* parameter.

nMaxFiles

An integer value that specifies the maximum number of files that should be returned. This value must be greater than zero and the *lpFileList* parameter must provide an array that is large enough to store information about each file.

Return Value

If the function succeeds, the return value is the number of files returned by the function. If the directory is empty or there are no files that match the specified wildcard file mask, the function will return zero. If the function fails, the return value is `FTP_ERROR`. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpEnumFiles** function provides a high-level interface for obtaining a list of available files in a directory on the server in a single function call. This is an alternative to opening a directory and returning information about each file by calling the **FtpGetNextFile** function in a loop.

This function temporarily changes the current working directory to the directory specified by the *lpSzDirectory* parameter. The current working directory will be restored to its original value when the function returns. The user must have the appropriate permissions to access the directory or this function will fail.

To obtain information on a subset of files in the directory, you can specify a wildcard file mask. For FTP and FTPS (SSL) sessions, this value is passed as a parameter to the LIST command and the server performs the wildcard matching. For SFTP (SSH) sessions the wildcard matching is performed by the library, and the standard conventions for Windows file wildcards are used.

By default, the *szFileName* member for each **FTPFILESTATUS** structure will contain the base file name. If the `FTP_ENUM_FULLPATH` option is specified, the function will return the full path name to the file. The library must be able to automatically determine the path delimiter that is used by the server. This is done by examining how the server identifies itself, the current directory format and the path the server returns for the current working directory. For example, UNIX based servers use the forward slash as a path delimiter. If the function cannot determine what the appropriate path delimiter is, it will ignore this option and return only the base file name.

This function will cause the current thread to block until the file listing completes, a timeout occurs or the operation is canceled. If the directory contains files that are larger than 4GB, the **FtpEnumFilesEx** function should be used to obtain the correct file size.

Example

```
LPFTPFILESTATUS lpFileList = new FTPFILESTATUS[MAXFILECOUNT];

// Return all of the regular files in the current working directory
INT nResult = FtpEnumFiles(hClient, NULL, NULL, FTP_ENUM_FILE,
                          lpFileList, MAXFILECOUNT);

if (nResult == FTP_ERROR)
{
    DWORD dwError = FtpGetLastError();
    _tprintf(_T("FtpEnumFiles failed, error 0x%08lx\n"), dwError);
    return;
}

_tprintf(_T("FtpEnumFiles returned %d files\n"), nResult);
for (INT nIndex = 0; nIndex < nResult; nIndex++)
{
    _tprintf(_T("file=\"%s\" size=%lu\n"), lpFileList[nIndex].szFileName,
            lpFileList[nIndex].dwFileSize);
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csftpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[FtpEnumFilesEx](#), [FtpGetFileStatus](#), [FtpGetFirstFile](#), [FtpGetNextFile](#), [FtpOpenDirectory](#)

FtpEnumFilesEx Function

```
INT WINAPI FtpEnumFilesEx(  
    HCLIENT hClient,  
    LPCTSTR lpszDirectory,  
    LPCTSTR lpszFileMask,  
    DWORD dwOptions,  
    LPFTPFILESTATUSEX lpFileList,  
    INT nMaxFiles  
);
```

The **FtpEnumFilesEx** function populates an array of structures that contain information about the files in a directory. This version of the function is designed to support files that are larger than 4GB.

Parameters

hClient

Handle to the client session.

lpszDirectory

A pointer to a string that specifies the name of a directory on the server. If this parameter is NULL or points to an empty string, the function will return the files in the current working directory. This string cannot contain wildcard characters and must specify a valid directory name that exists on the server.

lpszFileMask

A pointer to a string that specifies a wildcard file mask that is used to return a subset of files in the directory. If this parameter is NULL or an empty string then all of the files in the directory will be returned.

dwOptions

An unsigned integer value that specifies one or more options. This parameter can be a combination of one or more of the following values:

Constant	Description
FTP_ENUM_DEFAULT	The function will return both regular files and subdirectories.
FTP_ENUM_FILE	The function will return only regular files.
FTP_ENUM_DIRECTORY	The function will return only subdirectories.
FTP_ENUM_FULLPATH	The function will return the full path of the file or subdirectory.

lpFileList

A pointer to an array of [FTPFILESTATUSEX](#) structures which contains information about each of the files in the specified directory. This parameter cannot be NULL, and the array must be large enough to store the number of files specified by the *nMaxFiles* parameter.

nMaxFiles

An integer value that specifies the maximum number of files that should be returned. This value must be greater than zero and the *lpFileList* parameter must provide an array that is large enough to store information about each file.

Return Value

If the function succeeds, the return value is the number of files returned by the function. If the directory is empty or there are no files that match the specified wildcard file mask, the function will return zero. If the function fails, the return value is `FTP_ERROR`. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpEnumFilesEx** function provides a high-level interface for obtaining a list of available files in a directory on the server in a single function call. This is an alternative to opening a directory and returning information about each file by calling the **FtpGetNextFileEx** function in a loop.

This function temporarily changes the current working directory to the directory specified by the *lpzDirectory* parameter. The current working directory will be restored to its original value when the function returns. The user must have the appropriate permissions to access the directory or this function will fail.

To obtain information on a subset of files in the directory, you can specify a wildcard file mask. For FTP and FTPS (SSL) sessions, this value is passed as a parameter to the LIST command and the server performs the wildcard matching. For SFTP (SSH) sessions the wildcard matching is performed by the library, and the standard conventions for Windows file wildcards are used.

By default, the *szFileName* member for each **FTPFILESTATUSEX** structure will contain the base file name. If the `FTP_ENUM_FULLPATH` option is specified, the function will return the full path name to the file. The library must be able to automatically determine the path delimiter that is used by the server. This is done by examining how the server identifies itself, the current directory format and the path the server returns for the current working directory. For example, UNIX based servers use the forward slash as a path delimiter. If the function cannot determine what the appropriate path delimiter is, it will ignore this option and return only the base file name.

This function will cause the current thread to block until the file listing completes, a timeout occurs or the operation is canceled.

Example

```
LPFTPFILESTATUSEX lpFileList = new FTPFILESTATUSEX[MAXFILECOUNT];

// Return all of the regular files in the current working directory
INT nResult = FtpEnumFilesEx(hClient, NULL, NULL, FTP_ENUM_FILE,
                             lpFileList, MAXFILECOUNT);

if (nResult == FTP_ERROR)
{
    DWORD dwError = FtpGetLastError();
    _tprintf(_T("FtpEnumFilesEx failed, error 0x%08lx\n"), dwError);
    return;
}

_tprintf(_T("FtpEnumFilesEx returned %d files\n"), nResult);
for (INT nIndex = 0; nIndex < nResult; nIndex++)
{
    _tprintf(_T("file=\"%s\" size=%I64d\n"), lpFileList[nIndex].szFileName,
            lpFileList[nIndex].uiFileSize);
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: csftpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

FtpEnumTasks Function

```
INT WINAPI FtpEnumTasks(  
    UINT * lpTasks,  
    INT nMaxTasks,  
    DWORD dwOptions  
);
```

Return a list of active, suspended or finished asynchronous tasks.

Parameters

lpTasks

A pointer to an array of unsigned integer values that will contain unique task identifiers when the function returns. If this parameter is NULL, the function will return the number of tasks.

nMaxTasks

An integer value that specifies the maximum number of task identifiers that may be copied into the *lpTasks* array. If the *lpTasks* parameter is NULL, this value must be zero.

dwOptions

An unsigned integer that specifies the type of asynchronous tasks that may be returned by this function. It may be a combination of the following values:

Constant	Description
FTP_TASK_DEFAULT	The list of asynchronous task IDs should include both active and suspended tasks. This option is the same as specifying both the FTP_TASK_ACTIVE and FTP_TASK_SUSPENDED options.
FTP_TASK_ACTIVE	The list of asynchronous task IDs should include those tasks which are currently active. An active task represents a background connection to a server that is in the process of performing the requested action, such as uploading or downloading a file.
FTP_TASK_SUSPENDED	The list of asynchronous task IDs should include those tasks which have been suspended. A suspended task represents a background connection that has been established, but the worker thread is not scheduled for execution.
FTP_TASK_FINISHED	The list of asynchronous task IDs should include those tasks which have completed recently.

Return Value

If the function is successful, the return value is the number of task identifiers copied into the provided array. If there are no tasks which match the requested criteria, the return value is zero. A return value of FTP_ERROR indicates an error has occurred. To get extended error information, call the **FtpGetLastError** function.

Remarks

The **FtpEnumTasks** function can be used to obtain a list of numeric identifiers that represent the asynchronous tasks that have been started or those that have completed. These task IDs are used by other functions to reference the background worker thread that has been created and obtain

status information for the task. For example, the **FtpTaskDone** function can be used to determine if a particular task has completed, and the **FtpTaskWait** function can be used to wait for a task to complete and return an error status code if the background operation failed.

There is an internal limit of 128 asynchronous tasks per process that may be active at any one time. When a task completes, the status information about that task is maintained for period of time after the task has completed.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csftpv10.lib

FtpEventProc Function

```
VOID CALLBACK FtpEventProc(  
    HCLIENT hClient,  
    UINT nEventId,  
    DWORD dwError,  
    DWORD_PTR dwParam  
);
```

The **FtpEventProc** function is an application-defined callback function that processes events generated by the client.

Parameters

hClient

Handle to the client session.

nEventId

An unsigned integer which specifies which event occurred. For a complete list of events, refer to the **FtpRegisterEvent** function.

dwError

An unsigned integer which specifies any error that occurred. If no error occurred, then this parameter will be zero.

dwParam

A user-defined integer value which was specified when the event callback was registered.

Return Value

None.

Remarks

An application must register this callback function by passing its address to the **FtpRegisterEvent** function. This callback function is also used by asynchronous tasks to notify the application when the task has started and completed. The **FtpEventProc** function is a placeholder for the application-defined function name.

If the callback function is invoked by an asynchronous task, it will execute in the context of the worker thread that is managing the client session. You must ensure that any access to global or static variables are synchronized, otherwise the results may be unpredictable. It is recommended that you do not declare any static variables within the callback function itself.

If the application has a graphical user interface, you should never attempt to directly modify a UI control from within the callback function for an asynchronous task. Controls should only be modified by the same UI thread that created their window. One common approach to resolve this issue is to post a user-defined message to the main window to signal that the user interface needs to be updated. The message handler would then process the user-defined message and update the user interface as needed.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftpv10.lib

See Also

[FtpDisableEvents](#), [FtpEnableEvents](#), [FtpFreezeEvents](#), [FtpRegisterEvent](#)

Copyright © 2023 Catalyst Development Corporation. All rights reserved.

FtpFreezeEvents Function

```
INT WINAPI FtpFreezeEvents(  
    HCLIENT hClient,  
    BOOL bFreeze  
);
```

The **FtpFreezeEvents** function is used to suspend and resume event handling by the client.

Parameters

hClient

Handle to the client session.

bFreeze

A non-zero value specifies that event handling should be suspended by the client. A zero value specifies that event handling should be resumed.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

This function should be used when the application does not want to process events, such as when a modal dialog is being displayed. When events are suspended, all client events are queued. If events are re-enabled at a later point, those queued events will be sent to the application for processing. Note that only one of each event will be generated. For example, if the client has suspended event handling, and four read events occur, once event handling is resumed only one of those read events will be posted to the client. This prevents the application from being flooded by a potentially large number of queued events.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

FtpGetActivePorts Function

```
INT WINAPI FtpGetActivePorts(  
    HCLIENT hClient,  
    UINT * LpnLowPort,  
    UINT * LpnHighPort  
);
```

The **FtpGetActivePorts** function returns the local port numbers used for active mode file transfers.

Parameters

hClient

Handle to the client session.

lpnLowPort

Points to an unsigned integer that will contain the low port number when the function returns.

lpnHighPort

Points to an unsigned integer that will contain the high port number when the function returns.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

This function is used to determine the default port numbers being used for active mode file transfers. When using active mode, the client listens for an inbound connection from the server rather than establishing an outbound connection for the data transfer. In most cases, passive mode transfers are preferred because they mitigate potential compatibility issues with firewalls and NAT routers.

If active mode transfers are required, the default port range used when listening for the server connection is between 1024 and 5000. This is the standard range of ephemeral ports used by the Windows operating system. However, under some circumstances that range of ports may be too small, or a firewall may be configured to deny inbound connections on ephemeral ports. In that case, the **FtpSetActivePorts** function can be used to specify a different range of port numbers.

While it is technically permissible to assign the low and high port numbers to the same value, effectively specifying a single active port number, this is not recommended as it can cause the transfer to fail unexpectedly if multiple file transfers are performed. A minimum range of at least 1000 ports is recommended. For example, if you specify a low port value of 40000 then it is recommended that the high port value be at least 41000. The maximum port value is 65535.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

FtpGetBufferSize Function

```
INT WINAPI FtpGetBufferSize(  
    HCLIENT hClient  
);
```

The **FtpGetBufferSize** function returns the size in bytes of an internal buffer that will be used during data transfers.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the size of the internal buffer that will be used in data transfers. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The speed of data transfers, particularly on uploads, may be sensitive to network type and configuration, and the size of the internal buffer used for data transfers. The default size of this buffer will result in good performance for a wide range of network characteristics. A larger buffer will not necessarily result in better performance. For example, a value of 1460, which is the typical Maximum Transmission Unit (MTU), may be optimal in many situations.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftpv10.lib

See Also

[FtpSetBufferSize](#)

FtpGetChannelMode Function

```
INT WINAPI FtpGetChannelMode(  
    HCLIENT hClient,  
    INT nChannel  
);
```

The **FtpGetChannelMode** function returns the mode of the specified communications channel.

Parameters

hClient

Handle to the client session.

nChannel

An integer value which specifies which channel to return information for. It may be one of the following values:

Constant	Description
FTP_CHANNEL_COMMAND	Return information about the command channel. This is the communication channel used to send commands to the server and receive command result and status information from the server.
FTP_CHANNEL_DATA	Return information about the data channel. This is the communication channel used to send or receive data during a file transfer.

Return Value

If the function succeeds, the return value is the mode for the specified channel. If the function fails, it will return FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpGetChannelMode** function returns a integer which may be one of the following values:

Constant	Description
FTP_CHANNEL_CLEAR	The channel is not encrypted. This is the default mode for both channels when a standard, non-secure connection is established with the server.
FTP_CHANNEL_SECURE	The channel is encrypted. This is the default mode for both channels when a secure connection is established with the server.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csftpv10.lib

FtpGetClientQuota Function

```
INT WINAPI FtpGetClientQuota(  
    HCLIENT hClient,  
    LPFTPCLIENTQUOTA lpClientQuota  
);
```

The **GetClientQuota** function returns information about file quotas for the current client session.

Parameters

hClient

Handle to the client session.

lpClientQuota

A pointer to an [FTPCLIENTQUOTA](#) structure which contains the quota information returned by the server.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is `FTP_ERROR`. To get extended error information, call **GetLastError**.

Remarks

This method uses the XQUOTA command to obtain information for the current client session. If the server does not support this command, the function will fail.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csftpv10.lib`

FtpGetData Function

```
INT WINAPI FtpGetData(  
    HCLIENT hClient,  
    LPCTSTR lpszRemoteFile,  
    LPVOID lpvBuffer,  
    LPDWORD lpdwLength,  
    DWORD dwReserved  
);
```

The **FtpGetData** function transfers the contents of a file on the server to the specified buffer.

Parameters

hClient

Handle to the client session.

lpszRemoteFile

A pointer to a string that specifies the file on the server that will be transferred to the local system. The file naming conventions must be that of the host operating system.

lpvBuffer

A pointer to a byte buffer which will contain the data transferred from the server, or a pointer to a global memory handle which will reference the data when the function returns.

lpdwLength

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the *lpvBuffer* parameter. If the *lpvBuffer* parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the actual length of the file that was downloaded.

dwReserved

A reserved parameter. This value should always be zero.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpGetData** function is used to download the contents of a remote file into a local buffer. The function may be used in one of two ways, depending on the needs of the application. The first method is to pre-allocate a buffer large enough to store the contents of the file. In this case, the *lpvBuffer* parameter will point to the buffer that was allocated, the value that the *lpdwLength* parameter points to should be initialized to the size of that buffer.

The second method that can be used is have the *lpvBuffer* parameter point to a global memory handle which will contain the file data when the function returns. In this case, the value that the *lpdwLength* parameter points to must be initialized to zero. It is important to note that the memory handle returned by the function must be freed by the application, otherwise a memory leak will occur. See the example code below.

The **FtpGetText** function can be used to download a text file and store the contents in a string.

This function will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the FTP_EVENT_PROGRESS event will be

periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **FtpEnableEvents**, or by registering a callback function using the **FtpRegisterEvent** function.

To determine the current status of a file transfer while it is in progress, use the **FtpGetTransferStatus** function.

Example

```
HGLOBAL hgblBuffer = (HGLOBAL)NULL;
LPBYTE lpBuffer = (LPBYTE)NULL;
DWORD cbBuffer = 0;

// Return the file data into block of global memory allocated by
// the GlobalAlloc function; the handle to this memory will be
// returned in the hgblBuffer parameter
nResult = FtpGetData(hClient,
                    lpszRemoteFile,
                    &hgblBuffer,
                    &cbBuffer,
                    0);

if (nResult != FTP_ERROR)
{
    // Lock the global memory handle, returning a pointer to the
    // contents of the file data
    lpBuffer = (LPBYTE)GlobalLock(hgblBuffer);

    // After the data has been used, the handle must be unlocked
    // and freed, otherwise a memory leak will occur
    GlobalUnlock(hgblBuffer);
    GlobalFree(hgblBuffer);
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csftpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

FtpGetDirectory Function

```
INT WINAPI FtpGetDirectory(  
    HCLIENT hClient,  
    LPTSTR lpszDirectory,  
    INT cbDirectory  
);
```

The **FtpGetDirectory** function copies the current working directory on the server to the specified buffer.

Parameters

hClient

Handle to the client session.

lpszDirectory

Points to a buffer that will contain the name of the current working directory on the server. The file pathing and name conventions must be that of the server.

cbDirectory

The maximum number of characters that may be copied into the buffer, including the terminating null-character.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

This function sends the PWD command to the server.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

FtpGetDirectoryFormat Function

```
INT WINAPI FtpGetDirectoryFormat(  
    HCLIENT hClient  
);
```

The **FtpGetDirectoryFormat** function returns an identifier which specifies what format is being used by the server to list files. By default, the library will automatically determine the appropriate format, but this value may be overridden by the **FtpSetDirectoryFormat** function.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the currently selected directory format. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

Refer to the **FtpSetDirectoryFormat** function for a list of directory format types that are supported by the library. This function can be used to determine which format was selected by the library after a file listing has been retrieved.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftpv10.lib

FtpGetErrorString Function

```
INT WINAPI FtpGetErrorString(  
    DWORD dwErrorCode,  
    LPTSTR lpszDescription,  
    INT cbDescription  
);
```

The **FtpGetErrorString** function is used to return a description of a specific error code. Typically this is used in conjunction with the **FtpGetLastError** function for use with warning dialogs or as diagnostic messages.

Parameters

dwErrorCode

The error code for which a description is returned.

lpszDescription

A pointer to the buffer that will contain a description of the specified error code. This buffer should be at least 128 characters in length.

cbDescription

The maximum number of characters that may be copied into the description buffer.

Return Value

If the function succeeds, the return value is the length of the description string. If the function fails, the return value is zero, meaning that no description exists for the specified error code. Typically this indicates that the error code passed to the function is invalid.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[FtpGetLastError](#), [FtpSetLastError](#)

FtpGetFeatures Function

```
DWORD WINAPI FtpGetFeatures(  
    HCLIENT hClient  
);
```

The **FtpGetFeatures** function returns the server features available to the client.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is one or more bit flags which specify the features that are available to the client. If the function fails, it will return zero. Because it is possible that no features would be enabled, a return value of zero does not always indicate an error. An application should call **FtpGetLastError** to determine if an error code has been set.

Remarks

The **FtpGetFeatures** function returns a value which may be a combination of one or more of the following bit flags:

Constant	Description
FTP_FEATURE_SIZE	The server supports the SIZE command to determine the size of a file. If this feature is not enabled, the library will attempt to use the MLST or STAT command to determine the file size.
FTP_FEATURE_STAT	The server supports using the STAT command to return information about a specific file. If this feature is not enabled, the client may not be able to obtain information about a specific file such as its size, permissions or modification time.
FTP_FEATURE_MDTM	The server supports the MDTM command to obtain information about the modification time for a specific file. This command may also be used to set the file time on the server.
FTP_FEATURE_REST	The server supports restarting file transfers using the REST command. If this feature is not enabled, the client will not be able to restart file transfers and must upload or download the complete file.
FTP_FEATURE_SITE	The server supports site specific commands using the SITE command. If this feature is not enabled, no site specific commands will be sent to the server.
FTP_FEATURE_IDLE	The server supports setting the idle timeout period using the SITE IDLE command to specify the number of seconds that the client may idle before the server terminates the connection.
FTP_FEATURE_CHMOD	The server supports modifying the permissions of a specific file using the SITE CHMOD command. If this feature is not

	enabled, the client will not be able to set the permissions for a file.
FTP_FEATURE_AUTH	The server supports explicit SSL sessions using the AUTH command. If this feature is not enabled, the client will only be able to connect to a secure server that uses implicit SSL connections. Changing this feature has no effect on standard, non-secure connections.
FTP_FEATURE_PBSZ	The server supports the PBSZ command which specifies the buffer size used with secure data connections. If this feature is disabled, it may prevent the client from changing the protection level on the data channel. Changing this feature has no effect on standard, non-secure connections.
FTP_FEATURE_PROT	The server supports the PROT command which specifies the protection level for the data channel. If this feature is disabled, the client will be unable to change the protection level on the data channel. Changing this feature has no effect on standard, non-secure connections.
FTP_FEATURE_CCC	The server supports the CCC command which returns the command channel to a non-secure mode. Changing this feature has no effect on standard, non-secure connections.
FTP_FEATURE_HOST	The server supports the HOST command which enables a client to specify the hostname after establishing a connection with a server that supports virtual hosting.
FTP_FEATURE_MLST	The server supports the MLST command which returns status information for files. If this feature is enabled, the MLST command will be used instead of the STAT command.
FTP_FEATURE_MFMT	The server supports the MFMT command which is used to change the last modification time for a file. If this command is supported, it is used instead of the MDTM command to change the modification time for a file.
FTP_FEATURE_XCRC	The server supports the XCRC command which returns the CRC-32 checksum for the contents of a specified file. This command is used for file verification.
FTP_FEATURE_XMD5	The server supports the XMD5 command which returns an MD5 hash for the contents of a specified file. This command is used for file verification.
FTP_FEATURE_LANG	The server supports the LANG command which sets the language used for the current client session. Command responses and file naming conventions will use the specified language.
FTP_FEATURE_UTF8	The server supports the OPTS UTF-8 command which specifies UTF-8 encoding when specifying filenames. This feature is typically used in conjunction with setting the default language for the client session.
FTP_FEATURE_XQUOTA	The server supports the XQUOTA command which returns

	quota information for the current client session.
FTP_FEATURE_UTIME	The server supports the UTIME command which is used to change the last modification time for a specified file.

When a client connection is first established, features are enabled based on the server type and the server's response to the FEAT command. However, as the client issues commands to the server, if the server reports that the command is unrecognized that feature will automatically be disabled in the client.

For example, the first time an application calls the **FtpGetFileSize** function to determine the size of a file, the library will try to use the SIZE command. If the server reports that the SIZE command is not available, that feature will be disabled and the library will not use the command again during the session unless it is explicitly re-enabled. This is designed to prevent the library from repeatedly sending invalid commands to a server, which may result in the server aborting the connection.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csftpv10.lib

FtpGetFile Function

```
INT WINAPI FtpGetFile(  
    HCLIENT hClient,  
    LPCTSTR lpszLocalFile,  
    LPCTSTR lpszRemoteFile,  
    DWORD dwOptions,  
    DWORD dwOffset  
);
```

The **FtpGetFile** function transfers the specified file on the server to the local system.

Parameters

hClient

Handle to the client session.

lpszLocalFile

A pointer to a string that specifies the file on the local system that will be created, overwritten or appended to. The file pathing and name conventions must be that of the local host.

lpszRemoteFile

A pointer to a string that specifies the file on the server that will be transferred to the local system. The file naming conventions must be that of the host operating system.

dwOptions

An unsigned integer that specifies one or more options. This parameter may be any one of the following values:

Constant	Description
FTP_TRANSFER_DEFAULT	This option specifies the default transfer mode should be used. If the local file exists, it will be overwritten with the contents of the downloaded file.
FTP_TRANSFER_APPEND	This option specifies that if the local file exists, the contents of file on the server is appended to the local file. If the local file does not exist, it is created.

dwOffset

A byte offset which specifies where the file transfer should begin. The default value of zero specifies that the file transfer should start at the beginning of the file. A value greater than zero is typically used to restart a transfer that has not completed successfully. Note that specifying a non-zero offset requires that the server support the REST command to restart transfers.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

This function will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the FTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **FtpEnableEvents**, or by registering a callback function using the **FtpRegisterEvent** function.

To determine the current status of a file transfer while it is in progress, use the **FtpGetTransferStatus** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csftpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

FtpGetFileEx Function

```
INT WINAPI FtpGetFileEx(  
    HCLIENT hClient,  
    LPCTSTR lpszLocalFile,  
    LPCTSTR lpszRemoteFile,  
    DWORD dwOptions,  
    ULARGE_INTEGER uiOffset  
);
```

The **FtpGetFileEx** function transfers the specified file on the server to the local system. This version of the function is designed to support files that are larger than 4GB.

Parameters

hClient

Handle to the client session.

lpszLocalFile

A pointer to a string that specifies the file on the local system that will be created, overwritten or appended to. The file pathing and name conventions must be that of the local host.

lpszRemoteFile

A pointer to a string that specifies the file on the server that will be transferred to the local system. The file naming conventions must be that of the host operating system.

dwOptions

An unsigned integer that specifies one or more options. This parameter may be any one of the following values:

Constant	Description
FTP_TRANSFER_DEFAULT	This option specifies the default transfer mode should be used. If the local file exists, it will be overwritten with the contents of the downloaded file.
FTP_TRANSFER_APPEND	This option specifies that if the local file exists, the contents of file on the server is appended to the local file. If the local file does not exist, it is created.

uiOffset

A byte offset which specifies where the file transfer should begin. The default value of zero specifies that the file transfer should start at the beginning of the file. A value greater than zero is typically used to restart a transfer that has not completed successfully. Note that specifying a non-zero offset requires that the server support the REST command to restart transfers.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

This function will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the FTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **FtpEnableEvents**, or by registering a callback function using

the **FtpRegisterEvent** function.

To determine the current status of a file transfer while it is in progress, use the **FtpGetTransferStatusEx** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csftpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

FtpGetFileList Function

```
INT WINAPI FtpGetFileList(  
    HCLIENT hClient,  
    LPCTSTR lpszDirectory,  
    DWORD dwOptions,  
    LPTSTR lpszBuffer,  
    INT nMaxLength  
);
```

The **FtpGetFileList** function returns an unparsed list of files in the specified directory.

Parameters

hClient

Handle to the client session.

lpszDirectory

A pointer to a string that specifies the name of a directory and/or a wildcard file mask. The format of the directory name must match the file naming conventions of the server. If this parameter is NULL or points to an empty string, the current working directory will be used.

dwOptions

An unsigned integer that specifies one or more options. This parameter may be any one of the following values:

Constant	Description
FTP_LIST_DEFAULT	This option specifies the server should return a complete listing of files in the specified directory with as much detail as possible. This typically means that the file size, date, ownership and access rights will be returned to the client. Information about the files are returned in lines of text, with each line terminated by carriage return and linefeed (CRLF) characters. The exact format of the data returned is specific to the server operating system.
FTP_LIST_NAMEONLY	This option specifies the server should only return a list of file names, with no additional information about the file. Each file name is terminated by carriage return and linefeed (CRLF) characters.

lpszBuffer

A pointer to a string buffer that will contain the list of files when the function returns. This buffer should be large enough to store the complete file listing and a terminating null character. If the buffer is smaller than the total amount of data returned by the server, the data will be truncated. This parameter cannot be NULL.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer, including the terminating null character.

Return Value

If the function succeeds, the return value is the number of bytes copied into the string buffer, not including the terminating null character. If the function fails, the return value is FTP_ERROR. To get

extended error information, call **FtpGetLastError**.

Remarks

The **FtpGetFileList** function returns a list of files in the specified directory, copying the data to a string buffer. Unlike the other functions like **FtpEnumFiles** that parse a directory listing and return information in an **FTPFILESTATUS** structure, this function returns the unparsed file list data. The actual format of the data that is returned depends on the operating system and how the server implements file listings. For example, UNIX servers typically return the output from the **/bin/lis** command.

Some servers may not support file listings for any directory other than the current working directory. If an error is returned when specifying a directory name, try changing the current working directory using the **FtpChangeDirectory** function and then call this function again, passing NULL or an empty string as the *lpszDirectory* parameter.

This function can be particularly useful when the client is connected to a server that returns file listings in a format that is not recognized by the library. The application can retrieve the unparsed file listing from the server and parse the contents. Note that if you specify the **FTP_LIST_NAMEONLY** option, the data will only contain a list of file names and there will be no way for the application to know if they represent a regular file or a subdirectory.

This function is supported for both FTP and SFTP (SSH) connections, however the format of the data may differ depending on which protocol is used. Most UNIX based FTP servers will not list files and subdirectories that begin with a period, however most SFTP servers will return a list of all files, even those that begin with a period.

This function will cause the current thread to block until the file listing completes, a timeout occurs or the operation is canceled.

Example

```
TCHAR szFileList[MAXFILELISTSIZE];

nResult = FtpGetFileList(hClient, NULL, FTP_LIST_NAMEONLY,
                        szFileList, MAXFILELISTSIZE);

if (nResult != FTP_ERROR)
    _tprintf(_T("%s\n"), szFileList);
else
{
    DWORD dwError = FtpGetLastError();
    _tprintf(_T("Unable to list files (error 0x%08lx)\n"), dwError);
    return;
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

FtpGetFileNameEncoding Function

```
INT WINAPI FtpGetFileNameEncoding(  
    HCLIENT hClient  
);
```

The **FtpGetFileNameEncoding** function returns an identifier which specifies what type of encoding is being used when file names are sent to the server.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the type of encoding that is used. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

Refer to the **FtpSetFileNameEncoding** function for a list of encoding types that are supported by the library.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftpv10.lib

FtpGetFilePermissions Function

```
INT WINAPI FtpGetFilePermissions(  
    HCLIENT hClient,  
    LPCTSTR lpszFileName,  
    LPDWORD lpdwPermissions  
);
```

The **FtpGetFilePermissions** function returns information about the access permissions for a specific file on the server.

Parameters

hClient

Handle to the client session.

lpszFileName

A pointer to a string which contains the name of the file that the access permissions are to be returned for. The filename cannot contain any wildcard characters.

lpdwPermissions

A pointer to an unsigned integer which will contain the access permissions for the file when the function returns. The file permissions are represented as bit flags, and may be one or more of the following values:

Constant	Description
FILE_OWNER_READ	The owner has permission to open the file for reading. If the current user is the owner of the file, this grants the user the right to download the file to the local system.
FILE_OWNER_WRITE	The owner has permission to open the file for writing. If the current user is the owner of the file, this grants the user the right to replace the file. If this permission is set for a directory, this grants the user the right to create and delete files.
FILE_OWNER_EXECUTE	The owner has permission to execute the contents of the file. The file is typically either a binary executable, script or batch file. If this permission is set for a directory, this may also grant the user the right to open that directory and search for files in that directory.
FILE_GROUP_READ	Users in the specified group have permission to open the file for reading. If the current user is in the same group as the file owner, this grants the user the right to download the file.
FILE_GROUP_WRITE	Users in the specified group have permission to open the file for writing. On some platforms, this may also imply permission to delete the file. If the current user is in the same group as the file owner, this grants the user the right to replace the file. If this permission is set for a directory, this grants the user the right to create and delete files.
FILE_GROUP_EXECUTE	Users in the specified group have permission to execute the contents of the file. If this permission is set for a directory, this may also grant the user the right to open that directory and

	search for files in that directory.
FILE_WORLD_READ	All users have permission to open the file for reading. This permission grants any user the right to download the file to the local system.
FILE_WORLD_WRITE	All users have permission to open the file for writing. This permission grants any user the right to replace the file. If this permission is set for a directory, this grants any user the right to create and delete files.
FILE_WORLD_EXECUTE	All users have permission to execute the contents of the file. If this permission is set for a directory, this may also grant all users the right to open that directory and search for files in that directory.

Return Value

If the function succeeds, the return value is a result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

This function uses the STAT command to retrieve information about the specified file. On some systems, the STAT command will not return information on files that contain spaces or tabs in the filename. In this case, the function will fail and value pointed to by the *lpdwPermissions* parameter will be zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csftpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[FtpGetFileStatus](#), [FtpSetFilePermissions](#)

FtpGetFileSize Function

```
INT WINAPI FtpGetFileSize(  
    HCLIENT hClient,  
    LPCTSTR lpszFileName,  
    LPDWORD lpdwFileSize  
);
```

The **FtpGetFileSize** function returns the size of the specified file on the server.

Parameters

hClient

Handle to the client session.

lpszFileName

Points to a string that specifies the name of the remote file.

lpdwFileSize

Points to an unsigned integer that will contain the size of the specified file in bytes.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

This function uses the SIZE command to determine the length of the specified file. Not all servers implement this command, in which case the function call will fail, and the *lpdwFileSize* parameter will be set to zero.

Note that if the file on the server is a text file, it is possible that the value returned by this method will not match the size of the file when it is downloaded to the local system. This is because different operating systems use different sequences of characters to mark the end of a line of text, and when a file is transferred in text mode, the end of line character sequence is automatically converted to a carriage return-linefeed, which is the convention used by the Windows platform.

Some FTP servers will refuse to return the size of a file if the current file type is set to FILE_TYPE_ASCII because the size of a text file on the server may not accurately reflect what the size of the file will be on the local system.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[FtpGetFileStatus](#), [FtpOpenDirectory](#)

FtpGetFileSize Function

```
INT WINAPI FtpGetFileSizeEx(  
    HCLIENT hClient,  
    LPCTSTR lpszFileName,  
    ULARGE_INTEGER* lpuiFileSize  
);
```

The **FtpGetFileSizeEx** function returns the size of the specified file on the server. This version of the function is designed to support files that are larger than 4GB.

Parameters

hClient

Handle to the client session.

lpszFileName

Points to a string that specifies the name of the remote file.

lpuiFileSize

Points to a ULARGE_INTEGER structure that will contain the size of the specified file in bytes.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

This function uses the SIZE command to determine the length of the specified file. Not all servers implement this command, in which case the function call will fail, and the *lpdwFileSize* parameter will be set to zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[FtpGetFileStatusEx](#), [FtpOpenDirectory](#)

FtpGetFileStatus Function

```
BOOL WINAPI FtpGetFileStatus(  
    HCLIENT hClient,  
    LPCTSTR lpszFileName,  
    LPFTPFILESTATUS lpFileStatus  
);
```

The **FtpGetFileStatus** function returns information about a specific file on the server.

Parameters

hClient

Handle to the client session.

lpszFileName

A pointer to a string which contains the name of the file that status information will be returned on. The file name cannot contain any wildcard characters.

lpFileStatus

A pointer to an [FTPFILESTATUS](#) structure which contains information about the file returned by the server.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **FtpGetLastError**.

Remarks

This function uses the STAT command to retrieve information about the specified file. Unlike the **FtpGetFirstFile** and **FtpGetNextFile** functions, which read through a file list returned on the data channel, this function reads the result of a command string. For applications that need information about a specific file, using this function can be considerably faster than iterating through all of the files in a given directory. Note that not all servers support using the command in this way.

On some systems, the STAT command will not return information on files that contain spaces or tabs in the filename. In this case, the FTPFILESTATUS structure members will be empty strings and zero values.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

FtpGetFileStatusEx Function

```
BOOL WINAPI FtpGetFileStatusEx(  
    HCLIENT hClient,  
    LPCTSTR lpszFileName,  
    LPFTPFILESTATUSEX lpFileStatus  
);
```

The **FtpGetFileStatusEx** function returns information about a specific file on the server. This version of the function is designed to support files that are larger than 4GB.

Parameters

hClient

Handle to the client session.

lpszFileName

A pointer to a string which contains the name of the file that status information will be returned on. The file name cannot contain any wildcard characters.

lpFileStatus

A pointer to an [FTPFILESTATUSEX](#) structure which contains information about the file returned by the server.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **FtpGetLastError**.

Remarks

This function uses the STAT command to retrieve information about the specified file. Unlike the **FtpGetFirstFileEx** and **FtpGetNextFileEx** functions, which read through a file list returned on the data channel, this function reads the result of a command string. For applications that need information about a specific file, using this function can be considerably faster than iterating through all of the files in a given directory. Note that not all servers support using the command in this way.

On some systems, the STAT command will not return information on files that contain spaces or tabs in the filename. In this case, the FTPFILESTATUSEX structure members will be empty strings and zero values.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[FtpCloseDirectory](#), [FtpGetDirectoryFormat](#), [FtpGetFirstFileEx](#), [FtpGetNextFileEx](#), [FtpGetTransferStatusEx](#), [FtpOpenDirectory](#), [FtpSetDirectoryFormat](#)

FtpGetFileTime Function

```
INT WINAPI FtpGetFileTime(  
    HCLIENT hClient,  
    LPCTSTR lpszFileName,  
    LPSYSTEMTIME lpFileTime,  
    BOOL bLocalize  
);
```

The **FtpGetFileTime** function returns the modification time for the specified file on the server.

Parameters

hClient

Handle to the client session.

lpszFileName

Points to a string that specifies the name of the remote file.

lpFileTime

Points to a [SYSTEMTIME](#) structure that will be set to the current modification time for the remote file.

bLocalize

A boolean flag which specifies if the file time is localized to the current timezone. If this value is non-zero, then the file time is adjusted to that the time is local to the current system. If this value is zero, the file time is returned in UTC time.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is `FTP_ERROR`. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpGetFileTime** function can be used to determine the date and time that a file was last modified on the server. The time may either be localized to the current system, or it may be returned as UTC time. If you plan on changing the values returned in the `SYSTEMTIME` structure and then calling **FtpSetFileTime** function to modify the file time on the server, you should do not localize the time.

This function uses the `MDTM` command to determine the modification time of the specified file. If the server does not support this command, the function will attempt to use the `STAT` command to determine the file modification time.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csftpv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

See Also

[FtpGetFileStatus](#), [FtpOpenDirectory](#), [FtpSetFileTime](#)

FtpGetFileType Function

```
INT WINAPI FtpGetFileType(  
    HCLIENT hClient,  
    UINT * lpnFileType  
);
```

The **FtpGetFileType** function returns the default file type for the current client session.

Parameters

hClient

Handle to the client session.

lpnFileType

A pointer to an unsigned integer that will identify the current file type. This parameter cannot be NULL. When the function returns it will contain one of the following values:

Value	Description
FILE_TYPE_AUTO	The file type should be automatically determined based on the file name extension. If the file extension is unknown, the file type should be determined based on the contents of the file. The library has an internal list of common text file extensions, and additional file extensions can be registered using the FtpRegisterFileType function.
FILE_TYPE_ASCII	The file is a text file using the ASCII character set. For those servers which mark the end of a line with characters other than a carriage return and linefeed, it will be converted to the native client format. This is the file type used for directory listings.
FILE_TYPE_EBCDIC	The file is a text file using the EBCDIC character set. Local files will be converted to EBCDIC when sent to the server. Remote files will be converted to the native ASCII character set when retrieved from the server.
FILE_TYPE_IMAGE	The file is a binary file and no data conversion of any type is performed on the file. This is the default file type for most data files and executables. If the type of file cannot be automatically determined, it will always be considered a binary file.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

If this function is called when connected to an SFTP (SSH) server, the default file type will always be FILE_TYPE_IMAGE because SFTP does not differentiate between text files and binary files.

The **FtpSetFileType** function can be used to change the default file type.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csftpv10.lib

See Also

[FtpSetPassiveMode](#)

FtpGetFirstFile Function

```
BOOL WINAPI FtpGetFirstFile(  
    HCLIENT hClient,  
    LPFTPFILESTATUS lpFileStatus  
);
```

The **FtpGetFirstFile** function returns the first file in the directory listing returned by the server after a call to the **FtpOpenDirectory** function.

Parameters

hClient

Handle to the client session.

lpFileStatus

A pointer to an [FTPFILESTATUS](#) structure which contains information about the file returned by the server.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **FtpGetLastError**.

Remarks

This file list information returned by the server is cached by the library, allowing you to use this function to reposition back to the beginning of the file list.

Example

```
if (FtpOpenDirectory(hClient, _T("")) != FTP_ERROR)  
{  
    FTPFILESTATUS ftpFile;  
    BOOL bResult;  
  
    bResult = FtpGetFirstFile(hClient, &ftpFile);  
    while (bResult)  
    {  
        // The ftpFile structure contains information about the file  
        bResult = FtpGetNextFile(hClient, &ftpFile);  
    }  
  
    FtpCloseDirectory(hClient);  
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

FtpGetFirstFileEx Function

```
BOOL WINAPI FtpGetFirstFileEx(  
    HCLIENT hClient,  
    LPFTPFILESTATUSEX lpFileStatus  
);
```

The **FtpGetFirstFileEx** function returns the first file in the directory listing returned by the server after a call to the **FtpOpenDirectory** function. This version of the function is designed to support files that are larger than 4GB.

Parameters

hClient

Handle to the client session.

lpFileStatus

A pointer to an [FTPFILESTATUSEX](#) structure which contains information about the file returned by the server.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **FtpGetLastError**.

Remarks

This file list information returned by the server is cached by the library, allowing you to use this function to reposition back to the beginning of the file list.

Example

```
if (FtpOpenDirectory(hClient, _T("")) != FTP_ERROR)  
{  
    FTPFILESTATUSEX ftpFile;  
    BOOL bResult;  
  
    bResult = FtpGetFirstFileEx(hClient, &ftpFile);  
    while (bResult)  
    {  
        // The ftpFile structure contains information about the file  
        bResult = FtpGetNextFileEx(hClient, &ftpFile);  
    }  
  
    FtpCloseDirectory(hClient);  
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

FtpGetLastError Function

DWORD WINAPI FtpGetLastError();

Parameters

None.

Return Value

The return value is the last error code value for the current thread. Functions set this value by calling the **FtpSetLastError** function. The Return Value section of each reference page notes the conditions under which the function sets the last error code.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. You should call the **FtpGetLastError** function immediately when a function's return value indicates that an error has occurred. That is because some functions call **FtpSetLastError(0)** when they succeed, clearing the error code set by the most recently failed function.

Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or FTP_ERROR. Those functions which call **FtpSetLastError** when they succeed are noted on the function reference page.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csftpv10.lib

See Also

[FtpGetErrorString](#), [FtpSetLastError](#)

FtpGetMultipleFiles Function

```
INT WINAPI FtpGetMultipleFiles(  
    HCLIENT hClient,  
    LPCTSTR lpszLocalDirectory,  
    LPCTSTR lpszRemoteDirectory,  
    LPCTSTR lpszFileMask,  
    DWORD dwReserved  
);
```

The **FtpGetMultipleFiles** function copies one or more files from the server to the local host, using the specified wildcard.

Parameters

hClient

Handle to the client session.

lpszLocalDirectory

Pointer to a string which specifies the local directory where the files will be copied to. A NULL pointer or empty string specifies that files should be copied to the current working directory.

lpszRemoteDirectory

Pointer to a string which specifies the remote directory where the files will be copied from. A NULL pointer or empty string specifies that the files should be copied from the current working directory on the server.

lpszFileMask

Pointer to a string which specifies the files that are to be copied from the server to the local system. The file mask should follow the native conventions used for wildcard file matches on the server.

dwReserved

A reserved parameter. This value should always be zero.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpGetMultipleFiles** function is used to transfer files from the server to the local host which match a specified wildcard file mask. This function requires that the client be able to automatically list and parse directory listings from the server, otherwise an error will be returned. All files will be transferred using the current file type as specified by the **FtpSetFileType** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

FtpGetNextFile Function

```
BOOL WINAPI FtpGetNextFile(  
    HCLIENT hClient,  
    LPFTPFILESTATUS lpFileStatus  
);
```

The **FtpGetNextFile** function returns the next file in the directory listing returned by the server.

Parameters

hClient

Handle to the client session.

lpFileStatus

A pointer to an [FTPFILESTATUS](#) structure which contains information about the file returned by the server.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpGetNextFile** function returns the next file in the directory listing. If the last file has been returned, the function will return zero and the client should call the **FtpCloseDirectory** function to close the directory.

Example

```
if (FtpOpenDirectory(hClient, _T("")) != FTP_ERROR)  
{  
    FTPFILESTATUS ftpFile;  
    BOOL bResult;  
  
    bResult = FtpGetFirstFile(hClient, &ftpFile);  
    while (bResult)  
    {  
        // The ftpFile structure contains information about the file  
        bResult = FtpGetNextFile(hClient, &ftpFile);  
    }  
  
    FtpCloseDirectory(hClient);  
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

FtpGetNextFileEx Function

```
BOOL WINAPI FtpGetNextFile(  
    HCLIENT hClient,  
    LPFTPFILESTATUSEX lpFileStatus  
);
```

The **FtpGetNextFileEx** function returns the next file in the directory listing returned by the server. This version of the function is designed to support files that are larger than 4GB.

Parameters

hClient

Handle to the client session.

lpFileStatus

A pointer to an [FTPFILESTATUSEX](#) structure which contains information about the file returned by the server.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpGetNextFileEx** function returns the next file in the directory listing. If the last file has been returned, the function will return zero and the client should call the **FtpCloseDirectory** function to close the directory.

Example

```
if (FtpOpenDirectory(hClient, _T("")) != FTP_ERROR)  
{  
    FTPFILESTATUSEX ftpFile;  
    BOOL bResult;  
  
    bResult = FtpGetFirstFileEx(hClient, &ftpFile);  
    while (bResult)  
    {  
        // The ftpFile structure contains information about the file  
        bResult = FtpGetNextFileEx(hClient, &ftpFile);  
    }  
  
    FtpCloseDirectory(hClient);  
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

FtpGetPriority Function

```
INT WINAPI FtpGetPriority(  
    HCLIENT hClient  
);
```

The **FtpGetPriority** function returns a value which specifies the priority of file transfers.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the current file transfer priority. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpGetPriority** function can be used to determine the current priority assigned to file transfers performed by the client. It may be one of the following values:

Constant	Description
FTP_PRIORITY_NORMAL	The default priority which balances resource utilization and transfer speed. It is recommended that most applications use this priority.
FTP_PRIORITY_BACKGROUND	This priority significantly reduces the memory, processor and network resource utilization for the transfer. It is typically used with worker threads running in the background when the amount of time required perform the transfer is not critical.
FTP_PRIORITY_LOW	This priority lowers the overall resource utilization for the transfer and meters the bandwidth allocated for the transfer. This priority will increase the average amount of time required to complete a file transfer.
FTP_PRIORITY_HIGH	This priority increases the overall resource utilization for the transfer, allocating more memory for internal buffering. It can be used when it is important to transfer the file quickly, and there are no other threads currently performing file transfers at the time.
FTP_PRIORITY_CRITICAL	This priority can significantly increase processor, memory and network utilization while attempting to transfer the file as quickly as possible. If the file transfer is being performed in the main UI thread, this priority can cause the application to appear to become non-responsive. No events will be generated during the transfer.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csftpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[FtpSetPriority](#)

FtpGetProxyType Function

```
INT WINAPI FtpGetProxyType(  
    HCLIENT hClient  
);
```

The **FtpGetProxyType** function returns the type of proxy that the client is connected to. By default, no proxy server is specified and this function returns a value of FTP_PROXY_NONE. For a list of possible proxy server types, refer to the **FtpProxyConnect** function.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value identifies the type of proxy that the client is connected to. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[FtpConnect](#), [FtpProxyConnect](#)

FtpGetResultCode Function

```
INT WINAPI FtpGetResultCode(  
    HCLIENT hClient  
);
```

The **FtpGetResultCode** function reads the result code returned by the server in response to a command. The result code is a three-digit numeric code, and indicates if the operation succeeded, failed or requires additional action by the client.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

Result codes are three-digit numeric values returned by the server. They may be broken down into the following ranges:

Value	Description
100-199	Positive preliminary result. This indicates that the requested action is being initiated, and the client should expect another reply from the server before proceeding.
200-299	Positive completion result. This indicates that the server has successfully completed the requested action.
300-399	Positive intermediate result. This indicates that the requested action cannot complete until additional information is provided to the server.
400-499	Transient negative completion result. This indicates that the requested action did not take place, but the error condition is temporary and may be attempted again.
500-599	Permanent negative completion result. This indicates that the requested action did not take place.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftpv10.lib

See Also

[FtpCommand](#), [FtpGetResultString](#)

FtpGetResultString Function

```
INT WINAPI FtpGetResultString(  
    HCLIENT hClient,  
    LPTSTR lpszResult,  
    INT cbResult  
);
```

The **FtpGetResultString** function returns the last message sent by the server along with the result code.

Parameters

hClient

Handle to the client session.

lpszResult

A pointer to the buffer that will contain the result string returned by the server.

cbResult

The maximum number of characters that may be copied into the result string buffer, including the terminating null character.

Return Value

If the function succeeds, the return value is the length of the result string. If a value of zero is returned, this means that no result string was sent by the server.

If the function fails, the return value is `FTP_ERROR`. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpGetResultString** function is most useful when an error occurs because the server will typically include a brief description of the cause of the error. This can then be parsed by the application or displayed to the user. The result string is updated each time the client sends a command to the server and then calls **FtpGetResultCode** to obtain the result code for the operation.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csftpv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

FtpGetSecurityInformation Function

```
BOOL WINAPI FtpGetSecurityInformation(  
    HCLIENT hClient,  
    LPSECURITYINFO lpSecurityInfo  
);
```

The **FtpGetSecurityInformation** function returns security protocol, encryption and certificate information about the current client connection.

Parameters

hClient

Handle to the client session.

lpSecurityInfo

A pointer to a [SECURITYINFO](#) structure which contains information about the current client connection. The *dwSize* member of this structure must be initialized to the size of the structure before passing the address of the structure to this function.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **FtpGetLastError**.

Remarks

This function is used to obtain security related information about the current client connection to the server. It can be used to determine if a secure connection has been established, what security protocol was selected, and information about the server certificate. Note that a secure connection has not been established, the *dwProtocol* structure member will contain the value `SECURITY_PROTOCOL_NONE`.

Example

The following example notifies the user if the connection is secure or not:

```
SECURITYINFO securityInfo;  
  
securityInfo.dwSize = sizeof(SECURITYINFO);  
if (FtpGetSecurityInformation(hClient, &securityInfo))  
{  
    if (securityInfo.dwProtocol == SECURITY_PROTOCOL_NONE)  
    {  
        MessageBox(NULL, _T("The connection is not secure"),  
                    _T("Connection"), MB_OK);  
    }  
    else  
    {  
        if (securityInfo.dwCertStatus == SECURITY_CERTIFICATE_VALID)  
        {  
            MessageBox(NULL, _T("The connection is secure"),  
                        _T("Connection"), MB_OK);  
        }  
        else  
        {  
            MessageBox(NULL, _T("The server certificate not valid"),  
                        _T("Connection"), MB_OK);  
        }  
    }  
}
```

```
}  
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csftpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

FtpGetServerInformation Function

```
INT WINAPI FtpGetServerInformation(  
    HCLIENT hClient,  
    LPTSTR LpszSystemInfo,  
    INT nMaxLength  
);
```

The **FtpGetServerInformation** function returns information about the server, typically including the operating system type, version and platform.

Parameters

hClient

Handle to the client session.

lpszSystemInfo

A pointer to the buffer that will contain the system information returned by the server.

nMaxLength

The maximum number of characters that can be copied into the buffer, including the terminating null character.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

This function sends the SYST command to the server. The first word will identify the type of operating system. The format for the remaining information depends on the server type. Typically it is a description of the operating system version and hardware platform. For example, here are some strings commonly returned by various FTP servers:

Example	Description
UNIX Type: L8	A standard UNIX based server. This is the most common value returned by servers, and this indicates that the server supports UNIX file naming and directory listing conventions. This string may also include additional information such as the specific variant of UNIX and its version. The L8 portion of the string is a convention that lets the client know that a byte consists of 8 bits.
Windows_NT Version 5.0	A standard Windows based server, typically part of Internet Information Services (ISS). The server will use Windows file naming and directory listing conventions. The version identifies the specific release of Windows. For example, version 4.0 specifies Windows NT 4.0 and 5.0 specifies Windows 2000.
VMS V7.1 AlphaServer	A server running the VMS operating system. The server will use the standard file naming and directory listing conventions for that platform. Note that it is possible that a VMS system may also be configured to operate in a UNIX emulation mode, in which case it will return UNIX instead of VMS.
NetWare	A server running the NetWare operating system. The server will use

system type	the standard file naming and directory listing conventions for that platform. Note that it is possible that a NetWare system may be configured to operate in a UNIX emulation mode, in which case it return UNIX instead of NetWare.
WORLDGROUP Type: L8	A server running the WorldGroup software on the Windows platform. This server supports UNIX file naming and directory listing conventions. WorldGroup is a collaborative workgroup, email and file sharing service which includes an FTP server.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csftpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[FtpGetServerTimeZone](#), [FtpGetServerType](#)

FtpGetServerStatus Function

```
INT WINAPI FtpGetServerStatus(  
    HCLIENT hClient,  
    LPTSTR lpszStatus,  
    INT nMaxLength  
);
```

The **FtpGetServerStatus** function requests that the server return status information about itself.

Parameters

hClient

Handle to the client session.

lpszStatus

A pointer to the buffer that will contain the system status returned by the server.

nMaxLength

The maximum number of characters that can be copied into the buffer, including the terminating null character.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

This function sends the STAT command to the server. The format for the information returned depends on the server type. Typically it is a description of the server platform, version, current user and file transfer options.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[FtpGetServerInformation](#), [FtpGetServerType](#)

FtpGetServerTimeZone Function

```
INT WINAPI FtpGetServerTimeZone(  
    HCLIENT hClient,  
    LPLONG lpnTimeZone  
);
```

The **FtpGetServerTimeZone** function returns the timezone for the current server.

Parameters

hClient

Handle to the client session.

lpnTimeZone

A pointer to a signed long integer which will contain the timezone offset in seconds.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

This function sends the SITE ZONE command to the server to determine its timezone. The value returned is expressed as the number of seconds offset from Coordinated Universal Time (UTC). A positive value specifies a time west of UTC, while a negative value specifies a time east of UTC. For example, a value of 28800 would specify an offset of 8 hours west of UTC, which is the Pacific timezone.

The SIZE ZONE command is an extension that is not supported by all servers. If the server timezone cannot be determined, the function will fail and the value pointed to by the *lpnTimeZone* parameter will be zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftpv10.lib

See Also

[FtpGetClientQuota](#), [FtpGetServerInformation](#), [FtpGetServerStatus](#)

FtpGetServerType Function

```
INT WINAPI FtpGetServerType(  
    HCLIENT hClient  
);
```

The **FtpGetServerType** function returns the type of server the client has connected to.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is a numeric value which indicates the server type. If the function fails, the return value is FTP_ERROR. To get extended error information, call

FtpGetLastError.

Remarks

This function sends the SYST command to the server to determine the server type. The following server types are recognized by the library:

Constant	Description
FTP_SERVER_UNKNOWN	The server type could not be determined by issuing the SYST command. The server may not support the command, or the command may only be allowed when issued by an authenticated user.
FTP_SERVER_UNIX	The server is running on a UNIX based operating system. This can include Linux and other variants, as well as operating systems which emulate UNIX style file pathing and directory listings.
FTP_SERVER_MSDOS	The server is running on an MS-DOS based operating system. The server expects file pathing and naming conventions according to the standard MS-DOS format and returns directory listings similar to the output of the DIR command.
FTP_SERVER_WINDOWS	The server is running on a Windows based operating system. The server expects file pathing and naming conventions according to the standard Windows long filename format, and returns directory listings similar to the output of the DIR command. Note that Windows servers may be configured to return file and directory information in a format similar to UNIX systems, in which case the system may be identified as UNIX even though it is actually running on a Windows platform.
FTP_SERVER_VMS	The server is running on a DEC VMS based operating system. The server expects file pathing and naming conventions specific to that operating system. Note that VMS servers may be configured to return file and directory information in a format similar to UNIX systems, in which

	case the system may be identified as UNIX even though it is actually running on a VMS platform.
FTP_SERVER_NETWARE	The server is running on a NetWare based operating system. The server expects file pathing and naming conventions similar to the standard Windows long filename format, and returns directory listings that are similar to UNIX systems with the exception of the access and permissions flags for the file. Note that a NetWare system may return listings in different formats based on the filesystem and site specific options specified.
FTP_SERVER_OTHER	The server type was not recognized. An attempt will be made to automatically determine the correct file pathing and naming conventions used by the server. To obtain a list of files on the server, it may be necessary to use the FtpSetDirectoryFormat function to specify the directory listing format.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csftpv10.lib

[FtpGetClientQuota](#), [FtpGetServerInformation](#), [FtpGetServerStatus](#), [FtpSetDirectoryFormat](#)

FtpGetStatus Function

```
INT WINAPI FtpGetStatus(  
    HCLIENT hClient  
);
```

The **FtpGetStatus** function returns the current status of the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the client status code. If the function fails, the return value is `FTP_ERROR`. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpGetStatus** function returns a numeric code which identifies the current state of the client session. The following values may be returned:

Value	Constant	Description
1	<code>FTP_STATUS_IDLE</code>	The client is current idle and not sending or receiving data.
2	<code>FTP_STATUS_CONNECT</code>	The client is establishing a connection with the server.
3	<code>FTP_STATUS_READ</code>	The client is reading data from the server.
4	<code>FTP_STATUS_WRITE</code>	The client is writing data to the server.
5	<code>FTP_STATUS_DISCONNECT</code>	The client is disconnecting from the server.
6	<code>FTP_STATUS_OPENFILE</code>	The client is opening a data connection to the server.
7	<code>FTP_STATUS_CLOSEFILE</code>	The client is closing the data connection to the server.
8	<code>FTP_STATUS_GETFILE</code>	The client is downloading a file from the server.
9	<code>FTP_STATUS_PUTFILE</code>	The client is uploading a file to the server.
10	<code>FTP_STATUS_FILELIST</code>	The client is retrieving a file listing from the server.

In a multithreaded application, any thread in the current process may call this function to obtain status information for the specified client session. To obtain status information about a file transfer, use the **FtpGetTransferStatus** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csftpv10.lib`

See Also

FtpGetTaskError Function

```
DWORD WINAPI FtpGetTaskError(  
    UINT nTaskId  
);
```

Return the last error code for the specified asynchronous task.

Parameters

nTaskId

The task identifier.

Return Value

If the asynchronous task has completed successfully, this function returns a value of zero. A non-zero return value indicates an error has occurred.

Remarks

The **FtpGetTaskError** function returns the last error code associated with the specified asynchronous task. If the task completed successfully, the return value will be zero. If the task is still active, the function will return the error `ST_ERROR_TASK_ACTIVE`. If the task has been suspended, the function will return `ST_ERROR_TASK_SUSPENDED`. Any other value indicates that the task completed, but the operation has failed and the error code will specify the cause of the failure.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csftpv10.lib`

[FtpTaskAbort](#), [FtpTaskResume](#), [FtpTaskSuspend](#), [FtpTaskWait](#)

FtpGetTaskId Function

```
UINT WINAPI FtpGetTaskId(  
    HCLIENT hClient  
);
```

Return the asynchronous task identifier associated with the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is non-zero integer value that specifies a unique asynchronous task identifier. If the client handle is not associated with an asynchronous task, the function will return a value of zero.

Remarks

The **FtpGetTaskId** function will return the task ID that is associated with a client session. This is a unique unsigned integer value that references the worker thread that was created to manage the asynchronous client session. This function should only be called within an event handler that is invoked by a background task that has been started using a function such as **FtpAsyncGetFile**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftpv10.lib

See Also

[FtpTaskAbort](#), [FtpTaskDone](#), [FtpTaskResume](#), [FtpTaskSuspend](#), [FtpTaskWait](#)

FtpGetText Function

```
INT WINAPI FtpGetText(  
    HCLIENT hClient,  
    LPCTSTR lpszRemoteFile,  
    LPTSTR lpszBuffer,  
    INT nMaxLength  
);
```

The **FtpGetText** function copies the contents of a text file on the server to the specified string buffer.

Parameters

hClient

Handle to the client session.

lpszRemoteFile

A pointer to a string that specifies a text file on the server. The file pathing and naming conventions must be that of the host operating system.

lpszBuffer

A pointer to a string buffer which will contain the contents of the text file when the function returns. This buffer should be large enough to store the contents of the file, including a terminating null character. This parameter cannot be NULL.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer. This value must be larger than zero. If this value is smaller than the actual size of the text file, the data returned will be truncated.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpGetText** function is used to download a text file and store the contents in a string buffer. This function will always set the file type to FILE_TYPE_ASCII before downloading the file, and will restore the default file type before the method returns. Because binary files can include embedded null characters, this function should only be used with known text files.

This function has been included as a convenience for applications that need to retrieve relatively small text files and manipulate the contents as a string. If the Unicode version of this function is called, the contents of the text file is automatically converted to a Unicode string. If the size of the file is unknown or the text file is very large, it is recommended that you use the **FtpGetData** or **FtpGetFile** functions.

If you use the **FtpGetFileSize** function to determine how large the string buffer should be prior to calling this function, it is important to be aware that the actual number of characters may differ based on the end-of-line conventions used by the host operating system. For example, if you call **FtpGetFileSize** to obtain the size of a text file on a UNIX system, the value will not be large enough to store the complete file because UNIX uses a single linefeed (LF) character to indicate the end-of-line, while a Windows system will use a carriage-return and linefeed (CRLF) pair. To accommodate this difference, you should always allocate extra memory for the string buffer to

store the additional end-of-line characters.

FTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **FtpEnableEvents**, or by registering a callback function using the **FtpRegisterEvent** function.

To determine the current status of a file transfer while it is in progress, use the **FtpGetTransferStatus** function.

Example

```
LPTSTR lpszBuffer = (LPTSTR)calloc(MAXFILESIZE, sizeof(TCHAR));

if (lpszBuffer == NULL)
    return;

nResult = FtpGetText(hClient, lpszRemoteFile, lpszBuffer, MAXFILESIZE);
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

FtpGetTimeout Function

```
INT WINAPI FtpGetTimeout(  
    HCLIENT hClient  
);
```

The **FtpGetTimeout** function returns the number of seconds the client will wait for a response from the server. Once the specified number of seconds has elapsed, the function will fail and return to the caller.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the timeout period in seconds. If the function fails, the return value is `FTP_ERROR`. To get extended error information, call **FtpGetLastError**.

Remarks

The timeout value is only used with blocking client connections. A value of zero indicates that the default timeout period of 20 seconds should be used.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csftpv10.lib`

See Also

[FtpConnect](#), [FtpIsReadable](#), [FtpIsWritable](#), [FtpProxyConnect](#), [FtpRead](#), [FtpSetTimeout](#), [FtpWrite](#)

FtpGetTransferStatus Function

```
INT WINAPI FtpGetTransferStatus(  
    HCLIENT hClient,  
    LPFTPTRANSFERSTATUS lpStatus  
);
```

The **FtpGetTransferStatus** function returns information about the current file transfer in progress.

Parameters

hClient

Handle to the client session.

lpStatus

A pointer to an **FTPTRANSFERSTATUS** structure which contains information about the status of the current file transfer.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is **FTP_ERROR**. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpGetTransferStatus** function returns information about the current file transfer, including the average number of bytes transferred per second and the estimated amount of time until the transfer completes. If there is no file currently being transferred, this function will return the status of the last successful transfer made by the client.

In a multithreaded application, any thread in the current process may call this function to obtain status information for the specified client session.

If the option **FTP_OPTION_HIRES_TIMER** has been specified when connecting to the server, the values of the *dwTimeElapsed* and *dwTimeEstimated* members of the **FTPTRANSFERSTATUS** structure will be in milliseconds instead of seconds. You can use this option to obtain more accurate elapsed times when uploading or downloading small files over a fast network connection.

If you are uploading or downloading large files which exceed 4GB, you should use the **FtpGetTransferStatusEx** function which returns the size as a 64-bit value.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csftpv10.lib`

See Also

[FtpEnableEvents](#), [FtpGetFileStatus](#), [FtpGetTransferStatusEx](#), [FtpRegisterEvent](#), [FTPTRANSFERSTATUS](#), [FTPTRANSFERSTATUSEX](#)

FtpGetTransferStatusEx Function

```
INT WINAPI FtpGetTransferStatusEx(  
    HCLIENT hClient,  
    LPFTPTRANSFERSTATUS lpStatus  
);
```

The **FtpGetTransferStatusEx** function returns information about the current file transfer in progress. This version of the function is designed to support files that are larger than 4GB.

Parameters

hClient

Handle to the client session.

lpStatus

A pointer to an [FTPTRANSFERSTATUSEX](#) structure which contains information about the status of the current file transfer.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is `FTP_ERROR`. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpGetTransferStatusEx** function returns information about the current file transfer, including the average number of bytes transferred per second and the estimated amount of time until the transfer completes. If there is no file currently being transferred, this function will return the status of the last successful transfer made by the client.

In a multithreaded application, any thread in the current process may call this function to obtain status information for the specified client session.

If the option `FTP_OPTION_HIRES_TIMER` has been specified when connecting to the server, the values of the *dwTimeElapsed* and *dwTimeEstimated* members of the **FTPTRANSFERSTATUSEX** structure will be in milliseconds instead of seconds. You can use this option to obtain more accurate elapsed times when uploading or downloading small files over a fast network connection.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csftpv10.lib`

See Also

[FtpEnableEvents](#), [FtpGetFileStatus](#), [FtpGetTransferStatus](#), [FtpRegisterEvent](#), [FTPTRANSFERSTATUS](#), [FTPTRANSFERSTATUSEX](#)

FtpInitialize Function

```
BOOL WINAPI FtpInitialize(  
    LPCTSTR lpszLicenseKey,  
    LPINITDATA lpData  
);
```

The **FtpInitialize** function initializes the library and validates the specified license key at runtime.

Parameters

lpszLicenseKey

Pointer to a string that specifies the runtime license key to be validated. If this parameter is NULL, the library will validate the development license installed on the local system.

lpData

Pointer to an INITDATA data structure. This parameter may be NULL if the initialization data for the library is not required.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **FtpGetLastError**. All other client functions will fail until a license key has been successfully validated.

Remarks

This must be the first function that an application calls before using any of the other functions in the library. When a NULL license key is specified, the library will only function on the development system. Before redistributing the application to an end-user, you must insure that this function is called with a valid license key.

If the *lpData* argument is specified, it must point to an INITDATA structure which has been initialized by setting the *dwSize* member to the size of the structure. All other structure members should be set to zero. If the function is successful, then the INITDATA structure will be filled with identifying information about the library.

Although it is only required that **FtpInitialize** be called once for the current process, it may be called multiple times; however, each call must be matched by a corresponding call to **FtpUninitialize**.

This function dynamically loads other system libraries and allocates thread local storage. If you are calling the functions in this library from within another DLL, it is important that you do not call the **FtpInitialize** or **FtpUninitialize** functions from the **DllMain** function because it can result in deadlocks or access violation errors. If the DLL is linked with the C runtime library (CRT), it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csftpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

FtpIsBlocking Function

```
BOOL WINAPI FtpIsBlocking(  
    HCLIENT hClient  
);
```

The **FtpIsBlocking** function is used to determine if the client is currently performing a blocking operation.

Parameters

hClient

Handle to the client session.

Return Value

If the client is performing a blocking operation, the function returns a non-zero value. If the client is not performing a blocking operation, or the client handle is invalid, the function returns zero.

Remarks

Because a blocking operation can allow the application to be re-entered (for example, by pressing a button while the operation is being performed), it is possible that another blocking function may be called while it is in progress. Since only one thread of execution may perform a blocking operation at any one time, an error would occur. The **FtpIsBlocking** function can be used to determine if the client is already blocked, and if so, take some other action (such as warning the user that they must wait for the operation to complete).

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[FtpCancel](#), [FtpGetStatus](#), [FtpIsConnected](#), [FtpIsReadable](#), [FtpIsWritable](#), [FtpRead](#), [FtpWrite](#)

FtpIsConnected Function

```
BOOL WINAPI FtpIsConnected(  
    HCLIENT hClient  
);
```

The **FtpIsConnected** function is used to determine if the client is currently connected to a server.

Parameters

hClient

Handle to the client session.

Return Value

If the client is connected to a server, the function returns a non-zero value. If the client is not connected, or the client handle is invalid, the function returns zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftpv10.lib

See Also

[FtpGetStatus](#), [FtpIsBlocking](#), [FtpIsReadable](#), [FtpIsWritable](#)

FtpIsReadable Function

```
BOOL WINAPI FtpIsReadable(  
    HCLIENT hClient,  
    INT nTimeout,  
    LPDWORD lpdwAvail  
);
```

The **FtpIsReadable** function is used to determine if data is available to be read from the server.

Parameters

hClient

Handle to the client session.

nTimeout

Timeout for server response, in seconds. A value of zero specifies that the connection should be polled without blocking the current thread.

lpdwAvail

A pointer to an unsigned integer which will contain the number of bytes available to read. This parameter may be NULL if this information is not required.

Return Value

If the client can read data from the server within the specified timeout period, the function returns a non-zero value. If the client cannot read any data, the function returns zero.

Remarks

On some platforms, this value will not exceed the size of the receive buffer (typically 64K bytes). Because of differences between TCP/IP stack implementations, it is not recommended that your application exclusively depend on this value to determine the exact number of bytes available. Instead, it should be used as a general indicator that there is data available to be read.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csftpv10.lib

See Also

[FtpGetStatus](#), [FtpIsBlocking](#), [FtpIsConnected](#), [FtpIsWritable](#), [FtpRead](#)

FtpIsWritable Function

```
BOOL WINAPI FtpIsWritable(  
    HCLIENT hClient,  
    INT nTimeout  
);
```

The **FtpIsWritable** function is used to determine if data can be written to the server.

Parameters

hClient

Handle to the client session.

nTimeout

Timeout for server response, in seconds. A value of zero specifies that the connection should be polled without blocking the current thread.

Return Value

If the client can write data to the server within the specified timeout period, the function returns a non-zero value. If the client cannot write any data, the function returns zero.

Remarks

Although this function can be used to determine if some amount of data can be sent to the remote process it does not indicate the amount of data that can be written without blocking the client. In most cases, it is recommended that large amounts of data be broken into smaller logical blocks, typically some multiple of 512 bytes in length.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftpv10.lib

See Also

[FtpGetStatus](#), [FtpIsBlocking](#), [FtpIsConnected](#), [FtpIsReadable](#), [FtpWrite](#)

FtpLogin Function

```
INT WINAPI FtpLogin(  
    HCLIENT hClient,  
    LPCTSTR lpszUserName,  
    LPCTSTR lpszPassword,  
    LPCTSTR lpszAccount  
);
```

The **FtpLogin** function authenticates the specified user in on the server. This function must be called after the connection has been established, and before attempting to transfer files or perform any other function on the server.

Parameters

hClient

Handle to the client session.

lpszUserName

Points to a string that specifies the user name to be used to authenticate the current client session. If this parameter is NULL or an empty string, then the login is considered to be anonymous.

lpszPassword

Points to a string that specifies the password to be used to authenticate the current client session. This parameter may be NULL or an empty string if no password is required for the specified user, or if no username has been specified.

lpszAccount

Points to a string that specifies the account name to be used to authenticate the current client session. This parameter may be NULL or an empty string if no account name is required for the specified user.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

Some public FTP servers support anonymous logins, where a username and password are not required to access the server. In this case, both the *lpszUserName* and *lpszPassword* parameters can be NULL or specify empty strings. In most cases, access to the server using an anonymous login is restricted, with clients only having permission to download files. Servers may also restrict the maximum number of anonymous sessions that may be logged in at one time.

This function should only be used after calling the **FtpLogout** function, enabling you to log in as another user during the same session. Not all servers will permit a client to change user credentials during the same session. In most cases, it is preferable to disconnect from the server and re-connect using the new credentials rather than using this function.

This function is not supported with secure connections using the SSH protocol.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[FtpConnect](#), [FtpLogout](#), [FtpProxyConnect](#)

Copyright © 2023 Catalyst Development Corporation. All rights reserved.

FtpLogout Function

```
INT WINAPI FtpLogout(  
    HCLIENT hClient  
);
```

The **FtpLogout** function logs out the user associated with the current client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpLogout** function is used when the client wants to re-authenticate using a new username and password. Before any further action may be taken, other than disconnecting from the server, the **FtpLogin** function must be called to re-authenticate the client.

It is not necessary to call this function prior to disconnecting from the server because the user current user is automatically logged out when the **FtpDisconnect** function is called.

This function is not supported with secure connections using the SSH protocol.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

FtpMountStructure Function

```
INT WINAPI FtpMountStructure(  
    HCLIENT hClient,  
    LPCTSTR lpszFileSystem  
);
```

The **FtpMountStructure** function mounts a different file system or other directory data structure on the server.

Parameters

hClient

Handle to the client session.

lpszFileSystem

A pointer to a string which specifies the file system to mount on the server.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

This function sends the SMNT command to the server, which may not be supported on some platforms. Use of this command typically requires that the user have administrator privileges on the server.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[FtpCreateDirectory](#), [FtpRemoveDirectory](#)

FtpOpenDirectory Function

```
INT WINAPI FtpOpenDirectory(  
    HCLIENT hClient,  
    LPCTSTR lpszDirectory  
);
```

The **FtpOpenDirectory** function opens the specified directory on the server.

Parameters

hClient

Handle to the client session.

lpszDirectory

Pointer to the name of the directory that will be opened. The format of the directory name must match the filename conventions used by the server. If a NULL pointer or an empty string is specified, then the current working directory is opened.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpOpenDirectory** function opens the specified directory on the server using the LIST command. The contents of the directory can be read using the **FtpGetFirstFile** and **FtpGetNextFile** functions. The directory listing is returned on the data channel in one of several different formats. The library can recognize listing formats generated by UNIX, VMS and Windows servers, as well as those of other servers which emulate one of those common formats. Once the complete directory listing has been read, the directory must be closed by calling the **FtpCloseDirectory** function.

Because the directory listing is returned on the data channel, a file transfer cannot be performed while the directory is in the process of being read by the client. Applications which need to collect a list of files to download should first open the directory, read the contents and store the file names in an array. After the directory has been closed, the application can then start transferring the files to the local system.

Some servers may not support file listings for any directory other than the current working directory. If an error is returned when specifying a directory name, try changing the current working directory using the **FtpChangeDirectory** function and then call this function again, passing NULL or an empty string as the *lpszDirectory* parameter.

To obtain a list of all files in a directory using a single function call, use the **FtpEnumFiles** function. If the server lists files in a format that is not recognized by the library, the **FtpGetFileList** function can be used to obtain an unparsed file listing from the server.

Example

```
if (FtpOpenDirectory(hClient, NULL) != FTP_ERROR)  
{  
    FTPFILESTATUS ftpFile;  
    BOOL bResult;  
  
    bResult = FtpGetFirstFile(hClient, &ftpFile);  
    while (bResult)
```

```
{  
    // The ftpFile structure contains information about the file  
    bResult = FtpGetNextFile(hClient, &ftpFile);  
}  
  
FtpCloseDirectory(hClient);  
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csftpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

FtpOpenFile Function

```
INT WINAPI FtpOpenFile(  
    HCLIENT hClient,  
    LPCTSTR lpszFileName,  
    DWORD dwOpenMode,  
    DWORD dwOffset  
);
```

The **FtpOpenFile** function creates or opens the specified file on the server.

Parameters

hClient

Handle to the client session.

lpszFileName

Points to a string that specifies the name of the remote file to create or open. The file pathing and name conventions must be that of the server.

dwOpenMode

Specifies the type of access to the file. An application can open a file for reading, create a new file or append data to an existing file. This parameter should be one of the following values.

Constant	Description
FTP_FILE_READ	The file is opened for reading on the server. A data channel is created and the contents of the file are returned to the client.
FTP_FILE_WRITE	The file is opened for writing on the server. If the file does not exist, it will be created. If it does exist, it will be overwritten.
FTP_FILE_APPEND	The file is opened for writing on the server. All data will be appended to the end of the file.

dwOffset

A byte offset which specifies where the file transfer should begin. The default value of zero specifies that the file transfer should start at the beginning of the file. A value greater than zero is typically used to restart a transfer that has not completed successfully. Note that specifying a non-zero offset using FTP requires that the server support the REST command to restart transfers.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

Only one file may be opened at a time for each client session. Attempting to perform an action such as uploading or downloading another file while a file is currently open will result in an error. Typically this indicates that the application failed to call the **FtpCloseFile** function.

It is strongly recommended that most applications use the **FtpGetFile** or **FtpPutFile** functions to perform file transfers. These functions are easier to use, and have internal optimizations that improves the overall data transfer rate when compared to implementing the file transfer code in your own application.

When a file is created on the server, the file ownership and access rights are determined by the server. Some servers may provide a method to change these attributes through site-specific commands. Refer to the server's operating system documentation for more information about what commands may be available.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csftpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

FtpOpenFileEx Function

```
INT WINAPI FtpOpenFileEx(  
    HCLIENT hClient,  
    LPCTSTR lpszFileName,  
    DWORD dwOpenMode,  
    DWORD dwReserved,  
    ULARGE_INTEGER uiOffset  
);
```

The **FtpOpenFileEx** function creates or opens the specified file on the server. This version of the function is designed to support files that are larger than 4GB.

Parameters

hClient

Handle to the client session.

lpszFileName

Points to a string that specifies the name of the remote file to create or open. The file pathing and name conventions must be that of the server.

dwOpenMode

Specifies the type of access to the file. An application can open a file for reading, create a new file or append data to an existing file. This parameter should be one of the following values.

Constant	Description
FTP_FILE_READ	The file is opened for reading on the server. A data channel is created and the contents of the file are returned to the client.
FTP_FILE_WRITE	The file is opened for writing on the server. If the file does not exist, it will be created. If it does exist, it will be overwritten.
FTP_FILE_APPEND	The file is opened for writing on the server. All data will be appended to the end of the file.

dwReserved

An unsigned integer value that is reserved for future use. This parameter should always have a value of zero.

uiOffset

A byte offset which specifies where the file transfer should begin. The default value of zero specifies that the file transfer should start at the beginning of the file. A value greater than zero is typically used to restart a transfer that has not completed successfully. Note that specifying a non-zero offset using FTP requires that the server support the REST command to restart transfers.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

Only one file may be opened at a time for each client session. Attempting to perform an action such as uploading or downloading another file while a file is currently open will result in an error.

Typically this indicates that the application failed to call the **FtpCloseFile** function.

It is strongly recommended that most applications use the **FtpGetFileEx** or **FtpPutFileEx** functions to perform file transfers. These functions are easier to use, and have internal optimizations that improves the overall data transfer rate when compared to implementing the file transfer code in your own application.

When a file is created on the server, the file ownership and access rights are determined by the server. Some servers may provide a method to change these attributes through site-specific commands. Refer to the server's operating system documentation for more information about what commands may be available.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csftpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

FtpProxyConnect Function

```
HCLIENT WINAPI FtpProxyConnect(  
    UINT nProxyType,  
    LPCTSTR LpszProxyHost,  
    UINT nProxyPort,  
    LPCTSTR LpszProxyUser,  
    LPCTSTR LpszProxyPassword,  
    LPCTSTR LpszRemoteHost,  
    UINT nTimeout,  
    DWORD dwOptions,  
    LPSECURITYCREDENTIALS LpCredentials  
);
```

The **FtpProxyConnect** function establishes a connection through a proxy server and defines security related options to be used. Four basic proxy server types are recognized, and the library will automatically negotiate with the server to establish a connection through the proxy server to the destination server.

Parameters

nProxyType

An identifier which specifies the type of proxy server that is being connected to. This value must be defined as one of the following values:

Constant	Description
FTP_PROXY_NONE	This value specifies that no proxy server is being used. In this case, the FtpConnect function is called directly, ignoring the proxy parameters.
FTP_PROXY_USER	This value specifies that the client is not logged into the proxy server. The USER command is sent in the format username@ftpsite followed by the password. This is the format used with the Gauntlet proxy server.
FTP_PROXY_LOGIN	This value specifies that the client is logged into the proxy server. The USER command is then sent in the format username@ftpsite followed by the password. This is the format used by the InterLock proxy server.
FTP_PROXY_OPEN	This value specifies that the client is not logged into the proxy server. The OPEN command is sent specifying the host name, followed by the username and password.
FTP_PROXY_SITE	This value specifies that the client is logged into the server. The SITE command is sent, specifying the host name, followed by the username and the password.
FTP_PROXY_OTHER	This special proxy type specifies that another, undefined proxy server is being used. The client connects to the proxy host, but does not attempt to authenticate the client. The application is responsible for negotiating with the proxy server, typically using the FtpCommand function to send specific command sequences.

lpszProxyHost

A pointer to the name of the proxy server to connect through; this may be a fully-qualified domain name or an IP address.

lpszProxyPort

The port number the proxy server is listening on; a value of zero specifies that the default port number should be used.

lpszProxyUser

A pointer to the user name used to authenticate the client on the proxy server. Not all proxy servers require this information; it is recommended that you consult the proxy server documentation to determine if a username is required.

lpszProxyPassword

A pointer to the password used to authenticate the client on the proxy server. Not all proxy servers require this information; it is recommended that you consult the proxy server documentation to determine if a password is required.

lpszRemoteHost

A pointer to the name of the server that you want to connect to, through the proxy server.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
FTP_OPTION_PASSIVE	This option specifies the client should attempt to establish the data connection with the server. When the client uploads or downloads a file, normally the server establishes a second connection back to the client which is used to transfer the file data. However, if the local system is behind a firewall or a NAT router, the server may not be able to create the data connection and the transfer will fail. By specifying this option, it forces the client to establish an outbound data connection with the server. It is recommended that applications use passive mode whenever possible.
FTP_OPTION_FIREWALL	This option specifies the client should always use the host IP address to establish the data connection with the server, not the address returned by the server in response to the PASV command. This option may be necessary if the server is behind a router that performs Network Address Translation (NAT) and it returns an unreachable IP address for the data connection. If this option is specified, it will also enable passive mode data transfers.
FTP_OPTION_NOAUTH	This option specifies the server does not require authentication, or that it requires an alternate

	<p>authentication method. When this option is used, the client connection is flagged as authenticated as soon as the connection to the server has been established. Note that using this option to bypass authentication may result in subsequent errors when attempting to retrieve a directory listing or transfer a file. It is recommended that you consult the technical reference documentation for the server to determine its specific authentication requirements.</p>
FTP_OPTION_KEEPALIVE	<p>This option specifies the client should attempt to keep the connection with the server active for an extended period of time. It is important to note that regardless of this option, the server may still choose to disconnect client sessions that are holding the command channel open but are not performing file transfers.</p>
FTP_OPTION_VIRTUALHOST	<p>This option specifies the server supports virtual hosting, where multiple domains are hosted by a server using the same external IP address. If this option is enabled, the client will send the HOST command to the server upon establishing a connection.</p>
FTP_OPTION_VERIFY	<p>This option specifies that file transfers should be automatically verified after the transfer has completed. If the server supports the XMD5 command, the transfer will be verified by calculating an MD5 hash of the file contents. If the server does not support the XMD5 command, but does support the XCRC command, the transfer will be verified by calculating a CRC32 checksum of the file contents. If neither the XMD5 or XCRC commands are supported, the transfer is verified by comparing the size of the file. Automatic file verification is only performed for binary mode transfers because of the end-of-line conversion that may occur when text files are uploaded or downloaded.</p>
FTP_OPTION_TRUSTEDSITE	<p>This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using either the SSL or TLS protocols.</p>
FTP_OPTION_SECURE	<p>This option specifies the client should attempt to establish a secure connection with the server. This option is the same as specifying FTP_OPTION_SECURE_IMPLICIT which immediately performs the SSL/TLS protocol negotiation when the connection is established.</p>

FTP_OPTION_SECURE_IMPLICIT	This option specifies the client should attempt to immediately establish secure SSL/TLS connection with the server. This option is typically used when connecting to a server on port 990, which is the default port number used for FTPS.
FTP_OPTION_SECURE_EXPLICIT	This option specifies the client should establish a standard connection to the server and then use the AUTH command to negotiate an explicit secure connection. This option is typically used when connecting to the server on ports other than 990.
FTP_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
FTP_OPTION_TUNNEL	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established. This option also forces all connections to be outbound and enables the firewall compatibility features in the client.
FTP_OPTION_KEEPALIVE_DATA	This option specifies the client should attempt to keep the control connection active during a file transfer. Normally, when a data transfer is in progress, no additional commands are issued on the control channel until the transfer completes. Specifying this option automatically enables the FTP_OPTION_KEEPALIVE option and forces the client to continue to issue NOOP commands during the file transfer. This option only applies to FTP and FTPS connections and has no effect on connections using SFTP (SSH).
FTP_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
FTP_OPTION_FREETHREAD	This option specifies the handle returned by this function may be used by any thread, and is not limited to the thread which created it. The

	application is responsible for ensuring that access to the handle is synchronized across multiple threads.
FTP_OPTION_HIRES_TIMER	This option specifies the elapsed time for data transfers should be returned in milliseconds instead of seconds. This will return more accurate transfer times for smaller files being uploaded or downloaded using fast network connections.
FTP_OPTION_TLS_REUSE	This option specifies that TLS session reuse should be enabled for secure connections. This option is only supported on Windows 8.1 or Windows Server 2012 R2 and later platforms, and it should only be used when explicitly required by the server. This option is not compatible with servers built using OpenSSL 1.0.2 and earlier versions which do not provide Extended Master Secret (EMS) support as outlined in RFC7627.

lpCredentials

A pointer to a [SECURITYCREDENTIALS](#) structure. This parameter should be NULL if the connection is not secure or when client credentials are not required. Most servers do not require a client certificate to establish a secure connection. However, if the server does require a client certificate, the structure members *dwSize*, *lpzCertStore* and *lpzCertName* must be defined. Undefined structure members must be initialized to a value of zero or NULL and the *dwSize* member must be initialized to the size of the **SECURITYCREDENTIALS** structure.

Return Value

If the function succeeds, the return value is a handle to a client session. If the function fails, the return value is INVALID_CLIENT. To get extended error information, call **FtpGetLastError**.

Remarks

To prevent this function from blocking the main user interface thread, the application should create a background worker thread and establish a connection by calling **FtpProxyConnect** in that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each client session.

The username and password that is used to authenticate the client with the proxy server are not the same as those used to login to the target server. Once a connection has been established with the proxy server, the client must call the **FtpLogin** function to actually login to the server and begin a file transfer.

If the FTP_OPTION_KEEPALIVE option is specified, a background worker thread will be created to monitor the command channel and periodically send NOOP commands to the server if no commands have been sent recently. This can prevent the server from terminating the client connection during idle periods where no commands are being issued. However, it is important to keep in mind that many servers can be configured to also limit the total amount of time a client can be connected to the server, as well as the amount of time permitted between file transfers. If the server does not respond to the NOOP command, this option will be automatically disabled for the remainder of the client session.

If the FTP_OPTION_SECURE_EXPLICIT option is specified, the client will establish a standard connection to the server and send the AUTH TLS command to the server. If the server does not

accept this command, it will then send the AUTH SSL command. If both commands are rejected by the server, an explicit SSL session cannot be established. By default, both the command and data channels will be encrypted when a secure connection is established. To change this, use the **FtpSetChannelMode** function.

The *dwOptions* argument can be used to specify the threading model that is used by the library when a connection is established. By default, the handle is initially attached to the thread that created it. From that point on, until the it is released, only the owner may call functions using that handle. The ownership of the handle may be transferred from one thread to another using the **FtpAttachThread** function.

Specifying the FTP_OPTION_FREETHREAD option enables any thread to call any function using the handle, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the handle is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same handle.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csftpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

FtpPutData Function

```
INT WINAPI FtpPutData(  
    HCLIENT hClient,  
    LPCTSTR lpszFileName,  
    LPVOID lpvBuffer,  
    DWORD dwLength,  
    DWORD dwReserved  
);
```

The **FtpPutData** function transfers the contents of the specified buffer to a file on the server.

Parameters

hClient

Handle to the client session.

lpszFileName

A pointer to a string that specifies the file on the server that will be created, overwritten or appended to. The file naming conventions must be that of the host operating system.

lpvBuffer

A pointer to the data that will be copied to the server and stored in the specified file.

dwLength

The number of bytes to copy from the buffer.

dwReserved

A reserved parameter. This value should always be zero.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

If the *lpvBuffer* parameter is pointing to a Unicode string, it is important to note that the value of the *dwLength* parameter should specify the number of bytes, not the number of characters. When using UTF-16, each character is two bytes long and therefore the length of the buffer is effectively double the length of the string. Because Unicode strings can contain null characters, you must also set the current file type to FILE_TYPE_IMAGE prior to calling this function.

The **FtpPutText** function can be used to create a text file from the contents of a string.

This function will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the FTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **FtpEnableEvents**, or by registering a callback function using the **FtpRegisterEvent** function.

To determine the current status of a file transfer while it is in progress, use the **FtpGetTransferStatus** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csftpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[FtpChangeDirectory](#), [FtpEnableEvents](#), [FtpGetData](#), [FtpGetFile](#), [FtpGetTransferStatus](#), [FtpPutFile](#),
[FtpRegisterEvent](#), [FtpSetBufferSize](#)

FtpPutFile Function

```
INT WINAPI FtpPutFile(  
    HCLIENT hClient,  
    LPCTSTR lpszLocalFile,  
    LPCTSTR lpszRemoteFile,  
    DWORD dwOptions,  
    DWORD dwOffset  
);
```

The **FtpPutFile** function transfers the specified file on the local system to the server.

Parameters

hClient

Handle to the client session.

lpszLocalFile

A pointer to a string that specifies the file that will be transferred from the local system. The file pathing and name conventions must be that of the local host.

lpszRemoteFile

A pointer to a string that specifies the file on the server that will be created, overwritten or appended to. The file naming conventions must be that of the host operating system.

dwOptions

An unsigned integer that specifies one or more options. This parameter may be any one of the following values:

Constant	Description
FTP_TRANSFER_DEFAULT	This option specifies the default transfer mode should be used. If the remote file exists, it will be overwritten with the contents of the uploaded file.
FTP_TRANSFER_APPEND	This option specifies that if the remote file exists, the contents of the local file is appended to the remote file. If the remote file does not exist, it is created.

dwOffset

A byte offset which specifies where the file transfer should begin. The default value of zero specifies that the file transfer should start at the beginning of the file. A value greater than zero is typically used to restart a transfer that has not completed successfully. Note that specifying a non-zero offset requires that the server support the REST command to restart transfers.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

This function will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the FTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **FtpEnableEvents**, or by registering a callback function using the **FtpRegisterEvent** function.

To determine the current status of a file transfer while it is in progress, use the **FtpGetTransferStatus** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csftpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

FtpPutFileEx Function

```
INT WINAPI FtpPutFileEx(  
    HCLIENT hClient,  
    LPCTSTR lpszLocalFile,  
    LPCTSTR lpszRemoteFile,  
    DWORD dwOptions,  
    ULARGE_INTEGER uiOffset  
);
```

The **FtpPutFileEx** function transfers the specified file on the local system to the server. This version of the function is designed to support files that are larger than 4GB.

Parameters

hClient

Handle to the client session.

lpszLocalFile

A pointer to a string that specifies the file that will be transferred from the local system. The file pathing and name conventions must be that of the local host.

lpszRemoteFile

A pointer to a string that specifies the file on the server that will be created, overwritten or appended to. The file naming conventions must be that of the host operating system.

dwOptions

An unsigned integer that specifies one or more options. This parameter may be any one of the following values:

Constant	Description
FTP_TRANSFER_DEFAULT	This option specifies the default transfer mode should be used. If the remote file exists, it will be overwritten with the contents of the uploaded file.
FTP_TRANSFER_APPEND	This option specifies that if the remote file exists, the contents of the local file is appended to the remote file. If the remote file does not exist, it is created.

uiOffset

A byte offset which specifies where the file transfer should begin. The default value of zero specifies that the file transfer should start at the beginning of the file. A value greater than zero is typically used to restart a transfer that has not completed successfully. Note that specifying a non-zero offset requires that the server support the REST command to restart transfers.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

This function will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the FTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **FtpEnableEvents**, or by registering a callback function using

the **FtpRegisterEvent** function.

To determine the current status of a file transfer while it is in progress, use the **FtpGetTransferStatusEx** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csftpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[FtpChangeDirectory](#), [FtpEnableEvents](#), [FtpGetData](#), [FtpGetFileEx](#), [FtpGetMultipleFiles](#), [FtpGetTransferStatusEx](#), [FtpPutData](#), [FtpPutMultipleFiles](#), [FtpRegisterEvent](#), [FtpSetBufferSize](#), [FtpVerifyFile](#)

FtpPutMultipleFiles Function

```
INT WINAPI FtpPutMultipleFiles(  
    HCLIENT hClient,  
    LPCTSTR lpszLocalDirectory,  
    LPCTSTR lpszRemoteDirectory,  
    LPCTSTR lpszFileMask,  
    DWORD dwReserved  
);
```

The **FtpPutMultipleFiles** function copies one or more files from the local host to the server, using the specified wildcard.

Parameters

hClient

Handle to the client session.

lpszLocalDirectory

Pointer to a string which specifies the local directory where the files will be copied from. A NULL pointer or empty string specifies that files should be copied from the current working directory.

lpszRemoteDirectory

Pointer to a string which specifies the remote directory where the files will be copied to. A NULL pointer or empty string specifies that the files should be copied to the current working directory on the server.

lpszFileMask

Pointer to a string which specifies the files that are to be copied from the local system to the server. The file mask should follow the Windows conventions used for wildcard file matches.

dwReserved

A reserved parameter. This value should always be zero.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpPutMultipleFiles** function is used to transfer files from the local host to the server which match a specified wildcard file mask. All files will be transferred using the current file type as specified by the **FtpSetFileType** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csftpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[FtpChangeDirectory](#), [FtpGetFile](#), [FtpGetMultipleFiles](#), [FtpPutFile](#)

FtpPutText Function

```
INT WINAPI FtpPutText(  
    HCLIENT hClient,  
    LPCTSTR lpszRemoteFile,  
    LPCTSTR lpszBuffer  
);
```

The **FtpPutText** function creates a text file on the server using the contents of a string buffer.

Parameters

hClient

Handle to the client session.

lpszRemoteFile

A pointer to a string that specifies the text file on the server that will be created or overwritten. The file pathing and name conventions must be that of the server.

lpszBuffer

A pointer to a string that contains the text that will be stored in the file.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is `FTP_ERROR`. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpPutText** function is used to create a text file on the server from the contents of a string. If the specified file already exists on the server, its contents will be overwritten. This function will always set the file type to `FILE_TYPE_ASCII` before creating the file, and will restore the default file type before the method returns.

If the Unicode version of this function is called, the string will be converted to ASCII and then uploaded to the server. If you wish to store the contents of the string as Unicode on the server, you must set the current file type to `FILE_TYPE_IMAGE` and use the **FtpPutData** function. This function should never be used to upload binary data.

This function will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the `FTP_EVENT_PROGRESS` event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **FtpEnableEvents**, or by registering a callback function using the **FtpRegisterEvent** function.

To determine the current status of a file transfer while it is in progress, use the **FtpGetTransferStatus** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csftpv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

See Also

[FtpChangeDirectory](#), [FtpEnableEvents](#), [FtpGetText](#), [FtpGetTransferStatus](#), [FtpPutData](#), [FtpPutFile](#),

FtpRead Function

```
INT WINAPI FtpRead(  
    HCLIENT hClient,  
    LPBYTE lpBuffer,  
    INT cbBuffer  
);
```

The **FtpRead** function reads the specified number of bytes from the client socket and copies them into the buffer. The data may be of any type, and is not terminated with a null character.

Parameters

hClient

Handle to the client session.

lpBuffer

Pointer to the buffer in which the data will be copied.

cbBuffer

The maximum number of bytes to read and copy into the specified buffer. This value must be greater than zero.

Return Value

If the function succeeds, the return value is the number of bytes actually read. A return value of zero indicates that the server has closed the connection and there is no more data available to be read. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

When **FtpRead** is called and the client is in non-blocking mode, it is possible that the function will fail because there is no available data to read at that time. This should not be considered a fatal error. Instead, the application should simply wait to receive the next asynchronous notification that data is available.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[FtpEnableEvents](#), [FtpGetData](#), [FtpGetFile](#), [FtpIsBlocking](#), [FtpIsReadable](#), [FtpIsWritable](#), [FtpRegisterEvent](#), [FtpWrite](#)

FtpRegisterEvent Function

```
INT WINAPI FtpRegisterEvent(  
    HCLIENT hClient,  
    UINT nEventId,  
    FTPEVENTPROC LpEventProc,  
    DWORD_PTR dwParam  
);
```

The **FtpRegisterEvent** function registers an event handler for the specified event.

Parameters

hClient

Handle to the client session.

nEventId

An unsigned integer which specifies which event should be registered with the specified callback function. One of the following values may be used:

Constant	Description
FTP_EVENT_CONNECT	The control connection to the server has completed.
FTP_EVENT_DISCONNECT	The server has closed the control connection to the client. The client should read any remaining data and disconnect.
FTP_EVENT_OPENFILE	The data connection to the server has completed.
FTP_EVENT_CLOSEFILE	The server has closed the data connection to the client. The client should read any remaining data and close the data channel.
FTP_EVENT_READFILE	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
FTP_EVENT_WRITEFILE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
FTP_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
FTP_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.
FTP_EVENT_COMMAND	A command has been issued by the client and the server response has been received and processed. This event can be used to log the result codes and messages returned by the server in response to actions taken by the client.

FTP_EVENT_PROGRESS	The client is in the process of sending or receiving a file on the data channel. This event is called periodically during a transfer so that the client can update any user interface components such as a status control or progress bar.
FTP_EVENT_GETFILE	This event is generated when a file download has completed. If multiple files are being downloaded, this event will be generated for each file.
FTP_EVENT_PUTFILE	This event is generated when a file upload has completed. If multiple files are being uploaded, this event will be generated for each file.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **FtpEventProc** callback function. If this parameter is NULL, the callback for the specified event is disabled.

dwParam

A user-defined integer value that is passed to the callback function. If the application targets the x86 (32-bit) platform, this parameter must be a 32-bit unsigned integer. If the application targets the x64 (64-bit) platform, this parameter must be a 64-bit unsigned integer.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpRegisterEvent** function associates a callback function with a specific event. The event handler is an **FtpEventProc** function that is invoked when the event occurs. Arguments are passed to the function to identify the client session, the event type and the user-defined value specified when the event handler is registered. If the event occurs because of an error condition, the error code will be provided to the handler.

This function is typically used to register an event handler that is invoked while a file is being uploaded or downloaded. The FTP_EVENT_PROGRESS event will only be generated periodically during the transfer to ensure the application is not flooded with event notifications. It is guaranteed that at least one FTP_EVENT_PROGRESS notification will occur at the beginning of the transfer, and one at the end of the transfer when it has completed.

The callback function specified by the *lpEventProc* parameter must be declared using the **__stdcall** calling convention. This ensures the arguments passed to the event handler are pushed on to the stack in the correct order. Failure to use the correct calling convention will corrupt the stack and cause the application to terminate abnormally.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[FtpDisableEvents](#), [FtpEnableEvents](#), [FtpEventProc](#), [FtpFreezeEvents](#)

FtpRegisterFileType Function

```
BOOL WINAPI FtpRegisterFileType(  
    HCLIENT hClient,  
    LPCTSTR lpszExtension,  
    UINT nFileType  
);
```

The **FtpRegisterFileType** function associates a file name extension with a specific file type.

Parameters

hClient

Handle to the client session. If this parameter is `INVALID_CLIENT`, the file type is registered for all client sessions in the current process. If the parameter specifies a valid client session, then the association is made only for that specific session.

lpszExtension

A pointer to a null terminated string which specifies the file name extension. If this parameter is `NULL` or points to an empty string, the default file type will be changed for the client session.

nFileType

Specifies the type of file associated with the file extension. This parameter can be one of the following values.

Value	Description
<code>FILE_TYPE_ASCII</code>	The file is a text file using the ASCII character set. For those servers which mark the end of a line with characters other than a carriage return and linefeed, it will be converted to the native client format. This is the file type used for directory listings.
<code>FILE_TYPE_EBCDIC</code>	The file is a text file using the EBCDIC character set. Local files will be converted to EBCDIC when sent to the server. Remote files will be converted to the native ASCII character set when retrieved from the server.
<code>FILE_TYPE_IMAGE</code>	The file is a binary image and no data conversion of any type is performed on the file. This is typically the default file type for data file transfers. If the type of file that is being transferred is unknown, this file type should always be used.

Return Value

If the function succeeds, the return value non-zero. If the function fails, the return value is zero. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpRegisterFileType** function is used to associate specific file types with file name extensions. The library has an internal list of standard text file extensions which it automatically recognizes. This method can be used to extend or modify that list for the client session.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: csftpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[FtpSetPassiveMode](#)

FtpRemoveDirectory Function

```
INT WINAPI FtpRemoveDirectory(  
    HCLIENT hClient,  
    LPCTSTR lpszDirectory  
);
```

The **FtpRemoveDirectory** function removes the specified directory on the server.

Parameters

hClient

Handle to the client session.

lpszDirectory

Points to a string that specifies the name of the directory. The file pathing and name conventions must be that of the server.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

This function uses the RMD command to create the directory. The user must have the appropriate permission to remove the specified directory. Most servers will not permit you to remove a directory if it contains one or more files.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

FtpRenameFile Function

```
INT WINAPI FtpRenameFile(  
    HCLIENT hClient,  
    LPCTSTR lpszOldFileName,  
    LPCTSTR lpszNewFileName  
);
```

The **FtpRenameFile** function renames the specified file on the server. The file must exist, and the current user must have the appropriate permission to change the file name.

Parameters

hClient

Handle to the client session.

lpszOldFileName

Points to a string that specifies the name of the remote file to rename. The file pathing and name conventions must be that of the server.

lpszNewFileName

Points to a string that specifies the new name for the remote file. The file pathing and name conventions must be that of the server.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

This function causes two separate commands to be sent to the server, RNFR and RNT0. If either command fails, the function will fail and return an error code.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[FtpDeleteFile](#), [FtpGetFile](#), [FtpPutFile](#)

FtpReset Function

```
INT WINAPI FtpReset(  
    HCLIENT hClient  
);
```

The **FtpReset** function resets the client state and resynchronizes with the server. This function is typically called after an unexpected error has occurred, or an operation has been canceled.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The client cannot be reset while a file transfer is in progress or if the client is in a blocked state. To abort a file transfer, use the **FtpCancel** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[FtpCancel](#)

FtpSetActivePorts Function

```
INT WINAPI FtpSetActivePorts(  
    HCLIENT hClient,  
    UINT nLowPort,  
    UINT nHighPort  
);
```

The **FtpSetActivePorts** function changes the range of local port numbers used for active mode file transfers.

Parameters

hClient

Handle to the client session.

nLowPort

An unsigned integer that specifies the low port number.

lpnHighPort

An unsigned integer that specifies the high port number.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

This function is used to modify the range of local port numbers used for active mode file transfers. When using active mode, the client listens for an inbound connection from the server rather than establishing an outbound connection for the data transfer. In most cases, passive mode transfers are preferred because they mitigate potential compatibility issues with firewalls and NAT routers.

If active mode transfers are required, the default port range used when listening for the server connection is between 1024 and 5000. This is the standard range of ephemeral ports used by the Windows operating system. However, under some circumstances that range of ports may be too small, or a firewall may be configured to deny inbound connections on ephemeral ports. In that case, the **FtpSetActivePorts** function can be used to specify a different range of port numbers.

While it is technically permissible to assign the low and high port numbers to the same value, effectively specifying a single active port number, this is not recommended as it can cause the transfer to fail unexpectedly if multiple file transfers are performed. A minimum range of at least 1000 ports is recommended. For example, if you specify a low port value of 40000 then it is recommended that the high port value be at least 41000. The maximum port value is 65535.

To determine the current range of active port numbers being used, call the **FtpGetActivePorts** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

FtpSetBufferSize Function

```
INT WINAPI FtpSetBufferSize(  
    HCLIENT hClient,  
    INT nBufferSize  
);
```

The **FtpSetBufferSize** function sets the size in bytes of an internal buffer that will be used during data transfers.

Parameters

hClient

Handle to the client session.

nBufferSize

The size of an internal buffer, in bytes. Any value greater than or equal to zero is acceptable. If *nBufferSize* is zero, then the default value of 4096 will be used. If *nBufferSize* is less than 256 bytes, the buffer size will be set to 256. The maximum value of *nBufferSize* is 1048576 (1Mb).

Return Value

If the function succeeds, the return value is the size of the internal buffer that will be used. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The speed of data transfers, particularly on uploads, may be sensitive to network type and configuration, and the size of the internal buffer used for data transfers. The default size of this buffer will result in good performance for a wide range of network characteristics. A larger buffer will not necessarily result in better performance. For example, a multiple of 1460, which is the typical Maximum Transmission Unit (MTU), may be optimal in many situations.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

FtpSetChannelMode Function

```
INT WINAPI FtpSetChannelMode(  
    HCLIENT hClient,  
    INT nChannel,  
    INT nMode  
);
```

The **FtpSetChannelMode** function changes the security mode for the specified communication channel.

Parameters

hClient

Handle to the client session.

nChannel

An integer value which specifies which channel to return information for. It may be one of the following values:

Constant	Description
FTP_CHANNEL_COMMAND	Change information for the command channel. This is the communication channel used to send commands to the server and receive command result and status information from the server.
FTP_CHANNEL_DATA	Change information for the data channel. This is the communication channel used to send or receive data during a file transfer.

nMode

An integer value which specifies the new mode for the specified channel. It may be one of the following values:

Constant	Description
FTP_CHANNEL_CLEAR	Data sent and received on this channel should not be encrypted.
FTP_CHANNEL_SECURE	Data sent and received on this channel should be encrypted. Specifying this option requires that a secure connection has already been established with the server.

Return Value

If the function succeeds, the return value is the previous mode for the specified channel. If the function fails, it will return FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpSetChannelMode** function is used to change the default mode for the specified channel, and is typically used to control whether or not data is encrypted during a file transfer. If a standard, non-secure connection has been established with the server, an error will be returned if you specify the FTP_CHANNEL_SECURE mode for either channel.

If you have established a secure connection and then specify the FTP_CHANNEL_CLEAR mode for

the command channel, the client will send the CCC command to the server to indicate that commands should no longer be encrypted. If the server does not support this command, an error will be returned and the channel mode will remain unchanged. Once the command channel has been changed to clear mode, it cannot be changed back to secure mode. You must disconnect and re-connect to the server if you want to resume sending commands over an encrypted channel.

Changing the mode for the data channel requires that the server support the PROT command. If this command is not supported by the server, the function will fail and the channel mode will remain unchanged.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csftpv10.lib

See Also

[FtpGetChannelMode](#)

FtpSetDirectoryFormat Function

```
INT WINAPI FtpSetDirectoryFormat(  
    HCLIENT hClient,  
    INT nFormatId  
);
```

The **FtpSetDirectoryFormat** function is used to specify the format used by the server when returning a list of files. The format type is used internally by the library when parsing the file list returned by the server.

Parameters

hClient

Handle to the client session.

nFormatId

An identifier used to specify the format of the file list returned by the server. The following values are recognized:

Constant	Description
FTP_DIRECTORY_AUTO	This value specifies that the library should automatically determine the format of the file lists returned by the server. It is recommended that most applications use this value and allow the library to automatically determine the appropriate file listing format used by the server.
FTP_DIRECTORY_UNIX	This value specifies that the server returns file lists in the format commonly used by UNIX servers. Note that many servers can be configured to return file listings in this format, even if they are not actually a UNIX based platform. Consult the technical reference documentation for your server for more information.
FTP_DIRECTORY_MSDOS	This value specifies that the server returns file lists in the format commonly used by MS-DOS based systems. This includes Windows IIS servers. Long file names will be returned if supported by the underlying filesystem, such as NTFS or FAT32.
FTP_DIRECTORY_VMS	This value specifies that the server returns file lists in the format commonly used by VMS servers. Note that VMS servers can be configured to return a standard UNIX style listing in addition to the default VMS format.
FTP_DIRECTORY_STERLING_1	This value specifies that the server returns file listings in a proprietary format used by the Sterling server, which is used for EDI (Electronic Data Interchange) applications. This format uses a 13 byte status code.
FTP_DIRECTORY_STERLING_2	This value specifies that the server returns file listings in a proprietary format used by the Sterling server, which is used for EDI (Electronic Data Interchange)

	applications. This format uses a 10 byte status code.
FTP_DIRECTORY_NETWARE	This value specifies that the server returns file listings in a proprietary format used by NetWare servers. The format is similar to UNIX style listings except that file access and permissions are indicated by letter codes enclosed in brackets. This is the default format selected if the server identifies itself as a NetWare system.
FTP_DIRECTORY_MLSD	This value specifies that the server should return file listings in a machine-independent format as defined by RFC 3659. This format specifies file information as a sequence of name/value pairs, with the same format being used regardless of the operating system that the server is hosted on. Note that not all servers support this format, and some proxy servers may reject the command even if the remote server supports its use.

Return Value

If the function succeeds, the return value identifies the file list format used by the server. If the function fails, the return value is `FTP_ERROR`. To get extended error information, call **FtpGetLastError**.

Remarks

This function should only be used when the library cannot automatically determine the directory format returned by the server. To determine the format used by a server after a file list has been retrieved, use the **FtpGetDirectoryFormat** function.

The default directory format is determined both by the server's operating system and by analyzing the format of the data returned by the server. If the library is unable to automatically determine the format, it will attempt to parse the list of files as though it is a UNIX style listing.

If the `FTP_DIRECTORY_MLSD` format is specified, the file information returned by the server may differ from the default output of the `LIST` command. For example, on a UNIX based FTP server, the output of the `LIST` command is typically the same format that is used by the `/bin/lis` command, where file names are sorted and hidden files are not listed. However, the `MLSD` command may return an unsorted list of files that includes hidden files and directories.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csftpv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

FtpSetFeatures Function

```
DWORD WINAPI FtpSetFeatures(  
    HCLIENT hClient,  
    DWORD dwFeatures  
);
```

The **FtpSetFeatures** function specifies the server features available to the client.

Parameters

hClient

Handle to the client session.

dwFeatures

An unsigned integer that specifies one or more features. Refer to the documentation for the **FtpGetFeatures** function for a list of available features.

Return Value

If the function succeeds, the return value specifies the features that were previously enabled. If the function fails, it will return zero. Because it is possible that no features were enabled, a return value of zero does not always indicate an error. An application should call **FtpGetLastError** to determine if an error code has been set.

Remarks

The **FtpSetFeatures** function is used to enable a specific set of features for the current session. When a client connection is first established, features are enabled based on the server type and the server's response to the FEAT command. However, as the client issues commands to the server, if the server reports that the command is unrecognized that feature will automatically be disabled in the client. To enable or disable a specific feature, an application can use the **FtpEnableFeature** function.

For example, the first time an application calls the **FtpGetFileSize** function to determine the size of a file, the library will try to use the SIZE command. If the server reports that the SIZE command is not available, that feature will be disabled and the library will not use the command again during the session unless it is explicitly re-enabled. This is designed to prevent the library from repeatedly sending invalid commands to a server, which may result in the server aborting the connection.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftpv10.lib

[FtpEnableFeature](#), [FtpGetFeatures](#)

FtpSetFileMode Function

```
INT WINAPI FtpSetFileMode(  
    HCLIENT hClient,  
    UINT nMode  
);
```

The **FtpSetFileMode** function sets the default file transfer mode for the current client session.

Parameters

hClient

Handle to the client session.

nMode

Specifies the default type of data transfer mode for files being opened or created on the server. This parameter can be one of the following values.

Value	Description
FILE_MODE_STREAM	The data is transmitted as a stream of bytes. This is the default client transfer mode.
FILE_MODE_BLOCK	The data is transmitted as a series of data blocks preceded by one or more header bytes. This transfer mode is currently not supported.
FILE_MODE_COMPRESSED	The data is transmitted in compressed form. This transfer mode is currently not supported.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The file transfer mode should be set before a file is opened or created on the server. Once the transfer mode is set, it is in effect for all files that are subsequently opened or created.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[FtpOpenFile](#), [FtpSetFileStructure](#), [FtpSetFileType](#), [FtpSetPassiveMode](#)

FtpSetFileNameEncoding Function

```
INT WINAPI FtpSetFileNameEncoding(  
    HCLIENT hClient,  
    INT nEncoding  
);
```

The **FtpSetFileNameEncoding** function specifies what type of encoding will be used when file names are sent to the server.

Parameters

hClient

Handle to the client session.

nEncoding

An integer value which specifies the encoding type. It may be one of the following values:

Constant	Description
FTP_ENCODING_ANSI	File names are sent as 8-bit characters using the default character encoding for the current codepage. If the Unicode version of the functions are used, file names are converted from Unicode to ANSI using the current codepage before being sent to the server. This is the default encoding type.
FTP_ENCODING_UTF8	File names that contain non-ASCII characters are sent using UTF-8 encoding. This encoding type is only available on servers that advertise support for UTF-8 encoding and permit that encoding type to be enabled by the client.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpSetFileNameEncoding** function can be used to enable UTF-8 encoding of file names, which provides improved support for the use of international character sets. However, the server must provide support for UTF-8 encoding by advertising it in response to the FEAT command and it must support the OPTS command which is used to enable UTF-8 encoding. If the server does not advertise support for UTF-8, or the OPTS command fails with an error, then this function will fail with an error and the encoding type will not change.

Although it is possible to use the **FtpEnableFeature** function to explicitly enable the FTP_FEATURE_UTF8 feature, this is not recommended. If the server has not advertised support for UTF-8 encoding in response to the FEAT command, that typically indicates that UTF-8 encoding is not supported. Attempting to force UTF-8 encoding can result in unpredictable behavior when file names contain non-ASCII characters.

It is important to note that not all FTP servers support UTF-8 encoding, and in some cases servers which advertise support for UTF-8 encoding do not implement the feature correctly. For example, a server may allow a client to enable UTF-8 encoding, but once enabled will not permit the client to disable it. Some servers may advertise support for UTF-8 encoding, however if the underlying file system does not support UTF-8 encoded file names, any attempt to upload or download a file

may fail with an error indicating that the file cannot be found or created.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csftpv10.lib

FtpSetFilePermissions Function

```
INT WINAPI FtpSetFilePermissions(  
    HCLIENT hClient,  
    LPCTSTR lpszFileName,  
    DWORD dwPermissions  
);
```

The **FtpSetFilePermissions** function returns information about the access permissions for a specific file on the server.

Parameters

hClient

Handle to the client session.

lpszFileName

A pointer to a string which contains the name of the file to be updated. The filename cannot contain any wildcard characters.

dwPermissions

An unsigned integer which will specify the new access permissions for the file. The file permissions are represented as bit flags, and may be one or more of the following values combined with a bitwise Or operator:

Constant	Description
FILE_OWNER_READ	The owner has permission to open the file for reading. If the current user is the owner of the file, this grants the user the right to download the file to the local system.
FILE_OWNER_WRITE	The owner has permission to open the file for writing. If the current user is the owner of the file, this grants the user the right to replace the file. If this permission is set for a directory, this grants the user the right to create and delete files.
FILE_OWNER_EXECUTE	The owner has permission to execute the contents of the file. The file is typically either a binary executable, script or batch file. If this permission is set for a directory, this may also grant the user the right to open that directory and search for files in that directory.
FILE_GROUP_READ	Users in the specified group have permission to open the file for reading. If the current user is in the same group as the file owner, this grants the user the right to download the file.
FILE_GROUP_WRITE	Users in the specified group have permission to open the file for writing. On some platforms, this may also imply permission to delete the file. If the current user is in the same group as the file owner, this grants the user the right to replace the file. If this permission is set for a directory, this grants the user the right to create and delete files.
FILE_GROUP_EXECUTE	Users in the specified group have permission to execute the contents of the file. If this permission is set for a directory, this may also grant the user the right to open that directory and

	search for files in that directory.
FILE_WORLD_READ	All users have permission to open the file for reading. This permission grants any user the right to download the file to the local system.
FILE_WORLD_WRITE	All users have permission to open the file for writing. This permission grants any user the right to replace the file. If this permission is set for a directory, this grants any user the right to create and delete files.
FILE_WORLD_EXECUTE	All users have permission to execute the contents of the file. If this permission is set for a directory, this may also grant all users the right to open that directory and search for files in that directory.

Return Value

If the function succeeds, the return value is a result code. If the function fails, the return value is `FTP_ERROR`. To get extended error information, call **FtpGetLastError**.

Remarks

This function uses the `SITE CHMOD` command to set the permissions for the file. This command is typically only supported on servers that are hosted on UNIX based systems. If the command is not supported, an error will be returned.

Users who are familiar with the UNIX operating system will recognize the **chmod** command used to change the file permissions. However, it should be noted that the numeric value used as an argument to the command is in octal, not decimal. For example, issuing the command **chmod 644 filename.txt** on a UNIX based system will make the file readable and writable by the owner, and readable by other users in the owner's group as well as all other users. The value 644 is an octal value, which is equivalent to the decimal value 420. If you were to mistakenly specify 644 as the value for the *dwPermissions* parameter, rather than the decimal value of 420, the permissions on the file would be incorrect. It is strongly recommended that you use the pre-defined constants to prevent this sort of error.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csftpv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

FtpSetFileStructure Function

```
INT WINAPI FtpSetFileStructure(  
    HCLIENT hClient,  
    UINT nType  
);
```

The **FtpSetFileStructure** function sets the default file structure for the current client session, which indicates what type of file is being opened or created on the server.

Parameters

hClient

Handle to the client session.

nType

Specifies the default type of file structure being opened or created on the server. This parameter can be one of the following values.

Value	Description
FILE_STRUCT_NONE	The file has no inherent structure and is considered to be a stream of bytes. This is the default structure for file transfers.
FILE_STRUCT_RECORD	The file uses a record structure. This file structure is currently not supported.
FILE_STRUCT_PAGE	The file uses a page structure. This file structure is currently not supported.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The file structure should be set before a file is opened or created on the server. Once the file type is set, it is in effect for all files that are subsequently opened or created.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

FtpSetFileTime Function

```
INT WINAPI FtpSetFileTime(  
    HCLIENT hClient,  
    LPCTSTR LpszFileName,  
    LPSYSTEMTIME lpFileTime  
);
```

The **FtpSetFileTime** function sets the modification time for the specified file on the server.

Parameters

hClient

Handle to the client session.

lpszFileName

Points to a string that specifies the name of the remote file.

lpFileTime

Points to a [SYSTEMTIME](#) structure that specifies the new modification time for the remote file.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is `FTP_ERROR`. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpSetFileTime** function will change the modification time of a file on the server. The values specified in the `SYSTEMTIME` structure are expected to represent UTC time, not time adjusted for the local system's timezone. If the values do represent the local time, it must be converted to UTC time prior to calling this function. To populate the `SYSTEMTIME` structure with the current time, use the **GetSystemTime** function.

When connected to an FTP server, this function uses the `MDTM` command to set the modification time for the specified file. Not all servers implement this command, in which case the function call will fail. Note that some servers only support the `MDTM` command to return, but not change, the file modification time.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csftpv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

FtpSetFileType Function

```
INT WINAPI FtpSetFileType(  
    HCLIENT hClient,  
    UINT nFileType  
);
```

The **FtpSetFileType** function sets the default file type for the current client session, which indicates what type of file is being opened or created on the server.

Parameters

hClient

Handle to the client session.

nFileType

Specifies the default type of file being opened or created on the server. This parameter can be one of the following values.

Value	Description
FILE_TYPE_AUTO (0)	The file type should be automatically determined based on the file name extension. If the file extension is unknown, the file type should be determined based on the contents of the file. The library has an internal list of common text file extensions, and additional file extensions can be registered using the FtpRegisterFileType function.
FILE_TYPE_ASCII (1)	The file is a text file using the ASCII character set. For those servers which mark the end of a line with characters other than a carriage return and linefeed, it will be converted to the native client format. This is the file type used for directory listings.
FILE_TYPE_EBCDIC (2)	The file is a text file using the EBCDIC character set. Local files will be converted to EBCDIC when sent to the server. Remote files will be converted to the native ASCII character set when retrieved from the server. Not all servers support this file type. It is recommended that you only specify this type if you know that it is required by the server to transfer data correctly.
FILE_TYPE_IMAGE (3)	The file is a binary file and no data conversion of any type is performed on the file. This is the default file type for most data files and executable programs. If the type of file cannot be automatically determined, it will always be considered a binary file. If this file type is specified when uploading or downloading text files, the native end-of-line character sequences will be preserved.
FILE_TYPE_LOCAL (4)	The file is a binary file that uses the local byte size for the server platform. On most servers, this file type is considered to be the same as FILE_TYPE_IMAGE. Not all servers support this file type. It is recommended that you only specify this type if you know that it is required by the server to transfer data correctly.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return

value is `FTP_ERROR`. To get extended error information, call **FtpGetLastError**.

Remarks

The file type should be set before a file is opened or created on the server. Once the file type is set, it is in effect for all files that are subsequently opened or created. Some functions, such as **FtpOpenDirectory** and **FtpGetText**, will temporarily change the default file type to `FILE_TYPE_ASCII` and then restore the current file type when they return.

Calling this function has no practical effect when connected to an SFTP (SSH) server. They do not differentiate between text and binary files and the default file type will always be `FILE_TYPE_IMAGE`. If your application is uploading or downloading a text file, this difference between FTP and SFTP is important because the operating system that hosts the server may have different end-of-line character conventions than the client system. For example, if you download a text file from a UNIX system using SFTP, the end-of-line is indicated by a single linefeed (LF) character. However, on the Windows platform, the end-of-line is indicated by a carriage-return and linefeed sequence (CRLF).

The **FtpGetFileType** function can be used to determine the current file type.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csftpv10.lib`

FtpSetLastError Function

```
VOID WINAPI FtpSetLastError(  
    DWORD dwErrorCode  
);
```

The **FtpSetLastError** function sets the last error code for the current thread. This function is typically used to clear the last error by specifying a value of zero as the parameter.

Parameters

dwErrorCode

Specifies the last error code for the current thread.

Return Value

None.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or FTP_ERROR. Those functions which call **FtpSetLastError** when they succeed are noted on the function reference page.

Applications can retrieve the value saved by this function by using the **FtpGetLastError** function. The use of **FtpGetLastError** is optional; an application can call the function to determine the specific reason for a function failure.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftpv10.lib

FtpSetPassiveMode Function

```
INT WINAPI FtpSetPassiveMode(  
    HCLIENT hClient,  
    BOOL bPassiveMode  
);
```

The **FtpSetPassiveMode** function enables or disables passive mode file transfers for the specified client session.

Parameters

hClient

Handle to the client session.

bPassiveMode

A boolean flag which specifies that the client should enter passive mode and establish all connections with the server to transfer data.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

By default, the File Transfer Protocol uses active mode transfers, whereby the data connection is established from the server back to the local client. However, this can introduce problems for a client application that is behind a proxy server, firewall or a router which uses Network Address Translation (NAT). Enabling passive mode transfers instructs the client to create an outbound connection from the local system to the server for the data connection, similarly to how the control connection is established.

Not all servers may support passive mode, in which case an error will be returned to the client when this function is called.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

FtpSetPriority Function

```
INT WINAPI FtpSetPriority(  
    HCLIENT hClient,  
    INT nPriority  
);
```

The **FtpSetPriority** function specifies the priority for file transfers.

Parameters

hClient

Handle to the client session.

nPriority

An integer value which specifies the new priority for file transfers. It may be one of the following values:

Constant	Description
FTP_PRIORITY_NORMAL	The default priority which balances resource utilization and transfer speed. It is recommended that most applications use this priority.
FTP_PRIORITY_BACKGROUND	This priority significantly reduces the memory, processor and network resource utilization for the transfer. It is typically used with worker threads running in the background when the amount of time required perform the transfer is not critical.
FTP_PRIORITY_LOW	This priority lowers the overall resource utilization for the transfer and meters the bandwidth allocated for the transfer. This priority will increase the average amount of time required to complete a file transfer.
FTP_PRIORITY_HIGH	This priority increases the overall resource utilization for the transfer, allocating more memory for internal buffering. It can be used when it is important to transfer the file quickly, and there are no other threads currently performing file transfers at the time.
FTP_PRIORITY_CRITICAL	This priority can significantly increase processor, memory and network utilization while attempting to transfer the file as quickly as possible. If the file transfer is being performed in the main UI thread, this priority can cause the application to appear to become non-responsive. No events will be generated during the transfer.

Return Value

If the function succeeds, the return value is the previous file transfer priority. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpSetPriority** function can be used to control the processor usage, memory and network

bandwidth allocated for file transfers. The default priority balances resource utilization and transfer speed while ensuring that a single-threaded application remains responsive to the user. Lower priorities reduce the overall resource utilization at the expense of transfer speed. For example, if you create a worker thread to download a file in the background and want to ensure that it has a minimal impact on the process, the `FTP_PRIORITY_BACKGROUND` value can be used.

Higher priority values increase the memory allocated for the transfers and increases processor utilization for the transfer. The `FTP_PRIORITY_CRITICAL` priority maximizes transfer speed at the expense of system resources. It is not recommended that you increase the file transfer priority unless you understand the implications of doing so and have thoroughly tested your application. If the file transfer is being performed in the main UI thread, increasing the priority may interfere with the normal processing of Windows messages and cause the application to appear to become non-responsive. It is also important to note that when the priority is set to `FTP_PRIORITY_CRITICAL`, normal progress events will not be generated during the transfer.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csftpv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

[FtpGetPriority](#)

FtpSetTimeout Function

```
INT WINAPI FtpSetTimeout(  
    HCLIENT hClient,  
    UINT nTimeout  
);
```

The **FtpSetTimeout** function sets the number of seconds the client will wait for a response from the server. Once the specified number of seconds has elapsed, the function will fail and return to the caller.

Parameters

hClient

Handle to the client session.

nTimeout

The number of seconds to wait for a blocking operation to complete.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The timeout value is only used with blocking client connections.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csftpv10.lib

See Also

[FtpConnect](#), [FtpGetTimeout](#), [FtpIsReadable](#), [FtpIsWritable](#), [FtpProxyConnect](#), [FtpRead](#), [FtpWrite](#)

FtpTaskAbort Function

```
BOOL WINAPI FtpTaskAbort(  
    UINT nTaskId,  
    DWORD dwMilliseconds  
);
```

Abort the specified asynchronous task.

Parameters

nTaskId

The task identifier.

dwMilliseconds

An unsigned integer that specifies the number of milliseconds to wait for the background task to abort.

Return Value

If the function succeeds and the worker thread has terminated, the return value is non-zero. A return value of zero indicates that the worker thread is still running or an error has occurred. To get extended error information, call the **FtpGetLastError** function.

Remarks

The **FtpTaskAbort** function signals the background worker thread associated with the task ID to abort the current operation and terminate as soon as possible. If the *dwMilliseconds* parameter has a value of zero, the function returns immediately after the background thread has been signaled. If the *dwMilliseconds* parameter is non-zero, the function will wait that amount of time for the background thread to terminate.

This function should never be called from within the event handler for an asynchronous task because it can cause the process to deadlock. To abort a file transfer within an event handler, use the **FtpCancel** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftpv10.lib

See Also

[FtpTaskDone](#), [FtpTaskResume](#), [FtpTaskSuspend](#), [FtpTaskWait](#)

FtpTaskDone Function

```
BOOL WINAPI FtpTaskDone(  
    UINT nTaskId  
);
```

Determine if an asynchronous task has completed.

Parameters

nTaskId

The task identifier.

Return Value

If the asynchronous task has completed, this function returns a non-zero value. A return value of zero indicates that the worker thread is still running or an error has occurred. To get extended error information, call the **FtpGetLastError** function.

Remarks

The **FtpTaskDone** function is used to determine if the specified asynchronous task has completed. If you use this function to poll the status of a background task from within the main UI thread, you must ensure that Windows messages are processed so that the application remains responsive to the end-user. To check if a background transfer has completed, it is recommended that you use a timer to periodically call this function rather than calling it repeatedly within a loop.

To determine if the task completed successfully, the **FtpGetTaskError** function will return the last error code associated with the task. A return value of zero indicates success, while a non-zero return value specifies an error code that indicates the cause of the failure. The last error code for the task can also be retrieved using the **FtpTaskWait** function, which causes the application to wait for the asynchronous task to complete.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csftpv10.lib

See Also

[FtpGetTaskError](#), [FtpTaskAbort](#), [FtpTaskResume](#), [FtpTaskSuspend](#), [FtpTaskWait](#)

FtpTaskResume Function

```
BOOL WINAPI FtpTaskResume(  
    UINT nTaskId  
);
```

Resume execution of an asynchronous task.

Parameters

nTaskId

The task identifier.

Return Value

If the asynchronous task has resumed, this function returns a non-zero value. A return value of zero indicates that an error has occurred. To get extended error information, call the **FtpGetLastError** function.

Remarks

The **FtpTaskResume** function resumes execution of the background worker thread that was previously suspended using the **FtpTaskSuspend** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csftpv10.lib

See Also

[FtpTaskAbort](#), [FtpTaskDone](#), [FtpTaskSuspend](#), [FtpTaskWait](#)

FtpTaskSuspend Function

```
BOOL WINAPI FtpTaskSuspend(  
    UINT nTaskId  
);
```

Suspend execution of an asynchronous task.

Parameters

nTaskId

The task identifier.

Return Value

If the asynchronous task has resumed, this function returns a non-zero value. A return value of zero indicates that an error has occurred. To get extended error information, call the **FtpGetLastError** function.

Remarks

The **FtpTaskSuspend** function will suspend execution of the background worker thread associated with the task. Once the task has been suspended, it will no longer be scheduled for execution, however the client session will remain active and the task may be resumed using the **FtpTaskResume** function. Note that if a task is suspended for a long period of time, the background operation may fail because it has exceeded the timeout period imposed by the server.

This function should never be called from within the event handler for an asynchronous task because it can cause the process to deadlock.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csftpv10.lib

See Also

[FtpTaskAbort](#), [FtpTaskDone](#), [FtpTaskResume](#), [FtpTaskWait](#)

FtpTaskWait Function

```
BOOL WINAPI FtpTaskWait(  
    UINT nTaskId,  
    DWORD dwMilliseconds,  
    DWORD dwReserved,  
    LPDWORD lpdwElapsed,  
    LPDWORD lpdwError  
);
```

Wait for an asynchronous task to complete.

Parameters

nTaskId

The task identifier.

dwMilliseconds

An unsigned integer that specifies the number of milliseconds to wait for the background task to complete.

dwReserved

An unsigned integer reserved for future use. This value should always be zero.

lpdwElapsed

A pointer to an unsigned integer that will contain elapsed time in milliseconds when the function returns. If this information is not required, this parameter may be NULL.

lpdwError

A pointer to an unsigned integer that will contain the error code associated with the completed task. If this information is not required, this parameter may be NULL.

Return Value

If the function succeeds and the worker thread has terminated, the return value is non-zero. A return value of zero indicates that the worker thread is still running or an error has occurred. To get extended error information, call the **FtpGetLastError** function.

Remarks

The **FtpTaskWait** function waits for the specified task to complete. If the task is active and the *dwMilliseconds* parameter is non-zero, this function will cause the current working thread to block until the task completes or the amount of time exceeds the number of milliseconds specified by the caller. If the *dwMilliseconds* parameter is zero, then this function will poll the status of the task and return immediately to the caller.

If the specified task has already completed at the time this function is called, the function will return immediately without causing the current thread to block. If the *lpdwElapsed* parameter is not NULL, it will contain the number of milliseconds that it took for the task to complete. If the *lpdwError* parameter is not NULL, it will contain the last error code value that was set by the worker thread before it terminated. If this value is zero, that means that the background operation was successful and no error occurred. A non-zero value will indicate that the background operation has failed.

You should not call this function from the main UI thread with a long timeout period to wait for a background task to complete. Windows messages will not be processed while this function is blocked waiting for the background task to complete, and this can cause your application to

appear non-responsive to the end-user. If you have a GUI application and you need to periodically check to see if a task has completed, create a timer to periodically call the **FtpTaskDone** function. When it returns a non-zero value (indicating that the task has completed), you can safely call **FtpTaskWait** to obtain the elapsed time and last error code without blocking the current thread.

This function should never be called from within the event handler for an asynchronous task because it can cause the process to deadlock.

Example

```
UINT nTaskId;

// Begin a file transfer in the background

nTaskId = FtpAsyncGetFile(hClient,
                        lpszLocalFile,
                        lpszRemoteFile,
                        FTP_TRANSFER_DEFAULT,
                        0,
                        NULL,
                        0);

if (nTaskId != 0)
{
    DWORD dwError = NO_ERROR;
    DWORD dwElapsed = 0;

    // Wait for the transfer to complete
    FtpTaskWait(nTaskId, INFINITE, &dwElapsed, &dwError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csftpv10.lib

FtpUninitialize Function

```
VOID WINAPI FtpUninitialize();
```

The **FtpUninitialize** function terminates the use of the library.

Parameters

There are no parameters.

Return Value

None.

Remarks

An application is required to perform a successful **FtpInitialize** call before it can call any of the other library functions. When it has completed the use of library, the application must call **FtpUninitialize** to allow the library to free any resources allocated on behalf of the process. Any pending blocking or asynchronous calls in this process are canceled without posting any notification messages, and all sockets that were opened by the process are closed.

There must be a call to **FtpUninitialize** for every successful call to **FtpInitialize** made by a process. In a multithreaded environment, operations for all threads in the client are terminated.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csftpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

FtpUploadFile Function

```
BOOL WINAPI FtpUploadFile(  
    LPCTSTR lpszLocalFile,  
    LPCTSTR lpszFileURL,  
    UINT nTimeout  
    DWORD dwOptions  
    LPFTPTRANSFERSTATUS lpStatus  
    FTPEVENTPROC lpEventProc  
    DWORD_PTR dwParam  
);
```

The **FtpUploadFile** function uploads the specified file from the local system to the server.

Parameters

lpszLocalFile

A pointer to a string that specifies the file on the local system that will be uploaded to the server. The file pathing and name conventions must be that of the local host.

lpszFileURL

A pointer to a string that specifies the complete URL of the file that will be created or overwritten on the server. The URL must follow the conventions for the File Transfer Protocol and may specify either a standard or secure connection, alternate port number, username, password and optional working directory.

nTimeout

The number of seconds that the client will wait for a response before failing the operation. A value of zero specifies that the default timeout period of sixty seconds will be used.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
FTP_OPTION_PASSIVE	This option specifies the client should attempt to establish the data connection with the server. When the client uploads or downloads a file, normally the server establishes a second connection back to the client which is used to transfer the file data. However, if the local system is behind a firewall or a NAT router, the server may not be able to create the data connection and the transfer will fail. By specifying this option, it forces the client to establish an outbound data connection with the server. It is recommended that applications use passive mode whenever possible.
FTP_OPTION_FIREWALL	This option specifies the client should always use the host IP address to establish the data connection with the server, not the address returned by the server in response to the PASV command. This option may be necessary if the server is behind a router that performs Network Address Translation (NAT) and it

	returns an unreachable IP address for the data connection. If this option is specified, it will also enable passive mode data transfers.
FTP_OPTION_SECURE	This option specifies the client should attempt to establish a secure connection with the server. Note that the server must support secure connections using either the SSL or TLS protocol.
FTP_OPTION_SECURE_EXPLICIT	This option specifies the client should use the AUTH command to negotiate an explicit secure connection. Some servers may only require this when connecting to the server on ports other than 990.

lpStatus

A pointer to an FTPTRANSFERSTATUS structure which contains information about the status of the current file transfer. If this information is not required, a NULL pointer may be specified as the parameter.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **FtpEventProc** callback function. If this parameter is NULL, the callback for the specified event is disabled.

dwParam

A user-defined integer value that is passed to the callback function.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpUploadFile** function provides a convenient way for an application to upload a file in a single function call. Based on the connection information specified in the URL, it will connect to the server, authenticate the session, change the current working directory if necessary and then upload the file to the server. The URL must be complete, and specify either a standard or secure FTP scheme:

```
[ftp|ftps|sftp]://[username : password] @[remotehost] [:remoteport] /
[path / ...] [filename] [;type=a|i]
```

If no user name and password is provided, then the client session will be authenticated as an anonymous user. If a path is specified as part of the URL, the function will attempt to change the current working directory. Note that the path in an FTP URL is relative to the home directory of the user account and is not an absolute path starting at the root directory on the server. The URL scheme will always determine if the connection is secure, not the option. In other words, if the "ftp" scheme is used and the FTP_OPTION_SECURE option is specified, that option will be ignored. To establish a secure connection, either the "ftps" or "sftp" scheme must be specified.

The optional "type" value at the end of the file name determines if the file should be uploaded as a text or binary file. A value of "a" specifies that the file should be uploaded as a text file. A value of "i" specifies that the file should be uploaded as a binary file. If the type is not explicitly specified, the file will be uploaded as a binary file.

The *lpStatus* parameter can be used by the application to determine the final status of the

transfer, including the total number of bytes copied, the amount of time elapsed and other information related to the transfer process. If this information isn't needed, then this parameter may be specified as NULL.

The *lpEventProc* parameter specifies a pointer to a function which will be periodically called during the file transfer process. This can be used to check the status of the transfer by calling **FtpGetTransferStatus** and then update the program's user interface. For example, the callback function could calculate the percentage for how much of the file has been transferred and then update a progress bar control. The *dwParam* parameter is used in conjunction with the event handler and specifies a user-defined value that is passed to the callback function. One common use in a C++ program is to pass the *this* pointer as the value, and then cast it back to an object pointer inside the callback function. If no event handler is required, then a NULL pointer can be specified as the value for *lpEventProc* and the *dwParam* parameter will be ignored.

The **FtpUploadFile** function is designed to provide a simpler interface for uploading a file. However, complex connections such as those using a proxy server or a secure connection which uses a client certificate will require the program to establish the connection using **FtpConnect** and then use **FtpPutFile** to upload the file.

Example

```
FTPTRANSFERSTATUS ftpStatus;
LPCTSTR lpszLocalFile = _T("c:\\temp\\database.mdb");
LPCTSTR lpszFileURL =
_T("ftp://update:secret@ftp.example.com/updates/database.mdb");
BOOL bResult;

// Upload the file using the specified URL
bResult = FtpUploadFile(lpszLocalFile,
                        lpszFileURL,
                        FTP_OPTION_PASSIVE,
                        &ftpStatus,
                        NULL, 0);

if (!bResult)
{
    TCHAR szError[128];

    // Display a message box that describes the error
    FtpGetErrorString(FtpGetLastError(), szError, 128);
    MessageBox(NULL, szError, NULL, MB_ICONEXCLAMATION|MB_TASKMODAL);
    return;
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csftpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

FtpUploadFileEx Function

```
BOOL WINAPI FtpUploadFileEx(  
    LPCTSTR lpszLocalFile,  
    LPCTSTR lpszFileURL,  
    UINT nTimeout  
    DWORD dwOptions  
    LPFTPTRANSFERSTATUSEX lpStatus  
    FTPEVENTPROC lpEventProc  
    DWORD_PTR dwParam  
);
```

The **FtpUploadFileEx** function uploads the specified file from the local system to the server.

Parameters

lpszLocalFile

A pointer to a string that specifies the file on the local system that will be uploaded to the server. The file pathing and name conventions must be that of the local host.

lpszFileURL

A pointer to a string that specifies the complete URL of the file that will be created or overwritten on the server. The URL must follow the conventions for the File Transfer Protocol and may specify either a standard or secure connection, alternate port number, username, password and optional working directory.

nTimeout

The number of seconds that the client will wait for a response before failing the operation. A value of zero specifies that the default timeout period of sixty seconds will be used.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
FTP_OPTION_PASSIVE	This option specifies the client should attempt to establish the data connection with the server. When the client uploads or downloads a file, normally the server establishes a second connection back to the client which is used to transfer the file data. However, if the local system is behind a firewall or a NAT router, the server may not be able to create the data connection and the transfer will fail. By specifying this option, it forces the client to establish an outbound data connection with the server. It is recommended that applications use passive mode whenever possible.
FTP_OPTION_FIREWALL	This option specifies the client should always use the host IP address to establish the data connection with the server, not the address returned by the server in response to the PASV command. This option may be necessary if the server is behind a router that performs Network Address Translation (NAT) and it

	returns an unreachable IP address for the data connection. If this option is specified, it will also enable passive mode data transfers.
FTP_OPTION_SECURE	This option specifies the client should attempt to establish a secure connection with the server. Note that the server must support secure connections using either the SSL or TLS protocol.
FTP_OPTION_SECURE_EXPLICIT	This option specifies the client should use the AUTH command to negotiate an explicit secure connection. Some servers may only require this when connecting to the server on ports other than 990.

lpStatus

A pointer to an FTPTRANSFERSTATUSEX structure which contains information about the status of the current file transfer. If this information is not required, a NULL pointer may be specified as the parameter.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **FtpEventProc** callback function. If this parameter is NULL, the callback for the specified event is disabled.

dwParam

A user-defined integer value that is passed to the callback function.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpUploadFileEx** function provides a convenient way for an application to upload a file in a single function call. Based on the connection information specified in the URL, it will connect to the server, authenticate the session, change the current working directory if necessary and then upload the file to the server. The URL must be complete, and specify either a standard or secure FTP scheme:

```
[ftp|ftps|sftp]://[username : password] @] remotehost [:remoteport] /
[path / ...] [filename] [;type=a|i]
```

If no user name and password is provided, then the client session will be authenticated as an anonymous user. If a path is specified as part of the URL, the function will attempt to change the current working directory. Note that the path in an FTP URL is relative to the home directory of the user account and is not an absolute path starting at the root directory on the server. The URL scheme will always determine if the connection is secure, not the option. In other words, if the "ftp" scheme is used and the FTP_OPTION_SECURE option is specified, that option will be ignored. To establish a secure connection, either the "ftps" or "sftp" scheme must be specified.

The optional "type" value at the end of the file name determines if the file should be uploaded as a text or binary file. A value of "a" specifies that the file should be uploaded as a text file. A value of "i" specifies that the file should be uploaded as a binary file. If the type is not explicitly specified, the file will be uploaded as a binary file.

The *lpStatus* parameter can be used by the application to determine the final status of the

transfer, including the total number of bytes copied, the amount of time elapsed and other information related to the transfer process. If this information isn't needed, then this parameter may be specified as NULL.

The *lpEventProc* parameter specifies a pointer to a function which will be periodically called during the file transfer process. This can be used to check the status of the transfer by calling **FtpGetTransferStatus** and then update the program's user interface. For example, the callback function could calculate the percentage for how much of the file has been transferred and then update a progress bar control. The *dwParam* parameter is used in conjunction with the event handler and specifies a user-defined value that is passed to the callback function. One common use in a C++ program is to pass the *this* pointer as the value, and then cast it back to an object pointer inside the callback function. If no event handler is required, then a NULL pointer can be specified as the value for *lpEventProc* and the *dwParam* parameter will be ignored.

The **FtpUploadFileEx** function is designed to provide a simpler interface for uploading a file. However, complex connections such as those using a proxy server or a secure connection which uses a client certificate will require the program to establish the connection using **FtpConnect** and then use **FtpPutFileEx** to upload the file.

Example

```
FTPTRANSFERSTATUSEX ftpStatus;
LPCTSTR lpszLocalFile = _T("c:\\temp\\database.mdb");
LPCTSTR lpszFileURL =
_T("ftp://update:secret@ftp.example.com/updates/database.mdb");
BOOL bResult;

// Upload the file using the specified URL
bResult = FtpUploadFileEx(lpszLocalFile,
                          lpszFileURL,
                          FTP_OPTION_PASSIVE,
                          &ftpStatus,
                          NULL, 0);

if (!bResult)
{
    TCHAR szError[128];

    // Display a message box that describes the error
    FtpGetErrorString(FtpGetLastError(), szError, 128);
    MessageBox(NULL, szError, NULL, MB_ICONEXCLAMATION|MB_TASKMODAL);
    return;
}
```

Requirements

FtpValidateUrl Function

```
BOOL WINAPI FtpValidateUrl(  
    LPCTSTR LpszURL  
);
```

The **FtpValidateUrl** function determines if a string represents a valid FTP URL.

Parameters

LpszURL

A pointer to a string that specifies the URL to validate.

Return Value

If the specified URL is valid and the host name can be resolved to an IP address, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpValidateUrl** function will check the value of a string to ensure that it represents a complete, valid URL using either a standard or secure FTP scheme. This function will not establish a connection with the server to verify that it exists, it will only attempt to resolve the host name to an IP address. If the remote host is specified as an IP address, this function will check to make sure that the address is formatted correctly. Note that if you wish to specify an IPv6 address, you must enclose the address in brackets.

To establish a connection with a server using a URL, use the **FtpConnectUrl** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[FtpConnectUrl](#)

FtpVerifyFile Function

```
BOOL WINAPI FtpVerifyFile(  
    HCLIENT hClient,  
    LPCTSTR lpszLocalFile,  
    LPCTSTR lpszRemoteFile,  
    DWORD dwOptions  
);
```

The **FtpVerifyFile** function attempts to verify that the contents of a file on the local system are the same as the specified file on the server.

Parameters

hClient

Handle to the client session.

lpszLocalFile

A pointer to a string that specifies the name of file on the local system.

lpszRemoteFile

A pointer to a string that specifies the name of the file on the server.

dwOptions

Specifies the options that may be used when comparing the files. This parameter may be one or more of the following values:

Value	Description
FTP_VERIFY_DEFAULT	File verification should use the best option available based on the available server features. If the server supports the XMD5 command, the library will calculate an MD5 hash of the local file contents and compare the value with the file on the server. If the server does not support the XMD5 command, but it does support the XCRC command, the library will calculate a CRC32 checksum of the local file contents and compare the value with the file on the server. If the server does not support either the XMD5 or XCRC commands, the library will compare the size of the local and remote files.
FTP_VERIFY_SIZE	Files are verified by comparing the number of bytes of data in the local and remote files. This is the least reliable method, and should only be used if the server does not support either the XMD5 or XCRC commands.
FTP_VERIFY_CRC32	Files are verified by calculating a CRC32 checksum of the local file contents and comparing it with the value returned by the server in response to the XCRC command. This method should only be used if the server does not support the XMD5 command.
FTP_VERIFY_MD5	Files are verified by calculating an MD5 hash of the local file contents and comparing it with the value returned by the server in response to the XMD5 command. This is the preferred method for performing file verification.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpVerifyFile** function will attempt to verify that the contents of the local and remote files are identical using one of several methods, based on the features that the server supports. Preference will be given to the most reliable method available, using either an MD5 hash, a CRC-32 checksum or comparing the size of the file, in that order.

It is not recommended that you use this function with text files because of the different end-of-line conventions used by different operating systems. For example, a text file on a Windows system uses a carriage-return and linefeed pair to indicate the end of a line of text. However, on a UNIX system, a single linefeed is used to indicate the end of a line. This can cause the **FtpVerifyFile** function to indicate the files are not identical, even though the only difference is in the end-of-line characters that are used.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csftpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

FtpWrite Function

```
INT WINAPI FtpWrite(  
    HCLIENT hClient,  
    LPBYTE lpBuffer,  
    INT cbBuffer  
);
```

The **FtpWrite** function sends the specified number of bytes to the server.

Parameters

hClient

Handle to the client session.

lpBuffer

The pointer to the buffer which contains the data that is to be sent to the server.

cbBuffer

The number of bytes to send from the specified buffer.

Return Value

If the function succeeds, the return value is the number of bytes actually written. If the function fails, the return value is `FTP_ERROR`. To get extended error information, call **FtpGetLastError**.

Remarks

The return value may be less than the number of bytes specified by the *cbBuffer* parameter. In this case, the data has been partially written and it is the responsibility of the client application to send the remaining data at some later point. For non-blocking clients, the client must wait for the next asynchronous notification message before it resumes sending data.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csftpv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

- SYSTEMTIME

FTPCLIENTQUOTA Structure

This structure is used by the [FtpGetClientQuota](#) function to return information about the file quota for the current client session.

```
typedef struct _FTPCLIENTQUOTA
{
    DWORD    dwFileCount;
    DWORD    dwFileLimit;
    DWORD    dwDiskUsage;
    DWORD    dwDiskLimit;
} FTPCLIENTQUOTA, *LPFTPCLIENTQUOTA;
```

Members

dwFileCount

An unsigned integer value which specifies the number of files that the user has created. If file quotas have not been enabled for the current user, this value will be zero.

dwFileLimit

An unsigned integer value which specifies the maximum number of files that may be created by the user. If file quotas have not been enabled for the current user, this value will be zero.

dwDiskUsage

An unsigned integer value which specifies the number of bytes of disk storage that has been allocated by the current user. If file quotas have not been enabled for the current user, this value will be zero.

dwDiskLimit

An unsigned integer value which specifies the maximum number of bytes of disk storage that may be allocated by the current user. If file quotas have not been enabled for the current user, this value will be zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csftpv10.lib

FTPFILESTATUS Structure

This structure is used by the **FtpEnumFiles**, **FtpGetFirstFile** and **FtpGetNextFile** functions to return information about files on the server.

```
typedef struct _FTPFILESTATUS
{
    TCHAR          szFileName[FTP_MAXFILENAMELEN];
    TCHAR          szFileOwner[FTP_MAXOWNERNAMELEN];
    TCHAR          szFileGroup[FTP_MAXGROUPNAMELEN];
    BOOL           bIsDirectory;
    DWORD          dwFileSize;
    DWORD          dwFileLinks;
    DWORD          dwFileVersion;
    DWORD          dwFilePerms;
    SYSTEMTIME     stFileDate;
} FTPFILESTATUS, *LPFTPFILESTATUS;
```

Members

szFileName

A string buffer which contains the name of the file on the server.

szFileOwner

A string buffer which contains the name of the user that owns the file on the server. Note that not all server types support the concept of file ownership by a user. Some UNIX systems will not provide this information if an anonymous login was used. For the proprietary Sterling directory formats, the "mailbox" is stored in this member.

szFileGroup

A string buffer which contains the name of the group that owns the file on the server. Note that not all server types support the concept of file ownership by a group. For the proprietary Sterling directory formats, the "batch number" is stored in this member, with the character # prepended for the format FTP_DIRECTORY_STERLING_2.

bIsDirectory

A boolean flag which specifies if the file is actually a subdirectory.

dwFileSize

The size of the file in bytes on the server. Servers that return file information in an MS-DOS format will always set this value to zero if the file refers to a subdirectory. If the file is a text file, the file size on the server may be different than the size on the local host if different end-of-line character conventions are used. It should be noted that under VMS, the file size is reported in 512 byte blocks, so the size should be considered approximate on that platform.

dwFileLinks

The number of links to the file. Note that not all server types support the concept of file links, in which case this value will be zero.

dwFileVersion

The number of revisions made to the file. Note that not all server types support the concept of file versioning, in which case this value will be zero. Currently this value will only be non-zero for VMS platforms.

dwFilePerms

The permissions associated with the file. This value is actually a combination of bits that specify

the individual permissions for the file owner, group and world (all other users). For those familiar with UNIX, the file permissions are the same as those used by the `chmod` command. For the proprietary Sterling directory formats, a bit map representing the status codes and transfer protocol of the file is stored in this member.

stFileDate

A `SYSTEMTIME` structure which specifies the date that the file was created or last modified.

File Permissions

Constant	Description
<code>FILE_OWNER_READ</code>	The owner has permission to open the file for reading. If the current user is the owner of the file, this grants the user the right to download the file to the local system.
<code>FILE_OWNER_WRITE</code>	The owner has permission to open the file for writing. If the current user is the owner of the file, this grants the user the right to replace the file. If this permission is set for a directory, this grants the user the right to create and delete files.
<code>FILE_OWNER_EXECUTE</code>	The owner has permission to execute the contents of the file. The file is typically either a binary executable, script or batch file. If this permission is set for a directory, this may also grant the user the right to open that directory and search for files in that directory.
<code>FILE_GROUP_READ</code>	Users in the specified group have permission to open the file for reading. If the current user is in the same group as the file owner, this grants the user the right to download the file.
<code>FILE_GROUP_WRITE</code>	Users in the specified group have permission to open the file for writing. On some platforms, this may also imply permission to delete the file. If the current user is in the same group as the file owner, this grants the user the right to replace the file. If this permission is set for a directory, this grants the user the right to create and delete files.
<code>FILE_GROUP_EXECUTE</code>	Users in the specified group have permission to execute the contents of the file. If this permission is set for a directory, this may also grant the user the right to open that directory and search for files in that directory.
<code>FILE_WORLD_READ</code>	All users have permission to open the file for reading. This permission grants any user the right to download the file to the local system.
<code>FILE_WORLD_WRITE</code>	All users have permission to open the file for writing. This permission grants any user the right to replace the file. If this permission is set for a directory, this grants any user the right to create and delete files.
<code>FILE_WORLD_EXECUTE</code>	All users have permission to execute the contents of the file. If this permission is set for a directory, this may also grant all users the right to open that directory and search for files in that directory.

Sterling Status Codes

Bits 0-25 correspond to letters of the alphabet, most of which have distinct meanings in the Sterling formats.

Letter code	Bit position	Hexadecimal value
-------------	--------------	-------------------

A	0	1h
B	1	2h
C	2	4h
<i>n-th letter of alphabet</i>	n-1	2 to the (n-1) power
Z	25	2000000h

For the proprietary Sterling directory formats, bits 26-31 represent the transfer protocol associated with the file:

Protocol	Bit position	Hexadecimal value	Constant
TCP	26	4000000h	FTP_STERLING_STATUS_TCP
FTP	27	8000000h	FTP_STERLING_STATUS_FTP
BSC	28	10000000h	FTP_STERLING_STATUS_BSC
ASC	29	20000000h	FTP_STERLING_STATUS_ASC
FTS	30	40000000h	FTP_STERLING_STATUS_FTS
other	31	80000000h	FTP_STERLING_STATUS_OTHER

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csftpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

FTPFILESTATUSEX Structure

This structure is used by the **FtpEnumFilesEx**, **FtpGetFirstFileEx** and **FtpGetNextFileEx** functions to return information about files on the server. This structure is designed for use with extended functions that support files larger than 4GB.

```
typedef struct _FTPFILESTATUSEX
{
    TCHAR          szFileName[FTP_MAXFILENAMELEN];
    TCHAR          szFileOwner[FTP_MAXOWNERNAMELEN];
    TCHAR          szFileGroup[FTP_MAXGROUPNAMELEN];
    BOOL           bIsDirectory;
    ULARGE_INTEGER uiFileSize;
    DWORD          dwFileLinks;
    DWORD          dwFileVersion;
    DWORD          dwFilePerms;
    DWORD          dwFileFlags;
    SYSTEMTIME     stFileDate;
} FTPFILESTATUSEX, *LPFTPFILESTATUSEX;
```

Members

szFileName

A string buffer which contains the name of the file on the server.

szFileOwner

A string buffer which contains the name of the user that owns the file on the server. Note that not all server types support the concept of file ownership by a user. Some UNIX systems will not provide this information if an anonymous login was used. For the proprietary Sterling directory formats, the "mailbox" is stored in this member.

<i>n-th letter of alphabet</i>	n-1	2 to the (n-1) power
Z	25	2000000h

For the proprietary Sterling directory formats, bits 26-31 represent the transfer protocol associated with the file:

Protocol	Bit position	Hexadecimal value	Constant
TCP	26	4000000h	FTP_STERLING_STATUS_TCP
FTP	27	8000000h	FTP_STERLING_STATUS_FTP
BSC	28	10000000h	FTP_STERLING_STATUS_BSC
ASC	29	20000000h	FTP_STERLING_STATUS_ASC
FTS	30	40000000h	FTP_STERLING_STATUS_FTS
other	31	80000000h	FTP_STERLING_STATUS_OTHER

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csftpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

FTPTRANSFERSTATUS Structure

This structure is used by the **FtpGetTransferStatus** function to return information about a file transfer in progress.

```
typedef struct _FTPTRANSFERSTATUS
{
    DWORD    dwBytesTotal;
    DWORD    dwBytesCopied;
    DWORD    dwBytesPerSecond;
    DWORD    dwTimeElapsed;
    DWORD    dwTimeEstimated;
    TCHAR    szLocalFile[FTP_MAXFILENAMELEN];
    TCHAR    szRemoteFile[FTP_MAXFILENAMELEN];
} FTPTRANSFERSTATUS, *LPFTPTRANSFERSTATUS;
```

Members

dwBytesTotal

The total number of bytes that will be transferred. If the file is being copied from the server to the local host, this is the size of the remote file. If the file is being copied from the local host to the server, it is the size of the local file. If the file size cannot be determined, this value will be zero.

dwBytesCopied

The total number of bytes that have been copied.

dwBytesPerSecond

The average number of bytes that have been copied per second.

dwTimeElapsed

The number of seconds that have elapsed since the file transfer started.

dwTimeEstimated

The estimated number of seconds until the file transfer is completed. This is based on the average number of bytes transferred per second.

szLocalFile

A pointer to a string which specifies the local file that is being copied to or from the server.

szRemoteFile

A pointer to a string which specifies the remote file that is being copied to or from the local system.

Remarks

If the option `FTP_OPTION_HIRES_TIMER` has been specified when connecting to the server, the values returned in the *dwTimeElapsed* and *dwTimeEstimated* members will be in milliseconds instead of seconds. You can use this option to obtain more accurate elapsed times when uploading or downloading small files over a fast network connection.

If you are uploading or downloading large files which exceed 4GB, you should use the **FTPTRANSFERSTATUSEX** structure which uses 64-bit integers for the file size.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

INITDATA Structure

This structure contains information about the SocketTools library when the initialization function returns.

```
typedef struct _INITDATA
{
    DWORD        dwSize;
    DWORD        dwVersionMajor;
    DWORD        dwVersionMinor;
    DWORD        dwVersionBuild;
    DWORD        dwOptions;
    DWORD_PTR    dwReserved1;
    DWORD_PTR    dwReserved2;
    TCHAR        szDescription[128];
} INITDATA, *LPINITDATA;
```

Members

dwSize

Size of this structure. This structure member must be set to the size of the structure prior to calling the initialization function. Failure to do so will cause the function to fail.

dwVersionMajor

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the major version number for the library.

dwVersionMinor

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the minor version number for the library.

dwVersionBuild

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the build number for the library.

dwOptions

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

dwReserved1

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

dwReserved2

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

szDescription

A null terminated string which describes the library.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Unicode: Implemented as Unicode and ANSI versions.

SECURITYCREDENTIALS Structure

The **SECURITYCREDENTIALS** structure specifies the information needed by the library to specify additional security credentials, such as a client certificate or private key, when establishing a secure connection.

```
typedef struct _SECURITYCREDENTIALS
{
    DWORD    dwSize;
    DWORD    dwProtocol;
    DWORD    dwOptions;
    DWORD    dwReserved;
    LPCTSTR  lpszHostName;
    LPCTSTR  lpszUserName;
    LPCTSTR  lpszPassword;
    LPCTSTR  lpszCertStore;
    LPCTSTR  lpszCertName;
    LPCTSTR  lpszKeyFile;
} SECURITYCREDENTIALS, *LPSECURITYCREDENTIALS;
```

Members

dwSize

Size of this structure. If the structure is being allocated dynamically, this member must be set to the size of the structure and all other unused structure members must be initialized to a value of zero or NULL.

dwProtocol

A bitmask of supported security protocols. The value of this structure member is constructed by using a bitwise operator with any of the following values:

Constant	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_SSL	Either SSL 2.0 or SSL 3.0 should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, TLS will be excluded from the list of supported protocols. Both SSL 2.0 and 3.0 have been deprecated and will never be used unless explicitly specified. It is not recommended that you enable either of these protocols for secure connections because it will cause most servers to reject your connection request, even if a version of TLS is also specified.
SECURITY_PROTOCOL_TLS	Either the TLS 1.0, 1.1 or 1.2 protocol should be used when establishing a secure connection. The correct protocol is automatically selected, based on

	<p>what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers that reject any attempt to use the older SSL protocol and require that only TLS be used.</p>
SECURITY_PROTOCOL_TLS10	<p>The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.</p>
SECURITY_PROTOCOL_TLS11	<p>The TLS 1.1 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.</p>
SECURITY_PROTOCOL_TLS12	<p>The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This is the recommended version of TLS to use with secure connections.</p>
SECURITY_PROTOCOL_SSH	<p>Either version 1.0 or 2.0 of the Secure Shell protocol should be used when establishing the connection. The correct protocol is automatically selected based on the version of the protocol that is supported by the server.</p>
SECURITY_PROTOCOL_SSH1	<p>The Secure Shell 1.0 protocol should be used when establishing the connection. This is an older version of the protocol which should not be used unless explicitly required by the server. Most modern SSH server support version 2.0 of the protocol.</p>
SECURITY_PROTOCOL_SSH2	<p>The Secure Shell 2.0 protocol should be used when establishing the connection. This is the default version of the protocol that is supported by most SSH servers.</p>

dwOptions

A value which specifies one or options. This value should always be zero for connections using SSH. This member is constructed by using a bitwise operator with any of the following values:

Constant	Description
CREDENTIAL_STORE_CURRENT_USER	The library will attempt to open a store for the current user using the certificate store name provided in this structure. If no options are specified, then this is the default behavior.
CREDENTIAL_STORE_LOCAL_MACHINE	The library will attempt to open a local machine store using the certificate store name provided in this structure. If this option is specified, the library will always search for a local machine store before searching for the store by that name for the current user.
CREDENTIAL_STORE_FILENAME	The certificate store name is a file that contains the certificate and private key that will be used.

dwReserved

This structure member is reserved for future use and should always be initialized to zero.

lpszHostName

A pointer to a null terminated string which specifies the hostname that will be used when validating the server certificate. If this member is NULL, then the server certificate will be validated against the hostname used to establish the connection.

lpszUserName

A pointer to a null terminated string which identifies the owner of client certificate. Currently this member is not used by the library and should always be initialized as a NULL pointer.

lpszPassword

A pointer to a null terminated string which specifies the password needed to access the certificate. Currently this member is only used if the CREDENTIAL_STORE_FILENAME option has been specified. If there is no password associated with the certificate, then this member should be initialized as a NULL pointer.

lpszCertStore

A pointer to a null terminated string which specifies the name of the certificate store to open. A certificate store is a collection of certificates and their private keys, typically organized by how they are used. If this value is NULL or points to an empty string, the default certificate store "MY" will be used.

Store Name	Description
------------	-------------

CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as VeriSign and Thawte act as certification authorities.
----	---

MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. This corresponds to the "Personal" store that is displayed by the certificate manager utility and is the default store used by the library.
----	--

ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as VeriSign and Thawte are
------	---

installed as part of the operating system and periodically updated by Microsoft.

lpszCertName

A pointer to a null terminated string which specifies the name of the certificate to use. The library will first search the certificate store for a certificate with a matching "friendly name"; this is a name for the certificate that is assigned by the user. Note that the name must match completely, but the comparison is not case sensitive. If no matching certificate is found, the library will then attempt to find a certificate that has a matching common name (also called the certificate subject). This comparison is less stringent, and the first partial match will be returned. If this second search fails, the library will return an error indicating that the certificate could not be found. If the SECURITY_PROTOCOL_SSH protocol has been specified, this member should be NULL.

lpszKeyFile

A pointer to a null terminated string which specifies the name of the file which contains the private key required to establish the connection. This member is only used for SSH connections and should always be NULL when establishing a secure connection using SSL or TLS.

Remarks

A client application only needs to create this structure if the server requires that the client provide a certificate as part of the process of negotiating the secure session. If a certificate is required, note that it must have a private key associated with it. Attempting to use a certificate that does not have a private key will result in an error during the connection process indicating that the client credentials could not be established.

If you are using a local certificate store, with the certificate and private key stored in the registry, you can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU:" for the current user, or "HKLM:" for the local machine. For example, a certificate store name of "HKLM:MY" would specify the personal certificate store for the local machine, rather than the current user. If neither prefix is specified, then it will default to the certificate store for the current user. You can manage these certificates using the CertMgr.msc Microsoft Management Console (MMC) snap-in.

It is possible to load the certificate from a file rather than from current user's certificate store. The *dwOptions* member should be set to CREDENTIAL_STORE_FILENAME and the *lpszCertStore* member should specify the name of the file that contains the certificate and its private key. The file must be in Private Information Exchange (PFX) format, also known as PKCS#12. These certificate files typically have an extension of .pfx or .p12. Note that if a password was specified when the certificate file was created, it must be provided in the *lpszPassword* member or the library will be unable to access the certificate.

Note that the *lpszUserName* and *lpszPassword* members are values which are used to access the certificate store or private key file. They are not the credentials which are used when establishing the connection with the remote host or authenticating the client session.

The TLS 1.1 and TLS 1.2 protocols are only supported on Windows 7, Windows Server 2008 R2 and later versions of the platform. If these options are specified and the application is running on Windows XP or Windows Vista, the protocol version will be downgraded to TLS 1.0 for backwards compatibility with those platforms.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include ctools10.h

Unicode: Implemented as Unicode and ANSI versions.

SECURITYINFO Structure

This structure contains information about a secure connection that has been established with a server.

```
typedef struct _SECURITYINFO
{
    DWORD        dwSize;
    DWORD        dwProtocol;
    DWORD        dwCipher;
    DWORD        dwCipherStrength;
    DWORD        dwHash;
    DWORD        dwHashStrength;
    DWORD        dwKeyExchange;
    DWORD        dwCertStatus;
    SYSTEMTIME   stCertIssued;
    SYSTEMTIME   stCertExpires;
    LPCTSTR      lpszCertIssuer;
    LPCTSTR      lpszCertSubject;
    LPCTSTR      lpszFingerprint;
} SECURITYINFO, *LPSECURITYINFO;
```

Members

dwSize

Specifies the size of the data structure. This member must always be initialized to **sizeof(SECURITYINFO)** prior to passing the address of this structure to the function. Note that if this member is not initialized, an error will be returned indicating that an invalid parameter has been passed to the function.

dwProtocol

A numeric value which specifies the protocol that was selected to establish the secure connection. One of the following values will be returned:

Constant	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_SSL	Either SSL 2.0 or SSL 3.0 should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, TLS will be excluded from the list of supported protocols. Both SSL 2.0 and 3.0 have been deprecated and will never be used unless explicitly specified. It is not recommended that you enable either of these protocols for secure connections because it will cause most servers to reject your connection request, even if a version of TLS is also specified.
SECURITY_PROTOCOL_TLS	Either the TLS 1.0, 1.1 or 1.2 protocol should be

	<p>used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers that reject any attempt to use the older SSL protocol and require that only TLS be used.</p>
SECURITY_PROTOCOL_TLS10	<p>The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.</p>
SECURITY_PROTOCOL_TLS11	<p>The TLS 1.1 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.</p>
SECURITY_PROTOCOL_TLS12	<p>The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This is the recommended version of TLS to use with secure connections.</p>
SECURITY_PROTOCOL_SSH1	<p>The Secure Shell 1.0 protocol has been selected. This protocol has been deprecated and is no longer widely used. It is not recommended that this protocol be used when establishing secure connections. This protocol can only be specified when connecting to an SSH server and is not supported with any other application protocol.</p>
SECURITY_PROTOCOL_SSH2	<p>The Secure Shell 2.0 protocol has been selected. This is the most commonly used version of the protocol. It is recommended that this version of the protocol be used unless the server explicitly requires the client to use an earlier version. This protocol can only be specified when connecting to an SSH server and is not supported with any other application protocol.</p>

A numeric value which specifies the cipher that was selected when establishing the secure connection. One of the following values will be returned:

Constant	Description
SECURITY_CIPHER_RC2	The RC2 block cipher was selected. This is a variable key length cipher which supports keys between 40 and 128 bits, in 8-bit increments.
SECURITY_CIPHER_RC4	The RC4 stream cipher was selected. This is a variable key length cipher which supports keys between 40 and 128 bits, in 8-bit increments.
SECURITY_CIPHER_RC5	The RC5 block cipher was selected. This is a variable key length cipher which supports keys up to 2040 bits, in 8-bit increments.
SECURITY_CIPHER_DES	The DES (Data Encryption Standard) block cipher was selected. This is a fixed key length cipher, using 56-bit keys.
SECURITY_CIPHER_DES3	The Triple DES block cipher was selected. This cipher encrypts the data three times using different keys, effectively providing a 168-bit length key.
SECURITY_CIPHER_DESX	A variant of the DES block cipher which XORs an extra 64-bits of the key before and after the plaintext has been encrypted, increasing the key size to 184 bits.
SECURITY_CIPHER_AES	The Advanced Encryption Standard cipher (also known as the Rijndael cipher) is a fixed block size cipher which use a key size of 128, 192 or 256 bits. This cipher is supported on Windows XP SP3 and later versions of the operating system.
SECURITY_CIPHER_SKIPJACK	The Skipjack block cipher was selected. This is a fixed key length cipher, using 80-bit keys.
SECURITY_CIPHER_BLOWFISH	The Blowfish block cipher was selected. This is a variable key length cipher up to 448 bits, using a 64-bit block size.

dwCipherStrength

A numeric value which specifies the strength (the length of the cipher key in bits) of the cipher that was selected. Typically this value will be 128 or 256. 40-bit and 56-bit key lengths are considered weak encryption, and subject to brute force attacks. 128-bit and 256-bit key lengths are considered to be secure, and are the recommended key length for secure communications.

dwHash

A numeric value which specifies the hash algorithm which was selected. One of the following values will be returned:

Constant	Description
SECURITY_HASH_MD5	The MD5 algorithm was selected. Its use has been deprecated and is no longer considered to be cryptographically secure.

SECURITY_HASH_SHA1	The SHA-1 algorithm was selected. Its use has been deprecated and is no longer considered to be cryptographically secure.
SECURITY_HASH_SHA256	The SHA-256 algorithm was selected.
SECURITY_HASH_SHA384	The SHA-384 algorithm was selected.
SECURITY_HASH_SHA512	The SHA-512 algorithm was selected.

dwHashStrength

A numeric value which specifies the strength (the length in bits) of the message digest that was selected.

dwKeyExchange

A numeric value which specifies the key exchange algorithm which was selected. One of the following values will be returned:

Constant	Description
SECURITY_KEYEX_RSA	The RSA public key algorithm was selected.
SECURITY_KEYEX_KEA	The Key Exchange Algorithm (KEA) was selected. This is an improved version of the Diffie-Hellman public key algorithm.
SECURITY_KEYEX_DH	The Diffie-Hellman key exchange algorithm was selected.
SECURITY_KEYEX_ECDH	The Elliptic Curve Diffie-Hellman key exchange algorithm was selected. This is a variant of the Diffie-Hellman algorithm which uses elliptic curve cryptography. This key exchange algorithm is only supported on Windows XP SP3 and later versions of the operating system.

dwCertStatus

A numeric value which specifies the status of the certificate returned by the secure server. This member only has meaning for connections using the SSL or TLS protocols. One of the following values will be returned:

Constant	Description
SECURITY_CERTIFICATE_VALID	The certificate is valid.
SECURITY_CERTIFICATE_NOMATCH	The certificate is valid, but the domain name does not match the common name in the certificate.
SECURITY_CERTIFICATE_EXPIRED	The certificate is valid, but has expired.
SECURITY_CERTIFICATE_REVOKED	The certificate has been revoked and is no longer valid.
SECURITY_CERTIFICATE_UNTRUSTED	The certificate or certificate authority is not trusted on the local system.
SECURITY_CERTIFICATE_INVALID	The certificate is invalid. This typically indicates that the internal structure of the certificate has been damaged.

stCertIssued

A structure which contains the date and time that the certificate was issued by the certificate authority. If the issue date cannot be determined for the certificate, the SYSTEMTIME structure members will have zero values. This member only has meaning for connections using the SSL or TLS protocols.

stCertExpires

A structure which contains the date and time that the certificate expires. If the expiration date cannot be determined for the certificate, the SYSTEMTIME structure members will have zero values. This member only has meaning for connections using the SSL or TLS protocols.

lpszCertIssuer

A pointer to a string which contains information about the organization that issued the certificate. This string consists of one or more comma-separated tokens. Each token consists of an identifier, followed by an equal sign and a value. If the certificate issuer could not be determined, this member may be NULL. This member only has meaning for connections using the SSL or TLS protocols.

lpszCertSubject

A pointer to a string which contains information about the organization that the certificate was issued to. This string consists of one or more comma-separated tokens. Each token consists of an identifier, followed by an equal sign and a value. If the certificate subject could not be determined, this member may be NULL. This member only has meaning for connections using the SSL or TLS protocols.

lpszFingerprint

A pointer to a string which contains a sequence of hexadecimal values that uniquely identify the server. This member is only used when a connection has been established using the Secure Shell (SSH) protocol.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Unicode: Implemented as Unicode and ANSI versions.

SYSTEMTIME Structure

The **SYSTEMTIME** structure represents a date and time using individual members for the month, day, year, weekday, hour, minute, second, and millisecond.

```
typedef struct _SYSTEMTIME
{
    WORD wYear;
    WORD wMonth;
    WORD wDayOfWeek;
    WORD wDay;
    WORD wHour;
    WORD wMinute;
    WORD wSecond;
    WORD wMilliseconds;
} SYSTEMTIME, *LPSYSTEMTIME;
```

Members

wYear

Specifies the current year. The year value must be greater than 1601.

wMonth

Specifies the current month. January is 1, February is 2 and so on.

wDayOfWeek

Specifies the current day of the week. Sunday is 0, Monday is 1 and so on.

wDay

Specifies the current day of the month

wHour

Specifies the current hour.

wMinute

Specifies the current minute

wSecond

Specifies the current second.

wMilliseconds

Specifies the current millisecond.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include windows.h.

File Transfer Protocol Server Library

Implements a server that enables the application to send and receive files using the File Transfer Protocol.

Reference

- [Functions](#)
- [Data Structures](#)
- [Error Codes](#)

Library Information

File Name	CSFTSV10.DLL
Version	10.0.1468.2518
LibID	5CED7337-69F7-4662-B173-42FA4EEB64E3
Import Library	CSFTSV10.LIB
Dependencies	None
Standards	RFC 959, RFC 1579, RFC 2228

Overview

This library provides an interface for implementing an embedded, lightweight server that can be used to exchange files with a client using the standard File Transfer Protocol. The server can accept connections from any third-party application or a program developed using the SocketTools FTP client API.

The application specifies an initial server configuration and then responds to events that are raised by the API when the client sends a request to the server. An application may implement only minimal handlers for most events, in which case the default actions are performed for most standard FTP commands. However, an application may also use the event mechanism to filter specific commands or to extend the protocol by providing custom implementations of existing commands or add entirely new commands.

The server supports active and passive mode file transfers, has compatibility options for NAT router and firewall support, and provides support for secure file transfers using explicit TLS. Secure connections require a valid security certificate to be installed on the system.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). If you are using Visual C++ 6.0 it is required that you have Service Pack 6 (SP6) installed. You should install all updates for your development tools and have the current Windows SDK installed. The minimum recommended version of Visual Studio is Visual Studio 2010.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are using Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. It is recommended that you install the current service pack and all critical updates available for your version of the operating system.

This library provides an implementation of a multithreaded server which should only be used with

languages that support the creation of multithreaded applications. It is important that you do not attempt to link against static libraries which were not built with support for threading.

This product includes both 32-bit and 64-bit libraries. Native 64-bit CPU support requires the 64-bit version of Windows 7 or later versions of the Windows operating system.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

File Transfer Protocol Server Functions

Function	Description
FtpAddVirtualUser	Add a new virtual user for the specified server
FtpAuthenticateClient	Authenticate the client and assign access rights for the session
FtpChangeClientDirectory	Change the current working directory for the client session
FtpCreateServerCredentials	Create a new server security credentials structure
FtpDeleteServerCredentials	Delete a previously created security credentials structure
FtpDeleteVirtualUser	Delete a virtual user from the specified server
FtpDisconnectClient	Disconnect the specific client session, closing the control channel and aborting any file transfer
FtpEnableClientAccess	Enable or disable access rights for the specified client session
FtpEnableCommand	Enable or disable a specific server command
FtpEnumServerClients	Returns a list of active client sessions established with the specified server
FtpGetActiveClient	Return the client ID for the active client session associated with the current thread
FtpGetClientAccess	Return the access rights that have been granted to the client session
FtpGetClientAddress	Return the IP address of the specified client session
FtpGetClientCredentials	Return the credentials for the specified client session
FtpGetClientDirectory	Return the current working directory for a client session
FtpGetClientFileType	Return the current file type used for transfers by the specified client
FtpGetClientHomeDirectory	Return the home directory for an authenticated client session
FtpGetClientIdentity	Return the identity of the specified client session
FtpGetClientIdleTime	Return the idle timeout period for the specified client
FtpGetClientLocalPath	Return the full local path for the specified virtual path
FtpGetClientServer	Return the handle to the server that created the specified client session
FtpGetClientThreadId	Returns the thread ID associated with the specified client session
FtpGetClientUserName	Return the user name associated with the specified client session
FtpGetClientVirtualPath	Return the virtual path for a local file on the server
FtpGetCommandFile	Return the full path to the local file name or directory specified by the client
FtpGetCommandLine	Return the complete command line issued by the client
FtpGetCommandName	Return the name of the last command issued by the client
FtpGetCommandParam	Return the value of the specified parameter for the command issued by the client
FtpGetCommandParamCount	Return the number of parameters to the current command issued by the

	client
FtpGetCommandResult	Return the result code and a description of the last command processed by the server
FtpGetCommandUsage	Return the number of times a specific command has been issued by all clients
FtpGetProgramExitCode	Return the exit code of the last program executed by the client
FtpGetProgramName	Return the name of the last program executed by the client
FtpGetProgramOutput	Return a copy of the standard output from the last program executed by the client
FtpGetProgramText	Return a copy of the standard output from the last program in a string buffer
FtpGetRenamedFile	Return the original name of a file being renamed by the client
FtpGetServerAddress	Return the IP address for the server
FtpGetServerDirectory	Return the full path to the root directory assigned to the specified server
FtpGetServerError	Return information about the last server error that occurred
FtpGetServerIdentity	Return the identity and version information for the specified server
FtpGetServerLogFile	Return the current log file format and full path for the file
FtpGetServerMemoryUsage	Return the amount of memory allocated for the server and all client sessions
FtpGetServerName	Return the host name assigned to the server or specified client session
FtpGetServerOptions	Return the configuration options for the specified server
FtpGetServerPriority	Return the current priority assigned to the specified server
FtpGetServerStackSize	Return the initial size of the stack allocated for threads created by the server
FtpGetServerTransferInfo	Return information about the current file transfer for the client session
FtpGetServerUuid	Return the UUID assigned to the specified server
FtpGetServerUuidString	Return the UUID assigned to the server as a printable string
FtpIsClientAnonymous	Determine if the specified client has authenticated as an anonymous user
FtpIsClientAuthenticated	Determine if the specified client session has been authenticated
FtpIsCommandEnabled	Determine if the specified command is currently enabled or disabled
FtpRegisterProgram	Register a program for use with the SITE EXEC command
FtpRenameServerLogFile	Rename or delete the current log file being updated by the server
FtpSendResponse	Send a result code and optional message to the client in response to a command
FtpServerAsyncNotify	Enable or disable asynchronous notification of changes in server status
FtpServerDisableTrace	Disable logging of network function calls
FtpServerEnableTrace	Enable logging of network function calls to a file

FtpServerInitialize	Initialize the library and validate the specified license key at runtime
FtpServerProc	Callback function used to process server events
FtpServerRestart	Restart the server, terminating all active client sessions
FtpServerResume	Resume accepting client connections on the specified server
FtpServerStart	Start the server and begin accepting client connections
FtpServerStop	Stop the server and terminate all active client connections
FtpServerSuspend	Suspend accepting client connections on the specified server
FtpServerThrottle	Limit the number of active client connections, connections per address and connection rate
FtpServerUninitialize	Terminate use of the library by the application
FtpSetClientAccess	Change the access rights associated with the specified client session
FtpSetClientFileType	Change the current file type used for transfers by the specified client
FtpSetClientIdentity	Change the identity string associated with the specified client session
FtpSetClientIdleTime	Change the idle timeout period for the specified client session
FtpSetCommandFile	Change the name of the local file or directory that is the target of the current command
FtpSetServerAddress	Change the IP address that the server will use with passive data connections
FtpSetServerError	Set the last error code for the specified server session
FtpSetServerIdentity	Change the identity and version information for the specified server
FtpSetServerLogFile	Change the current log format, level of detail and file name
FtpSetServerName	Change the hostname assigned to the specified server or client session
FtpSetServerPriority	Change the priority assigned to the specified server
FtpSetServerStackSize	Change the initial size of the stack allocated for threads created by the server

FtpAddVirtualUser Function

```
BOOL WINAPI FtpAddVirtualUser(  
    HSERVER hServer,  
    UINT nHostId,  
    DWORD dwUserAccess,  
    LPCTSTR lpszUserName,  
    LPCTSTR lpszPassword,  
    LPCTSTR lpszDirectory  
);
```

Add a new virtual user for the specified server.

Parameters

hServer

The server handle.

nHostId

An integer value which identifies the virtual host. This parameter is reserved for future use and must always have a value of zero.

dwUserAccess

An integer value which specifies the access clients will be given when authenticated as this user. For a list of user access permissions, see [User Access Constants](#).

lpszUserName

A pointer to a string which specifies the user name. The maximum length of a username is 63 characters and it is recommended that names be limited to alphanumeric characters. Whitespace, control characters and certain symbols such as path delimiters and wildcard characters are not permitted. If an invalid character is included in the name, the function will fail with an error indicating the username is invalid. This parameter cannot be NULL and the name must be at least three characters in length. Usernames are not case sensitive.

lpszPassword

A pointer to a string which specifies the user password. The maximum length of a password is 63 characters and is limited to printable characters. Whitespace and control characters are not permitted. If an invalid character is included in the password, the function will fail with an error indicating the password is invalid. This parameter cannot be NULL and must be at least one character in length. Passwords are case sensitive.

lpszDirectory

A pointer to a string which specifies the directory that will be the virtual user's home directory. If the server was started in multi-user mode, this directory will be relative to the user directory created by the server, otherwise it will be relative to the server root directory. If the directory does not exist, it will be created the first time that the virtual user successfully logs in to the server. If this parameter is NULL or an empty string, a default home directory will be created for the virtual user.

Return Value

If the function succeeds, the return value is non-zero. If the server handle is invalid or the virtual host ID does not specify a valid host, the function will return zero. If the function fails, the last error code will be updated to indicate the cause of the failure.

Remarks

The **FtpAddVirtualUser** function adds a virtual user that is associated with the specified virtual host. When a client connects with the server and provides authentication credentials, the server will check if the username has been created using this function. If a match is found, the client access rights will be updated.

If you wish to modify the information for a user, it is not necessary to delete the username first. If this function is called with a username that already exists, that record is replaced with the values passed to this function. You cannot use this function to create a virtual user named "anonymous".

The virtual users created by this function exist only as long as the server is active. If you wish to maintain a persistent database of users and passwords, you are responsible for its implementation based on the requirements of your specific application. For example, a simple implementation would be to store the user information in a local XML or INI file and then read that configuration file after the server has started, calling this function for each user that is listed.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csftsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[FtpDeleteVirtualUser](#)

FtpAuthenticateClient Function

```
BOOL WINAPI FtpAuthenticateClient(  
    HSERVER hServer,  
    UINT nClientId,  
    DWORD dwUserAccess,  
    BOOL bCreateHome,  
    LPCTSTR lpszDirectory  
);
```

Authenticate the client and assign access rights for the session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

dwUserAccess

An unsigned integer which specifies one or more user access rights. For a list of user access rights that can be granted to the client, see [User Access Constants](#).

bCreateHome

An integer value that specifies if the server should create the home directory for the authenticated client if it does not already exist. If this value is non-zero, the home directory will be created. If value is zero, the home directory will not be created and if it does not exist, this function will fail.

lpszDirectory

A pointer to a string that specifies the home directory for the user. If an absolute path is specified, it will be relative to the server root directory. If a relative path is specified, it will be a subdirectory of the home directory for the server instance. If this parameter is NULL or an empty string, a home directory will be assigned based on the server home directory and the user name.

Return Value

If the the client session could be authenticated, the return value is non-zero. If the server handle and client ID do not specify a valid client session, or the client has already been authenticated, this function will return zero.

Remarks

The **FtpAuthenticateClient** function is used to authenticate a specific client session, typically in response to an FTP_CLIENT_USERAUTH event that indicates a client has requested authentication. This function is also used internally to automatically grant the appropriate access rights to local user and anonymous client sessions.

It is recommended that most applications specify FTP_ACCESS_DEFAULT as the *dwUserAccess* value for a client session, since this allows the server automatically grant the appropriate access based on the server configuration options for normal and anonymous users. If the server is going to be publicly accessible or third-party FTP clients will be used to access the server, you should always grant the FTP_ACCESS_LIST permission to clients. Many client applications will not function correctly if they are unable to obtain a list of files in the user's home directory.

If `FTP_ACCESS_RESTRICTED` is specified and the server was started in multi-user mode, the client session will be effectively locked to its home directory and cannot navigate to the server root directory. By default, restricted client sessions are also limited to only downloading files and requesting directory listings. If a client session is not restricted, the client can access files outside of its home directory. Regardless of this option, a client cannot access files outside of the server root directory.

If `FTP_ACCESS_RESTRICTED` or `FTP_ACCESS_ANONYMOUS` is specified, the client session will be authenticated in a restricted mode and the access rights for the session will persist until the client disconnects from the server. Unlike regular users, the access rights for a restricted client cannot be changed by the server at a later point. This restriction is designed to prevent the inadvertent granting of rights to an untrusted client that could compromise the security of the server.

If the *lpszDirectory* parameter is `NULL` or an empty string and the server has been started in multi-user mode, each user is assigned their own home directory based on their username. If the server has not been started in multi-user mode, then the default home directory will be the server root directory and is shared by all users. The **FtpGetClientHomeDirectory** function will return the full path to the home directory for an authenticated client.

If the `FTP_ACCESS_EXECUTE` permission is granted to the client session, it can execute external programs using the `SITE EXEC` command. Because the program is executed in the context of the server process, it is recommended that you limit access to this functionality and ensure that the programs being executed do not introduce any security risks to the operating system. This permission is never granted by default, and the `SITE EXEC` command will return an error if the client session is anonymous, regardless of whether this permission is granted or not.

This function should only be used for custom authentication schemes and is not necessary if you have used the **FtpAddVirtualUser** function to create virtual users.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csftsv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

[FtpAddVirtualUser](#), [FtpChangeClientDirectory](#), [FtpGetClientCredentials](#), [FtpGetClientDirectory](#), [FtpGetClientHomeDirectory](#)

FtpChangeClientDirectory Function

```
BOOL WINAPI FtpChangeClientDirectory(  
    HSERVER hServer,  
    UINT nClientId,  
    LPCTSTR lpszDirectory  
);
```

Change the current working directory for the specified client.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszDirectory

A pointer to a string which specifies the new current working directory for the client session. If this parameter is NULL or an empty string, the current working directory will be changed to the client home directory. If this parameter is not NULL, it must specify a directory that exists and is accessible by the server process.

Return Value

If the current working directory was changed, the return value is non-zero. If the server handle and client ID do not specify a valid client session, or the directory is invalid, this function will return zero.

Remarks

The **FtpChangeClientDirectory** function will change the current working directory for the specified client session. This function is called internally when the client sends the CWD or CDUP commands, however it may be explicitly used by the application to change the client's working directory in response to a server event.

This function cannot be used to change the current working directory for a client to an arbitrary directory outside of the server root directory. If the *lpszDirectory* parameter specifies a relative path (i.e.: a path that does not begin with a drive letter or leading path delimiter) then the new working directory will be relative to the current working directory. If an absolute path is specified, the absolute path must include the complete path to either the server root directory or the user's home directory, based on the permissions granted to the client session. If a path outside of the server root directory is specified, this function will fail with an access denied error.

Use caution when calling this function to override the directory specified by the client when it sends the CWD or CDUP commands. If your application changes the current working directory to one not specified by the client, it may cause unpredictable behavior in the client application because the actual path of the current working directory will not match the directory that was requested.

If this function is used to change the current working directory in response to the CWD command, you should not call the **FtpGetCommandParam** function and pass the command parameter as an argument to this function. You must use the **FtpGetCommandFile** function to obtain the directory name provided by the client prior to calling this function.

The application should never call the **SetCurrentDirectory** function in the Windows API to change

the current directory for the process to the working directory of a client session. Because the server is multithreaded and each client session is managed in its own thread, an application using this library should avoid using relative paths.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csftsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[FtpGetClientDirectory](#), [FtpGetClientHomeDirectory](#), [FtpGetCommandFile](#)

FtpCreateServerCredentials Function

```
BOOL WINAPI FtpCreateServerCredentials(  
    DWORD dwProtocol,  
    DWORD dwOptions,  
    LPCTSTR lpszUserName,  
    LPCTSTR lpszPassword,  
    LPCTSTR lpszCertStore,  
    LPCTSTR lpszCertName,  
    LPVOID lpvReserved,  
    LPSECURITYCREDENTIALS* lppCredentials  
);
```

The **FtpCreateServerCredentials** function creates a SECURITYCREDENTIALS structure.

Parameters

dwProtocol

A bitmask of supported security protocols. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_SSL	Either SSL 2.0 or SSL 3.0 should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, TLS will be excluded from the list of supported protocols. Both SSL 2.0 and 3.0 have been deprecated and will never be used unless explicitly specified. It is not recommended that you enable either of these protocols for secure connections because it will cause most servers to reject your connection request, even if a version of TLS is also specified.
SECURITY_PROTOCOL_TLS	Either the TLS 1.0, 1.1 or 1.2 protocol should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers that reject any attempt to use the older SSL protocol and require that only TLS be used.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol should be used when establishing a secure connection. This version is

	supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This is the recommended version of TLS to use with secure connections.

dwOptions

A value which specifies one or options. This member is constructed by using a bitwise operator with any of the following values:

Constant	Description
CREDENTIAL_STORE_CURRENT_USER	The library will attempt to open a store for the current user using the certificate store name provided in this structure. If no options are specified, then this is the default behavior.
CREDENTIAL_STORE_LOCAL_MACHINE	The library will attempt to open a local machine store using the certificate store name provided in this structure. If this option is specified, the library will always search for a local machine store before searching for the store by that name for the current user.
CREDENTIAL_STORE_FILENAME	The certificate store name is a file that contains the certificate and private key that will be used.

lpszUserName

A pointer to a string which specifies the certificate owner's username. A value of NULL specifies that no username is required. Currently this parameter is not used and any value specified will be ignored.

lpszPassword

A pointer to a string which specifies the certificate owner's password. A value of NULL specifies

that no password is required. This parameter is only used if a PKCS12 (PFX) certificate file is specified and that certificate has been secured with a password. This value will be ignored the current user or local machine certificate store is specified.

lpzCertStore

A pointer to a string which specifies the name of the certificate store to open. A certificate store is a collection of certificates and their private keys, typically organized by how they are used. If this value is NULL or points to an empty string, the default certificate store "MY" will be used.

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as VeriSign and Thawte act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. This corresponds to the "Personal" store that is displayed by the certificate manager utility and is the default store used by the library.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as VeriSign and Thawte are installed as part of the operating system and periodically updated by Microsoft.

lpzCertName

A pointer to a null terminated string which specifies the name of the certificate to use. The function will first search the certificate store for a certificate with a matching "friendly name"; this is a name for the certificate that is assigned by the user. Note that the name must match completely, but the comparison is not case sensitive. If no matching certificate is found, the function will then attempt to find a certificate that has a matching common name (also called the certificate subject). This comparison is less stringent, and the first partial match will be returned. If this second search fails, the function will return an error indicating that the certificate could not be found.

lpvReserved

Pointer reserved for future use. Set it to NULL when using this function.

lppCredentials

Pointer to an [LPSECURITYCREDENTIALS](#) pointer. The memory for the credentials structure will be allocated by this function and must be released by calling the **FtpDeleteServerCredentials** function when it is no longer needed. The pointer value must be set to NULL before the function is called. It is important to note that this is a pointer to a pointer variable, not a pointer to the SECURITYCREDENTIALS structure itself.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **FtpGetServerError**.

Remarks

The structure that is created by this function may be used as client credentials when establishing a secure connection. This is particularly useful for programming languages other than C/C++ which may not support C structures or pointers. The pointer to the SECURITYCREDENTIALS structure can

be declared as an unsigned integer variable which is passed by reference to this function, and then passed by value to the **FtpServerStart** function.

Example

```
// Create the server credentials that identifies the certificate
// that will be used for secure connections
LPSECURITYCREDENTIALS lpSecCred = NULL;

FtpCreateServerCredentials(SEcurity_PROTOCOL_DEFAULT,
                           0,
                           NULL,
                           NULL,
                           lpzCertStore,
                           lpzCertName,
                           NULL,
                           &lpSecCred);

// Start the server
hServer = FtpServerStart(lpzLocalHost,
                        FTP_PORT_DEFAULT,
                        FTP_SERVER_LOCALUSER | FTP_SERVER_UNIXMODE |
FTP_SERVER_SECURE,
                        &ftpConfig,
                        lpEventHandler,
                        0,
                        lpSecCred);
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csftsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

FtpDeleteServerCredentials Function

```
VOID WINAPI FtpDeleteServerCredentials(  
    LPSECURITYCREDENTIALS* LppCredentials  
);
```

The **FtpDeleteServerCredentials** function deletes an existing **SECURITYCREDENTIALS** structure.

Parameters

lppCredentials

Pointer to an LPSECURITYCREDENTIALS pointer. On exit from the function, the pointer value will be NULL.

Return Value

None.

Example

```
if (lpSecCred != NULL)  
    FtpDeleteServerCredentials(&lpSecCred);
```

Remarks

This function can be used to release the memory allocated for the credentials after the server has been started.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csftsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

FtpDeleteVirtualUser Function

```
BOOL WINAPI FtpDeleteVirtualUser(  
    HSERVER hServer,  
    UINT nHostId,  
    LPCTSTR LpszUserName  
);
```

Remove a virtual user from the specified host.

Parameters

hServer

The server handle.

nHostId

An integer value which identifies the virtual host. This parameter is reserved for future use and must always have a value of zero.

lpszUserName

A pointer to a string which specifies the user that will be removed. This parameter cannot be a NULL pointer or an empty string.

Return Value

If the function succeeds, the return value is non-zero. If the server handle is invalid or the virtual host ID does not specify a valid host, the function will return zero. If the function fails, the last error code will be updated to indicate the cause of the failure.

Remarks

This function removes a virtual user that was created by a previous call to the **FtpAddVirtualUser** function. This function will not match partial usernames and wildcard characters cannot be used to delete multiple users. Usernames are not case sensitive. You cannot use this function to delete the "anonymous" user.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[FtpAddVirtualUser](#)

FtpDisconnectClient Function

```
BOOL WINAPI FtpDisconnectClient(  
    HSERVER hServer,  
    UINT nClientId  
);
```

Close the control connection for the specified client and release the resources allocated for the session

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

Return Value

If the function succeeds, the return value is non-zero. If the server handle and client ID do not specify a valid client session, the function will return zero.

Remarks

The **FtpDisconnectClient** function will close the control channel, disconnecting the client from the server and terminating the client session thread. Resources that we allocated for the client, such as memory and open handles, will be released back to the operating system. If the client was in the process of transferring a file, the transfer will be aborted. This performs the same operation as if the client sent the QUIT command to the server.

This function sends an internal control message that notifies the server that this session should be terminated. When the session thread is signaled that it should terminate, it will abort any active file transfers and begin to release the resources allocated for that session. To ensure that the client session terminates gracefully, there may be a brief period of time where the session thread is still active after this function has returned.

After this function returns, the application should never use the same client ID with another function. Client IDs are unique to the session over the lifetime of the server, and are not reused.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftsv10.lib

See Also

[FtpServerRestart](#), [FtpServerStop](#)

FtpEnableClientAccess Function

```
BOOL WINAPI FtpEnableClientAccess(  
    HSERVER hServer,  
    UINT nClientId,  
    DWORD dwUserAccess,  
    BOOL bEnable  
);
```

Enable or disable access rights for the specified client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

dwUserAccess

An unsigned integer which specifies an access right to enable or disable. For a list of user access rights that can be granted to the client, see [User Access Constants](#).

bEnable

An integer value which specifies if permission should be granted or revoked for the specified access right. If this value is non-zero, permission is granted to the client to perform the action specified by the *dwUserAccess* parameter. If this value is zero, that permission is revoked.

Return Value

If the function succeeds, the return value is non-zero. If the server handle and client ID do not specify a valid client session, the function will return zero. This function can only be used with authenticated clients. If the client session has not been authenticated, the return value will be zero.

Remarks

The **FtpEnableClientAccess** function is used to enable or disable access to specific functionality by the client. The function can only change a single access right and cannot be used to enable or disable multiple access rights in a single function call. To change multiple user access rights for the client, use the **FtpSetClientAccess** function.

This function cannot be used to change the access rights for a restricted or anonymous user. Those rights are granted when the client session is authenticated and will persist until the client disconnects from the server. This restriction is designed to prevent the inadvertent granting of rights to an untrusted client that could compromise the security of the server.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftsv10.lib

See Also

[FtpAuthenticateClient](#), [FtpGetClientAccess](#), [FtpSetClientAccess](#)

FtpEnableCommand Function

```
BOOL WINAPI FtpEnableCommand(  
    HSERVER hServer,  
    LPCTSTR lpszCommand,  
    BOOL bEnable  
);
```

Enable or disable a specific server command

Parameters

hServer

The server handle.

lpszCommand

A pointer to a NULL terminated string that specifies the name of the command to be enabled or disabled. The command name is not case-sensitive, but the value must otherwise match the exact name. Partial matches are not recognized by this function. This parameter cannot be NULL.

bEnable

An integer value which specifies if the command should be enabled or disabled. If the value is non-zero, the command is enabled. If the value is zero, the command will be disabled.

Return Value

If the function succeeds, the return value is non-zero. If the server handle is invalid or the command is not recognized, the function will return zero. If the function fails, the **FtpGetServerError** function will return more information about the last error that has occurred.

Remarks

The **FtpEnableCommand** function is used to enable or disable access to a specific command on the server. When a command is disabled, it will also disable any corresponding feature related to that command. For example, if the MDTM command is disabled and a client issues the FEAT command to request a list of supported features, the command will no longer be listed. This function is typically used to enable or disable certain commands for compatibility with older client software. The **FtpIsCommandEnabled** function can be used to determine if a command is enabled or not.

The command name provided to this function must match the commands defined in RFC 959 or related protocol standards. It is important to distinguish between commands recognized by an FTP server and the commands that client programs may use. For example, the standard Windows FTP command line program provides commands such as GET and PUT to download and upload files. However, those are not the actual commands sent to a server. Instead, the corresponding server commands issued by a client application would be RETR (retrieve) and STOR (store). Refer to [File Transfer Protocol Commands](#) for a complete list of server commands.

Some commands cannot be disabled because they are required to perform essential server functions. For example, the USER and PASS commands are required to perform client authentication and therefore cannot be disabled. If you attempt to disable a required command, this function will return zero and the last error code will be set to ST_ERROR_COMMAND_REQUIRED. Because this function affects all clients connected to the server, it should not be used to limit access to certain commands for specific clients. Instead, either assign the client the appropriate permissions using the **FtpAuthenticateClient** function, or use an

event handler to filter the commands.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csftsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[FtpAuthenticateClient](#), [FtpIsCommandEnabled](#)

FtpEnumServerClients Function

```
INT WINAPI FtpEnumServerClients(  
    HSERVER hServer,  
    DWORD dwReserved  
    UINT * lpClients,  
    INT nMaxClients  
);
```

Return a list of active client sessions established with the specified server.

Parameters

hServer

Handle to the server socket.

dwReserved

An unsigned integer value that is reserved for future use. This parameter should always be zero.

lpClients

Pointer to an array of unsigned integers which will contain client IDs that uniquely identifies each client when the function returns. If this parameter is NULL, then the function will return the number of active client connections established with the server.

nMaxClients

Maximum number of client IDs to be returned in the *lpClients* array. If the *lpClients* parameter is NULL, this parameter should have a value of zero.

Return Value

If the function succeeds, the return value is the number of active client connections to the server. If the function fails, the return value is FTP_ERROR. To get extended error information, call

FtpGetServerError.

Remarks

If the *nMaxClients* parameter is less than the number of active client connections, the function will fail and the last error code will be set to the error ST_ERROR_BUFFER_TOO_SMALL. To dynamically determine the number of active connections, call the function with the *lpClients* parameter with a value of NULL, and the *nMaxClients* parameter with a value of zero.

Example

```
INT nClients = FtpEnumServerClients(hServer, 0, NULL, 0);  
  
if (nClients > 0)  
{  
    UINT *lpClients = NULL;  
  
    // Allocate memory for an array of client IDs  
    lpClients = (UINT *)LocalAlloc(LPTR, nClients * sizeof(UINT));  
  
    if (lpClients == NULL)  
    {  
        // Virtual memory has been exhausted  
        return;  
    }  
  
    nClients = FtpEnumServerClients(hServer, 0, lpClients, nClients);  
}
```

```
if (nClients == FTP_ERROR)
{
    // Unable to obtain list of connected clients
    return;
}

for (INT nIndex = 0; nIndex < nClients; nIndex++)
{
    TCHAR szUserName[FTP_MAXUSERNAME];

    if (FtpGetClientUserName(hServer, lpClients[nIndex], szUserName,
FTP_MAXUSERNAME))
    {
        // Perform some action with the client user name
    }
}

// Free the memory allocated for the client IDs
LocalFree((HLOCAL)lpClients);
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftsv10.lib

See Also

[FtpServerStart](#)

FtpGetActiveClient Function

```
UINT WINAPI FtpGetActiveClient(  
    HSERVER hServer  
);
```

Return the client ID for the active client session associated with the current thread.

Parameters

hServer

The server handle.

Return Value

If the function succeeds, the return value is the unique ID associated with the client session for the current thread. If the server handle is invalid or there is no client session active on the current thread, the return value is zero.

Remarks

The **FtpGetActiveClient** function is used to obtain the client ID associated with the current thread. This means this function will only return a client ID if it is called within an event handler or a function called by an event handler. If this function is called by a function that is not executing within the context of an event handler it will return a value of zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csftsv10.lib

FtpGetClientAccess Function

```
BOOL WINAPI FtpGetClientAccess(  
    HSERVER hServer,  
    UINT nClientId,  
    LPDWORD lpdwUserAccess  
);
```

Return the access rights that have been granted to the client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpdwUserAccess

A pointer to an unsigned integer which specifies one or more access rights for the client session. For a list of user access rights that can be granted to the client, see [User Access Constants](#). This parameter cannot be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the server handle and client ID do not specify a valid client session, the function will return zero. This function can only be used with authenticated clients. If the client session has not been authenticated, the return value will be zero.

Remarks

The **FtpGetClientAccess** function is used to obtain all of the access rights that are currently granted to an authenticated client session. The **FtpEnableClientAccess** function can be used to enable or disable specific permissions, and the **FtpSetClientAccess** function can change multiple access rights at once.

Example

```
DWORD dwUserAccess = 0;  
  
// Check if the client is a restricted user  
  
if (FtpGetClientAccess(hServer, nClientId, &dwUserAccess))  
{  
    if (dwUserAccess & FTP_ACCESS_RESTRICTED)  
    {  
        _tprintf(_T("Client %u authenticated as a restricted user\n"),  
nClientId);  
        return;  
    }  
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftsv10.lib

Copyright © 2023 Catalyst Development Corporation. All rights reserved.

FtpGetClientAddress Function

```
INT WINAPI FtpGetClientAddress(  
    HSERVER hServer,  
    UINT nClientId,  
    LPTSTR lpszAddress,  
    INT nMaxLength  
);
```

Return the IP address of the specified client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszAddress

A pointer to a string buffer that will contain the client IP address, terminated with a null character. To accommodate both IPv4 and IPv6 addresses, this buffer should be at least 46 characters in length. This parameter cannot be NULL.

nMaxLength

An integer value that specifies the maximum number of characters can be copied into the string buffer, including the terminating null character. This value must be greater than zero. If the buffer size is too small, the function will fail.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If either the server handle or the client ID is invalid, or the buffer is not large enough to store the complete address, the function will return a value of zero.

Remarks

The format and length of IPv4 and IPv6 address strings are very different. An IPv4 address string looks like "192.168.0.20", while an IPv6 address string can look something like "fd7c:2f6a:4f4f:ba34::a32". If your application checks for the format of these address strings, it needs to be aware of the differences. You also need to make sure that you're providing enough space to display or store an address to avoid buffer overruns.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

FtpGetClientCredentials Function

```
BOOL WINAPI FtpGetClientCredentials(  
    HSERVER hServer,  
    UINT nClientId,  
    LPFTPCLIENTCREDENTIALS lpCredentials  
);
```

Return the user credentials for the specified client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpCredentials

A pointer to an **FTPCLIENTCREDENTIALS** structure that will contain information about the user when the function returns. This parameter cannot be NULL.

Return Value

If the user credentials for the client session are available, the return value is non-zero. If the server handle and client ID do not specify a valid client session, or the client has not requested authentication, this function will return zero.

Remarks

The **FtpGetClientCredentials** function is used to obtain the username and password that was provided by the client when it requested authentication. Typically this function is used in an event handler to validate the credentials provided by the client. If the credentials are considered valid, the event handler would then call the **FtpAuthenticateClient** function to specify that the session has been authenticated.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[FtpAuthenticateClient](#), [FTPCLIENTCREDENTIALS](#)

FtpGetClientDirectory Function

```
INT WINAPI FtpGetClientDirectory(  
    HSERVER hServer,  
    UINT nClientId,  
    LPTSTR LpszDirectory,  
    INT nMaxLength  
);
```

Returns the current working directory for the specified client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszDirectory

A pointer to a string buffer that will contain the current working directory for the specified client session, terminated with a null character. This buffer should be at least MAX_PATH characters in length. This parameter cannot be NULL.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer, including the terminating null character. This value must be larger than zero or the function will fail.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If the server handle and client ID do not specify a valid client session, the function will return zero.

Remarks

This function returns the full path to the current working directory for the specified client session. For example, if the server root directory is C:\ProgramData\MyServer and the current working directory for the client is /Research/Documents, this function will return C:\ProgramData\MyServer\Research\Documents as the current working directory for the client session.

It is important to note that the current working directory for client sessions is virtual, and does not reflect the current working directory for the server process. To change the current working directory for a client, use the **FtpChangeClientDirectory** function.

This function should only be used with client sessions that have been authenticated. Unauthenticated clients are not assigned a current working directory and this function will return zero, with the last error code set to ST_ERROR_AUTHENTICATION_REQUIRED.

To convert a full path to the virtual path for a specific client session, use the **FtpGetClientVirtualPath** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csftsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[FtpChangeClientDirectory](#), [FtpGetClientHomeDirectory](#), [FtpGetClientVirtualPath](#)

FtpGetClientFileType Function

```
BOOL WINAPI FtpGetClientFileType(  
    HSERVER hServer,  
    UINT nClientId,  
    UINT * lpnFileType  
);
```

Return the current file type used for transfers by the specified client.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpnFileType

A pointer to an unsigned integer value that will contain the current file type used by the client for data transfers. This parameter cannot be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the server handle and client ID do not specify a valid client session, the function will return zero.

Remarks

The **FtpGetClientFileType** function will return the current file type that has been specified by the client sending the TYPE command to the server. The file type determines if there is any conversion performed on the data that is being exchanged between the client and server. The following file types are supported:

Value	Description
FILE_TYPE_ASCII (1)	The file is a text file using the ASCII character set. For those clients which use a different end-of-line character sequence, the text file has been converted to the local format which uses the carriage return (CR) and linefeed (LF) characters.
FILE_TYPE_IMAGE (3)	The file is a binary file and no data conversion of any type has been performed on the file. This is the default file type for most data files and executable programs. If the client specified this file type when appending to a text file, the file will contain the end-of-line sequences used by its native operating system.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftsv10.lib

FtpGetClientHomeDirectory Function

```
INT WINAPI FtpGetClientHomeDirectory(  
    HSERVER hServer,  
    UINT nClientId,  
    LPTSTR lpszDirectory,  
    INT nMaxLength  
);
```

Returns the home directory for the specified client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszDirectory

A pointer to a string buffer that will contain the home directory for the specified client session, terminated with a null character. This buffer should be at least MAX_PATH characters in length. This parameter cannot be NULL.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer, including the terminating null character. This value must be larger than zero or the function will fail.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If the server handle and client ID do not specify a valid client session, the function will return zero.

Remarks

This function returns the full path to the home working directory assigned to the specified client session. This will be the same path to the home directory specified when the **FtpAuthenticateClient** function was used to authenticate the client session. If a home directory was not explicitly assigned when the client was authenticated, then this function returns the default home directory that was created for the client, or the server root directory if the FTP_SERVER_MULTUSER option was not specified when the server was started.

This function should only be used with client sessions that have been authenticated. Unauthenticated clients are not assigned a home directory and this function will return zero, with the last error code set to ST_ERROR_AUTHENTICATION_REQUIRED.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

FtpGetClientIdentity Function

```
INT WINAPI FtpGetClientIdentity(  
    HSERVER hServer,  
    UINT nClientId,  
    LPTSTR lpszIdentity,  
    INT nMaxLength  
);
```

Return the identity of the specified client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszIdentity

A pointer to a string buffer that will contain the identity of the client when the function returns, terminated with a null character. This parameter cannot be NULL. It is recommended that this buffer be at least 32 characters in length.

nMaxLength

An integer value that specifies the maximum number of characters can be copied into the string buffer, including the terminating null character. This value must be greater than zero. If the buffer size is too small, the function will fail.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If the server handle is invalid, or the buffer is not large enough to store the complete path, the function will return a value of zero. If the client did not identify itself, this function will return zero.

Remarks

The **FtpGetClientIdentity** function returns the string that the client used to identify itself to the server. The client may use either the CLNT or CSID command to identify itself. Although the CLNT command is considered to be deprecated, it is supported for backwards compatibility with older clients. The identity string does not have any standard format and is used for informational purposes only and does not affect the operation of the server in any way. Not all clients identify themselves, in which case this function will return zero and the *lpszIdentity* string buffer will be set to an empty string.

If the client does identify itself, it typically uses the name of the client application that was used to establish the connection. The application may choose to assign an identity to a client session for its own internal purposes using the **FtpSetClientIdentity** function, regardless of whether the client identifies itself.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

FtpGetClientIdleTime Function

```
UINT WINAPI FtpGetClientIdleTime(  
    HSERVER hServer,  
    UINT nClientId,  
    UINT * lpnElapsed  
);
```

Return the idle timeout period for the specified client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpnElapsed

A pointer to an unsigned integer value that will contain the number of seconds the client session has been idle. This parameter may be NULL if this information is not required.

Return Value

If the function succeeds, the return value is client idle timeout period in seconds. If the server handle and client ID do not specify a valid client session, the function will return zero.

Remarks

The **FtpGetClientIdleTime** function will return the number of seconds that the client may remain idle before being automatically disconnected by the server. The idle time of a client session is based on the last time a command was issued to the server or when a file data transfer completed. The server will never disconnect a client that is in the process of uploading or downloading a file, regardless of the idle timeout period.

The default idle timeout period for a client is 900 seconds (15 minutes), however the server can be configured to use a different value and individual clients can request the timeout period be changed by sending the IDLE command to the server. For a client to be able to change its own timeout period, it must be granted the FTP_ACCESS_IDLE permission. The minimum timeout period for a client is 60 seconds, the maximum is 7200 seconds (2 hours). An application can change the timeout period for a specific client session using the **FtpSetClientIdleTime** function.

It is important to note that the idle timeout period only affects authenticated clients.

Unauthenticated clients use a different internal timer that limits the amount of time they can remain connected to the server before successfully authenticating with a valid username and password. By default, the authentication timeout period is 60 seconds and is set when the server is started; it cannot be changed for an individual client session.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftsv10.lib

See Also

[FtpSetClientIdleTime](#)

FtpGetClientLocalPath Function

```
INT WINAPI FtpGetClientLocalPath(  
    HSERVER hServer,  
    UINT nClientId,  
    LPCTSTR lpszVirtualPath,  
    LPTSTR lpszLocalPath,  
    INT nMaxLength,  
);
```

Return the full local path for a virtual filename or directory on the server.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszVirtualPath

A pointer to a string that specifies an virtual path on the server. This parameter cannot be NULL.

lpszLocalPath

A pointer to a string buffer that will contain the full local path, terminated with a null-character. This buffer should be at least MAX_PATH characters to accommodate the complete path. This parameter cannot be NULL.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer, including the terminating null character. This value must be greater than zero.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If the server handle and client ID do not specify a valid client session, the function will return zero. If the string buffer is not large enough to contain the complete path, this function will return zero and the last error code will be set to ST_ERROR_BUFFER_TOO_SMALL.

Remarks

The **FtpGetClientLocalPath** function takes a virtual path and returns the full path to the specified file or directory on the local system. The virtual path may be absolute or relative to the current working directory for the client session. This function will recognize a tilde at the beginning of the path to specify the client home directory.

To obtain the virtual path for a local file or directory, use the **FtpGetClientVirtualPath** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

FtpGetClientServer Function

```
HSERVER WINAPI FtpGetClientServer(  
    UINT nClientId  
);
```

The **FtpGetClientServer** function returns a handle to the server that created the specified client session.

Parameters

nClientId

An unsigned integer which uniquely identifies the client session.

Return Value

If the function succeeds, the return value is the handle to the server that created the client session.

If the function fails, the return value is `INVALID_SERVER`. To get extended error information, call the **FtpGetServerError** function.

Remarks

The **FtpGetClientServer** function returns the handle to the server that created the client session and is typically used within a notification message handler. If the server is in the process of shutting down, or the client session thread is terminating, this function will fail and return `INVALID_SERVER` indicating that the session ID is invalid.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `csftools10.h`.

Import Library: `csftsv10.lib`

[FtpServerAsyncNotify](#)

FtpGetClientThreadId Function

```
DWORD WINAPI FtpGetClientThreadId(  
    HSERVER hServer,  
    UINT nClientId  
);
```

Returns the thread ID associated with the specified client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

Return Value

If the function succeeds, the return value is a thread ID. If the function fails, the return value is zero. To get extended error information, call the **FtpGetServerError** function.

Remarks

The **FtpGetClientThreadId** function returns a thread ID that can be used to identify the thread that is managing the client session. The thread ID can be used with other Windows API functions such as **OpenThread**. Exercise caution when using thread-related functions, interfering with the normal operation of the thread can have unexpected results. You should never use this function to obtain a thread handle and then call the **TerminateThread** function to terminate a client session. This will prevent the thread from releasing the resources that were allocated for the session and can leave the server in an unstable state. To terminate a client session, use the **FtpDisconnectClient** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftsv10.lib

[FtpEnumServerClients](#), [FtpGetActiveClient](#)

FtpGetClientUserName Function

```
INT WINAPI FtpGetClientUserName(  
    HSERVER hServer,  
    UINT nClientId,  
    LPTSTR LpszUserName,  
    INT nMaxLength  
);
```

Return the user name associated with the specified client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszUserName

A pointer to a string buffer that will contain the user name associated with the client session. This buffer must be large enough to store the complete user name, including the terminating null character. This parameter cannot be NULL.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer, including the terminating null character. This parameter must have a value larger than zero.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If the server handle and client ID do not specify a valid client session, the function will return zero.

Remarks

The **FtpGetClientUserName** function returns the user name associated with an authenticated client session. If the client has not authenticated itself by sending the USER and PASS commands, this function will return zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[FtpAuthenticateClient](#), [FtpGetClientAccess](#), [FtpGetClientHomeDirectory](#)

FtpGetClientVirtualPath Function

```
INT WINAPI FtpGetClientVirtualPath(  
    HSERVER hServer,  
    UINT nClientId,  
    LPCTSTR lpszLocalPath,  
    LPTSTR lpszVirtualPath,  
    INT nMaxLength,  
);
```

Return the virtual path for a local file on the server.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszLocalPath

A pointer to a string that specifies an absolute path on the local system. This parameter cannot be NULL.

lpszVirtualPath

A pointer to a string buffer that will contain the virtual path, terminated with a null-character. This buffer should be at least MAX_PATH characters to accommodate the complete path. This parameter cannot be NULL.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer, including the terminating null character. This value must be greater than zero.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If the server handle and client ID do not specify a valid client session, the function will return zero. If the string buffer is not large enough to contain the complete path, this function will return zero and the last error code will be set to ST_ERROR_BUFFER_TOO_SMALL.

Remarks

A virtual path for the client is either relative to the server root directory, or the client home directory if the client was authenticated as a restricted user. These virtual paths are what the client will see as an absolute path on the server. For example, if the server was configured to use "C:\ProgramData\MyServer" as the root directory, and the *lpszLocalPath* parameter was specified as "C:\ProgramData\MyServer\Documents\Research", this function would return the virtual path to that directory as "/Documents/Research".

If the client session was authenticated as a restricted user, then the virtual path is always relative to the client home directory instead of the server root directory. This is because restricted users are isolated to their own home directory and any subdirectories. For example, if restricted user "John" has a home directory of "C:\ProgramData\MyServer\Users\John" and the *lpszLocalPath* parameter was specified as "C:\ProgramData\MyServer\Users\John\Accounting\Projections.pdf" this function would return the virtual path as "/Accounting/Projections.pdf".

If the *lpszLocalPath* parameter specifies a file or directory outside of the server root directory, this function will return zero and the last error code will be set to ST_ERROR_INVALID_FILE_NAME. This function can only be used with authenticated clients. If the *nClientId* parameter specifies a client session that has not been authenticated, this function will return zero and the last error code will be ST_ERROR_AUTHENTICATION_REQUIRED.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csftsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[FtpGetCommandFile](#), [FtpGetClientLocalPath](#)

FtpGetCommandFile Function

```
INT WINAPI FtpGetCommandFile(  
    HSERVER hServer,  
    UINT nClientId,  
    LPTSTR lpszFileName,  
    INT nMaxLength  
);
```

Get the full path to the local file name or directory specified by the client

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszFileName

A pointer to a string buffer that will contain the full path to a file name or directory specified by the client when it issued a command. The string buffer will be null terminated and must be large enough to store the complete file path. This parameter cannot be NULL.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer. It is recommended that the buffer be at least MAX_PATH characters in size. If the maximum length specified is smaller than the actual length of the full path, this function will fail.

Return Value

An integer value which specifies the number of characters copied into the buffer, not including the terminating null character. If the function fails, the return value will be zero and the

FtpGetServerError function can be used to retrieve the last error code. If the last error code is returned as a value of zero, this means that the command issued by the client accepts a file name as an argument, but the client did not specify one.

Remarks

The **FtpGetCommandFile** function is used to obtain the full path to a local file name or directory specified by the client as an argument to a standard FTP command. For example, if the client sends the RETR command to the server, this function will return the complete path to the local file that the client wants to download. This function will only work with those standard commands that perform some action on a file or directory.

This function should always be used to obtain the file name for a command that performs a file or directory operation. The **FtpGetCommandParam** function will return the actual command parameter, but the file name will typically be relative to the user home directory or server root directory, and cannot be passed directly to a Windows API function. The **FtpGetCommandFile** function normalizes the path provided by the client and ensures that it specifies a file or directory name in the correct location.

To change the file or directory name that is the target of the current command, use the **FtpSetCommandFile** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csftsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[FtpGetClientDirectory](#), [FtpGetClientHomeDirectory](#), [FtpGetCommandLine](#), [FtpGetCommandParam](#),
[FtpSetCommandFile](#)

FtpGetCommandLine Function

```
INT WINAPI FtpGetCommandLine(  
    HSERVER hServer,  
    UINT nClientId,  
    LPTSTR LpszCmdLine,  
    INT nMaxLength  
);
```

Return the complete command line issued by the client.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszCmdLine

A pointer to a string buffer that will contain the command, including all arguments. The string buffer will be null terminated and must be large enough to store the complete command line. If this parameter is NULL, the function will return the length of the command line.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer. The internal limit on the maximum length of a command is 1024 characters. If the maximum length specified is smaller than the actual length of the complete command, this function will fail.

Return Value

An integer value which specifies the number of characters copied into the buffer, not including the terminating null character. If the function fails, the return value will be zero and the

FtpGetServerError function can be used to retrieve the last error code. If the last error code has a value of zero then no command has been issued by the client.

Remarks

The **FtpGetCommandLine** function is used to obtain the command that was issued by the client, and is commonly used inside FTP_CLIENT_COMMAND and FTP_CLIENT_RESULT event handlers to pre-process and post-process client commands, respectively. When the function returns, the string buffer provided by the caller will contain the complete command, including all command parameters. Any extraneous whitespace will be removed, however quoted parameters will be retained as-is.

To obtain a specific parameter to a command, use the **FtpGetCommandParam** function. The **FtpGetCommandParamCount** function will return the number of command parameters that were provided by the client. If the command sent by the client is used to perform an action on a file or directory, the **FtpGetCommandFile** function should be called to obtain the full path to the specified file rather than using the value of the command parameter.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

FtpGetCommandName Function

```
INT WINAPI FtpGetCommandName
    HSERVER hServer,
    UINT nClientId,
    LPTSTR lpszCommand,
    INT nMaxLength
);
```

Return the name of the last command issued by the client.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszCommand

A pointer to a string buffer that will contain the command name. The string buffer will be null terminated and must be large enough to store the complete command name. If this parameter is NULL, the function will only return the length of the current command in characters, not including the terminating null character.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer, including the terminating null character. If the maximum length specified is smaller than the actual length of the parameter, this function will fail. If the *lpszCommand* parameter is NULL, this value should be zero.

Return Value

An integer value which specifies the number of characters copied into the buffer, not including the terminating null character. If the function fails, the return value will be zero and the **FtpGetServerError** function can be used to retrieve the last error code. If the last error code is returned as a value of zero, this means that no command has been issued by the client.

Remarks

The **FtpGetCommandName** function is used to obtain the name of the last command that was issued by the client. The command name returned by this function will always be capitalized, regardless of how it was sent by the client. This function is typically used inside `FTP_CLIENT_COMMAND` and `FTP_CLIENT_RESULT` event handlers to pre-process and post-process client commands, respectively.

The **FtpGetCommandParam** function can be used to return the value of individual command parameters specified by the client. The **FtpGetComandLine** function can be used to obtain the complete command line issued by the client.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csftsv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

FtpGetCommandParam Function

```
INT WINAPI FtpGetCommandParam
    HSERVER hServer,
    UINT nClientId,
    INT nParam,
    LPTSTR lpszParam,
    INT nMaxLength
);
```

Return the value of the specified command parameter from the last command issued by the client.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

nParam

An integer value which specifies the command parameter. A value of zero specifies the command itself, while values greater than zero specify a particular parameter. This function will fail if this value is less than zero or greater than the number of parameters available.

lpszParam

A pointer to a string buffer that will contain the command parameter. The string buffer will be null terminated and must be large enough to store the complete parameter value. If this parameter is NULL, the function will only return the length of the specified parameter in characters, not including the terminating null character.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer, including the terminating null character. The internal limit on the maximum length of a command is 1024 characters. If the maximum length specified is smaller than the actual length of the parameter, this function will fail. If the *lpszParam* parameter is NULL, this value should be zero.

Return Value

An integer value which specifies the number of characters copied into the buffer, not including the terminating null character. If the function fails, the return value will be zero and the **FtpGetServerError** function can be used to retrieve the last error code. If the last error code is returned as a value of zero, this means that no command has been issued by the client.

Remarks

The **FtpGetCommandParam** function is used to obtain a specific parameter for the last command that was issued by the client. If the parameter was surrounded in quotes, those quotes will be included in the value returned by this function. This function is typically used inside FTP_CLIENT_COMMAND and FTP_CLIENT_RESULT event handlers to pre-process and post-process client commands, respectively.

The **FtpGetCommandParamCount** function will return the number of command parameters that were provided by the client. If the command sent by the client is used to perform an action on a file or directory, the **FtpGetCommandFile** function should be called to obtain the full path to the

specified file rather than using the value of the command parameter. To obtain the complete command line, use the **FtpGetCommandLine** function.

[FtpGetCommandParamCount](#)

FtpGetCommandParamCount Function

```
INT WINAPI FtpGetCommandParamCount
    HSERVER hServer,
    UINT nClientId
);
```

Return the number of command parameters for the last command issued by the client.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

Return Value

An integer value which specifies the number of parameters that were specified in the last command issued by the client. If the command did not include any parameters, this function will return zero. If the client has not issued a command, or the client session ID is invalid, this function will return -1.

Remarks

The **FtpGetCommandParamCount** function is used to determine the number of parameters specified in the last client command, and the maximum value that may be passed as the parameter index to the **FtpGetCommandParam** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftsv10.lib

See Also

[FtpGetCommandLine](#), [FtpGetCommandName](#), [FtpGetCommandParam](#)

FtpGetCommandResult Function

```
INT WINAPI FtpGetCommandResult(  
    HSERVER hServer,  
    UINT nClientId,  
    LPTSTR lpszResult,  
    INT nMaxLength  
);
```

Return the result code and description for the last command issued by the client.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszResult

A pointer to a string buffer that will contain the description of the result code. The string buffer will be null terminated up to the maximum number of characters specified by the caller. This parameter can be NULL if this information is not required.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer. If the *lpszResult* parameter is NULL, this value should be zero.

Return Value

An integer value which specifies the result code for the last command issued by the client. A return value of zero indicates that the command has not completed and there is no result code available.

Remarks

The **FtpGetCommandResult** function is used to determine the result of the last command that was issued by the client and is typically called in the `FTP_CLIENT_RESULT` event handler. This function should only be called after a command has been processed or the **FtpSendResponse** function has been called.

The result code is a three-digit integer value that indicates the success or failure of a command. Whenever a client sends a command to the server, the server must respond with this numeric code, and optionally a text message that further describes the result. The text message may be a single line, or it may span multiple lines, with each line of text terminated by a carriage return and linefeed. Result codes are generally broken down into the following categories:

Result Code	Description
100-199	Result codes in this range indicate that the requested action is being initiated, and the client should expect another reply from the server before proceeding. This is normally used with file transfers, indicating to the client that the data transfer has started.
200-299	Result codes in this range indicate that the server has successfully completed the requested action. One exception is the 202 result code which indicates that the command is not implemented, but the client should not consider this to be an error condition.

300-399	Result codes in this range indicate that the requested action cannot complete until additional information is provided to the server. This is normally used with commands that require a specific sequence to complete. For example, the server will send the 331 result code in response to the USER command, which tells the client that it must send the PASS command to complete the authentication process.
400-499	Result codes in this range indicate that the requested action did not take place, but the error condition is temporary and may be attempted again. This error response is usually the result of a failed authentication attempt or a file transfer that could not complete.
500-599	Result codes in this range indicate that the requested action did not take place and the failure is permanent. The client should not attempt to send the command again. This error response is usually the result of an invalid command name, a syntax error or the client not having the appropriate access rights to a resource.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csftsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[FtpSendResponse](#)

FtpGetCommandUsage Function

```
UINT WINAPI FtpGetCommandUsage(  
    HSERVER hServer,  
    LPCTSTR LpszCommand  
);
```

Return the number of times a specific command has been issued by all clients.

Parameters

hServer

The server handle.

lpszCommand

A pointer to a string that specifies a command name. The name is not case-sensitive, but must match a valid server command exactly. This parameter cannot be NULL.

Return Value

If the function succeeds, the return value is the number of times the command has been issued by all clients since the server was started. If the server handle or command name is invalid, or the command has never been issued, the return value will be zero.

Remarks

The command name provided to this function must match the commands defined in RFC 959 or related protocol standards. It is important to distinguish between commands recognized by an FTP server and the commands that client programs may use. For example, the standard Windows FTP command line program provides commands such as GET and PUT to download and upload files. However, those are not the actual commands sent to a server. Instead, the corresponding server commands issued by a client application would be RETR (retrieve) and STOR (store). Refer to [File Transfer Protocol Commands](#) for a complete list of server commands.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftsv10.lib

FtpGetProgramExitCode Function

```
BOOL WINAPI FtpGetProgramExitCode(  
    HSERVER hServer,  
    UINT nClientId,  
    LPDWORD lpdwExitCode  
);
```

Return the exit code of the last program executed by the client.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpdwExitCode

A pointer to an unsigned integer that will contain the program exit code when the function returns. This parameter cannot be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the server handle and client ID do not specify a valid client session, the function will return zero.

Remarks

The **FtpGetProgramExitCode** function returns the exit code of a registered program that was executed by the client using the SITE EXEC command. By convention, most programs return an exit code in the range of 0-255, with an exit code of zero indicating success. The exit code is commonly used by custom programs to communicate status information back to the server application.

Permission to use the SITE EXEC is not granted to authenticated users by default, and is limited to only those programs which are explicitly registered with the server. Exercise caution when allowing a client to execute a program on the server because this can expose the server to significant security risks. The programs that are registered for use with the SITE EXEC command should be thoroughly tested before being deployed on the server and should only be console programs that write to standard output.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csftsv10.lib

See Also

[FtpGetProgramName](#), [FtpGetProgramOutput](#), [FtpRegisterProgram](#)

FtpGetProgramName Function

```
INT WINAPI FtpGetProgramName(  
    HSERVER hServer,  
    UINT nClientId,  
    LPTSTR lpszProgramName,  
    INT nMaxLength  
);
```

Return the name of the last program executed by the client.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszProgramName

A pointer to a string buffer that will contain the name of the last program executed by the client. This parameter cannot be NULL and should be at least 32 characters in size.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer, including the terminating null character. This parameter must have a value greater than zero.

Return Value

If the function succeeds, the return value is the length of the command name. If the server handle and client ID do not specify a valid client session, the function will return zero. If the client has not executed any programs, this function will return zero.

Remarks

The **FtpGetProgramName** function returns the name of the last program that was executed by the client using the SITE EXEC command. The name that is returned is the alias assigned to the program, not the full path to the executable file. The server application would typically use this function in an event handler when processing the FTP_CLIENT_EXECUTE event to determine which program has been executed on behalf of the client. The **FtpGetProgramExitCode** function will return the program's exit code and the **FtpGetProgramOutput** function can be used to obtain a copy of the output generated by the program.

Permission to use the SITE EXEC is not granted to authenticated users by default, and is limited to only those programs which are explicitly registered with the server. Exercise caution when allowing a client to execute a program on the server because this can expose the server to significant security risks. The programs that are registered for use with the SITE EXEC command should be thoroughly tested before being deployed on the server and should only be console programs that write to standard output.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[FtpGetProgramExitCode](#), [FtpGetProgramOutput](#), [FtpRegisterProgram](#)

FtpGetProgramOutput Function

```
DWORD WINAPI FtpGetProgramOutput(  
    HSERVER hServer,  
    UINT nClientId,  
    LPBYTE lpBuffer,  
    DWORD dwBufferSize  
);
```

Return a copy of the standard output from the last program executed by the client.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpBuffer

A pointer to a buffer that will contain the output from the last program executed by the client. If this parameter is NULL, the function will return the number of bytes of data that was output by the program. Note that this output is not null terminated.

dwBufferSize

The maximum number of bytes that can be copied into the buffer. If the *lpBuffer* parameter is NULL, this value should be zero.

Return Value

If the function succeeds, the return value is the number of bytes copied into the specified buffer. If the server handle and client ID do not specify a valid client session, the function will return zero. If the client has not executed any programs, the return value will be zero.

Remarks

The **FtpGetProgramOutput** function is used to obtain a copy of the output generated by the program executed using the SITE EXEC command. To determine the number of bytes of output available to read, call this function with the *lpBuffer* parameter as NULL and the *dwBufferSize* parameter with a value of zero. The return value will be the number of bytes of data that was output by the program. It should be noted that for Unicode builds, the buffer is a byte array, not an array of characters, and will not be null terminated.

This function returns the raw output from the command which may contain escape sequences, control characters and embedded nulls. When the application processes the output returned by this function, it should never coerce the buffer pointer to an LPTSTR value because there is no guarantee that the data will be null-terminated. To obtain the output from the command as a string, use the **FtpGetProgramText** function.

Example

```
LPBYTE lpBuffer = NULL; // A pointer to the output buffer  
DWORD cbBuffer = 0;     // Number of bytes in the output buffer  
  
// Determine the number of bytes in the output buffer  
cbBuffer = FtpGetProgramOutput(hServer, nClientId, NULL, 0);  
  
if (cbBuffer > 0)
```

```
{
    // Allocate memory for the buffer
    lpBuffer = (LPBYTE)LocalAlloc(LPTR, cbBuffer + 1);

    // Copy the program output to the buffer
    if (lpBuffer != NULL)
        cbBuffer = FtpGetProgramOutput(hServer, nClientId, lpBuffer, cbBuffer +
1);
}

// Free the memory allocated for the buffer when finished
if (lpBuffer != NULL)
{
    LocalFree((HLOCAL)lpBuffer);
    lpBuffer = NULL;
    cbBuffer = 0;
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csftsv10.lib

See Also

[FtpGetProgramExitCode](#), [FtpGetProgramName](#), [FtpGetProgramText](#), [FtpRegisterProgram](#)

FtpGetProgramText Function

```
INT WINAPI FtpGetProgramText(  
    HSERVER hServer,  
    UINT nClientId,  
    LPTSTR LpszBuffer,  
    INT nMaxLength  
);
```

Return a copy of the standard output from the last program in a string buffer.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszBuffer

A pointer to a buffer that will contain the output from the last program executed by the client as a string. If this parameter is NULL, the function will return the number of bytes of characters that was output by the program, not including a terminating null character.

nMaxLength

The maximum number of bytes that can be copied into the buffer. If the *lpszBuffer* parameter is NULL, this value should be zero.

Return Value

If the function succeeds, the return value is the number of characters copied into the specified string buffer, not including the terminating null character. If the server handle and client ID do not specify a valid client session, the function will return zero. If the client has not executed any programs, the return value will be zero.

Remarks

The **FtpGetProgramText** function is used to obtain a copy of the output generated by the program executed using the SITE EXEC command. To determine the number of characters of output available to read, call this function with the *lpszBuffer* parameter as NULL and the *nMaxLength* parameter with a value of zero. The return value will be the number of characters that were output by the program. If the application dynamically allocates the string buffer, make sure that it allocates an extra character for the terminating null character.

This function will only return textual output from the command and any non-printable control characters and the escape character will be replaced with a space. To obtain the unfiltered output from the last command that was executed, use the **FtpGetProgramOutput** function.

Example

```
LPTSTR lpszBuffer = NULL; // A pointer to the output buffer  
INT cchBuffer = 0; // Number of bytes in the output buffer  
  
// Determine the number of bytes in the output buffer  
cchBuffer = FtpGetProgramText(hServer, nClientId, NULL, 0);  
  
if (cchBuffer > 0)  
{
```

```
// Allocate memory for the string buffer
lpszBuffer = (LPTSTR)LocalAlloc(LPTR, (cchBuffer + 1) * sizeof(TCHAR));

// Copy the program output to the buffer
if (lpszBuffer != NULL)
    cchBuffer = FtpGetProgramText(hServer, nClientId, lpszBuffer, cchBuffer
+ 1);
}

// Free the memory allocated for the buffer when finished
if (lpszBuffer != NULL)
{
    LocalFree((HLOCAL)lpszBuffer);
    lpszBuffer = NULL;
    cchBuffer = 0;
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csftsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[FtpGetProgramExitCode](#), [FtpGetProgramName](#), [FtpGetProgramOutput](#), [FtpRegisterProgram](#)

FtpGetRenamedFile Function

```
INT WINAPI FtpGetRenamedFile(  
    HSERVER hServer,  
    UINT nClientId,  
    LPTSTR lpszFileName,  
    INT nMaxLength  
);
```

Return the original name of a file being renamed by the client.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszFileName

A pointer to a string buffer that will contain the full path of the last file or directory that was renamed. It is recommended that this buffer be at least MAX_PATH characters in size. The value of this parameter cannot be NULL.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer, including the terminating null characters. This parameter must have a value larger than zero.

Return Value

If the function succeeds, the return value is the length of the file or directory path, not including the terminating null character. If the server handle and client ID do not specify a valid client session, the function will return zero. If the client has not renamed a file or directory, this function will return zero.

Remarks

When a client wishes to rename a file or directory, it must send two commands in sequence to the server. The first command is RNFR (rename from) which specifies the original name of the file or directory to be renamed. The second command is RNTD (rename to) and must be sent immediately after the RNFR command and specifies the new name for the file or directory. The **FtpGetRenamedFile** function will return the full path of the local file or directory that was specified by the RNFR command. Typically this function is used by an event handler that processes the FTP_CLIENT_COMMAND event to determine the original path name.

This function is only guaranteed to return a meaningful value when called within the context of the FTP_CLIENT_COMMAND event. Calling this function outside of the event handler will return the path of the last renamed file, but there is no way to determine at what point the client issued the command to rename a file or directory. To obtain the new file or directory name, the **FtpGetCommandFile** function should be called from within the event handler.

The RNFR and RNTD commands can also be used to move a file or directory to a new location. For example, they could be used to move a file from one directory to another. An application should never make the assumption that the paths of the original and new file will be the same.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csftsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[FtpGetCommandFile](#)

FtpGetServerAddress Function

```
INT WINAPI FtpGetServerAddress(  
    HSERVER hServer,  
    UINT nClientId,  
    LPTSTR lpszAddress,  
    INT nMaxLength  
);
```

Return the IP address of the server.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session. This value may be zero.

lpszAddress

A pointer to a string buffer that will contain the server IP address, terminated with a null character. To accommodate both IPv4 and IPv6 addresses, this buffer should be at least 46 characters in length. This parameter cannot be NULL.

nMaxLength

An integer value that specifies the maximum number of characters can be copied into the string buffer, including the terminating null character. This value must be greater than zero. If the buffer size is too small, the function will fail.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If either the server handle or the client ID is invalid, or the buffer is not large enough to store the complete address, the function will return a value of zero.

Remarks

This function will return the IP address assigned to the specified server as a printable string. If the *nClientId* parameter has a value of zero, this function will return the IP address assigned to the local system. If the FTP_SERVER_NATROUTER option was specified when the server was started, this function will return the external IP address assigned to the system. If the *nClientId* parameter specifies a valid client session, this function will return the IP address that the client used to establish the connection with the server. To determine the IP address assigned to the client, use the **FtpGetClientAddress** function.

The format and length of IPv4 and IPv6 address strings are very different. An IPv4 address string looks like "192.168.0.20", while an IPv6 address string can look something like "fd7c:2f6a:4f4f:ba34::a32". If your application checks for the format of these address strings, it needs to be aware of the differences. You also need to make sure that you're providing enough space to display or store an address to avoid buffer overruns.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[FtpGetClientAddress](#), [FtpGetServerName](#), [FtpSetServerAddress](#)

FtpGetServerDirectory Function

```
INT WINAPI FtpGetServerDirectory(  
    HSERVER hServer,  
    LPTSTR lpszDirectory,  
    INT nMaxLength  
);
```

Return the full path to the root directory assigned to the specified server.

Parameters

hServer

The server handle.

lpszDirectory

A pointer to a string buffer that will contain the server root directory, terminated with a null character. It is recommended that this buffer be at least MAX_PATH characters in length. This parameter cannot be NULL.

nMaxLength

An integer value that specifies the maximum number of characters can be copied into the string buffer, including the terminating null character. This value must be greater than zero. If the buffer size is too small, the function will fail.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If the server handle is invalid, or the buffer is not large enough to store the complete path, the function will return a value of zero.

Remarks

The **FtpGetServerDirectory** function will return the full path to the root directory assigned to the server instance. The root directory may be specified as part of the server configuration, or if no directory is specified by the application, a temporary root directory will be created and this function can be used to obtain the full path to the directory. When the application specifies a root directory, it may use environment variables such as %AppData% in the path. This function will return the fully resolved path name, with all environment variables expanded.

There is no corresponding function to change the server root directory after the server has started. To change the root directory, you must stop the server using the **FtpServerStop** function and then start another instance of the server with a configuration that specifies the new directory.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[FtpGetServerAddress](#), [FtpGetServerIdentity](#), [FtpGetServerName](#)

FtpGetServerError Function

```
DWORD WINAPI FtpGetServerError(  
    HSERVER hServer,  
    LPTSTR lpszError,  
    INT nMaxLength  
);
```

Return the last server error code and a description of the error.

Parameters

hServer

The server handle.

lpszError

A pointer to a string buffer that will contain a description of the error. If the error description is not needed, this parameter may be NULL.

nMaxLength

An integer that specifies the maximum number of characters that can be copied into the error string buffer, including the terminating null character. If the *lpszError* parameter is NULL, this value should be zero.

Return Value

An unsigned integer value that specifies the last error that occurred. A value of zero indicates that there was no error.

Remarks

Error codes are unsigned 32-bit values which are private to each server. You should call the **FtpGetServerError** function immediately when a function's return value indicates that an error has occurred. That is because some functions clear the last error code when they succeed.

If the *hServer* parameter is specified with a value of INVALID_SERVER, this function will return the last error that occurred for the current thread. This value should only be used when the function does not have access to a valid server handle, such as when the **FtpServerStart** function fails.

It is important to note that the error codes returned by this function are different than the command result codes that are defined in RFC 959, the standard protocol specification for FTP. This function is used to determine reason that an API function has failed, and should not be used to determine if a command issued by the client was successful. The **FtpSendResponse** function is used to send result codes to the client, and the **FtpGetCommandResult** function can be used to determine the result of the last command sent by the client.

Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_SERVER or FTP_ERROR. Those functions which clear the last error code when they succeed are noted on the function reference page.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

FtpGetServerIdentity Function

```
INT WINAPI FtpGetServerIdentity(  
    HSERVER hServer,  
    LPTSTR lpszIdentity,  
    INT nMaxLength  
);
```

Return the identity of the specified server.

Parameters

hServer

The server handle.

lpszIdentity

A pointer to a string buffer that will contain the identity of the server when the function returns, terminated with a null character. This parameter cannot be NULL. It is recommended that this buffer be at least 32 characters in length.

nMaxLength

An integer value that specifies the maximum number of characters can be copied into the string buffer, including the terminating null character. This value must be greater than zero. If the buffer size is too small, the function will fail.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If the server handle is invalid, or the buffer is not large enough to store the complete path, the function will return a value of zero.

Remarks

The **FtpGetServerIdentity** function returns the identity string that was specified as part of the server configuration. It is used for informational purposes only and does not affect the operation of the server. Typically the string specifies the name of the application and a version number, and is displayed whenever a client establishes its initial connection to the server. The **FtpSetServerIdentity** function can be used to change the identity string associated with the server.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[FtpGetClientIdentity](#), [FtpSetClientIdentity](#), [FtpSetServerIdentity](#)

FtpGetServerLogFile Function

```
BOOL WINAPI FtpGetServerLogFile(  
    HSERVER hServer,  
    UINT * lpnLogFormat,  
    UINT * lpnLogLevel,  
    LPTSTR lpszFileName,  
    INT nMaxLength  
);
```

Return the current log file format and the full path to the file.

Parameters

hServer

The server handle.

lpnLogFormat

A pointer to an integer value that will contain the log file format being used when the function returns. If this information is not needed, this parameter may be NULL. The following formats are supported:

Constant	Description
FTP_LOGFILE_NONE (0)	This value specifies that the server should not create or update a log file.
FTP_LOGFILE_COMMON (1)	This value specifies that the log file should use the common log format that records a subset of information in a fixed format. This log format usually only provides information about file transfers.
FTP_LOGFILE_EXTENDED (2)	This value specifies that the log file should use the standard W3C extended log file format. This is an extensible format that can provide additional information about the client session.

lpnLogLevel

A pointer to an integer value that will contain the level of detail the server uses when generating the log file. The minimum value is 1 and the maximum value is 10. If this information is not needed, this parameter may be NULL.

lpszFileName

A pointer to a string buffer that will contain the full path to the log file. This parameter may be NULL if this information is not required.

nMaxLength

An integer that specifies the maximum number of characters that can be copied into the file name string, including the terminating null character. If the *lpszFileName* parameter is NULL, this value should be zero.

Return Value

An integer value which specifies the current log file format. Refer to the **FTPSEVERCONFIG** structure definition for a list of supported log file formats. If the server handle is invalid or logging has not been enabled, this function will return a value of zero.

Remarks

If the server is configured with logging enabled, but a log file name is not explicitly provided, then the server will automatically generate one. This function can be used to get the full path to the current log file along with the format that is being used to record client session data. Normally the log file is held open by the server thread while it is active, however you can call the **FtpRenameServerLogFile** function to explicitly rename or delete the log file.

To change the name of the log file, the log file format or level of detail, use the **FtpSetServerLogFile** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csftsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

FtpGetServerMemoryUsage Function

```
BOOL WINAPI FtpGetServerMemoryUsage(  
    HSERVER hServer,  
    ULARGE_INTEGER * LpMemUsage  
);
```

Return the amount of memory allocated for the server and all client sessions.

Parameters

hServer

The server handle.

lpMemUsage

A pointer to a ULARGE_INTEGER variable which will specify how much memory has been allocated by the server. This parameter will be initialized to a value of zero by the function and updated with the total number of bytes allocated by the server and all active client sessions when it returns.

Return Value

If the function succeeds, the return value is non-zero and the memory usage value will be updated. If the server handle is invalid, or the server cannot be locked, the return value is zero. Call the **FtpGetServerError** function to determine the cause of the failure.

Remarks

This function returns the amount of memory allocated by the server and all active client sessions. It enumerates all of memory allocations made by the server process and client session threads and returns the total number of bytes allocated for the server process. This value reflects the amount of memory explicitly allocated by this library and does not reflect the total working set size of the process, or memory allocated by any other libraries. To determine the working set size for the process, refer to the Win32 **GetProcessWorkingSetSize** and **GetProcessMemoryInfo** functions.

This function forces the server into a locked state, and all client sessions will block until the function returns. Because this function enumerates all heaps allocated for the server process, it can be an expensive operation, particularly when there are a large number of active clients connected to the server. Frequent use of this function can significantly degrade the performance of the server. It is primarily intended for use as a debugging tool to determine if memory usage is the result of an increase in active client sessions. If the value returned by the function remains reasonably constant, but the amount of memory allocated for the process continues to grow, it could indicate a memory leak in some other area of the application.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

FtpGetServerName Function

```
INT WINAPI FtpGetServerName(  
    HSERVER hServer,  
    UINT nClientId,  
    LPTSTR lpszHostName,  
    INT nMaxLength  
);
```

Return the host name assigned to the specified server.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session. This value may be zero.

lpszHostName

A pointer to a string buffer that will contain the server host name, terminated with a null character. It is recommended that this buffer be at least 64 characters in length. This parameter cannot be NULL.

nMaxLength

An integer value that specifies the maximum number of characters can be copied into the string buffer, including the terminating null character. This value must be greater than zero. If the buffer size is too small, the function will fail.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If either the server handle or the client ID is invalid, or the buffer is not large enough to store the complete hostname, the function will return a value of zero.

Remarks

This function will return the host name assigned to the specified server. If the *nClientId* parameter has a value of zero, the function will return the default host name that was specified as part of the server configuration. If no host name was explicitly assigned to the server, then it will return the local system name. If the *nClientId* parameter specifies a client session, then it this function will return the host name that the client used to establish the connection. If the client sends the HOST command to the server, this function will return the host name provided by the client.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[FtpGetServerAddress](#)

FtpGetServerPriority Function

```
INT WINAPI FtpGetServerPriority(  
    HSERVER hServer  
);
```

Return the current priority assigned to the specified server.

Parameters

hServer

The server handle.

Return Value

If the function succeeds, the return value is the priority for the specified server. If the function fails, the return value is FTP_PRIORITY_INVALID. To get extended error information, call **FtpGetServerError**.

Remarks

The **FtpGetServerPriority** function can be used to determine the current priority assigned to the server. It will return one of the following values:

Constant	Description
FTP_PRIORITY_BACKGROUND (0)	This priority significantly reduces the memory, processor and network resource utilization for the server. It is typically used with lightweight services running in the background that are designed for few client connections. The server thread will be assigned a lower scheduling priority and will be frequently forced to yield execution to other threads.
FTP_PRIORITY_LOW (1)	This priority lowers the overall resource utilization for the server and meters the processor utilization for the server thread. The server thread will be assigned a lower scheduling priority and will occasionally be forced to yield execution to other threads.
FTP_PRIORITY_NORMAL (2)	The default priority which balances resource and processor utilization. This is the priority that is initially assigned to the server when it is started, and it is recommended that most applications use this priority.
FTP_PRIORITY_HIGH (3)	This priority increases the overall resource utilization for the server and the thread will be given higher scheduling priority. It is not recommended that this priority be used on a system with a single processor.
FTP_PRIORITY_CRITICAL (4)	This priority can significantly increase processor, memory and network utilization. The server thread will be given higher scheduling priority and will be more responsive to client connection requests. It is not recommended that this priority be used on a system with a single processor.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cstools10.h.

Import Library: csftsv10.lib

[FtpServerStart](#), [FtpSetServerPriority](#)

FtpGetServerStackSize Function

```
DWORD WINAPI FtpGetServerStackSize(  
    SOCKET hServer  
);
```

Return the initial size of the stack allocated for threads created by the server.

Parameters

hServer

The server handle.

Return Value

If the function succeeds, the return value is the amount of memory that will be allocated for the stack in bytes. If the function fails, the return value is zero. To get extended error information, call **FtpGetServerError**.

Remarks

The **FtpGetServerStackSize** function returns the initial amount of memory that is committed to the stack for each thread created by the server. By default, the stack size for each thread is set to 256K for 32-bit processes and 512K for 64-bit processes.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `csftools10.h`.

Import Library: `csftsv10.lib`

FtpGetServerTransferInfo Function

```
BOOL WINAPI FtpGetServerTransferInfo(  
    HSERVER hServer,  
    UINT nClientId,  
    LPFTPSEVERTRANSFER lpTransferInfo  
);
```

Return information about the file transfer that was performed by the server for the specified client.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpTransferInfo

A pointer to an **FTPSEVERTRANSFER** structure that will contain information about the last file transfer. This parameter cannot be NULL, and the *dwSize* member of the structure must be initialized to specify the structure size prior to calling this function.

Return Value

If the function succeeds, the return value is non-zero. If the server handle and client ID do not specify a valid client session, the function will return zero. This function should only be called after the client has issued the APPE, RETR, STOR or STOU commands to initiate a file transfer, otherwise the return value will be zero.

Remarks

The **FtpGetServerTransferInfo** function is used to obtain information about the last file transfer that was performed by the server for the specified client. This function is typically called within an event handler to determine how many bytes of data were transferred, the type of file and the full path to the file on the local system.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

FtpGetServerUuid Function

```
INT WINAPI FtpGetServerUuid(  
    HSERVER hServer,  
    UUID * LpUuid  
);
```

Return the UUID assigned to the specified server.

Parameters

hServer

The server handle.

lpUuid

A pointer to a UUID structure that will contain the server UUID when the function returns. This parameter cannot be NULL.

Return Value

If the function succeeds, the return value is non-zero. If either the server handle is invalid or the pointer to the UUID structure is NULL, the function will return a value of zero.

Remarks

The **FtpGetServerUuid** function returns the Universally Unique Identifier (UUID) that has been assigned to the server. The UUID may either be generated by the application and assigned as part of the server configuration, or an ephemeral UUID may be automatically generated when the server is started. To obtain a printable string version of the UUID, use the **FtpGetServerUuidString** function.

There is no corresponding function to change the UUID assigned to an active server. The server UUID is assigned when the server is started, and it must be a unique value that is maintained throughout the lifetime of the server. To change the UUID associated with the server, the server must be stopped using the **FtpServerStop** function and another instance of the server started with the new UUID.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csftsv10.lib

See Also

[FtpGetServerUuidString](#), [FTPSEVERCONFIG](#)

FtpGetServerUuidString Function

```
INT WINAPI FtpGetServerUuidString(  
    HSERVER hServer,  
    LPTSTR lpszHostUuid,  
    INT nMaxLength  
);
```

Return the UUID assigned to the server as a printable string.

Parameters

hServer

The server handle.

lpszHostUuid

A pointer to a string buffer that will contain the server UUID, terminated with a null character. It is recommended that this buffer be at least 40 characters in length. This parameter cannot be NULL.

nMaxLength

An integer value that specifies the maximum number of characters can be copied into the string buffer, including the terminating null character. This value must be greater than zero. If the buffer size is too small, the function will fail.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If either the server handle or the buffer is not large enough to store the complete UUID string, the function will return a value of zero.

Remarks

The **FtpGetServerUuidString** function returns the Universally Unique Identifier (UUID) that has been assigned to the server. The UUID may either be generated by the application and assigned as part of the server configuration, or an ephemeral UUID may be automatically generated when the server is started. To obtain the numeric UUID value, use the **FtpGetServerUuid** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csftsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

FtpIsClientAnonymous Function

```
BOOL WINAPI FtpIsClientAnonymous(  
    HSERVER hServer,  
    UINT nClientId  
);
```

Determine if the specified client has authenticated as an anonymous user.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

Return Value

If the client session has been authenticated, this function will return a non-zero value, otherwise it will return zero. If the server handle and client ID are valid, and the client session has been authenticated, this function will clear the last error code.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csftsv10.lib

FtpIsClientAuthenticated Function

```
BOOL WINAPI FtpIsClientAuthenticated(  
    HSERVER hServer,  
    UINT nClientId  
);
```

Determine if the specified client session has been authenticated.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

Return Value

If the client session has been authenticated, this function will return a non-zero value, otherwise it will return zero. If the server handle and client ID are valid, this function will clear the last error code.

Requirements

FtpIsCommandEnabled Function

```
BOOL WINAPI FtpIsCommandEnabled(  
    HSERVER hServer,  
    LPCTSTR LpszCommand  
);
```

Determine if a specific server command has been enabled or disabled.

Parameters

hServer

The server handle.

lpszCommand

A pointer to a NULL terminated string that specifies the name of the command. The command name is not case-sensitive, but the value must otherwise match the exact command name.

Partial matches are not recognized by this function. This parameter cannot be NULL.

Return Value

If the command is enabled, this function will return a non-zero value. If the command is disabled, the server handle is invalid or the command name does not match a supported command, this function will return zero.

Remarks

The **FtpIsCommandEnabled** function is used to determine whether a specific command is enabled. Typically this function is used in an event handler to make sure the command issued by a client is recognized by the server and enabled for use. Commands can be enabled and disabled using the **FtpEnableCommand** function.

This function does not account for the permissions granted to a specific client session. Clients are assigned access rights when they are authenticated using the **FtpAuthenticateClient** function, and certain commands can be limited by the permissions granted to the client. For example, even though the STOR command is enabled, a client must have the FTP_ACCESS_WRITE permission to use the command to upload a file to the server. For a list of access rights, see [User Access Constants](#).

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

FtpRegisterProgram Function

```
BOOL WINAPI FtpRegisterProgram(  
    HSERVER hServer,  
    UINT nHostId,  
    LPCTSTR lpszCommandName,  
    LPCTSTR lpszProgramFile,  
    LPCTSTR lpszParameters,  
    LPCTSTR lpszDirectory  
);
```

Register a program for use with the SITE EXEC command.

Parameters

hServer

The server handle.

nHostId

An unsigned integer that identifies the virtual host associated with the program. This value should always be zero.

lpszCommandName

A pointer to a string which specifies the name of the site specific command. This is the name that is passed to the SITE EXEC command and does not need to match the actual name of the executable file on the local system. The maximum length of the command name is 32 characters. This parameter cannot be NULL.

lpszProgramFile

A pointer to a string that specifies the full path to the executable program. This parameter cannot be NULL.

lpszParameters

A pointer to a string that specifies additional parameters for the program. If the program does not require any command line parameters, this value may be NULL or point to an empty string.

lpszDirectory

A pointer to a string that specifies the current working directory for the program. If this parameter is NULL or points to an empty string, the server will use the current working directory of the client that issues the SITE EXEC command.

Return Value

If the function succeeds, the return value is non-zero. If the server handle and client ID do not specify a valid client session, the function will return zero.

Remarks

The **FtpRegisterProgram** function registers an executable program for use with the SITE EXEC command. Because this can present a significant security risk to the server, clients are not given permission to use this command by default. A client must be explicitly granted permission to use SITE EXEC by including FTP_ACCESS_EXECUTE as one of the permissions when authenticating the client session with the **FtpAuthenticateClient** function or creating a virtual user using the **FtpAddVirtualUser** function.

To give the server complete control over what programs can be executed using SITE EXEC, the program must be registered with the server and referenced by an alias specified by the

lpszCommandName parameter. The maximum length of a program name is 31 characters and it must be at least 3 characters in length. The name must only consist of alphanumeric characters and the first character of the program name cannot be numeric. The program name is not case-sensitive, however convention is to use upper-case characters. If a program name is specified that already has been registered, it will be updated with the new information provided by this function.

The *lpszProgramFile* string specifies file name of the program that will be executed. You should not install any executable programs in the server root directory or its subdirectories. A client should never have the ability to directly access the executable file itself. It is permitted to have multiple command names that reference the same executable file. The only requirement is that the command names be unique. The program name may contain environment variables surrounded by % symbols. For example, %ProgramFiles% would be expanded to the **C:\Program Files** folder.

It is important to note that the program specified by *lpszProgramFile* must be an executable file, not a script or batch file. If the program name does not contain a directory path, then the standard Windows pathing rules will be used when searching for an executable file that matches the given name. It is recommended that you always provide a full path to the executable file.

The *lpszParameters* string is used to define optional command line parameters that will be included with the command. This string can contain placeholders that are replaced by additional parameters specified by the client when it sends the SITE EXEC command. First replacement parameter is %1, the second is %2 and so on.

The executable program that is registered using this function must be a console application that writes to standard output. Programs that write directly to a console, or programs written to use a Windows user interface are not supported and will yield unpredictable results. In most cases, those programs that do not use standard input and output will be forcibly terminated by the server. If the program attempts to read from standard input, it will immediately encounter an end-of-file condition. Programs executed by the SITE EXEC command have no input; it is similar to a program that has its input redirected from the NUL: device. If the program must process a file on the server, the local file name should be passed as a command line parameter.

The output from the program will be redirected back to the client control channel. The output should be textual, with each line of text terminated by a carriage return and linefeed (CRLF). Programs that write binary data to standard output, particular data with embedded nulls, will yield unpredictable results and are not supported. To ensure that the program output conforms to the protocol standard, any non-printable characters will be replaced with a space and each line of output will be prefixed by a single space. The server application can obtain a copy of the output from the last command by calling the **FtpGetProgramOutput** function.

If the server is running on a system with User Account Control (UAC) enabled and does not have elevated privileges, do not register a program that requires elevated privileges or has a manifest that specifies the requestedExecutionLevel as requiring administrative privileges.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csftsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[FtpGetProgramExitCode](#), [FtpGetProgramName](#), [FtpGetProgramOutput](#)

FtpRenameServerLogFile Function

```
BOOL WINAPI FtpRenameServerLogFile(  
    HSERVER hServer,  
    LPCTSTR lpszFileName  
);
```

Rename or delete the current log file being updated by the server.

Parameters

hServer

The server handle.

lpszFileName

A pointer to a string that specifies the file name the current log file should be renamed to. If this parameter is NULL or an empty string, the current log file will be deleted.

Return Value

If the function succeeds, the return value is non-zero. If the server handle does not specify a valid server, the function will return zero. If logging is not currently enabled for the server, this function will return zero.

Remarks

The **FtpRenameServerLogFile** function is used to rename or delete the current log file. Note that this does not change the current log file name or disable logging by the server. It only changes the file name of the current log file, or removes the log file if the *lpszFileName* parameter is NULL. This can be useful if you want your server to perform log file rotation, archiving the current log file. By renaming the current log file, the server will automatically create a new log file with original file name.

This function must be used to rename or delete the current log file while logging is active because the server holds an open handle on the file. The application should not use the **FtpGetServerLogFile** function to obtain the log file name and then use the **MoveFileEx** or **DeleteFile** functions with that file.

To disable logging, use the **FtpSetServerLogFile** function and specify the logging format as FTP_LOGFILE_NONE.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[FtpGetServerLogFile](#), [FtpSetServerLogFile](#)

FtpSendResponse Function

```
BOOL WINAPI FtpSendResponse(  
    HSERVER hServer,  
    UINT nClientId,  
    UINT nResultCode,  
    LPCTSTR lpszMessage  
);
```

Send a result code and message to the client in response to a command.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

nResultCode

An unsigned integer value which specifies the result code.

lpszMessage

A pointer to a string which specifies a message to be sent to the client. If this parameter is NULL or points to an empty string, a default message associated with the result code will be used.

Return Value

If the result code and message text was sent to the client, the return value is non-zero. If the server handle and client ID do not specify a valid client session, or the result code is invalid, this function will return zero.

Remarks

The **FtpSendResponse** function is used to respond to a command issued by the client. Command responses are normally handled by the server as a normal part of processing a command and this function is only used if the application has implemented custom commands or wishes to modify the standard responses sent by the server. The message may be a maximum of 2048 characters and may include embedded carriage-return and linefeed characters. If no message is specified, then a default message will be sent based on the result code.

Result codes must be three digits (in the range of 100 through 999) and although this function will support the use of non-standard result codes, it is recommended that the client application use the standard codes defined in RFC 959 whenever possible. The use of non-standard result codes may cause problems with FTP clients that expect specific result codes in response to a particular command. For more information, refer to the **FtpGetCommandResult** function.

This function should only be called once in response to a command sent by the client. If a result code has already been sent in response to a command and this function is called, it will fail and return a value of zero. This is necessary because sending multiple result codes in response to a single command may cause unpredictable behavior by the client.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csftsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[FtpGetCommandResult](#)

FtpServerAsyncNotify Function

```
BOOL WINAPI FtpServerAsyncNotify(  
    HSERVER hServer,  
    HWND hWnd,  
    UINT uMsg  
);
```

Enable or disable asynchronous notification of changes in server status.

Parameters

hServer

The server handle.

hWnd

A handle to the window whose window procedure will receive the notification message.

uMsg

The user-defined message that will be sent to the notification window.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call the **FtpGetServerError** function.

Remarks

The **FtpServerAsyncNotify** function is used by an application to enable or disable asynchronous notifications. The message window is typically the main UI window and these notifications are used signal to the application that it should update the user interface. If the *hWnd* parameter is not NULL, it must specify a valid window handle and the user-defined message must have a value of **WM_USER** or higher. The application cannot specify a notification message that is reserved by the operating system. The pseudo-handle **HWND_BROADCAST** cannot be specified as the notification window. If the *hWnd* parameter is NULL, notifications for the specified server will be disabled.

When asynchronous notifications are enabled for a server, the server will post the user-defined message to the window whenever there is a change in status or after a client has connected or disconnected from the server. The *wParam* message parameter will contain the notification message and the *lParam* message parameter will contain the handle to the server or the client ID. The following notification messages are defined:

Constant	Description
FTP_NOTIFY_STARTUP	This notification is sent when the server has started and is preparing to accept client connections. This notification is only sent once, and only if asynchronous notifications are enabled immediately after the FtpServerStart function is called. This message will not be sent once the server has begun accepting client connections or when notification messages are disabled and then subsequently re-enabled at a later time. The <i>lParam</i> message parameter will specify the handle to the server.
FTP_NOTIFY_LISTEN	This notification is sent when the server is listening for client connections. This notification message may be sent

	to the application multiple times over the lifetime of the server. If the server was suspended, this notification will be sent after the application calls the FtpServerResume function to resume accepting client connections. The <i>lParam</i> message parameter will specify the handle to the server.
FTP_NOTIFY_SUSPEND	This notification is sent when the server suspends accepting new connections because the application has called the FtpServerSuspend function. This notification message may be sent to the application multiple times over the lifetime of the server. The <i>lParam</i> message parameter will specify the handle to the server.
FTP_NOTIFY_RESTART	This notification is sent when the server is restarted using the FtpServerRestart function. Note that the server socket handle provided by the <i>lParam</i> message parameter will specify the new socket handle of the restarted server instance, not the original socket handle. The <i>lParam</i> message parameter will specify the handle to the server.
FTP_NOTIFY_CONNECT	This notification is sent when the server accepts a client connection and the thread that manages the client session has begun processing network events for that client. This message notification will not be sent if the client connection is rejected by the server. The <i>lParam</i> message parameter will specify the unique ID of the client that connected to the server.
FTP_NOTIFY_DISCONNECT	This notification is sent when the client disconnects from the server and the client socket has been closed. This notification message may not occur for each client session that is forced to terminate as the result of the server being stopped using the FtpServerStop function. The <i>lParam</i> message parameter will specify the unique ID of the client that disconnected from the server.
FTP_NOTIFY_SHUTDOWN	This notification is sent when the server thread is in the process of terminating. At the time the application processes this notification message, the server handle in <i>lParam</i> will reference the defunct server and cannot be used with other server functions. The <i>lParam</i> message parameter will specify the handle to the server.

If asynchronous notifications are enabled, you should never use those notifications as a replacement for an event handler. When an event occurs, the callback function that handles the event is invoked in the context of the thread that manages the client session. The application should exchange data with the client within that event handler and not in response to a notification message. These notification messages should only be used to update the application UI in response to changes in the status of the server.

The FTP_NOTIFY_CONNECT and FTP_NOTIFY_DISCONNECT notifications are different from the other server notifications because the *lParam* message parameter does not specify the server

handle, but rather the unique client ID associated with the session that connected to or disconnected from the server. Use the **FtpGetClientServer** function to obtain a handle to the server that created the client session. Note that at the time the application processes the FTP_NOTIFY_DISCONNECT notification message, the client session will have already terminated.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cstools10.h.

FtpServerDisableTrace Function

```
BOOL WINAPI FtpServerDisableTrace();
```

Disable the logging of network function calls.

Parameters

None.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **FtpGetServerError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csftsv10.lib

See Also

[FtpServerEnableTrace](#)

FtpServerEnableTrace Function

```
BOOL WINAPI FtpServerEnableTrace(  
    LPCTSTR lpszTraceFile,  
    DWORD dwTraceFlags  
);
```

Enable the logging of network function calls to a file.

Parameters

lpszTraceFile

A pointer to a string that specifies the name of the log file. If this parameter is NULL or points to an empty string, a log file is created in the temporary directory for the current user.

dwTraceFlags

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
TRACE_DEFAULT (0)	All function calls are written to the trace file. This is the default value.
TRACE_ERROR (1)	Only those function calls which fail are recorded in the trace file.
TRACE_WARNING (2)	Only those function calls which fail, or return values which indicate a warning, are recorded in the trace file.
TRACE_HEXDUMP (4)	All functions calls are written to the trace file, plus all the data that is sent or received is displayed, in both ASCII and hexadecimal format.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call [FtpGetServerError](#).

Remarks

When trace logging is enabled, the log file is opened, appended to and closed for each socket function call. Using the same file name, you can do the same in your application to add additional information to the file if needed. This can provide an application-level context for the entries made by the library. Make sure that the file is closed after the data has been written. If a file name is not specified by the caller, a file named **cstrace.log** will be created in the temporary directory for the current user.

The TRACE_HEXDUMP option can produce very large files, since all data that is being sent and received by the application is logged. To reduce the size of the file, you can enable and disable logging around limited sections of code that you wish to analyze.

To redistribute an application that includes this debug logging functionality, the **cstrcv10.dll** library must be included as part of the installation package. This library provides the trace logging features, and if it is not available the **FtpServerEnableTrace** function will fail. Note that this is a standard Windows DLL and does not need to be registered, it only needs to be redistributed with your application.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csftsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[FtpServerDisableTrace](#)

FtpServerInitialize Function

```
BOOL WINAPI FtpServerInitialize(  
    LPCTSTR lpszLicenseKey,  
    LPINITDATA lpData  
);
```

The **FtpServerInitialize** function initializes the library and validates the specified license key at runtime.

Parameters

lpszLicenseKey

Pointer to a string that specifies the runtime license key to be validated. If this parameter is NULL, the library will validate the development license installed on the local system.

lpData

Pointer to an INITDATA data structure. This parameter may be NULL if the initialization data for the library is not required.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **FtpGetServerError**. All other functions will fail until a license key has been successfully validated.

Remarks

This must be the first function that an application calls before using any of the other functions in the library. When a NULL license key is specified, the library will only function on the development system. Before redistributing the application to an end-user, you must insure that this function is called with a valid license key.

If the *lpData* argument is specified, it must point to an INITDATA structure which has been initialized by setting the *dwSize* member to the size of the structure. All other structure members should be set to zero. If the function is successful, then the INITDATA structure will be filled with identifying information about the library.

Although it is only required that **FtpServerInitialize** be called once for the current process, it may be called multiple times; however, each call must be matched by a corresponding call to **FtpServerUninitialize**.

This function dynamically loads other system libraries and allocates thread local storage. If you are calling the functions in this library from within another DLL, it is important that you do not call the **FtpServerInitialize** or **FtpServerUninitialize** functions from the **DllMain** function because it can result in deadlocks or access violation errors. If the DLL is linked with the C runtime library (CRT), it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csftsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

Copyright © 2023 Catalyst Development Corporation. All rights reserved.

FtpServerProc Function

```
VOID CALLBACK FtpServerProc(  
    HSERVER hServer,  
    UINT nClientId,  
    UINT nEventId,  
    DWORD dwError,  
    DWORD_PTR dwParam  
);
```

The **FtpServerProc** function is an application-defined callback function that processes events generated by the server process.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client that has issued a request to the server.

nEventId

An unsigned integer which specifies which event occurred. For a list of events, see [Server Event Constants](#).

dwError

An unsigned integer which specifies any error that occurred. If no error occurred, then this parameter will be zero. The **FtpGetServerError** function can be used to obtain additional information about the error code.

dwParam

A user-defined integer value which was specified when the server was started. This value is guaranteed to be large enough to store a pointer or handle value on both 32-bit and 64-bit platforms.

Return Value

None.

Remarks

The FTP_CLIENT_COMMAND event can be used to filter commands issued by the client. If the command performs an operation on a file or directory, the **FtpGetCommandFile** function can be used to obtain the file name on the server that the client specified. It is possible for the application to change the file name using the **FtpSetCommandFile** function to direct the server to use a different file than the one specified by the client. If the file name is changed and the event handler returns a value of zero, the server will perform the default action for the command using the new file name.

The FTP_CLIENT_TIMEOUT event will only occur for authenticated client sessions. The server has a second, internal timer that is maintained for unauthenticated sessions that requires the client to successfully authenticate itself within a fixed period of time. If a client does not authenticate within the allowed time period, the server will automatically close the control channel. For more information, refer to the documentation for the *nAuthTime* member of the **FTP_SERVER_CONFIG** structure.

The callback function will be called in the context of the thread that is currently managing the

client session. You must ensure that any access to global or static variables are synchronized, otherwise the results may be unpredictable. It is recommended that you do not declare any static variables within the callback function itself.

If the application has a graphical user interface, you should never attempt to directly modify a UI control from within an event handler. Controls should only be modified by the same UI thread that created their window. To change the user interface in response to a server event, use the **FtpServerAsyncNotify** function to enable asynchronous notifications and update the UI in response to the notification message.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csftsv10.lib

See Also

[FtpServerAsyncNotify](#), [FtpServerStart](#)

FtpServerRestart Function

```
HSERVER WINAPI FtpServerRestart(  
    HSERVER hServer  
);
```

Restart the server, terminating all active client sessions.

Parameters

hServer

The server handle.

Return Value

If the function succeeds, the return value is the new handle for the specified server. If the function fails, the return value is `INVALID_SERVER`. To get extended error information, call

FtpGetServerError.

Remarks

The **FtpServerRestart** function will restart the specified server, terminating all active client sessions. The server handle that is returned by the function is the handle for the new server instance, and the old handle value is no longer valid. If the function is unable to restart the server for any reason, the server thread is terminated. The server retains all of the configuration parameters from the previous instance, however the statistical information (such as the number of clients, files transferred, etc.) will be reset.

If an application calls this function from within an event handler, the active client session (the client for which the event handler was invoked) may not get a disconnect notification. It is recommended that this function only be called by the same thread that created the server using the **FtpServerStart** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csftsv10.lib`

See Also

[FtpServerStart](#), [FtpServerStop](#)

FtpServerResume Function

```
BOOL WINAPI FtpServerResume(  
    HSERVER hServer  
);
```

Resume accepting client connections.

Parameters

hServer

Handle to the server.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **FtpGetServerError**.

Remarks

The **FtpServerResume** function instructs the server to resume accepting new client connections after the **FtpServerSuspend** function has been called.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csftsv10.lib

See Also

[FtpServerRestart](#), [FtpServerStart](#), [FtpServerStop](#), [FtpServerSuspend](#), [FtpServerThrottle](#)

FtpServerStart Function

```
HSERVER WINAPI FtpServerStart(  
    LPCTSTR lpszLocalHost,  
    UINT nLocalPort,  
    DWORD dwOptions,  
    LPFTPSEVERCONFIG lpServerConfig,  
    FTPSERVPROC lpServerProc,  
    DWORD_PTR dwServerParam,  
    LPSECURITYCREDENTIALS lpCredentials  
);
```

The **FtpServerStart** function begins listening for client connections on the specified local address and port number. The server is started in its own thread and manages the client sessions independently of the calling thread. All interaction with the server and its client sessions takes place inside the callback function specified by the caller.

Parameters

lpszLocalHost

A pointer to a string which specifies the local hostname or IP address address that the server should be bound to. If this parameter is NULL or an empty string, then an appropriate address will automatically be used. If a specific address is used, the server will only accept client connections on the network interface that is bound to that address.

nLocalPort

The port number the server should use to listen for client connections. If a value of zero is specified, the server will use the standard port number 21 to listen for connections, or port 990 if the server is configured to use implicit SSL. The port number used by the application must be unique and multiple instances of a server cannot use the same port number. It is recommended that a port number greater than 5000 be used for private, application-specific implementations.

dwOptions

An unsigned integer value that specifies the options used when creating an instance of the server. For a list of options, see [Server Option Constants](#).

lpServerConfig

A pointer to an **FTPSEVERCONFIG** structure that specifies the configuration options for the server. If this parameter is NULL, then default configuration parameters will be used that starts the server in a restrictive mode.

lpServerProc

Specifies the address of the application defined callback function. For more information about the callback function, see the description of the **FtpServerProc** callback function. If this parameter is NULL, a default internal handler is used to process client commands.

dwServerParam

A user-defined integer value that is passed to the callback function. If the *lpServerProc* parameter is NULL, this value should be zero. This value is guaranteed to be large enough to store a pointer or handle value on both 32-bit and 64-bit platforms.

lpCredentials

Pointer to a **SECURITYCREDENTIALS** structure. If this parameter is NULL, the default security credentials for the server host name will be used. If security is enabled for the server, it is recommended that you provide a pointer to this structure with specific information about the

server certificate that should be used. If the security options are not specified in the server configuration, this parameter is ignored.

Return Value

If the function succeeds, the return value is a handle to a server session. If the function fails, the return value is `INVALID_SERVER`. To get extended error information, call **FtpGetServerError**.

Remarks

In most cases, the *lpzLocalHost* parameter should be a NULL pointer or an empty string. On a multihomed system, this will enable the server to accept connections on any appropriately configured network adapter. Specifying a hostname or IP address will limit client connections to that particular address. Note that the hostname or address must be one that is assigned to the local system, otherwise an error will occur.

If an IPv6 address is specified as the local address, the system must have an IPv6 stack installed and configured, otherwise the function will fail.

To listen for connections on any suitable IPv4 interface, specify the special dotted-quad address "0.0.0.0". You can accept connections from clients using either IPv4 or IPv6 on the same socket by specifying the special IPv6 address "::0", however this is only supported on Windows 7 and Windows Server 2008 R2 or later platforms. If no local address is specified, then the server will only listen for connections from clients using IPv4. This behavior is by design for backwards compatibility with systems that do not have an IPv6 TCP/IP stack installed.

The handle returned by this function references the listening socket that was created when the server was started. The service is managed in another thread, and all interaction with the server and active client connections are performed inside the event handler. To disconnect all active connections, close the listening socket and terminate the server thread, call the **FtpServerStop** function.

The host UUID that is defined as part of the server configuration should be generated using the **uuidgen** utility that is included with the Windows SDK. You should not use the UUID that is provided in the example code, it is for demonstration purposes only. If no host UUID is specified in the server configuration, an ephemeral UUID will be generated automatically when the server is started.

If the server is started with security enabled, the *lpCredentials* parameter should be used to provide the server certificate information in a **SECURITYCREDENTIALS** structure. If the pointer is NULL, this function will search for a certificate that matches the hostname provided as part of the server configuration. This requires that the server certificate be installed in the personal certificate store of the current process user, and it must have a private key associated with it. To use a certificate with a different name, or one that is stored in a PFX file, a **SECURITYCREDENTIALS** structure must be defined and passed to this function.

Example

```
HSERVER hServer;
FTPSEVERCONFIG ftpConfig;

// Initialize the server configuration
ZeroMemory(&ftpConfig, sizeof(FTPSEVERCONFIG));
ftpConfig.dwSize = sizeof(ftpConfig);
ftpConfig.nMaxClients = 20;
ftpConfig.nMaxGuests = 5;
ftpConfig.nLogFormat = FTP_LOGFILE_EXTENDED;
ftpConfig.nAuthTime = 30;
```

```
ftpConfig.nIdleTime = 120;
ftpConfig.lpszIdentity = _T("MyProgram");
ftpConfig.lpszHostName = _T("server.company.com");
ftpConfig.lpszHostUuid = _T("10000000-1000-1000-1000-100000000000");
ftpConfig.lpszDirectory = _T("%ProgramData%\MyProgram\Files");
ftpConfig.lpszLogFile = _T("%ProgramData%\MyProgram\Server.log");

// Start the server
hServer = FtpServerStart(lpszLocalHost,
                        FTP_PORT_DEFAULT,
                        FTP_SERVER_LOCALUSER | FTP_SERVER_UNIXMODE,
                        &ftpConfig,
                        lpEventHandler,
                        0,
                        NULL);
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csftsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

FtpServerStop Function

```
BOOL WINAPI FtpServerStop(  
    HSERVER hServer  
);
```

Stop the server, terminating all active client sessions and releasing the resources that were allocated for the server.

Parameters

hServer

The server handle.

Return Value

If the function succeeds, the return value is non-zero. If the server handle is invalid, the function will return a value of zero.

Remarks

The **FtpServerStop** function instructs the server to stop accepting client connections, disconnects all active client connections and terminates the thread that is managing the server session. The handle is no longer valid after the server has been stopped and should no longer be used. Note that it is possible that the actual handle value may be re-used at a later point when a new server is started. An application should always consider the server handle to be opaque and never depend on it being a specific value.

If an application calls this function from within an event handler, the active client session (the client for which the event handler was invoked) may not get a disconnect notification. It is recommended that this function only be called by the same thread that created the server using the **FtpServerStart** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csftsv10.lib

See Also

[FtpServerRestart](#), [FtpServerStart](#)

FtpServerSuspend Function

```
BOOL WINAPI FtpServerSuspend(  
    HSERVER hServer  
);
```

Suspend the server and reject new client connections.

Parameters

hServer

Handle to the server.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **FtpGetServerError**.

Remarks

The **FtpServerSuspend** function instructs the server to suspend accepting new client connections. Any incoming client connections will be rejected with an error message indicating that the server is currently unavailable. To resume accepting client connections, call the **FtpServerResume** function. Suspending the server will have no effect on clients that have already established a connection with the server.

It is recommended that you only suspend a server if absolutely necessary, and only for brief periods of time. If you want to limit the number of active client connections or control the connection rate for clients, use the **FtpServerThrottle** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftsv10.lib

See Also

[FtpServerRestart](#), [FtpServerResume](#), [FtpServerStart](#), [FtpServerStop](#), [FtpServerThrottle](#)

FtpServerThrottle Function

```
BOOL WINAPI FtpServerThrottle(  
    HSERVER hServer,  
    UINT nMaxClients,  
    UINT nMaxClientsPerAddress,  
    UINT nMaxGuests,  
    DWORD dwConnectionRate  
);
```

The **FtpServerThrottle** function limits the number of active client connections, connections per address and connection rate.

Parameters

hServer

Handle to the server.

nMaxClients

An integer value which specifies the maximum number of clients that may connect to the server. A value of zero specifies that there is no fixed limit to the number of client connections. A value of -1 specifies that the maximum number of clients should not be changed.

nMaxClientsPerAddress

An integer value which specifies the maximum number of clients that may connect to the server from the same IP address. A value of zero specifies that there is no fixed limit to the number of client connections per address. By default, there is a limit of four client connections per address. A value of -1 specifies that the maximum number of clients should not be changed.

nMaxGuests

An integer value which specifies the maximum number of guest users that may login to the server. A value of zero disables guest logins and requires that all clients authenticate with a valid username and password. A value of -1 specifies that the maximum number of guest users should not be changed.

dwConnectionRate

A value which specifies a restriction on the rate of client connections, limiting the number of connections that will be accepted within that period of time. A value of zero specifies that there is no restriction on the rate of client connections. The higher this value, the fewer the number of connections that will be accepted within a specific period of time. By default, there is no limit on the client connection rate. A value of -1 specifies that the connection rate should not be changed.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **FtpGetServerError**.

Remarks

The **FtpServerThrottle** function is used to limit the number of connections and the connection rate to minimize the potential impact of a large number of client connections over a short period of time. This can be used to protect the server from a client application that is malfunctioning or a deliberate denial-of-service attack in which the attacker attempts to flood the server with connection attempts.

If the maximum number of client connections or maximum number of connections per address is exceeded, the server will reject subsequent connection attempts until the number of active client sessions drops below the specified threshold. Note that adjusting these values lower than the current connection limits will not affect clients that have already connected to the server. For example, if the **FtpServerStart** function is called with the maximum number of clients set to 100, and then **FtpServerThrottle** is called lowering that value to 75, no existing client connections will be affected by the change. However, the server will not accept any new connections until the number of active clients drops below 75.

Increasing the connection rate value will force the server to slow down the rate at which it will accept incoming client connection requests. For example, setting this parameter to a value of 1000 would limit the server to accepting one client connection every second, while a value of 250 would allow the server to accept four client connections per second. Note that significantly increasing the amount of time the server must wait to accept client connections can exceed the connection backlog queue, resulting in client connections being rejected.

It is recommended that you always specify conservative connection limits for your server application based on expected usage. Allowing an unlimited number of client connections can potentially expose the system to denial-of-service attacks and should never be done for servers that are accessible over the Internet.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csftsv10.lib

See Also

[FtpServerRestart](#), [FtpServerResume](#), [FtpServerStart](#), [FtpServerSuspend](#)

FtpServerUninitialize Function

```
VOID WINAPI FtpServerUninitialize();
```

The **FtpServerUninitialize** function terminates the use of the library.

Parameters

There are no parameters.

Return Value

None.

Remarks

An application is required to perform a successful **FtpServerInitialize** call before it can call any of the other library functions. When it has completed the use of library, the application must call **FtpServerUninitialize** to allow the library to free any resources allocated on behalf of the process. Any pending blocking or asynchronous calls in this process are canceled without posting any notification messages, and all sockets that were opened by the process are closed.

There must be a call to **FtpServerUninitialize** for every successful call to **FtpServerInitialize** made by a process. Operations for all threads in the server are terminated.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csftsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[FtpServerInitialize](#), [FtpServerStart](#), [FtpServerStop](#)

FtpSetClientAccess Function

```
BOOL WINAPI FtpSetClientAccess(  
    HSERVER hServer,  
    UINT nClientId,  
    DWORD dwUserAccess  
);
```

Change the access rights associated with the specified client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

dwUserAccess

An unsigned integer which specifies one or more user access rights. For a list of user access rights that can be granted to the client, see [User Access Constants](#).

Return Value

If the function succeeds, the return value is non-zero. If the server handle and client ID do not specify a valid client session, the function will return zero. This function can only be used with authenticated clients. If the client session has not been authenticated, the return value will be zero.

Remarks

The **FtpSetClientAccess** function can change the access rights for an authenticated client session. This function can only be used after the **FtpAuthenticateClient** function has been used to grant the initial set of access rights to the client. The **FtpEnableClientAccess** function can be used to grant or revoke a specific permission for the client session.

The *dwUserAccess* parameter has a value of FTP_ACCESS_DEFAULT, then default permissions will be granted to the client session. A normal client cannot be changed to a restricted or anonymous client using this function. If the FTP_ACCESS_RESTRICTED or FTP_ACCESS_ANONYMOUS access flags are specified, this function will fail.

This function cannot be used to change the access rights for a restricted or anonymous user. Those rights are granted when the client session is authenticated and will persist until the client disconnects from the server. This restriction is designed to prevent the inadvertent granting of rights to an untrusted client that could compromise the security of the server.

Example

```
DWORD dwUserAccess = 0;  
  
// Allow the client to execute programs using SITE EXEC  
if (FtpGetClientAccess(hServer, nClientId, &dwUserAccess))  
{  
    if (!(dwUserAccess & FTP_ACCESS_ANONYMOUS))  
        FtpSetClientAccess(hServer, nClientId, dwUserAccess |  
FTP_ACCESS_EXECUTE);  
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csftsv10.lib

[FtpAuthenticateClient](#), [FtpEnableClientAccess](#), [FtpGetClientAccess](#)

FtpSetClientFileType Function

```
BOOL WINAPI FtpSetClientFileType(  
    HSERVER hServer,  
    UINT nClientId,  
    UINT nFileType  
);
```

Change the current file type used for transfers by the specified client.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

nFileType

Specifies the type of file that will be uploaded or downloaded. This parameter determines whether subsequent file transfers require any data conversion and may be one of the following values.

Value	Description
FILE_TYPE_ASCII (1)	The file is a text file using the ASCII character set. For those clients which use a different end-of-line character sequence, the text file has been converted to the local format which uses the carriage return (CR) and linefeed (LF) characters.
FILE_TYPE_IMAGE (3)	The file is a binary file and no data conversion of any type has been performed on the file. This is the default file type for most data files and executable programs. If the client specified this file type when appending to a text file, the file will contain the end-of-line sequences used by its native operating system.

Return Value

If the function succeeds, the return value is non-zero. If the server handle and client ID do not specify a valid client session, the function will return zero.

Remarks

The **FtpSetClientFileType** function will change the default file type that is used for subsequent transfers by the client. If the file type is set to FILE_TYPE_ASCII then the server will automatically convert any end-of-line character sequences to match the format used by the local system. For example, if the client is connecting from a UNIX based system, the server will convert a single linefeed character to a carriage return (CR) and linefeed (LF) sequence. If the file type is set to FILE_TYPE_IMAGE, then no conversion is performed.

This function can be used to override the file type specified by filtering the TYPE command issued by the client. For example, it could be used to force file transfers to use a specific type based on the file extension, regardless of the type specified by the client. To determine the current file type set by the client, use the **FtpGetClientFileType** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csftsv10.lib

See Also

[FtpGetClientFileType](#)

FtpSetClientIdentity Function

```
BOOL WINAPI FtpSetClientIdentity(  
    HSERVER hServer,  
    UINT nClientId,  
    LPCTSTR lpszIdentity  
);
```

Change the identity of the specified client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszIdentity

A pointer to a string that identifies the client. If this parameter is NULL or specifies an empty string, the current identity for the client is cleared. The maximum length of the identity string is 64 characters, including the terminating null character.

Return Value

If the function succeeds, the return value is non-zero. If the server handle or client ID is invalid, the function will return a value of zero.

Remarks

The **FtpSetClientIdentity** function associates a string value with the client that can be used to identify the session. The identity string does not have any standard format and is used for informational purposes only. Typically it is used to identify the client application that was used to establish the connection. Changing the client identity has no effect on the operation of the server. To obtain the identity string currently associated with the client, use the **FtpGetClientIdentity** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[FtpGetClientIdentity](#), [FtpGetServerIdentity](#), [FtpSetServerIdentity](#)

FtpSetClientIdleTime Function

```
UINT WINAPI FtpSetClientIdleTime(  
    HSERVER hServer,  
    UINT nClientId,  
    UINT nTimeout  
);
```

Change the idle timeout period for the specified client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

nTimeout

An unsigned integer value that specifies the number of seconds that the client may remain idle. If this value is zero, the default idle timeout period for the server will be used.

Return Value

If the function succeeds, the return value is the previous client idle timeout period in seconds. If the server handle and client ID do not specify a valid client session, the function will return zero.

Remarks

The **FtpSetClientIdleTime** function will change the number of seconds that the client may remain idle before being automatically disconnected by the server. The minimum timeout period for a client is 60 seconds, the maximum is 7200 seconds (2 hours). The idle time of a client session is based on the last time a command was issued to the server or when a data transfer completed.

If the value INFINITE is specified as the timeout period, the client activity timer will be refreshed, extending the idle timeout period for the session. This is typically done inside an event handler to prevent the client from being disconnected due to inactivity.

To obtain the current idle timeout period for a client, along with the amount of time the client has been idle, use the **FtpGetClientIdleTime** function.

This timeout period only affects authenticated clients. Unauthenticated clients use a different internal timer that limits the amount of time they can remain connected to the server and that value cannot be changed for individual client sessions.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftsv10.lib

[FtpGetClientIdleTime](#)

FtpSetCommandFile Function

```
BOOL WINAPI FtpSetCommandFile(  
    HSERVER hServer,  
    UINT nClientId,  
    LPCTSTR lpszFileName  
);
```

Change the name of the local file or directory that is the target of the current command.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszFileName

A pointer to a string that specifies the new file name. This parameter may be NULL to specify that the original file or directory name should be used.

Return Value

If the function succeeds, the return value is non-zero. If the server handle and client ID do not specify a valid client session, the function will return zero.

Remarks

The **FtpSetCommandFile** function is used by the application to change the target file or directory name for the current command from within an FTP_EVENT_COMMAND event handler. This can be used to effectively redirect the client to use a different file than the one that was actually requested. For example, if the client issues the RETR command to download a file from the server, this function can be used to redirect the command to use a different file name. To obtain the full path to the file or directory that is the target of the current command, use the **FtpGetCommandFile** function.

The *lpszFileName* parameter specifies the path to the new file or directory name. If the path is absolute, then it will be used as-is. If the path is relative, it will be relative to the current working directory for the client session. The full path to this file is not limited to the server root directory or its subdirectory, it can specify a file anywhere on the local system. If this parameter is a NULL pointer, or points to an empty string, then the server will revert to using the actual file or directory name specified by the command. This enables the application to effectively undo a previous call to this function to change the target file name.

Typically this function would be used to redirect a client to a file or directory that it may not normally have access to. Exercise caution when using this function to provide access to data that is stored outside of the server root directory. Incorrect use of this function could expose the server to security risks or cause unpredictable behavior by client applications.

This function should only be called within the context of the FTP_EVENT_COMMAND event, and only for those commands that perform an action on a file or directory. If the current command does not target a file or directory, this function will return zero and the last error code will be set to ST_ERROR_INVALID_COMMAND. To obtain the name of the current command issued by the client, use the **FtpGetCommandName** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csftsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

FtpSetServerAddress Function

```
BOOL WINAPI FtpSetServerAddress(  
    HSERVER hServer,  
    LPCTSTR lpszAddress  
);
```

Change the IP address that the server will use with passive data connections.

Parameters

hServer

The server handle.

lpszAddress

A pointer to a string that specifies the IP address that the server should use for passive mode data transfers. This parameter cannot be NULL.

Return Value

If the function succeeds, the return value is non-zero. If either the server handle or the IP address is invalid the function will return a value of zero.

Remarks

The **FtpSetServerAddress** function changes the IP address that the server will use when a client transfers a file using a passive mode data connection. In passive mode, the server will create a second passive (listening) socket that will accept an incoming connection from the client. The server sends the IP address and port number allocated for that socket to the client, and the client establishes the data connection to the server using that address. The IP address that the server sends to the client is normally the same as the IP address that the client used to establish the control connection, however if the server is located behind a router that performs Network Address Translation (NAT), the IP address reported to the client may not be usable.

This function enables your application to set the external IP address for the server to a specific value, rather than the server attempting to automatically discover its own external address. If you wish to set the external address for the server manually, call the **FtpServerStart** function without the FTP_SERVER_EXTERNAL option and then call this function to set the external IP address to the desired value.

This function will not change the IP address the server is using to listen for client connections. The only way to change the listening IP address is to stop and restart the server using the new address. This function only changes the IP address that is reported to clients when a passive data connection is used. Incorrect use of this function can prevent the client from establishing a data connection to the server. The address must be in the same address family as the local address that the server was started with. For example, if the server was started using an IPv4 address, the IP address passed to this function cannot be an IPv6 address.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

FtpSetServerError Function

```
VOID WINAPI FtpSetServerError(  
    HSERVER hServer,  
    DWORD dwError  
);
```

Set the last error code for the specified server session.

Parameters

hServer

The server handle.

dwError

An unsigned integer that specifies an error code.

Return Value

None.

Remarks

Error codes are unsigned 32-bit values which are private to each server session. Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_SERVER or FTP_ERROR.

If the *hServer* parameter is specified as INVALID_SERVER, this function will set the last error code for the current thread, but will not change the error code associated with any server session. This should only be done if the application does not have access to a valid server handle.

If the *dwError* parameter is specified with a value of zero, this effectively clears the error code for the last function that failed. Those functions which clear the last error code when they succeed are noted on the function reference page.

Applications can retrieve the value saved by this function by using the **FtpGetServerError** function to determine the specific reason for a function failure.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftsv10.lib

See Also

FtpSetServerIdentity Function

```
BOOL WINAPI FtpSetServerIdentity(  
    HSERVER hServer,  
    LPCTSTR lpszIdentity  
);
```

Change the identity of the specified server.

Parameters

hServer

The server handle.

lpszIdentity

A pointer to a string that identifies the server. If this parameter is NULL or specifies an empty string, the current identity for the server is reset to a default value. The maximum length of the identity string is 64 characters, including the terminating null character.

Return Value

If the function succeeds, the return value is non-zero. If the server handle is invalid, the function will return a value of zero.

Remarks

The **FtpSetClientIdentity** function changes a string value used by the server to identify itself to clients. The identity string does not have any standard format and is used for informational purposes only. Typically it consists of the application name and a version number. Changing the server identity has no effect on the operation of the server. To obtain the identity string currently associated with the server, use the **FtpGetServerIdentity** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

FtpSetServerLogFile Function

```
BOOL WINAPI FtpSetServerLogFile(  
    HSERVER hServer,  
    UINT nLogFormat,  
    UINT nLogLevel,  
    LPCTSTR lpszFileName  
);
```

Change the current log format, level of detail and file name.

Parameters

hServer

The server handle.

nLogFormat

An integer value that specifies the format used when creating or updating the server log file. The following formats are supported:

Constant	Description
FTP_LOGFILE_NONE (0)	This value specifies that the server should not create or update a log file.
FTP_LOGFILE_COMMON (1)	This value specifies that the log file should use the common log format that records a subset of information in a fixed format. This log format usually only provides information about file transfers.
FTP_LOGFILE_EXTENDED (2)	This value specifies that the log file should use the standard W3C extended log file format. This is an extensible format that can provide additional information about the client session.

nLogLevel

An integer value that specifies the level of detail that should be generated in the log file. The minimum value is 1 and the maximum value is 10. If this parameter is zero, it is the same as specifying a log file format of FTP_LOGFILE_NONE and will disable logging by the server.

lpszFileName

A pointer to a string that specifies the name of the log file that should be created or appended to. If the server was configured with logging enabled and this parameter is NULL or an empty string, the current log file name will not be changed. If the log file does not exist, it will be created. If it does exist, the contents of the log file will be appended to.

Return Value

If the function succeeds, the return value is non-zero. If the server handle does not specify a valid server, the function will return zero.

Remarks

The **FtpSetServerLogFile** function can be used to change the current log file name, the format of the log file or the level of detail recorded in the log file. In some situations it may be desirable to delete the current log file contents when changing the format or ensure that a new log file is created. To do this, combine the *nLogFormat* parameter with the constant FTP_LOGFILE_DELETE.

The higher the value of the *nLogLevel* parameter, the greater the level of detail that is recorded by the server. A log level of 1 instructs the server to only record file transfers, while a level of 10 instructs the server to record all commands processed by the server. Because a higher level of logging detail can negatively impact the performance of the server, it is recommended that you do not exceed a level of 5 for most applications. A log level of 10 should only be used for debugging purposes.

Example

```
UINT nLogFormat = FTP_LOGFILE_NONE;
UINT nLogLevel = 0;
UINT nNewLevel = 5;
BOOL bChanged = FALSE;

// Change the level of detail for the current log file if logging
// has been enabled and the current level is a lower value

if (FtpGetServerLogFile(hServer, &nLogFormat, &nLogLevel, NULL, 0))
{
    if (nLogFormat != FTP_LOGFILE_NONE && nLogLevel < nNewLevel)
        bChanged = FtpSetServerLogFile(hServer, nLogFormat, nNewLevel, NULL);
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csftsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

FtpSetServerName Function

```
BOOL WINAPI FtpSetServerName(  
    HSERVER hServer,  
    UINT nClientId,  
    LPCTSTR lpszHostName  
);
```

Change the host name assigned to the specified server or client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session. This value may be zero.

lpszHostName

A pointer to a string that specifies the new host name assigned to the server or client session. If this value is NULL or points to an empty string, the current host name will be changed to use the default host name.

Return Value

If the function succeeds, the return value is non-zero. If either the server handle or the client ID is invalid, or the buffer is not large enough to store the complete hostname, the function will return a value of zero.

Remarks

This function will change the host name assigned to the specified client session. If the *nClientId* parameter has a value of zero, the function will change default host name that was assigned to the server as part of the server configuration. If the *nClientId* parameter specifies a valid client session and the *lpszHostName* parameter is NULL, the host name associated with the client session will be changed to the current host name assigned to the server.

When a client connects to the server, it can specify the host name that it used to establish the connection by sending the HOST command. This is typically used with virtual hosting, where one server may accept client connections for multiple domains. The **FtpGetServerName** function will return the host name specified by the client, and **FtpSetServerName** can be used by the application to either explicitly assign a different host name to the client session, or override the host name provided by the client.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

FtpSetServerPriority Function

```
INT WINAPI FtpSetServerPriority(  
    HSERVER hServer,  
    INT nPriority  
);
```

Change the priority assigned to the specified server.

Parameters

hServer

The server handle.

nPriority

An integer value which specifies the new priority for the server. It may be one of the following values:

Constant	Description
FTP_PRIORITY_BACKGROUND (0)	This priority significantly reduces the memory, processor and network resource utilization for the server. It is typically used with lightweight services running in the background that are designed for few client connections. The server thread will be assigned a lower scheduling priority and will be frequently forced to yield execution to other threads.
FTP_PRIORITY_LOW (1)	This priority lowers the overall resource utilization for the server and meters the processor utilization for the server thread. The server thread will be assigned a lower scheduling priority and will occasionally be forced to yield execution to other threads.
FTP_PRIORITY_NORMAL (2)	The default priority which balances resource and processor utilization. This is the priority that is initially assigned to the server when it is started, and it is recommended that most applications use this priority.
FTP_PRIORITY_HIGH (3)	This priority increases the overall resource utilization for the server and the thread will be given higher scheduling priority. It is not recommended that this priority be used on a system with a single processor.
FTP_PRIORITY_CRITICAL (4)	This priority can significantly increase processor, memory and network utilization. The server thread will be given higher scheduling priority and will be more responsive to client connection requests. It is not recommended that this priority be used on a system with a single processor.

Return Value

If the function succeeds, the return value is the previous priority assigned to the server. If the function fails, the return value is FTP_PRIORITY_INVALID. To get extended error information, call **FtpGetServerError**.

Remarks

The **FtpSetServerPriority** function can be used to change the current priority assigned to the specified server. Client connections that are accepted after this function is called will inherit the new priority as their default priority. Previously existing client connections will not be affected by this function.

Higher priority values increase the thread priority and processor utilization for each client session. You should only change the server priority if you understand the impact it will have on the system and have thoroughly tested your application. Configuring the server to run with a higher priority can have a negative effect on the performance of other programs running on the system.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cstools10.h`.

Import Library: `csftsv10.lib`

See Also

[FtpGetServerPriority](#), [FtpServerStart](#)

FtpSetServerStackSize Function

```
BOOL WINAPI FtpSetServerStackSize(  
    SOCKET hServer,  
    DWORD dwStackSize  
);
```

Change the initial size of the stack allocated for threads created by the server.

Parameters

hServer

Handle to the server socket.

dwStackSize

The amount of memory that will be committed to the stack for each thread created by the server. If this value is zero, a default stack size will be used.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **FtpGetServerError**.

Remarks

The **FtpSetServerStackSize** function changes the initial amount of memory that is committed to the stack for each thread created by the server. By default, the stack size for each thread is set to 256K for 32-bit processes and 512K for 64-bit processes. Increasing or decreasing the stack size will only affect new threads that are created by the server, it will not affect those threads that have already been created to manage active client sessions. It is recommended that most applications use the default stack size.

You should not change the stack size unless you understand the impact that it will have on your system and have thoroughly tested your application. Increasing the initial commit size of the stack will remove pages from the total system commit limit, and every page of memory that is reserved for stack cannot be used for any other purpose.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `csftools10.h`

Import Library: `csftsv10.lib`

File Transfer Protocol Server Data Structures

- FTPCLIENTCREDENTIALS
- FTPSERVERCONFIG
- FTPSERVERTRANSFER
- INITDATA
- SECURITYCREDENTIALS

FTPCLIENTCREDENTIALS Structure

The **FTPCLIENTCREDENTIALS** structure defines the credentials used to authenticate a specific user.

```
typedef struct _FTPCLIENTCREDENTIALS
{
    DWORD dwSize;
    DWORD dwFlags;
    TCHAR szHostName[FTP_MAXHOSTNAME];
    TCHAR szUserName[FTP_MAXUSERNAME];
    TCHAR szPassword[FTP_MAXPASSWORD];
} FTPCLIENTCREDENTIALS, *LPFTPCLIENTCREDENTIALS;
```

Members

dwSize

An unsigned integer value that specifies the size of the structure.

dwFlags

An unsigned integer value reserved for future use. This member will always be initialized to a value of zero.

szHostName

A pointer to a string that specifies the server host name.

szUserName

A pointer to a string that specifies the user name.

szPassword

A pointer to a string that specifies the user password.

Remarks

When an instance of this structure is passed to the **FtpGetClientCredentials** function, this member must be initialized to the size of the structure and all other members must be initialized with a value of zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Unicode: Implemented as Unicode and ANSI versions.

See Also

FTPSERVERCONFIG Structure

The **FTPSERVERCONFIG** structure provides the configuration information used to create an instance of an FTP server.

```
typedef struct _FTPSERVERCONFIG
{
    DWORD    dwSize;
    UINT     nMaxClients;
    UINT     nMaxClientsPerAddress;
    UINT     nMaxGuests;
    UINT     nLogFormat;
    UINT     nLogLevel;
    UINT     nMinPort;
    UINT     nMaxPort;
    UINT     nAuthFail;
    UINT     nAuthTime;
    UINT     nIdleTime;
    UINT     nExecTime;
    LPCTSTR  lpszIdentity;
    LPCTSTR  lpszHostUuid;
    LPCTSTR  lpszHostName;
    LPCTSTR  lpszRootPath;
    LPCTSTR  lpszTempPath;
    LPCTSTR  lpszLogFile;
} FTPSERVERCONFIG, *LPFTPSERVERCONFIG;
```

Members

dwSize

An unsigned integer value that specifies the size of the structure.

nMaxClients

An integer value that specifies the maximum number of active client connections that will be accepted by the server. If the maximum number of clients is reached, any further connections are rejected by the server until one or more clients close their connection to the server or are disconnected. A value of zero specifies the default configuration value of 100 connections should be used.

nMaxClientsPerAddress

An integer value that specifies the maximum number of active client connections per IP address that will be accepted by the server. If the maximum number of clients from the same IP address is reached, any further connections are rejected until one of the clients closes its connection to the server. A value of zero specifies the default configuration value of 4 connections per address should be used.

nMaxGuests

An integer value that specifies the maximum number of anonymous client connections. If the server does not permit anonymous connections, this value is ignored. It is recommended that this value always be less than the value of the *nMaxClients* member. A value of zero specifies that the default configuration limit of 20 anonymous connections should be used.

nLogFormat

An integer value that specifies the format used when creating or updating the server log file. The following formats are supported:

--	--

Constant	Description
FTP_LOGFILE_NONE (0)	This value specifies that the server should not create or update a log file.
FTP_LOGFILE_COMMON (1)	This value specifies that the log file should use the common log format that records a subset of information in a fixed format. This log format usually only provides information about file transfers.
FTP_LOGFILE_EXTENDED (2)	This value specifies that the log file should use the standard W3C extended log file format. This is an extensible format that can provide additional information about the client session.

nLogLevel

An integer value that specifies the level of detail that should be generated in the log file. The minimum value is 1 and the maximum value is 10. If the ***nLogFormat*** member specifies a valid log file format and this value is zero, a default level of detail will be selected based on the format. The common log file format generally contains less information by default, only logging the data transfers between the client and server. The W3C extended log file format defaults to a higher level of detail that includes additional information about the client session. The higher the level of detail, the larger the log file will be.

nMinPort

An integer value that specifies the minimum range of port numbers that will be used with passive data connections. A value of zero specifies that the default value of 30000 should be used. The minimum value of this member is 5000 and the maximum value is 65535. If the value is non-zero, it must be less than the value of the ***nMaxPort*** structure member.

nMaxPort

An integer value that specifies the maximum range of port numbers that will be used with passive data connections. A value of zero specifies the default value of 65535 should be used. The minimum value of this member is 5000 and the maximum value is 65535. If the value is non-zero, it must be greater than the value of the ***nMinPort*** structure member.

nAuthFail

An integer value that specifies the maximum number of user authentication attempts that are permitted until the server terminates the client connection. A value of zero specifies that the default configuration limit of 3 authentication attempts per login should be allowed. The maximum number of authentication attempts is 10.

nAuthTime

An integer value that specifies the maximum number of user authentication attempts that are permitted until the server terminates the client connection. A value of zero specifies the default value of 60 seconds. If the value is non-zero, the minimum value is 20 seconds and the maximum value is 300 seconds (5 minutes). This value is used to ensure that a client has successfully authenticated itself within a limited period of time. This prevents a potential denial-of-service attack against the server where clients establish connections and hold them open without authentication. In conjunction with the ***nAuthFail*** member, this also limits the ability of a client to attempt to probe the server for valid username and password combinations.

nIdleTime

An integer value that specifies the maximum number of seconds that a client session may be

idle before the server closes the control connection to the client. A value of zero specifies the default value of 900 seconds (15 minutes). If the value is non-zero, the minimum value is 60 seconds and the maximum value is 7200 seconds (2 hours). This value is used to initialize the default idle timeout period for each client session. A client may request that the server change the idle timeout period for its session by sending the SITE IDLE command. The server determines if a client is idle based on the time the last command was issued and whether or not a file transfer is in progress.

nExecTime

An unsigned integer value that specifies the maximum number of seconds that an external program is permitted to run on the server. External programs are registered using the **FtpRegisterProgram** function, and are executed by the client sending the SITE EXEC command to the server. If this value is zero, the default timeout period of 5 seconds will be used. The minimum execution time is 1 second and the maximum time limit is 30 seconds.

lpszIdentity

A pointer to a string that identifies the server. It is used for informational purposes only and has no effect on the operation of the server. If this member is not initialized to a value, then a default identity will be used. The server identity is provided when a client establishes the initial connection and when the client sends the STAT or CSID commands. If this member is defined, it is recommended that you only use printable ASCII characters.

lpszHostUuid

A pointer to a string that specifies a Universally Unique Identifier (UUID) that is used to uniquely identify the server. This value can be used when storing information about the server, and should be generated using a utility such as **uuidgen** which is included with Visual Studio. This structure member may be initialized to an empty string, in which case a temporary UUID will be randomly generated.

lpszHostName

A pointer to a string that specifies the fully-qualified host name for the server. If this structure member is initialized with an empty string, the local host name assigned to the Windows system will be used. This value does not need to correspond to the actual host name associated with the server's IP address. This value is used for informational purposes only and has no effect on the operation of the server.

lpszRootPath

A pointer to a string that specifies the path to the root directory for the server. If this structure member is initialized with an empty string, the current working directory for the process will be used as the root directory. It is recommended that you provide a full path to an existing directory and do not specify the root of a local or network drive. If the path does not exist at the time the server is started, it will be automatically created.

lpszTempPath

A pointer to a string that specifies the path to the temporary directory for the server. If this structure member is initialized with an empty string, the current temporary directory for the process will be used. The temporary directory cannot be the same as the root directory, and it is strongly recommended that you do not specify the root of a local or network drive. If the path does not exist at the time the server is started, it will be automatically created.

lpszLogFile

A pointer to a string that specifies the name of the server log file to create, if a logging format has been specified. If logging is enabled and this member is an empty string, then a default log file name will be created. If the file name does not include a path, then the file is created in the

server log directory. If the file name includes a path, the log file will be created using that specific name. If the server is in multi-user mode, then the default location for log files will be the Logs subdirectory in the server root directory. If the server is not in multi-user mode, the default location for log files will be the temporary directory for the server process.

Remarks

When an instance of this structure is passed to the **FtpServerStart** function, the *dwSize* member must be initialized to the size of the structure, otherwise the function will fail with an error indicating that the configuration is invalid.

The *nMaxClients* member limits the total number of client connections and the *nMaxGuests* member limits the total number of guest connections. The server will notify the client if either number of connections has been exceeded and will automatically close the connection. However, one difference is that a new client that exceeds the maximum number of connections will not generate any events; a client that exceeds the maximum number of guest connections will generate events. The reason for the difference is that the check for the number of active clients is made immediately after the client connects to the server, prior to session context being created for that client. The check for the number of anonymous clients is made later, after the client has sent the USER and PASS commands to the server. For more control over how the server accepts client connections, use the **FtpServerThrottle** function.

If the server is running on a system that is behind a firewall that restricts the range of port numbers for inbound connections, the *nMinPort* and *nMaxPort* members can be used to limit the ports which the server will use to listen for passive data connections from clients. By default, the server will use data port numbers that range from 30000 to 65535, which is typical for many firewall configurations. If you provide your own port range, the minimum number of ports available must be at least 1000. Specifying a port range that is too small will cause the **FtpServerStart** function to fail with an error indicating that the server configuration is invalid.

When specifying the root directory for the server configuration, it is important to consider that a client's access to files on the system will be limited to these directories and any subdirectories. If a root directory is not specified, then one will be created using the current working directory for the process. The root directory path may include environment variables surrounded by % symbols and these will be expanded.

If you have configured the server to permit clients to upload files, you must ensure that your application has permission to create files in the directory that you specify. A recommended location for the server root directory would be a subdirectory of the %ALLUSERSPROFILE% directory. Using the environment variable ensures that your server will work correctly on different versions of Windows. If the root directory does not exist at the time that the server is started, it will be created.

For servers that are publicly accessible, or where you want files to be accessible across multiple server sessions, you should always populate the *szHostUuid* member with a valid UUID string, and the *szDirectory* member should specify an absolute path to an existing directory.

If the FTP_SERVER_MULTUSER option is specified, the server will start in multi-user mode, with each user assigned to their own home directory based on their username. This option will cause the server to create a directory structure in the root directory that includes three subdirectories: Public, Users and Logs. The Public directory is the home directory for anonymous users, and they are isolated to that directory. The Users directory is where the user home directories are created. The Logs directory is where log files are created by default. If this option is not specified, then no subdirectories are created and all users will share the server root directory by default.

If the `FTP_SERVER_LOCALUSER` option is specified, the server will never attempt to authenticate the local Administrator or Guest accounts. This is done to prevent clients from attempting to probe for the administrator account password. However, the application can override this behavior by implementing a handler for the `FTP_CLIENT_LOGIN` event.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Unicode: Implemented as Unicode and ANSI versions.

See Also

[FtpServerStart](#), [FtpServerStop](#), [FtpServerThrottle](#)

FTPSEVERTRANSFER Structure

The **FTPSEVERTRANSFER** structure provides information about the last file transfer performed by a client.

```
typedef struct _FTPSEVERTRANSFER
{
    DWORD          dwSize;
    DWORD          dwReserved;
    DWORD          dwFileAccess;
    DWORD          dwTimeElapsed;
    ULARGE_INTEGER uiBytesCopied;
    TCHAR          szFileName[MAX_PATH];
} FTPSEVERTRANSFER, *LPFTPSEVERTRANSFER;
```

Members

dwSize

An unsigned integer value that specifies the size of the structure.

dwReserved

An unsigned integer value that is reserved for future use. This value will always be zero.

dwFileAccess

An unsigned integer value that specifies the how the local file was accessed. It can be one of the following values:

Constant	Description
FTP_FILE_READ (0)	The file was opened for reading. This mode indicates that the client issued the RETR command to download the contents of a file from the server to the client system. The <i>szFileName</i> member specifies the name of the local file on the server that was downloaded by the client.
FTP_FILE_WRITE (1)	The file was opened for writing. This mode indicates that the client issued the STOR or STOU command to upload the contents of a file from the client system to server. The <i>szFileName</i> member specifies the name of the local file on the server that was created by the client. If a file already existed with the name name, it was replaced.
FTP_FILE_APPEND (2)	The file was opened for writing. This mode indicates the client issued the APPE command to upload the contents of a file from the client system and append the data to a file on the server. If the file did not exist, then it was created. The <i>szFileName</i> member specifies the name of the local file that was appended to or created by the client.

dwTimeElapsed

The amount of time that it took for the file transfer to complete in milliseconds. This value is limited to the resolution of the system timer, which is typically in the range of 10 to 16 milliseconds. This value may be zero if the transfer occurred over a local network or on the same host using a loopback address.

uiBytesCopied

A 64-bit integer value that specifies the total number of bytes copied during the file transfer. This value is represented by a `ULARGE_INTEGER` union which provides support for those programming languages that do not have intrinsic support for 64-bit integers. For more information, refer to the Windows SDK documentation. The application should not make the assumption that this is the actual size of the file. If the client specified a restart offset using the REST command, this value would only represent the number of bytes transferred from that byte offset, not the total file size.

szFileName

A pointer to a string value that will contain the full path to the local file that was transferred. The ***dwFileAccess*** member determines whether the file name represents a file that was downloaded by the client, or uploaded from the client and stored on the server.

Remarks

When an instance of this structure is passed to the **FtpGetServerTransferInfo** function, the ***dwSize*** member must be initialized to the size of the structure, otherwise the function will fail with an error indicating that the parameter is invalid. All other members should be initialized to a value of zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Unicode: Implemented as Unicode and ANSI versions.

INITDATA Structure

This structure contains information about the SocketTools library when the initialization function returns.

```
typedef struct _INITDATA
{
    DWORD        dwSize;
    DWORD        dwVersionMajor;
    DWORD        dwVersionMinor;
    DWORD        dwVersionBuild;
    DWORD        dwOptions;
    DWORD_PTR    dwReserved1;
    DWORD_PTR    dwReserved2;
    TCHAR        szDescription[128];
} INITDATA, *LPINITDATA;
```

Members

dwSize

Size of this structure. This structure member must be set to the size of the structure prior to calling the initialization function. Failure to do so will cause the function to fail.

dwVersionMajor

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the major version number for the library.

dwVersionMinor

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the minor version number for the library.

dwVersionBuild

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the build number for the library.

dwOptions

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

dwReserved1

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

dwReserved2

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

szDescription

A null terminated string which describes the library.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Unicode: Implemented as Unicode and ANSI versions.

SECURITYCREDENTIALS Structure

The **SECURITYCREDENTIALS** structure specifies the information needed by the library to specify additional security credentials, such as a client certificate or private key, when establishing a secure connection.

```
typedef struct _SECURITYCREDENTIALS
{
    DWORD    dwSize;
    DWORD    dwProtocol;
    DWORD    dwOptions;
    DWORD    dwReserved;
    LPCTSTR  lpszHostName;
    LPCTSTR  lpszUserName;
    LPCTSTR  lpszPassword;
    LPCTSTR  lpszCertStore;
    LPCTSTR  lpszCertName;
    LPCTSTR  lpszKeyFile;
} SECURITYCREDENTIALS, *LPSECURITYCREDENTIALS;
```

Members

dwSize

Size of this structure. If the structure is being allocated dynamically, this member must be set to the size of the structure and all other unused structure members must be initialized to a value of zero or NULL.

dwProtocol

A bitmask of supported security protocols. The value of this structure member is constructed by using a bitwise operator with any of the following values:

Constant	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_SSL	Either SSL 2.0 or SSL 3.0 should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, TLS will be excluded from the list of supported protocols. Both SSL 2.0 and 3.0 have been deprecated and will never be used unless explicitly specified. It is not recommended that you enable either of these protocols for secure connections because it will cause most servers to reject your connection request, even if a version of TLS is also specified.
SECURITY_PROTOCOL_TLS	Either the TLS 1.0, 1.1 or 1.2 protocol should be used when establishing a secure connection. The correct protocol is automatically selected, based on

	what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers that reject any attempt to use the older SSL protocol and require that only TLS be used.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This is the recommended version of TLS to use with secure connections.

dwOptions

A value which specifies one or options. This member is constructed by using a bitwise operator with any of the following values:

Constant	Description
CREDENTIAL_STORE_CURRENT_USER	The library will attempt to open a store for the current user using the certificate store name provided in this structure. If no options are specified, then this is the default behavior.
CREDENTIAL_STORE_LOCAL_MACHINE	The library will attempt to open a local machine store using the certificate store name provided in this structure. If this option is specified, the library will always search for a local machine store before searching for the store by that name for the current user.
CREDENTIAL_STORE_FILENAME	The certificate store name is a file that contains the certificate and private key that

will be used.

dwReserved

This structure member is reserved for future use and should always be initialized to zero.

lpszHostName

A pointer to a null terminated string which specifies the hostname that will be used when validating the server certificate. If this member is NULL, then the server certificate will be validated against the hostname used to establish the connection.

lpszUserName

A pointer to a null terminated string which identifies the owner of client certificate. Currently this member is not used by the library and should always be initialized as a NULL pointer.

lpszPassword

A pointer to a null terminated string which specifies the password needed to access the certificate. Currently this member is only used if the CREDENTIAL_STORE_FILENAME option has been specified. If there is no password associated with the certificate, then this member should be initialized as a NULL pointer.

lpszCertStore

A pointer to a null terminated string which specifies the name of the certificate store to open. A certificate store is a collection of certificates and their private keys, typically organized by how they are used. If this value is NULL or points to an empty string, the default certificate store "MY" will be used.

Store Name	Description
------------	-------------

CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as VeriSign and Thawte act as certification authorities.
----	---

MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. This corresponds to the "Personal" store that is displayed by the certificate manager utility and is the default store used by the library.
----	--

ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as VeriSign and Thawte are installed as part of the operating system and periodically updated by Microsoft.
------	--

lpszCertName

A pointer to a null terminated string which specifies the name of the certificate to use. The library will first search the certificate store for a certificate with a matching "friendly name"; this is a name for the certificate that is assigned by the user. Note that the name must match completely, but the comparison is not case sensitive. If no matching certificate is found, the library will then attempt to find a certificate that has a matching common name (also called the certificate subject). This comparison is less stringent, and the first partial match will be returned. If this second search fails, the library will return an error indicating that the certificate could not be found. If the SECURITY_PROTOCOL_SSH protocol has been specified, this member should be NULL.

lpszKeyFile

A pointer to a null terminated string which specifies the name of the file which contains the private key required to establish the connection. This member is only used for SSH connections

and should always be NULL when establishing a secure connection using SSL or TLS.

Remarks

A client application only needs to create this structure if the server requires that the client provide a certificate as part of the process of negotiating the secure session. If a certificate is required, note that it must have a private key associated with it. Attempting to use a certificate that does not have a private key will result in an error during the connection process indicating that the client credentials could not be established.

If you are using a local certificate store, with the certificate and private key stored in the registry, you can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU:" for the current user, or "HKLM:" for the local machine. For example, a certificate store name of "HKLM:MY" would specify the personal certificate store for the local machine, rather than the current user. If neither prefix is specified, then it will default to the certificate store for the current user. You can manage these certificates using the CertMgr.msc Microsoft Management Console (MMC) snap-in.

It is possible to load the certificate from a file rather than from current user's certificate store. The *dwOptions* member should be set to CREDENTIAL_STORE_FILENAME and the *lpzCertStore* member should specify the name of the file that contains the certificate and its private key. The file must be in Private Information Exchange (PFX) format, also known as PKCS#12. These certificate files typically have an extension of .pfx or .p12. Note that if a password was specified when the certificate file was created, it must be provided in the *lpzPassword* member or the library will be unable to access the certificate.

Note that the *lpzUserName* and *lpzPassword* members are values which are used to access the certificate store or private key file. They are not the credentials which are used when establishing the connection with the remote host or authenticating the client session.

The TLS 1.1 and TLS 1.2 protocols are only supported on Windows 7, Windows Server 2008 R2 and later versions of the platform. If these options are specified and the application is running on Windows XP or Windows Vista, the protocol version will be downgraded to TLS 1.0 for backwards compatibility with those platforms.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include ctools10.h

Unicode: Implemented as Unicode and ANSI versions.

Hypertext Transfer Protocol Client Library

Transfer files between the local system and a web server, execute scripts and perform remote file management functions.

Reference

- [Data Structures](#)
- [Error Codes](#)

Library Information

File Name	CSHTPV10.DLL
Version	10.0.1468.2518
LibID	FAA72D93-4063-474E-97DE-25BA304E1098
Import Library	CSHTPV10.LIB
Dependencies	None
Standards	RFC 1945, RFC 2616

Overview

The Hypertext Transfer Protocol (HTTP) is a lightweight, stateless application protocol that is used to access resources on web servers, as well as send data to those servers for processing. The library provides direct, low-level access to the server and the commands that are used to retrieve resources (i.e.: documents, images, etc.). The library also provides a simple interface for downloading resources to the local host, similar to how the HTTP library can be used to download files.

In a typical session, the library is used to establish a connection, send a request (to download a resource, post data for processing, etc.), read the data returned by the server and then disconnect. It is the responsibility of the client to process the data returned by the server, depending on the type of resource that was requested.

This library supports secure connections using the standard SSL and TLS protocols.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). If you are using Visual C++ 6.0 it is required that you have Service Pack 6 (SP6) installed. You should install all updates for your development tools and have the current Windows SDK installed. The minimum recommended version of Visual Studio is Visual Studio 2010.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are using Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. It is recommended that you install the current service pack and all critical updates available for your version of the operating system.

This product includes both 32-bit and 64-bit libraries. Native 64-bit CPU support requires the 64-bit version of Windows 7 or later versions of the Windows operating system.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

Hypertext Transfer Protocol Functions

Function	Description
HttpAddFormField	Add the form field and its value to the specified form
HttpAddFormFile	Add the contents of the file to the specified form
HttpAsyncConnect	Establish an asynchronous connection to the specified server
HttpAsyncGetData	Copy the contents of a resource on the server to a local buffer
HttpAsyncGetFile	Copy a file from the server to the local system
HttpAsyncGetFileEx	Copy a file from the server to the local system, use with files larger than 4GB
HttpAsyncPostData	Post data from a local buffer to a script executed on the server
HttpAsyncPostJson	Post JSON formatted data to a script executed on the server
HttpAsyncPostXml	Post XML formatted data to a script executed on the server
HttpAsyncProxyConnect	Establish an asynchronous connection to a proxy server
HttpAsyncPutData	Create a file on the server using the contents of a local buffer
HttpAsyncPutFile	Copy a file from the local system to the server
HttpAsyncPutFileEx	Copy a file from the local system to the server, use with files larger than 4GB
HttpAsyncSubmitForm	Submit the specified form to the server for processing
HttpAttachThread	Attach the specified client handle to another thread
HttpAuthenticate	Specify authentication information for restricted resources
HttpCancel	Cancel the current blocking operation
HttpClearForm	Remove all defined fields from the specified form
HttpCloseFile	Close the file opened on the server
HttpCommand	Send a command to the server
HttpConnect	Connect to the specified server
HttpConnectUrl	Establish a client connection using the specified URL
HttpCreateFile	Create or replace a file on the server
HttpCreateForm	Create a new form and return the form handle
HttpCreateSecurityCredentials	Create a new security credentials structure
HttpDeleteFile	Remove a file from the server
HttpDeleteFormField	Delete the form field and its value from the specified form
HttpDeleteHeaders	Delete all of the response or request headers for the current session
HttpDeleteSecurityCredentials	Delete a previously created security credentials structure
HttpDestroyForm	Destroy the specified form and free the memory allocated for it

HttpDisableEvents	Disable asynchronous event notification
HttpDisableTrace	Disable logging of socket function calls to the trace log
HttpDisconnect	Disconnect from the current server
HttpDownloadFile	Download a file from the server to the local system
HttpEnableCompression	Enable or disable support for data compression
HttpEnableEvents	Enable asynchronous event notification
HttpEnableTrace	Enable logging of socket function calls to a file
HttpEnumTasks	Return a list of asynchronous tasks
HttpEventProc	Callback function that processes events generated by the client
HttpFreezeEvents	Suspend asynchronous event processing
HttpGetBearerToken	Return the current OAuth 2.0 bearer token for the client session
HttpGetCookie	Return information about the specified cookie
HttpGetData	Copy the specified resource to a local buffer
HttpGetEncodingType	Determines which content encoding option is enabled
HttpGetErrorString	Return a description for the specified error code
HttpGetFile	Copy a file from the server to the local system
HttpGetFileEx	Copy a file from the server to the local system, use with large files over 4GB
HttpGetFileSize	Return the size of a file on the server
HttpGetFileSizeEx	Return the size of a file on the server, supports large files over 4GB
HttpGetFileTime	Return the date and time a file on the server was last modified
HttpGetFirstCookie	Return the first cookie set by the server
HttpGetFirstHeader	Return the name and value of the first request or response header field
HttpGetFormProperties	Return the properties of the specified form
HttpGetLastError	Return the last error code
HttpGetNextCookie	Return the next cookie set by the server
HttpGetNextHeader	Return the name and value of the next request or response header field
HttpGetOption	Return the enabled/disabled state of a specified option
HttpGetPriority	Return the current priority for file transfers
HttpGetRequestHeader	Return the value of the specified request header field
HttpGetResponseHeader	Return the value of the specified response header field
HttpGetResultCode	Return the result code from the previous command
HttpGetResultString	Return the result string from the previous command
HttpGetSecurityInformation	Return security information about the current client connection
HttpGetStatus	Return the current client status

HttpGetTaskError	Return the last error code for the specified asynchronous task
HttpGetTaskId	Return the unique task identifier associated with the specified client session
HttpGetText	Download the contents of a text file or resource to a string buffer
HttpGetTimeout	Return the number of seconds until an operation times out
HttpGetTransferStatus	Return data transfer statistics
HttpInitialize	Initialize the library and validate the specified runtime license key
HttpIsBlocking	Determine if the client is blocked, waiting for information
HttpIsConnected	Determine if the client is connected to the server
HttpIsReadable	Determine if data can be read from the server
HttpIsWritable	Determine if data can be written to the server
HttpOpenFile	Open a file on the server for reading
HttpPatchData	Submits JSON or XML patch data to the server and returns the response
HttpPostData	Submit data to the server using the POST command and returns the response
HttpPostFile	Submit the contents of a local file to the server
HttpPostJson	Post JSON formatted data to the server and returns the response
HttpPostXml	Post XML formatted data to the server and returns the response
HttpProxyConnect	Establish a connection with the specified proxy server
HttpPutData	Create a file on the server using the contents of a local buffer
HttpPutDataEx	Submit data to the server using the PUT command and returns the response
HttpPutFile	Copy a file from the local system to the server
HttpPutFileEx	Copy a file from the local system to the server, use with large files over 4GB
HttpPutText	Create a text file on the server from the contents of a string buffer
HttpPutTextEx	Submit text to the server using the PUT command and returns the response
HttpRead	Read data from the server
HttpRegisterEvent	Register an event callback function
HttpSetBearerToken	Set the value of the OAuth 2.0 bearer token for the client session
HttpSetCookie	Set the value of the specified cookie
HttpSetEncodingType	Specifies the type of encoding to be applied to data submitted to the server
HttpSetFormProperties	Modify the properties of the specified form
HttpSetLastError	Set the last error code
HttpSetOption	Enable or disable the specified option

HttpSetPriority	Set the priority for file transfers
HttpSetRequestHeader	Set the value of a request header field
HttpSetTimeout	Set the number of seconds until an operation times out
HttpSubmitForm	Submit the specified form to the server for processing
HttpTaskAbort	Abort the specified asynchronous task
HttpTaskDone	Determine if an asynchronous task has completed
HttpTaskResume	Resume execution of an asynchronous task
HttpTaskSuspend	Suspend execution of an asynchronous task
HttpTaskWait	Wait for an asynchronous task to complete
HttpUninitialize	Terminate use of the library by the application
HttpUploadFile	Upload a file from the local system to the server
HttpValidateUrl	Check the contents of a string to ensure it represents a valid URL
HttpVerifyFile	Compare the size of a local file against a file stored on the server
HttpWrite	Write data to the server

HttpAddFormField Function

```
INT WINAPI HttpAddFormField(  
    HFORM hForm,  
    LPCTSTR lpszFieldName,  
    LPVOID lpFieldData,  
    DWORD cbFieldData,  
    DWORD dwReserved  
);
```

The **HttpAddFormField** function adds a new field to the specified form.

Parameters

hForm

Handle to the virtual form.

lpszFieldName

A pointer to a string which specifies the name of the field to add to the form. If this parameter is NULL or points to an empty string, then a default field name will be assigned.

lpFieldData

A pointer to the form field data. Typically this will either be a pointer to an array of bytes or a string which specifies the value for the form field. If no data is to be associated with the form field, then this argument may be NULL.

cbFieldData

An unsigned integer value which specifies the number of bytes of data in the form field. If this value is 0xFFFFFFFF (-1) then it is assumed that the *lpFieldData* parameter is a pointer to a null-terminated string. If *lpFieldData* is NULL, this value must be zero.

dwReserved

A reserved parameter. This value must be zero.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpAddFormField** function is used to add a field and its associated value to a form created using the **HttpCreateForm** function. If the field name has already been added to the form, the previous value is deleted and replaced by the new value.

Example

```
HFORM hForm = INVALID_FORM;  
HGLOBAL hgb1Result = (HGLOBAL)NULL;  
DWORD cbResult = 0;  
INT nResult = 0;  
  
hForm = HttpCreateForm(_T("/login.php"), HTTP_METHOD_POST, HTTP_FORM_ENCODED);  
  
if (hForm == INVALID_FORM)  
    return;  
  
HttpAddFormField(hForm, _T("UserName"), lpszUserName, (DWORD)-1L, 0);  
HttpAddFormField(hForm, _T("Password"), lpszPassword, (DWORD)-1L, 0);
```

```
nResult = HttpSubmitForm(hClient, hForm, &hgblResult, &cbResult, 0);
HttpDestroyForm(hForm);

if (hgblResult != NULL)
{
    LPBYTE lpBuffer = (LPBYTE)GlobalLock(hgblResult);

    // lpBuffer points to data returned by the server after the form
    // data was submitted

    GlobalUnlock(hgblResult);
    GlobalFree(hgblResult);
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cshttpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[HttpAddFormFile](#), [HttpClearForm](#), [HttpCreateForm](#), [HttpDeleteFormField](#), [HttpSubmitForm](#)

HttpAddFormFile Function

```
INT WINAPI HttpAddFormFile(  
    HFORM hForm,  
    LPCTSTR lpszFieldName,  
    LPCTSTR lpszFileName,  
    DWORD dwReserved  
);
```

The **HttpAddFormFile** function adds the contents of a file to the specified form.

Parameters

hForm

Handle to the virtual form.

lpszFieldName

A pointer to a string which specifies the name of the field to add to the form. If this parameter is NULL or points to an empty string, then a default field name will be assigned.

lpszFileName

A pointer to a string which specifies the name of the file. The contents of the file will be added to the form data that is submitted to the server.

dwReserved

A reserved parameter. This value must be zero.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cshttpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[HttpAddFormField](#), [HttpClearForm](#), [HttpCreateForm](#), [HttpDeleteFormField](#), [HttpPostFile](#), [HttpSubmitForm](#)

HttpAsyncConnect Function

```
HCLIENT WINAPI HttpAsyncConnect(  
    LPCTSTR lpszRemoteHost,  
    UINT nRemotePort,  
    UINT nTimeout,  
    DWORD dwOptions,  
    DWORD dwVersion,  
    LPSECURITYCREDENTIALS lpCredentials,  
    HWND hEventWnd,  
    UINT uEventMsg  
);
```

The **HttpAsyncConnect** function is used to establish a connection with the server.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

The application should create a background worker thread and establish a connection by calling **HttpConnect** within that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each client session.

Parameters

lpszRemoteHost

A pointer to the name of the server to connect to. This may be a fully-qualified domain name or an IP address.

nRemotePort

The port number the server is listening on. A value of zero specifies that the default port number should be used. For standard connections, the default port number is 80. For secure connections, the default port number is 443.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
HTTP_OPTION_NOCACHE	This instructs the server to not return a cached copy of the resource. When connected to an HTTP 1.0 or earlier server, this directive may be ignored.
HTTP_OPTION_KEEPALIVE	This instructs the server to maintain a persistent connection between requests. This can improve performance because it eliminates the need to establish a separate connection for each resource that is requested. If the server does not support

	<p>the keep-alive option, the client will automatically reconnect when each resource is requested. Although it will not provide any performance benefits, this allows the option to be used with all servers.</p>
HTTP_OPTION_REDIRECT	<p>This option specifies the client should automatically handle resource redirection. If the server indicates that the requested resource has moved to a new location, the client will close the current connection and request the resource from the new location. Note that it is possible that the redirected resource will be located on a different server.</p>
HTTP_OPTION_PROXY	<p>This option specifies the client should use the default proxy configuration for the local system. If the system is configured to use a proxy server, then the connection will be automatically established through that proxy; otherwise, a direct connection to the server is established. The local proxy configuration can be changed using the system Control Panel.</p>
HTTP_OPTION_ERRORDATA	<p>This option specifies the client should return the content of an error response from the server, rather than returning an error code. Note that this option will disable automatic resource redirection, and should not be used with HTTP_OPTION_REDIRECT.</p>
HTTP_OPTION_TUNNEL	<p>This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established.</p>
HTTP_OPTION_TRUSTEDSITE	<p>This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using either the SSL or TLS protocols.</p>
HTTP_OPTION_SECURE	<p>This option specifies the client should attempt to establish a secure connection with the server. Note that the server must support secure connections using either the SSL or TLS protocol.</p>
HTTP_OPTION_SECURE_FALLBACK	<p>This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and</p>

	cipher suites that use RC4, MD5 and SHA1.
HTTP_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
HTTP_OPTION_FREETHREAD	This option specifies the handle returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the handle is synchronized across multiple threads.
HTTP_OPTION_HIRES_TIMER	This option specifies the elapsed time for data transfers should be returned in milliseconds instead of seconds. This will return more accurate transfer times for smaller amounts of data over fast network connections.

dwVersion

The requested protocol version used when sending requests to the server. The high word should specify the major version, and the low word should specify the minor version number. The HTTPVERSION macro can be used to create version value.

lpCredentials

Pointer to credentials structure [SECURITYCREDENTIALS](#). This parameter is only used if the HTTP_OPTION_SECURE option is specified for the connection. This parameter may be NULL, in which case no client credentials will be provided to the server. If client credentials are required, the fields *dwSize*, *lpzCertStore*, and *lpzCertName* must be defined, while other fields may be left undefined. Set *dwSize* to the size of the **SECURITYCREDENTIALS** structure.

hEventWnd

The handle to the event notification window. This window receives messages which notify the client of various asynchronous network events that occur.

uEventMsg

The message identifier that is used when an asynchronous network event occurs. This value should be greater than WM_USER as defined in the Windows header files.

Return Value

If the function succeeds, the return value is a handle to a client session. If the function fails, the return value is INVALID_CLIENT. To get extended error information, call **HttpGetLastError**.

Remarks

When a message is posted to the notification window, the low word of the *lParam* parameter contains the event identifier. The high word of *lParam* contains the low word of the error code, if an error has occurred. The *wParam* parameter contains the client handle. One or more of the

following event identifiers may be sent:

Constant	Description
HTTP_EVENT_CONNECT	The connection to the server has completed. The high word of the <i>lParam</i> parameter should be checked, since this notification message will be posted if an error has occurred.
HTTP_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
HTTP_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
HTTP_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
HTTP_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
HTTP_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.
HTTP_EVENT_COMMAND	A command has been issued by the client and the server response has been received and processed. This event can be used to log the result codes and messages returned by the server in response to actions taken by the client.
HTTP_EVENT_PROGRESS	The client is in the process of sending or receiving data from the server. This event is called periodically during a transfer so that the client can update any user interface components such as a status control or progress bar.
HTTP_EVENT_REDIRECT	This event is generated when a the server indicates that the requested resource has been moved to a new location. The new resource location may be on the same server, or it may be located on another server. Check the value of the Location header field to determine where the resource has been moved to.

To cancel asynchronous notification and return the client to a blocking mode, use the **HttpDisableEvents** function.

The *dwOptions* argument can be used to specify the threading model that is used by the library when a connection is established. By default, the handle is initially attached to the thread that created it. From that point on, until the it is released, only the owner may call functions using that handle. The ownership of the handle may be transferred from one thread to another using the

HttpAttachThread function.

Specifying the HTTP_OPTION_FREETHREAD option enables any thread to call any function using the handle, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the handle is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same handle.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cshttpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

HttpAsyncGetData Function

```
UINT WINAPI HttpAsyncGetData(  
    HCLIENT hClient,  
    LPCTSTR lpszResource,  
    LPVOID lpvBuffer,  
    LPDWORD lpdwLength,  
    DWORD dwOptions,  
    HTTPEVENTPROC lpEventProc,  
    DWORD_PTR dwParam  
);
```

Copies the contents of a resource on the server to the specified buffer.

Parameters

hClient

Handle to the client session.

lpszResource

A pointer to a string that specifies the resource on the server that will be transferred to the local system.

lpvBuffer

A pointer to a byte buffer which will contain the data transferred from the server, or a pointer to a global memory handle which will reference the data when the function returns.

lpdwLength

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the *lpvBuffer* parameter. If the *lpvBuffer* parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the actual length of the file that was downloaded.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
HTTP_TRANSFER_DEFAULT	The default transfer mode. The resource data is copied to the local system exactly as it is stored on the server.
HTTP_TRANSFER_CONVERT	If the resource being downloaded from the server is textual, the data is automatically converted so that the end of line character sequence is compatible with the Windows platform. Individual carriage return or linefeed characters are converted to carriage return/linefeed character sequences.
HTTP_TRANSFER_COMPRESS	This option informs the server that the client is willing to accept compressed data. If the server supports compression for the specified resource, then the data will be automatically expanded before being returned to the caller. This option is selected by default if compression has been enabled using the

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **HttpEventProc** callback function. This parameter may be NULL if you do not wish to implement an event handler.

dwParam

A user-defined integer value that is passed to the callback function. This parameter is ignored if the *lpEventProc* parameter is NULL.

Return Value

If the function succeeds, the return value is non-zero integer value that specifies a unique asynchronous task identifier. If the function fails, the return value is zero. To get extended error information, call the **HttpGetLastError** function. The application should treat the task ID as an opaque value and never make an assumption about the sequence in which IDs are assigned to a background task.

Remarks

The **HttpAsyncGetData** function is used to download the contents of a server resource into a local buffer. This function is similar to the **HttpGetData** function, however it retrieves the contents of the file using a background worker thread and does not block the current working thread. This enables the application to continue to perform other operations while the file is being copied to the local system.

Because this function works asynchronously, it is important that the memory allocated for the buffer is not released before the asynchronous task completes. If you provide a buffer that is allocated on the stack, such as with the example listed below, then you must ensure that your code does not return from the function while the data is being downloaded. In the example, this is achieved by calling the **HttpTaskWait** function. You can also perform other operation and poll the status of the task by calling the **HttpTaskDone** function. If you wish to return from the calling function immediately, then you must dynamically allocate memory for the *lpvBuffer* and *lpdwLength* parameters on the heap and free that memory after the task has completed and the data is no longer needed.

If the address of an event handler is provided to this function, it is guaranteed that the handler will be invoked with the HTTP_EVENT_CONNECT event after the connection has been established, and the HTTP_EVENT_DISCONNECT event after the transfer has completed. This enables your application to know when the data transfer is about to begin, and immediately before the worker thread is terminated. The worker thread creates a secondary connection to the server with its own session handle. This ensures that the asynchronous operation will not interfere with the current client session. Your application can interact with this background worker thread using the client handle that is passed to the event handler.

The *lpvBuffer* parameter may be specified in one of two ways, depending on the needs of the application. It can either be a pre-allocated buffer large enough to store the contents of the file or it can specify the address of a global memory handle that will contain the data. If it points to a pre-allocated buffer, the *lpdwLength* parameter must be initialized to the maximum number of bytes that can be copied into the buffer. If specifies the address of a global memory handle, then *lpdwLength* must be initialized to a value of zero. See the example code below.

Example

```
HGLOBAL hgb1Buffer = NULL;
```

```

DWORD dwLength = 0;
UINT nTaskId;

// Copy the data into block of global memory allocated by
// the GlobalAlloc function; the handle to this memory will be
// returned in the hgb1Buffer parameter

nTaskId = HttpAsyncGetData(hClient,
                           lpszResource,
                           &hgb1Buffer,
                           &dwLength,
                           HTTP_TRANSFER_DEFAULT,
                           NULL, 0);

if (nTaskId != 0)
{
    DWORD dwError = NO_ERROR;
    DWORD dwElapsed = 0;

    // Wait for the transfer to complete
    HttpTaskWait(nTaskId, INFINITE, &dwElapsed, &dwError);

    // Lock the global memory handle, returning a pointer to the
    // contents of the file data
    lpBuffer = (LPBYTE)GlobalLock(hgb1Buffer);

    // After the data has been used, the handle must be unlocked
    // and freed, otherwise a memory leak will occur
    GlobalUnlock(hgb1Buffer);
    GlobalFree(hgb1Buffer);
}

```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cshttpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

HttpAsyncGetFile Function

```
UINT WINAPI HttpAsyncGetFile(  
    HCLIENT hClient,  
    LPCTSTR lpszLocalFile,  
    LPCTSTR lpszRemoteFile,  
    DWORD dwOptions,  
    DWORD dwOffset,  
    HTTPEVENTPROC lpEventProc,  
    DWORD_PTR dwParam  
);
```

Downloads the specified file from the server to the local system.

Parameters

hClient

Handle to the client session.

lpszLocalFile

A pointer to a string that specifies the file on the local system that will be created, overwritten or appended to. The file pathing and name conventions must be that of the local host.

lpszRemoteFile

A pointer to a string that specifies the file on the server that will be transferred to the local system.

dwOptions

An unsigned integer that specifies one or more options. This parameter may be any one of the following values:

Constant	Description
HTTP_TRANSFER_DEFAULT	The default transfer mode. The resource data is copied to the local system exactly as it is stored on the server.
HTTP_TRANSFER_CONVERT	If the resource being downloaded from the server is textual, the data is automatically converted so that the end of line character sequence is compatible with the Windows platform. Individual carriage return or linefeed characters are converted to carriage return/linefeed character sequences.
HTTP_TRANSFER_COMPRESS	This option informs the server that the client is willing to accept compressed data. If the server supports compression for the specified resource, then the data will be automatically expanded before being returned to the caller. This option is selected by default if compression has been enabled using the HttpEnableCompression function. This option is ignored if the <i>dwOffset</i> parameter is non-zero.

dwOffset

A byte offset which specifies where the file transfer should begin. The default value of zero specifies that the file transfer should start at the beginning of the file. A value greater than zero

is typically used to restart a transfer that has not completed successfully. Note that specifying a non-zero offset requires that the server support the REST command to restart transfers.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **HttpEventProc** callback function. This parameter may be NULL if you do not wish to implement an event handler.

dwParam

A user-defined integer value that is passed to the callback function. This parameter is ignored if the *lpEventProc* parameter is NULL.

Return Value

If the function succeeds, the return value is non-zero integer value that specifies a unique asynchronous task identifier. If the function fails, the return value is zero. To get extended error information, call the **HttpGetLastError** function. The application should treat the task ID as an opaque value and never make an assumption about the sequence in which IDs are assigned to a background task.

Remarks

The **HttpAsyncGetFile** function is used to download the contents of a remote file to a file on the local system. This function is similar to the **HttpGetFile** function, however it retrieves the file using a background worker thread and does not block the current working thread. This enables the application to continue to perform other operations while the file is being transferred to the local system.

If the address of an event handler is provided to this function, it is guaranteed that the handler will be invoked with the HTTP_EVENT_CONNECT event after the connection has been established, and the HTTP_EVENT_DISCONNECT event after the transfer has completed. This enables your application to know when the file transfer is about to begin, and immediately before the worker thread is terminated. During the file transfer, the callback function will be invoked periodically with the HTTP_EVENT_PROGRESS event. The client session handle is passed to the event handler, allowing you to call functions such as **HttpGetTransferStatus** to determine the amount of data that has been copied.

To determine when the transfer has completed without implementing an event handler, periodically call the **HttpTaskDone** function. If you wish to block the current thread and wait for the transfer to complete, call the **HttpTaskWait** function. To stop a background file transfer that is in progress, call the **HttpTaskAbort** function. This will signal the background worker thread to cancel the transfer and terminate the session.

This function can be called multiple times to download multiple files in the background; however, most servers limit the number of simultaneous connections that can originate from a single IP address. It is recommended that you only perform two simultaneous background transfers from the same server at any one time. The application should not make any assumptions about the order in which multiple background transfers may complete or how they are sequenced. For example, it should never be assumed that a background task with a lower task ID will complete before a task with a higher ID value.

Example

```
UINT nTaskId;  
  
// Begin a file transfer in the background
```

```
nTaskId = HttpAsyncGetFile(hClient,
                           lpszLocalFile,
                           lpszRemoteFile,
                           HTTP_TRANSFER_DEFAULT,
                           0, NULL, 0);

if (nTaskId != 0)
{
    DWORD dwError = NO_ERROR;
    DWORD dwElapsed = 0;

    // Wait for the transfer to complete
    HttpTaskWait(nTaskId, INFINITE, &dwElapsed, &dwError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cshttpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

HttpAsyncGetFileEx Function

```
UINT WINAPI HttpAsyncGetFileEx(  
    HCLIENT hClient,  
    LPCTSTR lpszLocalFile,  
    LPCTSTR lpszRemoteFile,  
    DWORD dwOptions,  
    ULARGE_INTEGER uiOffset,  
    HTTPEVENTPROC lpEventProc,  
    DWORD_PTR dwParam  
);
```

Downloads the specified file from the server to the local system. This version of the function is designed to support files that are larger than 4GB.

Parameters

hClient

Handle to the client session.

lpszLocalFile

A pointer to a string that specifies the file on the local system that will be created, overwritten or appended to. The file pathing and name conventions must be that of the local host.

lpszRemoteFile

A pointer to a string that specifies the file on the server that will be transferred to the local system. The file naming conventions must be that of the host operating system.

dwOptions

An unsigned integer that specifies one or more options. This parameter may be any one of the following values:

Constant	Description
HTTP_TRANSFER_DEFAULT	The default transfer mode. The resource data is copied to the local system exactly as it is stored on the server.
HTTP_TRANSFER_CONVERT	If the resource being downloaded from the server is textual, the data is automatically converted so that the end of line character sequence is compatible with the Windows platform. Individual carriage return or linefeed characters are converted to carriage return/linefeed character sequences.
HTTP_TRANSFER_COMPRESS	This option informs the server that the client is willing to accept compressed data. If the server supports compression for the specified resource, then the data will be automatically expanded before being returned to the caller. This option is selected by default if compression has been enabled using the HttpEnableCompression function. This option is ignored if the <i>dwOffset</i> parameter is non-zero.

uiOffset

A byte offset which specifies where the file transfer should begin. The default value of zero

specifies that the file transfer should start at the beginning of the file. A value greater than zero is typically used to restart a transfer that has not completed successfully. Note that specifying a non-zero offset requires that the server support the REST command to restart transfers.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **HttpEventProc** callback function. This parameter may be NULL if you do not wish to implement an event handler.

dwParam

A user-defined integer value that is passed to the callback function. This parameter is ignored if the *lpEventProc* parameter is NULL.

Return Value

If the function succeeds, the return value is non-zero integer value that specifies a unique asynchronous task identifier. If the function fails, the return value is zero. To get extended error information, call the **HttpGetLastError** function. The application should treat the task ID as an opaque value and never make an assumption about the sequence in which IDs are assigned to a background task.

Remarks

The **HttpAsyncGetFileEx** function is used to download the contents of a remote file to a file on the local system. This function is similar to the **HttpGetFileEx** function, however it retrieves the file using a background worker thread and does not block the current working thread. This enables the application to continue to perform other operations while the file is being transferred to the local system.

If the address of an event handler is provided to this function, it is guaranteed that the handler will be invoked with the HTTP_EVENT_CONNECT event after the connection has been established, and the HTTP_EVENT_DISCONNECT event after the transfer has completed. This enables your application to know when the file transfer is about to begin, and immediately before the worker thread is terminated. During the file transfer, the callback function will be invoked periodically with the HTTP_EVENT_PROGRESS event. The client session handle is passed to the event handler, allowing you to call functions such as **HttpGetTransferStatusEx** to determine the amount of data that has been copied.

To determine when the transfer has completed without implementing an event handler, periodically call the **HttpTaskDone** function. If you wish to block the current thread and wait for the transfer to complete, call the **HttpTaskWait** function. To stop a background file transfer that is in progress, call the **HttpTaskAbort** function. This will signal the background worker thread to cancel the transfer and terminate the session.

This function can be called multiple times to download multiple files in the background; however, most servers limit the number of simultaneous connections that can originate from a single IP address. It is recommended that you only perform two simultaneous background transfers from the same server at any one time. The application should not make any assumptions about the order in which multiple background transfers may complete or how they are sequenced. For example, it should never be assumed that a background task with a lower task ID will complete before a task with a higher ID value.

Requirements

HttpAsyncPostData Function

```
UINT WINAPI HttpAsyncPostData(  
    HCLIENT hClient,  
    LPCTSTR lpszResource,  
    LPVOID lpvBuffer,  
    DWORD cbBuffer,  
    LPVOID lpvResult,  
    LPDWORD lpcbResult,  
    DWORD dwOptions,  
    HTTPEVENTPROC LpEventProc,  
    DWORD_PTR dwParam  
);
```

Post data from a local buffer to a script executed on the server.

Parameters

hClient

Handle to the client session.

lpszResource

A pointer to a string that specifies the resource that the data will be posted to on the server. Typically this is the name of a script that will be executed. This string may specify a valid URL for the current server that the client is connected to.

lpvBuffer

A pointer to the data that will be provided to the script. This parameter may be NULL if the script does not require any additional data from the client.

cbBuffer

The number of bytes to copy from the buffer. If this *lpvBuffer* parameter is NULL, this value should be zero.

lpvResult

A pointer to a byte buffer which will contain the data returned by the server, or a pointer to a global memory handle which will reference the data when the function returns.

lpcbResult

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the *lpvBuffer* parameter. If the *lpvResult* parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the actual number of bytes of data that was returned.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
HTTP_POST_DEFAULT	The default post mode. The contents of the buffer are encoded and sent as standard form data. The data returned by the server is copied to the result buffer exactly as it is returned from the server.

HTTP_POST_CONVERT	If the data being returned from the server is textual, it is automatically converted so that the end of line character sequence is compatible with the Windows platform. Individual carriage return or linefeed characters are converted to carriage return/linefeed character sequences. Note that this option does not have any effect on the form data being submitted to the server, only on the data returned by the server.
HTTP_POST_MULTIPART	The contents of the buffer being sent to the server consists of multipart form data and will be sent as-is without any encoding.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **HttpEventProc** callback function. This parameter may be NULL if you do not wish to implement an event handler.

dwParam

A user-defined integer value that is passed to the callback function. This parameter is ignored if the *lpEventProc* parameter is NULL.

Return Value

If the function succeeds, the return value is non-zero integer value that specifies a unique asynchronous task identifier. If the function fails, the return value is zero. To get extended error information, call the **HttpGetLastError** function. The application should treat the task ID as an opaque value and never make an assumption about the sequence in which IDs are assigned to a background task.

Remarks

The **HttpAsyncPostData** function is used to submit data to a script that executes on the server and then copy the output from that script into a local buffer. This function is similar to the **HttpPostData** function, however it submits the data using a background worker thread and does not block the current working thread. This enables the application to continue to perform other operations while the data is being sent and the response from the server is being returned to the caller.

Because this function works asynchronously, it is important that the memory allocated for the *lpvBuffer* and *lpvResult* parameters will not be released before the asynchronous task completes. If you provide pointers to memory that is allocated on the stack, ensure that your code does not return from the function until the background task completes. This can be achieved by calling the **HttpTaskWait** function or periodically calling the **HttpTaskDone** function to determine if the operation has completed. If you wish to return from the calling function immediately, then you must dynamically allocate memory on the heap and free that memory after the task has completed and the data is no longer needed.

If the address of an event handler is provided to this function, it is guaranteed that the handler will be invoked with the HTTP_EVENT_CONNECT event after the connection has been established, and the HTTP_EVENT_DISCONNECT event after the transfer has completed. This enables your application to know when the file transfer is about to begin, and immediately before the worker thread is terminated.

The *lpvResult* parameter may be specified in one of two ways, depending on the needs of the

application. It can either be a pre-allocated buffer large enough to store the contents of the server response or it can specify the address of a global memory handle that will contain the data. If it points to a pre-allocated buffer, the *lpcbResult* parameter must be initialized to the maximum number of bytes that can be copied into the buffer. If specifies the address of a global memory handle, then *lpcbResult* must be initialized to a value of zero. See the example code below.

If you wish to submit XML formatted data to the server, it is recommended that you use the **HttpAsyncPostXml** function instead.

Example

```
HGLOBAL hgblBuffer = (HGLOBAL)NULL;
LPBYTE lpBuffer = (LPBYTE)NULL;
DWORD cbBuffer = 0;
UINT nTaskId;

// Store the script output into block of global memory allocated by
// the GlobalAlloc function; the handle to this memory will be
// returned in the hgblBuffer parameter. Since the output from the
// script is textual, the HTTP_POST_CONVERT option is used

nTaskId = HttpAsyncPostData(hClient,
                           lpzResource,
                           lpParameters,
                           cbParameters,
                           &hgblBuffer,
                           &cbBuffer,
                           HTTP_POST_CONVERT,
                           NULL, 0);

if (nTaskId != 0)
{
    DWORD dwError = NO_ERROR;
    DWORD dwElapsed = 0;

    // Wait for the task to complete
    HttpTaskWait(nTaskId, INFINITE, &dwElapsed, &dwError);

    // Lock the global memory handle, returning a pointer to the
    // output data from the script
    lpBuffer = (LPBYTE)GlobalLock(hgblBuffer);

    // After the data has been used, the handle must be unlocked
    // and freed, otherwise a memory leak will occur
    GlobalUnlock(hgblBuffer);
    GlobalFree(hgblBuffer);
}
```

HttpAsyncPostJson Function

```
UINT WINAPI HttpAsyncPostJson(  
    HCLIENT hClient,  
    LPCTSTR lpszResource,  
    LPCTSTR lpszJsonData,  
    LPVOID lpvResult,  
    LPDWORD lpcbResult,  
    DWORD dwOptions,  
    HTTPEVENTPROC lpEventProc,  
    DWORD_PTR dwParam  
);
```

Submit JSON formatted data to the server and return the response to the caller.

Parameters

hClient

Handle to the client session.

lpszResource

A pointer to a string that specifies the resource name that the JSON data will be submitted to. Typically this is the name of a script on the server.

lpszJsonData

A pointer to a string that specifies the JSON data that will be submitted to the server.

lpvResult

A pointer to a byte buffer which will contain the data returned by the server, or a pointer to a global memory handle which will reference the data when the function returns.

lpcbResult

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the *lpvBuffer* parameter. If the *lpvResult* parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the actual number of bytes of data that was returned.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
HTTP_POST_DEFAULT	The default post mode. The contents of the buffer are encoded and sent as standard form data. The data returned by the server is copied to the result buffer exactly as it is returned from the server.
HTTP_POST_CONVERT	If the data being returned from the server is textual, it is automatically converted so that the end of line character sequence is compatible with the Windows platform. Individual carriage return or linefeed characters are converted to carriage return/linefeed character sequences. Note that this option does not have any effect on the form data being submitted to the server, only on the data returned by the

server.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **HttpEventProc** callback function. This parameter may be NULL if you do not wish to implement an event handler.

dwParam

A user-defined integer value that is passed to the callback function. This parameter is ignored if the *lpEventProc* parameter is NULL.

Return Value

If the function succeeds, the return value is non-zero integer value that specifies a unique asynchronous task identifier. If the function fails, the return value is zero. To get extended error information, call the **HttpGetLastError** function. The application should treat the task ID as an opaque value and never make an assumption about the sequence in which IDs are assigned to a background task.

Remarks

The **HttpAsyncPostJson** function is used to submit JSON formatted data to a script that executes on the server and then copy the output from that script into a local buffer. It automatically sets the correct content type and encoding required for submitting JSON data to a server, however it does not parse the JSON data itself to ensure that it is well-formed. Your application is responsible for ensuring that the JSON data that is being submitted to the server is formatted correctly. This function is similar to the **HttpPostJson** function, however it submits the data using a background worker thread and does not block the current working thread.

Because this function works asynchronously, it is important that the memory allocated for the *lpzJsonData* and *lpvResult* parameters will not be released before the asynchronous task completes. If you provide pointers to memory that is allocated on the stack, ensure that your code does not return from the function until the background task completes. This can be achieved by calling the **HttpTaskWait** function or periodically calling the **HttpTaskDone** function to determine if the operation has completed. If you wish to return from the calling function immediately, then you must dynamically allocate memory on the heap and free that memory after the task has completed and the data is no longer needed.

If the address of an event handler is provided to this function, it is guaranteed that the handler will be invoked with the HTTP_EVENT_CONNECT event after the connection has been established, and the HTTP_EVENT_DISCONNECT event after the transfer has completed. This enables your application to know when the file transfer is about to begin, and immediately before the worker thread is terminated.

The *lpvResult* parameter may be specified in one of two ways, depending on the needs of the application. It can either be a pre-allocated buffer large enough to store the contents of the server response or it can specify the address of a global memory handle that will contain the data. If it points to a pre-allocated buffer, the *lpcbResult* parameter must be initialized to the maximum number of bytes that can be copied into the buffer. If specifies the address of a global memory handle, then *lpcbResult* must be initialized to a value of zero. See the example code below.

Example

```
HGLOBAL hgb1Buffer = (HGLOBAL)NULL;  
LPBYTE lpBuffer = (LPBYTE)NULL;  
DWORD cbBuffer = 0;
```

```

UINT nTaskId;

// Store the script output into block of global memory allocated by
// the GlobalAlloc function; the handle to this memory will be
// returned in the hgblBuffer parameter. Since the output from the
// script is textual, the HTTP_POST_CONVERT option is used

nTaskId = HttpAsyncPostJson(hClient,
                           lpszResource,
                           lpszJsonData,
                           &hgblBuffer,
                           &cbBuffer,
                           HTTP_POST_CONVERT,
                           NULL, 0);

if (nTaskId != 0)
{
    DWORD dwError = NO_ERROR;
    DWORD dwElapsed = 0;

    // Wait for the task to complete
    HttpTaskWait(nTaskId, INFINITE, &dwElapsed, &dwError);

    // Lock the global memory handle, returning a pointer to the
    // output data from the script
    lpBuffer = (LPBYTE)GlobalLock(hgblBuffer);

    // After the data has been used, the handle must be unlocked
    // and freed, otherwise a memory leak will occur
    GlobalUnlock(hgblBuffer);
    GlobalFree(hgblBuffer);
}

```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cshttpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

HttpAsyncPostXml Function

```
UINT WINAPI HttpAsyncPostXml(  
    HCLIENT hClient,  
    LPCTSTR lpszResource,  
    LPCTSTR lpszXmlData,  
    LPVOID lpvResult,  
    LPDWORD lpcbResult,  
    DWORD dwOptions,  
    HTTPEVENTPROC LpEventProc,  
    DWORD_PTR dwParam  
);
```

Submit XML formatted data to the server and return the response to the caller.

Parameters

hClient

Handle to the client session.

lpszResource

A pointer to a string that specifies the resource name that the XML data will be submitted to. Typically this is the name of a script on the server.

lpszXmlData

A pointer to a string that specifies the XML data that will be submitted to the server.

lpvResult

A pointer to a byte buffer which will contain the data returned by the server, or a pointer to a global memory handle which will reference the data when the function returns.

lpcbResult

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the *lpvBuffer* parameter. If the *lpvResult* parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the actual number of bytes of data that was returned.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
HTTP_POST_DEFAULT	The default post mode. The contents of the buffer are encoded and sent as standard form data. The data returned by the server is copied to the result buffer exactly as it is returned from the server.
HTTP_POST_CONVERT	If the data being returned from the server is textual, it is automatically converted so that the end of line character sequence is compatible with the Windows platform. Individual carriage return or linefeed characters are converted to carriage return/linefeed character sequences. Note that this option does not have any effect on the form data being submitted to the server, only on the data returned by the

server.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **HttpEventProc** callback function. This parameter may be NULL if you do not wish to implement an event handler.

dwParam

A user-defined integer value that is passed to the callback function. This parameter is ignored if the *lpEventProc* parameter is NULL.

Return Value

If the function succeeds, the return value is non-zero integer value that specifies a unique asynchronous task identifier. If the function fails, the return value is zero. To get extended error information, call the **HttpGetLastError** function. The application should treat the task ID as an opaque value and never make an assumption about the sequence in which IDs are assigned to a background task.

Remarks

The **HttpAsyncPostXml** function is used to submit XML formatted data to a script that executes on the server and then copy the output from that script into a local buffer. It automatically sets the correct content type and encoding required for submitting XML data to a server, however it does not parse the XML data itself to ensure that it is well-formed. Your application is responsible for ensuring that the XML data that is being submitted to the server is formatted correctly. This function is similar to the **HttpPostXml** function, however it submits the data using a background worker thread and does not block the current working thread.

Because this function works asynchronously, it is important that the memory allocated for the *lpSzXmlData* and *lpvResult* parameters will not be released before the asynchronous task completes. If you provide pointers to memory that is allocated on the stack, ensure that your code does not return from the function until the background task completes. This can be achieved by calling the **HttpTaskWait** function or periodically calling the **HttpTaskDone** function to determine if the operation has completed. If you wish to return from the calling function immediately, then you must dynamically allocate memory on the heap and free that memory after the task has completed and the data is no longer needed.

If the address of an event handler is provided to this function, it is guaranteed that the handler will be invoked with the HTTP_EVENT_CONNECT event after the connection has been established, and the HTTP_EVENT_DISCONNECT event after the transfer has completed. This enables your application to know when the file transfer is about to begin, and immediately before the worker thread is terminated.

The *lpvResult* parameter may be specified in one of two ways, depending on the needs of the application. It can either be a pre-allocated buffer large enough to store the contents of the server response or it can specify the address of a global memory handle that will contain the data. If it points to a pre-allocated buffer, the *lpcbResult* parameter must be initialized to the maximum number of bytes that can be copied into the buffer. If specifies the address of a global memory handle, then *lpcbResult* must be initialized to a value of zero. See the example code below.

Example

```
HGLOBAL hgb1Buffer = (HGLOBAL)NULL;  
LPBYTE lpBuffer = (LPBYTE)NULL;  
DWORD cbBuffer = 0;
```

```

UINT nTaskId;

// Store the script output into block of global memory allocated by
// the GlobalAlloc function; the handle to this memory will be
// returned in the hgblBuffer parameter. Since the output from the
// script is textual, the HTTP_POST_CONVERT option is used

nTaskId = HttpAsyncPostXml(hClient,
                          lpszResource,
                          lpszXmlData,
                          &hgblBuffer,
                          &cbBuffer,
                          HTTP_POST_CONVERT,
                          NULL, 0);

if (nTaskId != 0)
{
    DWORD dwError = NO_ERROR;
    DWORD dwElapsed = 0;

    // Wait for the task to complete
    HttpTaskWait(nTaskId, INFINITE, &dwElapsed, &dwError);

    // Lock the global memory handle, returning a pointer to the
    // output data from the script
    lpBuffer = (LPBYTE)GlobalLock(hgblBuffer);

    // After the data has been used, the handle must be unlocked
    // and freed, otherwise a memory leak will occur
    GlobalUnlock(hgblBuffer);
    GlobalFree(hgblBuffer);
}

```

HttpAsyncProxyConnect Function

```
HCLIENT WINAPI HttpAsyncProxyConnect(  
    UINT nProxyType,  
    LPCTSTR LpszProxyHost,  
    UINT nProxyPort,  
    LPCTSTR LpszProxyUser,  
    LPCTSTR LpszProxyPassword,  
    LPCTSTR LpszRemoteHost,  
    UINT nRemotePort,  
    UINT nTimeout,  
    DWORD dwOptions,  
    DWORD dwVersion,  
    LPSECURITYCREDENTIALS LpCredentials,  
    HWND hEventWnd,  
    UINT uEventMsg  
);
```

The **HttpAsyncProxyConnect** function is used to establish a connection with a proxy server.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

The application should create a background worker thread and establish a connection by calling **HttpProxyConnect** within that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each client session.

Parameters

nProxyType

An unsigned integer which specifies the type of proxy that the client is connecting to. The supported proxy server types are as follows:

Constant	Description
HTTP_PROXY_NONE	A direct connection will be established with the server. When this value is specified the proxy parameters are ignored.
HTTP_PROXY_STANDARD	A standard connection is established through the specified proxy server, and all resource requests will be specified using a complete URL. This proxy type should be used with standard connections.
HTTP_PROXY_SECURE	A secure connection is established through the specified proxy server. This proxy type should be used with secure connections and the HTTP_OPTION_SECURE option should also be set via the <i>dwOptions</i> parameter.
HTTP_PROXY_WINDOWS	The configuration options for the current system should be used. If the system is configured to use a proxy server, then the connection will be automatically established through that proxy; otherwise, a direct connection to the server is established. These settings are the same proxy server

lpszProxyHost

A pointer to a string which specifies the proxy server host name or IP address. This argument is ignored if the proxy type is set to HTTP_PROXY_NONE or HTTP_PROXY_WINDOWS and no proxy configuration has been specified for the local system.

nProxyPort

The port number that the proxy server is listening for connections on. A value of zero specifies that the default port number 80 should be used. Note that in most cases, a proxy server is not configured to use the default port. This argument is ignored if the proxy type is set to HTTP_PROXY_NONE or HTTP_PROXY_WINDOWS and no proxy configuration has been specified for the local system.

lpszProxyUser

A pointer to a string which specifies the user name that will be used to authenticate the client session to the proxy server. If the server does not require user authentication, then a NULL pointer may be passed in this argument.

lpszProxyPassword

A pointer to a string which specifies the password that will be used to authenticate the client session to the proxy server. If the server does not require user authentication, then a NULL pointer may be passed in this argument.

lpszRemoteHost

A pointer to a string which specifies the name of the server to connect to through the proxy server. This may be a fully-qualified domain name or an IP address.

nRemotePort

The port number the server is listening on. A value of zero specifies that the default port number should be used. For standard connections, the default port number is 80. For secure connections, the default port number is 443.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
HTTP_OPTION_NOCACHE	This instructs the server to not return a cached copy of the resource. When connected to an HTTP 1.0 or earlier server, this directive may be ignored.
HTTP_OPTION_KEEPALIVE	This instructs the server to maintain a persistent connection between requests. This can improve performance because it eliminates the need to establish a separate connection for each resource that is requested. If the server does not support the keep-alive option, the client will automatically reconnect when each resource is requested.

	Although it will not provide any performance benefits, this allows the option to be used with all servers.
HTTP_OPTION_REDIRECT	This option specifies the client should automatically handle resource redirection. If the server indicates that the requested resource has moved to a new location, the client will close the current connection and request the resource from the new location. Note that it is possible that the redirected resource will be located on a different server.
HTTP_OPTION_ERRORDATA	This option specifies the client should return the content of an error response from the server, rather than returning an error code. Note that this option will disable automatic resource redirection, and should not be used with HTTP_OPTION_REDIRECT.
HTTP_OPTION_TUNNEL	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the proxy server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established.
HTTP_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using either the SSL or TLS protocols.
HTTP_OPTION_SECURE	This option specifies the client should attempt to establish a secure connection with the server. Note that the server must support secure connections using either the SSL or TLS protocol.
HTTP_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
HTTP_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a

	connection using IPv6 regardless if this option has been specified.
HTTP_OPTION_FREETHREAD	This option specifies the handle returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the handle is synchronized across multiple threads.
HTTP_OPTION_HIRES_TIMER	This option specifies the elapsed time for data transfers should be returned in milliseconds instead of seconds. This will return more accurate transfer times for smaller amounts of data over fast network connections.

dwVersion

The requested protocol version used when sending requests to the server. The high word should specify the major version, and the low word should specify the minor version number. The HTTPVERSION macro can be used to create version value.

lpCredentials

Pointer to credentials structure [SECURITYCREDENTIALS](#). This parameter is only used if the HTTP_OPTION_SECURE option is specified for the connection. This parameter may be NULL, in which case no client credentials will be provided to the server. If client credentials are required, the fields *dwSize*, *lpzCertStore*, and *lpzCertName* must be defined, while other fields may be left undefined. Set *dwSize* to the size of the **SECURITYCREDENTIALS** structure.

hEventWnd

The handle to the event notification window. This window receives messages which notify the client of various asynchronous network events that occur.

uEventMsg

The message identifier that is used when an asynchronous network event occurs. This value should be greater than WM_USER as defined in the Windows header files.

Return Value

If the function succeeds, the return value is a handle to a client session. If the function fails, the return value is INVALID_CLIENT. To get extended error information, call **HttpGetLastError**.

Remarks

If the HTTP_PROXY_WINDOWS proxy type is specified, then the proxy configuration for the local system is used. If no proxy server has been defined, then the proxy-related parameters will be ignored and the function will establish a connection directly to the server.

When a message is posted to the notification window, the low word of the *lParam* parameter contains the event identifier. The high word of *lParam* contains the low word of the error code, if an error has occurred. The *wParam* parameter contains the client handle. One or more of the following event identifiers may be sent:

Constant	Description
HTTP_EVENT_CONNECT	The connection to the server has completed. The high word of the <i>lParam</i> parameter should be checked, since this notification message will be posted if an error has occurred.

HTTP_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
HTTP_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
HTTP_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
HTTP_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
HTTP_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.
HTTP_EVENT_COMMAND	A command has been issued by the client and the server response has been received and processed. This event can be used to log the result codes and messages returned by the server in response to actions taken by the client.
HTTP_EVENT_PROGRESS	The client is in the process of sending or receiving data from the server. This event is called periodically during a transfer so that the client can update any user interface components such as a status control or progress bar.
HTTP_EVENT_REDIRECT	This event is generated when a the server indicates that the requested resource has been moved to a new location. The new resource location may be on the same server, or it may be located on another server. Check the value of the Location header field to determine where the resource has been moved to.

To cancel asynchronous notification and return the client to a blocking mode, use the **HttpDisableEvents** function.

The *dwOptions* argument can be used to specify the threading model that is used by the library when a connection is established. By default, the handle is initially attached to the thread that created it. From that point on, until the it is released, only the owner may call functions using that handle. The ownership of the handle may be transferred from one thread to another using the **HttpAttachThread** function.

Specifying the HTTP_OPTION_FREETHREAD option enables any thread to call any function using the handle, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the handle is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same

handle.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cshttpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

HttpAsyncPutData Function

```
UINT WINAPI HttpAsyncPutData(  
    HCLIENT hClient,  
    LPCTSTR lpszFileName,  
    LPVOID lpvBuffer,  
    DWORD dwLength,  
    DWORD dwReserved,  
    HTTPEVENTPROC lpEventProc,  
    DWORD_PTR dwParam  
);
```

Copies the contents of the specified buffer to a file on the server.

Parameters

hClient

Handle to the client session.

lpszFileName

A pointer to a string that specifies the file on the server that will be created, overwritten or appended to. The file naming conventions must be that of the host operating system.

lpvBuffer

A pointer to the data that will be copied to the server and stored in the specified file.

dwLength

The number of bytes to copy from the buffer.

dwReserved

A reserved parameter. This value should always be zero.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **HttpEventProc** callback function. This parameter may be NULL if you do not wish to implement an event handler.

dwParam

A user-defined integer value that is passed to the callback function. This parameter is ignored if the *lpEventProc* parameter is NULL.

Return Value

If the function succeeds, the return value is non-zero integer value that specifies a unique asynchronous task identifier. If the function fails, the return value is zero. To get extended error information, call the **HttpGetLastError** function. The application should treat the task ID as an opaque value and never make an assumption about the sequence in which IDs are assigned to a background task.

Remarks

The **HttpAsyncPutData** function is used to upload the contents of a local buffer to the server. This function is similar to the **HttpPutData** function, however it uses a background worker thread and does not block the current working thread. This enables the application to continue to perform other operations while the data is being sent to the server.

Because this function works asynchronously, it is important that the memory allocated for the buffer is not released before the asynchronous task completes. If you provide a buffer that is

allocated on the stack, ensure that your code does not return from the function while the data is being uploaded. This can be achieved by calling the **HttpTaskWait** function or periodically calling the **HttpTaskDone** function to determine if the transfer has completed. If you wish to return from the calling function immediately, then you must dynamically allocate memory for the *lpvBuffer* parameter on the heap and free that memory after the task has completed and the data is no longer needed.

If the address of an event handler is provided to this function, it is guaranteed that the handler will be invoked with the HTTP_EVENT_CONNECT event after the connection has been established, and the HTTP_EVENT_DISCONNECT event after the transfer has completed. This enables your application to know when the data transfer is about to begin, and immediately before the worker thread is terminated. The worker thread creates a secondary connection to the server with its own session handle. This ensures that the asynchronous operation will not interfere with the current client session. Your application can interact with this background worker thread using the client handle that is passed to the event handler.

If the *lpvBuffer* parameter is pointing to a Unicode string, it is important to note that the value of the *dwLength* parameter should specify the number of bytes, not the number of characters. When using UTF-16, each character is two bytes long and therefore the length of the buffer is effectively double the length of the string. Because Unicode strings can contain null characters, you must also set the current file type to FILE_TYPE_IMAGE prior to calling this function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cshttpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

HttpAsyncPutFile Function

```
UINT WINAPI HttpAsyncPutFile(  
    HCLIENT hClient,  
    LPCTSTR lpszLocalFile,  
    LPCTSTR lpszRemoteFile,  
    DWORD dwOptions,  
    DWORD dwOffset,  
    HTTPEVENTPROC lpEventProc,  
    DWORD_PTR dwParam  
);
```

Uploads the specified file from the local system to the server.

Parameters

hClient

Handle to the client session.

lpszLocalFile

A pointer to a string that specifies the file that will be transferred from the local system. The file pathing and name conventions must be that of the local host.

lpszRemoteFile

A pointer to a string that specifies the file on the server that will be created, overwritten or appended to. The file naming conventions must be that of the host operating system.

dwOptions

An unsigned integer that specifies one or more options. This parameter may be any one of the following values:

Constant	Description
HTTP_TRANSFER_DEFAULT	This option specifies the default transfer mode should be used. If the remote file exists, it will be overwritten with the contents of the uploaded file.

dwOffset

A byte offset which specifies where the file transfer should begin. The default value of zero specifies that the file transfer should start at the beginning of the file. A value greater than zero is typically used to restart a transfer that has not completed successfully. Note that specifying a non-zero offset requires that the server support the REST command to restart transfers.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **HttpEventProc** callback function. This parameter may be NULL if you do not wish to implement an event handler.

dwParam

A user-defined integer value that is passed to the callback function. This parameter is ignored if the *lpEventProc* parameter is NULL.

Return Value

If the function succeeds, the return value is non-zero integer value that specifies a unique asynchronous task identifier. If the function fails, the return value is zero. To get extended error

information, call the **HttpGetLastError** function. The application should treat the task ID as an opaque value and never make an assumption about the sequence in which IDs are assigned to a background task.

Remarks

The **HttpAsyncPutFile** function is used to upload the contents of a local file to the server. This function is similar to the **HttpPutFile** function, however it uploads the file using a background worker thread and does not block the current working thread. This enables the application to continue to perform other operations while the file is being transferred to the server.

If the address of an event handler is provided to this function, it is guaranteed that the handler will be invoked with the HTTP_EVENT_CONNECT event after the connection has been established, and the HTTP_EVENT_DISCONNECT event after the transfer has completed. This enables your application to know when the file transfer is about to begin, and immediately before the worker thread is terminated. During the file transfer, the callback function will be invoked periodically with the HTTP_EVENT_PROGRESS event. The client session handle is passed to the event handler, allowing you to call functions such as **HttpGetTransferStatus** to determine the amount of data that has been copied.

To determine when the transfer has completed without implementing an event handler, periodically call the **HttpTaskDone** function. If you wish to block the current thread and wait for the transfer to complete, call the **HttpTaskWait** function. To stop a background file transfer that is in progress, call the **HttpTaskAbort** function. This will signal the background worker thread to cancel the transfer and terminate the session.

This function can be called multiple times to upload multiple files in the background; however, most servers limit the number of simultaneous connections that can originate from a single IP address. It is recommended that you only perform two simultaneous background transfers from the same server at any one time. The application should not make any assumptions about the order in which multiple background transfers may complete or how they are sequenced. For example, it should never be assumed that a background task with a lower task ID will complete before a task with a higher ID value.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstoools10.h

Import Library: cshttpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[HttpAsyncGetData](#), [HttpAsyncGetFile](#), [HttpAsyncPutData](#), [HttpEventProc](#), [HttpPutFile](#), [HttpTaskDone](#), [HttpTaskWait](#)

HttpAsyncPutFileEx Function

```
UINT WINAPI HttpAsyncPutFileEx(  
    HCLIENT hClient,  
    LPCTSTR lpszLocalFile,  
    LPCTSTR lpszRemoteFile,  
    DWORD dwOptions,  
    ULARGE_INTEGER uiOffset,  
    HTTPEVENTPROC lpEventProc,  
    DWORD_PTR dwParam  
);
```

Uploads the specified file from the local system to the server. This version of the function is designed to support files that are larger than 4GB.

Parameters

hClient

Handle to the client session.

lpszLocalFile

A pointer to a string that specifies the file that will be transferred from the local system. The file pathing and name conventions must be that of the local host.

lpszRemoteFile

A pointer to a string that specifies the file on the server that will be created, overwritten or appended to. The file naming conventions must be that of the host operating system.

dwOptions

An unsigned integer that specifies one or more options. This parameter may be any one of the following values:

Constant	Description
HTTP_TRANSFER_DEFAULT	This option specifies the default transfer mode should be used. If the remote file exists, it will be overwritten with the contents of the uploaded file.

uiOffset

A byte offset which specifies where the file transfer should begin. The default value of zero specifies that the file transfer should start at the beginning of the file. A value greater than zero is typically used to restart a transfer that has not completed successfully. Note that specifying a non-zero offset requires that the server support the REST command to restart transfers.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **HttpEventProc** callback function. This parameter may be NULL if you do not wish to implement an event handler.

dwParam

A user-defined integer value that is passed to the callback function. This parameter is ignored if the *lpEventProc* parameter is NULL.

Return Value

If the function succeeds, the return value is non-zero integer value that specifies a unique

asynchronous task identifier. If the function fails, the return value is zero. To get extended error information, call the **HttpGetLastError** function. The application should treat the task ID as an opaque value and never make an assumption about the sequence in which IDs are assigned to a background task.

Remarks

The **HttpAsyncPutFileEx** function is used to upload the contents of a local file to the server. This function is similar to the **HttpPutFileEx** function, however it uploads the file using a background worker thread and does not block the current working thread. This enables the application to continue to perform other operations while the file is being transferred to the server.

If the address of an event handler is provided to this function, it is guaranteed that the handler will be invoked with the HTTP_EVENT_CONNECT event after the connection has been established, and the HTTP_EVENT_DISCONNECT event after the transfer has completed. This enables your application to know when the file transfer is about to begin, and immediately before the worker thread is terminated. During the file transfer, the callback function will be invoked periodically with the HTTP_EVENT_PROGRESS event. The client session handle is passed to the event handler, allowing you to call functions such as **HttpGetTransferStatusEx** to determine the amount of data that has been copied.

To determine when the transfer has completed without implementing an event handler, periodically call the **HttpTaskDone** function. If you wish to block the current thread and wait for the transfer to complete, call the **HttpTaskWait** function. To stop a background file transfer that is in progress, call the **HttpTaskAbort** function. This will signal the background worker thread to cancel the transfer and terminate the session.

This function can be called multiple times to upload multiple files in the background; however, most servers limit the number of simultaneous connections that can originate from a single IP address. It is recommended that you only perform two simultaneous background transfers from the same server at any one time. The application should not make any assumptions about the order in which multiple background transfers may complete or how they are sequenced. For example, it should never be assumed that a background task with a lower task ID will complete before a task with a higher ID value.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cshttpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[HttpAsyncGetFileEx](#), [HttpEventProc](#), [HttpGetFileEx](#), [HttpPutFileEx](#), [HttpTaskDone](#), [HttpTaskWait](#)

HttpAsyncSubmitForm Function

```
UINT WINAPI HttpAsyncSubmitForm(  
    HCLIENT hClient,  
    HFORM hForm,  
    LPVOID lpvResult,  
    LPDWORD lpcbResult,  
    DWORD dwOptions,  
    HTTPEVENTPROC lpEventProc,  
    DWORD_PTR dwParam  
);
```

Submit the specified form to the server for processing and return the response to the caller.

Parameters

hClient

Handle to the client session.

hForm

Handle to the virtual form which contains the data to be submitted to the server.

lpvResult

A pointer to a byte buffer which will contain the data returned by the server, or a pointer to a global memory handle which will reference the data when the function returns.

lpcbResult

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the *lpvBuffer* parameter. If the *lpvResult* parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the actual number of bytes of data that was returned.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
HTTP_SUBMIT_DEFAULT	The default post mode. The contents of the buffer are encoded and sent as standard form data. The data returned by the server is copied to the result buffer exactly as it is returned from the server.
HTTP_SUBMIT_CONVERT	If the data being returned from the server is textual, it is automatically converted so that the end of line character sequence is compatible with the Windows platform. Individual carriage return or linefeed characters are converted to carriage return/linefeed character sequences. Note that this option does not have any effect on the form data being submitted to the server, only on the data returned by the server.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more

information about the callback function, see the description of the **HttpEventProc** callback function. This parameter may be NULL if you do not wish to implement an event handler.

dwParam

A user-defined integer value that is passed to the callback function. This parameter is ignored if the *lpEventProc* parameter is NULL.

Return Value

If the function succeeds, the return value is non-zero integer value that specifies a unique asynchronous task identifier. If the function fails, the return value is zero. To get extended error information, call the **HttpGetLastError** function. The application should treat the task ID as an opaque value and never make an assumption about the sequence in which IDs are assigned to a background task.

Remarks

The **HttpAsyncSubmitForm** function is used to submit form data to a script that executes on the server and then copy the output from that script into a local buffer. This function is similar to the **HttpSubmitForm** function, however it submits the data using a background worker thread and does not block the current working thread. This enables the application to continue to perform other operations while the data is being sent and the response from the server is being returned to the caller.

Because this function works asynchronously, it is important that the memory allocated for the *lpvResult* parameter will not be released before the asynchronous task completes. If you provide a buffer that is allocated on the stack, ensure that your code does not return from the function until the background task completes. This can be achieved by calling the **HttpTaskWait** function or periodically calling the **HttpTaskDone** function to determine if the operation has completed. If you wish to return from the calling function immediately, then you must dynamically allocate the buffer on the heap and free that memory after the task has completed and the data is no longer needed.

Do not call the **HttpDestroyForm** function to release the memory allocated for the virtual form until the background task completes. Doing so may result in unpredictable behavior and could cause your application to terminate abnormally.

If the address of an event handler is provided to this function, it is guaranteed that the handler will be invoked with the HTTP_EVENT_CONNECT event after the connection has been established, and the HTTP_EVENT_DISCONNECT event after the transfer has completed. This enables your application to know when the file transfer is about to begin, and immediately before the worker thread is terminated.

The *lpvResult* parameter may be specified in one of two ways, depending on the needs of the application. It can either be a pre-allocated buffer large enough to store the contents of the server response or it can specify the address of a global memory handle that will contain the data. If it points to a pre-allocated buffer, the *lpcbResult* parameter must be initialized to the maximum number of bytes that can be copied into the buffer. If specifies the address of a global memory handle, then *lpcbResult* must be initialized to a value of zero. See the example code below.

Example

```
HFORM hForm = INVALID_FORM;  
HGLOBAL hgb1Result = (HGLOBAL)NULL;  
DWORD cbResult = 0;  
INT nResult = 0;  
UINT nTaskId;
```

```

hForm = HttpCreateForm(_T("/login.php"), HTTP_METHOD_POST, HTTP_FORM_ENCODED);

if (hForm == INVALID_FORM)
    return;

HttpAddFormField(hForm, _T("UserName"), lpszUserName, (DWORD)-1L, 0);
HttpAddFormField(hForm, _T("Password"), lpszPassword, (DWORD)-1L, 0);

nTaskId = HttpAsyncSubmitForm(hClient, hForm, &hgblResult, &cbResult, 0);

if (nTaskId != 0)
{
    DWORD dwError = NO_ERROR;
    DWORD dwElapsed = 0;

    // Wait for the task to complete
    HttpTaskWait(nTaskId, INFINITE, &dwElapsed, &dwError);

    // Get a pointer to the data returned by the server
    LPBYTE lpBuffer = (LPBYTE)GlobalLock(hgblResult);

    // lpBuffer now points to data returned by the server after
    // the form data was submitted

    // Release the memory allocated for the buffer
    GlobalUnlock(hgblResult);
    GlobalFree(hgblResult);
}

// Release the memory allocated for the virtual form
HttpDestroyForm(hForm);

```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

HttpAttachThread Function

```
DWORD WINAPI HttpAttachThread(  
    HCLIENT hClient  
    DWORD dwThreadId  
);
```

The **HttpAttachThread** function attaches the specified client handle to another thread.

Parameters

hClient

Handle to the client session.

dwThreadId

The ID of the thread that will become the new owner of the handle. A value of zero specifies that the current thread should become the owner of the client handle.

Return Value

If the function succeeds, the return value is the thread ID of the previous owner. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

When a client handle is created, it is associated with the current thread that created it. Normally, if another thread attempts to perform an operation using that handle, an error is returned since it does not own the handle. This is used to ensure that other threads cannot interfere with an operation being performed by the owner thread. In some cases, it may be desirable for one thread in a client application to create the client handle, and then pass that handle to another worker thread. The **HttpAttachThread** function can be used to change the ownership of the handle to the new worker thread. By preserving the return value from the function, the original owner of the handle can be restored before the worker thread terminates.

This function should be called by the new thread immediately after it has been created, and if the new thread does not release the handle itself, the ownership of the handle should be restored to the parent thread before it terminates. Under no circumstances should **HttpAttachThread** be used to forcibly release a handle allocated by another thread while a blocking operation is in progress. To cancel an operation, use the **HttpCancel** function and then release the handle after the blocking function exits and control is returned to the current thread.

Note that the *dwThreadId* parameter is presumed to be a valid thread ID and no checks are performed to ensure that the thread actually exists. Specifying an invalid thread ID will orphan the handle until the **HttpUninitialize** function is called.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cshttp10.lib

HttpAuthenticate Function

```
INT WINAPI HttpAuthenticate(  
    HCLIENT hClient,  
    UINT nAuthType,  
    LPCTSTR lpszUserName,  
    LPCTSTR lpszPassword  
);
```

Parameters

hClient

Handle to the client session.

nAuthType

An unsigned integer value which specifies the method to be used when authenticating the client. The following values are recognized.

Constant	Description
HTTP_AUTH_NONE	No client authentication should be performed. The <i>lpszUserName</i> and <i>lpszPassword</i> parameters are ignored and current authentication settings are cleared.
HTTP_AUTH_BASIC	The Basic authentication scheme should be used. This option is supported by all servers that support at least version 1.0 of the protocol. The user credentials are not encrypted and Basic authentication should not be used over standard (non-secure) connections. Most web services which use Basic authentication require the connection to be secure.
HTTP_AUTH_BEARER	The Bearer authentication scheme should be used. This authentication method does not require a user name and the <i>lpszPassword</i> parameter must specify the OAuth 2.0 bearer token issued by the service provider. If the access token has expired, the request will fail with an authorization error. This function will not automatically refresh an expired token.

lpszUserName

A null terminated string which specifies the user name used to authenticate the client session. This parameter may be NULL or an empty string if a user name is not required for the specified authentication type.

lpszPassword

A pointer to a string that specifies the password used to authenticate the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

This function will set the **Authorization** request header for the client session using the credentials provided by the caller. This function will always override any custom **Authorization** header value that may have been previously set using the **HttpSetRequestHeader** function.

If both the *lpszUserName* and *lpszPassword* parameters are NULL pointers or specify zero length strings, the current authentication type will always be set to HTTP_AUTH_NONE regardless of the value of the *nAuthType* parameter. This effectively clears the current user credentials for the client session.

If the web service requires OAuth 2.0 authentication, it is recommended you use the **HttpSetBearerToken** function to specify the access token.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstoools10.h

Import Library: cshttpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[HttpAsyncConnect](#), [HttpConnect](#), [HttpSetBearerToken](#), [HttpSetRequestHeader](#)

HttpCancel Function

```
INT WINAPI HttpCancel(  
    HCLIENT hClient  
);
```

The **HttpCancel** function cancels any outstanding blocking operation in the client, causing the blocking function to fail. The application may then retry the operation or terminate the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

When the **HttpCancel** function is called, the blocking function will not immediately fail. An internal flag is set which causes the blocking operation to exit with an error. This means that the application cannot cancel an operation and immediately perform some other operation. Instead it must allow the calling stack to unwind, returning back to the blocking operation before making any further function calls.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cshttpv10.lib

See Also

[HttpIsBlocking](#)

HttpClearForm Function

```
INT WINAPI HttpClearForm(  
    HFORM hForm  
);
```

The **HttpClearForm** function clears the specified form, removing all fields.

Parameters

hForm

Handle to the virtual form.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cshttpv10.lib

See Also

[HttpAddFormField](#), [HttpAddFormFile](#), [HttpCreateForm](#), [HttpDeleteFormField](#), [HttpDestroyForm](#), [HttpSubmitForm](#)

HttpCloseFile Function

```
INT WINAPI HttpCloseFile(  
    HCLIENT hClient  
);
```

The **HttpCloseFile** function flushes the internal client buffers and closes the previously opened file on the server.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

If the file is opened for writing, all buffered data is written to the server before the file is closed. This may cause the client to block until all of the data can be written. The client application should not perform any other action until the function returns.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cshttpv10.lib

See Also

[HttpCommand](#), [HttpGetData](#), [HttpGetFile](#), [HttpOpenFile](#), [HttpPutData](#), [HttpPutFile](#)

HttpCommand Function

```
INT WINAPI HttpCommand(  
    HCLIENT hClient,  
    LPCTSTR lpszCommand,  
    LPCTSTR lpszResource,  
    LPBYTE lpParameter,  
    DWORD cbParameter,  
    DWORD dwReserved  
);
```

The **HttpCommand** function sends a command to the server and returns the result code back to the caller. This function is typically used for extended commands not directly supported by the API.

Parameters

hClient

Handle to the client session.

lpszCommand

A pointer to a string which specifies the command to be executed by the server. The following table lists the standard commands recognized by most HTTP servers. Other commands may also be used, such as those extensions used by WebDAV to edit and manage files on a server.

Command	Description
GET	Return the contents of the specified resource. This command is recognized by all servers.
HEAD	Return only header information for the specified resource. This command is recognized by servers that support at least version 1.0 of the protocol.
POST	Post data to the specified resource. This command is recognized by servers that support at least version 1.0 of the protocol.
PUT	Create or replace the specified resource on the server. This command is recognized by servers that support at least version 1.0 of the protocol. Not all servers support this command.
DELETE	Delete the specified resource from the server. This command is recognized by servers that support at least version 1.1 of the protocol. Not all servers support this command.

lpszResource

A pointer to a string which specifies the resource to be used with the command. This can be the name of a file, an executable script or any other valid resource name recognized by the server. Resource names must be absolute and include the complete path to the resource.

lpParameter

A pointer to a byte array which contains data that is to be passed to the command as one or more parameters. Typically this is used to pass additional information to a script that executes on the server. The data is encoded according to the encoding type specified for the client session. If the resource does not require any parameters, this value should be NULL.

cbParameter

Specifies the number of bytes stored in the parameter buffer. If the resource does not require

any parameters, this value should be zero.

dwReserved

A reserved parameter. This value should always be zero.

Return Value

If the function succeeds, the return value is the result code returned by the server. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

Not all servers support all of the listed commands, and some commands may require specific changes to the server configuration. In particular, the PUT and DELETE commands typically require that configuration changes be made by the site administrator. All servers will support the use of the GET command, and all servers that support at least version 1.0 of the protocol will support the POST command.

If the *lpSzResource* parameter specifies a path that contains reserved or restricted characters, such as a space, it will automatically be URL encoded by the library.

It is permissible to include a query string in the resource name specified by the *lpSzResource* parameter. Query strings begin with a question mark, and then are followed by one or more name/value pairs separated by an equal sign. For example, the following resource includes a query string:

```
/cgi-bin/test.cgi?field1=value1&field2=value2
```

In this case, the query string is "?field1=value1&field2=value2". If the query string contains reserved or restricted characters, such as spaces, then it will be automatically URL encoded prior to being sent to the server. If additional resource data is specified in the *lpParameter* argument along with a query string in the resource name, the action taken by the library depends on the command being sent. If the command is a POST or PUT command, then query string is included with command request to the server and the parameter data is sent separately. For example, if the POST command was used, the script running on the server would see that both query data and form data has been provided to it. However, if any other command is specified, the parameter data is simply appended to the query string.

The *lpParameter* argument is used to pass additional information to the server when a resource is requested. This is most commonly used to provide information to scripts, similar to how arguments are used when executing a program from the command line. Unless the POST command is being executed, the data in the buffer will automatically be encoded using the current encoding mechanism specified for the client. By default, the data is URL encoded, which means that any spaces and non-printable characters are converted to printable characters before submitted to the server. The type of encoding that is performed can be set by calling the **HttpSetEncodingType** function. Although the default encoding is appropriate for most applications, those that submit XML formatted data may need to change the encoding type.

Only one request may be in progress at one time for each client session. Use the **HttpCloseFile** function to terminate the request after all of the data has been read from the server.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cshttp10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

HttpConnect Function

```
HCLIENT WINAPI HttpConnect(  
    LPCTSTR lpszRemoteHost,  
    UINT nRemotePort,  
    UINT nTimeout,  
    DWORD dwOptions,  
    DWORD dwVersion,  
    LPSECURITYCREDENTIALS lpCredentials  
);
```

Parameters

lpszRemoteHost

A pointer to the name of the server to connect to; this may be a fully-qualified domain name or an IP address.

nRemotePort

The port number the server is listening on; a value of zero specifies that the default port number should be used. For standard connections, the default port number is 80. For secure connections, the default port number is 443.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
HTTP_OPTION_NOCACHE	This instructs the server to not return a cached copy of the resource. When connected to an HTTP 1.0 or earlier server, this directive may be ignored.
HTTP_OPTION_KEEPALIVE	This instructs the server to maintain a persistent connection between requests. This can improve performance because it eliminates the need to establish a separate connection for each resource that is requested. If the server does not support the keep-alive option, the client will automatically reconnect when each resource is requested. Although it will not provide any performance benefits, this allows the option to be used with all servers.
HTTP_OPTION_REDIRECT	This option specifies the client should automatically handle resource redirection. If the server indicates that the requested resource has moved to a new location, the client will close the current connection and request the resource from the new location. Note that it is possible that the

	<p>redirected resource will be located on a different server.</p>
HTTP_OPTION_PROXY	<p>This option specifies the client should use the default proxy configuration for the local system. If the system is configured to use a proxy server, then the connection will be automatically established through that proxy; otherwise, a direct connection to the server is established. The local proxy configuration can be changed using the system Control Panel.</p>
HTTP_OPTION_ERRORDATA	<p>This option specifies the client should return the content of an error response from the server, rather than returning an error code. Note that this option will disable automatic resource redirection, and should not be used with HTTP_OPTION_REDIRECT.</p>
HTTP_OPTION_TUNNEL	<p>This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established.</p>
HTTP_OPTION_TRUSTEDSITE	<p>This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using either the SSL or TLS protocols.</p>
HTTP_OPTION_SECURE	<p>This option specifies the client should attempt to establish a secure connection with the server. Note that the server must support secure connections using either the SSL or TLS protocol.</p>
HTTP_OPTION_SECURE_FALLBACK	<p>This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.</p>
HTTP_OPTION_PREFER_IPV6	<p>This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.</p>

HTTP_OPTION_FREETHREAD	This option specifies the handle returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the handle is synchronized across multiple threads.
HTTP_OPTION_HIRES_TIMER	This option specifies the elapsed time for data transfers should be returned in milliseconds instead of seconds. This will return more accurate transfer times for smaller amounts of data over fast network connections.

dwVersion

The requested protocol version used when sending requests to the server. The high word should specify the major version, and the low word should specify the minor version number. The HTTPVERSION macro can be used to create version value.

lpCredentials

Pointer to credentials structure [SECURITYCREDENTIALS](#). This parameter is only used if the HTTP_OPTION_SECURE option is specified for the connection. This parameter may be NULL, in which case no client credentials will be provided to the server. If client credentials are required, the fields *dwSize*, *lpzCertStore*, and *lpzCertName* must be defined, while other fields may be left undefined. Set *dwSize* to the size of the **SECURITYCREDENTIALS** structure.

Return Value

If the function succeeds, the return value is a handle to a client session. If the function fails, the return value is INVALID_CLIENT. To get extended error information, call **HttpGetLastError**.

Remarks

The *dwOptions* argument can be used to specify the threading model that is used by the library when a connection is established. By default, the handle is initially attached to the thread that created it. From that point on, until the it is released, only the owner may call functions using that handle. The ownership of the handle may be transferred from one thread to another using the **HttpAttachThread** function.

Specifying the HTTP_OPTION_FREETHREAD option enables any thread to call any function using the handle, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the handle is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same handle.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cshttpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

HttpConnectUrl Function

```
HCLIENT WINAPI HttpConnectUrl(  
    LPCTSTR lpszURL,  
    UINT nTimeout,  
    DWORD dwOptions  
);
```

The **HttpConnectUrl** function establishes a connection with the specified server using a URL.

Parameters

lpszURL

A pointer to a string which specifies the URL for the server. The URL must follow the conventions for the Hypertext Transfer Protocol and may specify either a standard or secure connection, alternate port number, username, password and optional working directory.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
HTTP_OPTION_NOCACHE	This instructs the server to not return a cached copy of the resource. When connected to an HTTP 1.0 or earlier server, this directive may be ignored.
HTTP_OPTION_KEEPALIVE	This instructs the server to maintain a persistent connection between requests. This can improve performance because it eliminates the need to establish a separate connection for each resource that is requested. If the server does not support the keep-alive option, the client will automatically reconnect when each resource is requested. Although it will not provide any performance benefits, this allows the option to be used with all servers.
HTTP_OPTION_REDIRECT	This option specifies the client should automatically handle resource redirection. If the server indicates that the requested resource has moved to a new location, the client will close the current connection and request the resource from the new location. Note that it is possible that the redirected resource will be located on a different server.
HTTP_OPTION_PROXY	This option specifies the client should use the default proxy configuration for the local system. If the system is configured to use a proxy server,

	then the connection will be automatically established through that proxy; otherwise, a direct connection to the server is established. The local proxy configuration can be changed using the system Control Panel.
HTTP_OPTION_ERRORDATA	This option specifies the client should return the content of an error response from the server, rather than returning an error code. Note that this option will disable automatic resource redirection, and should not be used with HTTP_OPTION_REDIRECT.
HTTP_OPTION_TUNNEL	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established.
HTTP_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using either the SSL or TLS protocols.
HTTP_OPTION_SECURE	This option specifies the client should attempt to establish a secure connection with the server. Note that the server must support secure connections using either the SSL or TLS protocol.
HTTP_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
HTTP_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
HTTP_OPTION_FREETHREAD	This option specifies the handle returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the handle is synchronized across multiple

	threads.
HTTP_OPTION_HIRES_TIMER	This option specifies the elapsed time for data transfers should be returned in milliseconds instead of seconds. This will return more accurate transfer times for smaller amounts of data over fast network connections.

Return Value

If the function succeeds, the return value is a handle to a client session. If the function fails, the return value is `INVALID_CLIENT`. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpConnectUrl** function uses an HTTP URL to establish a connection with a server. The URL must be in the following format:

```
[http|https]://[username : password] @[remotehost] [:remoteport] / [path / ...] [filename]
```

If no user name and password is provided, then the client session will be authenticated as an anonymous user. The URL scheme will always determine if the connection is secure, not the option. In other words, if the "http" scheme is used and the `HTTP_OPTION_SECURE` option is specified, that option will be ignored. To establish a secure connection, the "https" scheme must be specified. The **HttpValidateUrl** function can be used to verify that a URL is valid prior to calling this function.

The **HttpConnectUrl** function is designed to provide a simpler, more convenient interface to establishing a connection with a server. However, complex connections such as those using a proxy server or a secure connection which uses a client certificate will require the program to use the lower-level connection functions. If you only need to upload or download a file using a URL, then refer to the **HttpUploadFile** and **HttpDownloadFile** functions.

The *dwOptions* argument can be used to specify the threading model that is used by the library when a connection is established. By default, the handle is initially attached to the thread that created it. From that point on, until the it is released, only the owner may call functions using that handle. The ownership of the handle may be transferred from one thread to another using the **HttpAttachThread** function.

Specifying the `HTTP_OPTION_FREETHREAD` option enables any thread to call any function using the handle, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the handle is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same handle.

Example

```
HCLIENT hClient;
LPCTSTR lpszURL = _T("http://sockettools.com/");

// Connect to the site specified by the URL
hClient = HttpConnectUrl(lpszURL, HTTP_TIMEOUT, HTTP_OPTION_DEFAULT);

if (hClient == INVALID_CLIENT)
{
    TCHAR szError[128];
```

```
// Display a message box that describes the error
HttpGetErrorString(HttpGetLastError(), szError, 128);
MessageBox(NULL, szError, NULL, MB_ICONEXCLAMATION|MB_TASKMODAL);
return;
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cshttpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[HttpConnect](#), [HttpDisconnect](#), [HttpDownloadFile](#), [HttpUploadFile](#), [HttpValidateUrl](#)

HttpCreateFile Function

```
INT WINAPI HttpCreateFile(  
    HCLIENT hClient,  
    LPCTSTR lpszRemoteFile,  
    DWORD dwLength,  
    DWORD dwOffset  
);
```

The **HttpCreateFile** function creates the specified file on the server.

Parameters

hClient

Handle to the client session.

lpszRemoteFile

Points to a string that specifies the name of the file being created on the server. The client must have the appropriate access rights to create the file or an error will be returned.

dwLength

Specifies the length of the file that will be created on the server. This value must be greater than zero.

dwOffset

Specifies a byte offset in the file. If this value is greater than zero, the server must support the ability to specify a byte range with the request to create the file, otherwise this function will fail.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpCreateFile** function uses the PUT command to create the file. The server must support this command and the user must have the appropriate permission to create the specified file. If this function is successful, the client should then use the **HttpWrite** function to send the contents of the file to the server. Once all of the data has been written, the **HttpCloseFile** function should be called to close the file and complete the operation. Note that this function is typically only accepted by servers that support version 1.1 of the protocol or later.

When using **HttpWrite** to send the contents of the file to the server, it is recommended that the data be written in logical blocks that are no larger than 8,192 bytes in size. Attempting to write very large amounts of data in a single call can either cause the thread to block or, in the case of an asynchronous connection, return an error if the internal buffers cannot accommodate all of the data. To send the entire contents of a file in a single function call, use the **HttpPutData** function instead of calling **HttpCreateFile**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cshttpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

HttpCreateFileEx Function

```
INT WINAPI HttpCreateFileEx(  
    HCLIENT hClient,  
    LPCTSTR lpszRemoteFile,  
    ULARGE_INTEGER uiLength,  
    ULARGE_INTEGER uiOffset  
);
```

The **HttpCreateFileEx** function creates the specified file on the server. This version of the function is designed to support files that are larger than 4GB.

Parameters

hClient

Handle to the client session.

lpszRemoteFile

Points to a string that specifies the name of the file being created on the server. The client must have the appropriate access rights to create the file or an error will be returned.

uiLength

Specifies the length of the file that will be created on the server. This value must be greater than zero.

uiOffset

Specifies a byte offset into the file. If this value is greater than zero, the server must support the ability to specify a byte range with the request to create the file, otherwise this function will fail.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpCreateFileEx** function uses the PUT command to create the file. The server must support this command and the user must have the appropriate permission to create the specified file. If this function is successful, the client should then use the **HttpWrite** function to send the contents of the file to the server. Once all of the data has been written, the **HttpCloseFile** function should be called to close the file and complete the operation. Note that this function is typically only accepted by servers that support version 1.1 of the protocol or later.

When using **HttpWrite** to send the contents of the file to the server, it is recommended that the data be written in logical blocks that are no larger than 8,192 bytes in size. Attempting to write very large amounts of data in a single call can either cause the thread to block or, in the case of an asynchronous connection, return an error if the internal buffers cannot accommodate all of the data. To send the entire contents of a file in a single function call, use the **HttpPutData** function instead of calling **HttpCreateFileEx**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cshtpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

HttpCreateForm Function

```
HFORM WINAPI HttpCreateForm(  
    LPCTSTR lpszAction,  
    UINT nFormMethod,  
    UINT nFormType,  
    DWORD dwReserved  
);
```

The **HttpCreateForm** function creates a new form and returns a handle for use with the other form-related functions.

Parameters

lpszAction

A pointer to a string which specifies the name of the resource that the form data will be submitted to. Typically this is the name of a script that is executed on the server.

nFormMethod

An unsigned integer value which specifies how the form data will be submitted to the server. This parameter may be one of the following values:

Constant	Description
HTTP_METHOD_DEFAULT	The form data should be submitted using the default method, using the GET command.
HTTP_METHOD_GET	The form data should be submitted using the GET command. This method should be used when the amount of form data is relatively small. If the total amount of form data exceeds 2048 bytes, it is recommended that the POST method be used instead.
HTTP_METHOD_POST	The form data should be submitted using the POST command. This is the preferred method of submitting larger amounts of form data. If the total amount of form data exceeds 2048 bytes, it is recommended that the POST method be used.

nFormType

An unsigned integer value which specifies the type of form and how the data will be encoded when it is submitted to the server. This parameter may be one of the following values:

Constant	Description
HTTP_FORM_DEFAULT	The form data should be submitted using the default encoding method.
HTTP_FORM_ENCODED	The form data should be submitted as URL encoded values. This is typically used when the GET method is used to submit the data to the server.
HTTP_FORM_MULTIPART	The form data should be submitted as multipart form data. This is typically used when the POST method is used to submit a file to the server. Note that the script must understand how to process multipart form data if this form

type is specified.

dwReserved

A reserved parameter. This value must be zero.

Return Value

If the function succeeds, the return value is a handle to the virtual form. If the function fails, the return value is `INVALID_FORM`. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpCreateForm** function is used to create a new form that will be populated with values and then submitted to the server for processing. When the form is no longer needed, it should be destroyed using the **HttpDestroyForm** function.

Example

```
HFORM hForm = INVALID_FORM;
HGLOBAL hgblResult = (HGLOBAL)NULL;
DWORD cbResult = 0;
INT nResult = 0;

hForm = HttpCreateForm(_T("/login.php"), HTTP_METHOD_POST, HTTP_FORM_ENCODED);

if (hForm == INVALID_FORM)
    return;

HttpAddFormField(hForm, _T("UserName"), lpszUserName, (DWORD)-1L, 0);
HttpAddFormField(hForm, _T("Password"), lpszPassword, (DWORD)-1L, 0);

nResult = HttpSubmitForm(hClient, hForm, &hgblResult, &cbResult, 0);
HttpDestroyForm(hForm);

if (hgblResult != NULL)
{
    LPBYTE lpBuffer = (LPBYTE)GlobalLock(hgblResult);

    // lpBuffer points to data returned by the server after the form
    // data was submitted

    GlobalUnlock(hgblResult);
    GlobalFree(hgblResult);
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `cshttpv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

See Also

[HttpAddFormField](#), [HttpAddFormFile](#), [HttpClearForm](#), [HttpDeleteFormField](#), [HttpDestroyForm](#), [HttpSubmitForm](#)

HttpCreateSecurityCredentials Function

```
BOOL WINAPI HttpCreateSecurityCredentials(  
    DWORD dwProtocol,  
    DWORD dwOptions,  
    LPCTSTR lpszUserName,  
    LPCTSTR lpszPassword,  
    LPCTSTR lpszCertStore,  
    LPCTSTR lpszCertName,  
    LPVOID lpvReserved,  
    LPSECURITYCREDENTIALS* lppCredentials  
);
```

The **HttpCreateSecurityCredentials** function creates a **SECURITYCREDENTIALS** structure.

Parameters

dwProtocol

A bitmask of supported security protocols. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_SSL	Either SSL 2.0 or SSL 3.0 should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, TLS will be excluded from the list of supported protocols. Both SSL 2.0 and 3.0 have been deprecated and will never be used unless explicitly specified. It is not recommended that you enable either of these protocols for secure connections because it will cause most servers to reject your connection request, even if a version of TLS is also specified.
SECURITY_PROTOCOL_TLS	Either the TLS 1.0, 1.1 or 1.2 protocol should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers that reject any attempt to use the older SSL protocol and require that only TLS be used.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol should be used when establishing a secure connection. This version is

	supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This is the recommended version of TLS to use with secure connections.

dwOptions

A value which specifies one or options. This member is constructed by using a bitwise operator with any of the following values:

Constant	Description
CREDENTIAL_STORE_CURRENT_USER	The library will attempt to open a store for the current user using the certificate store name provided in this structure. If no options are specified, then this is the default behavior.
CREDENTIAL_STORE_LOCAL_MACHINE	The library will attempt to open a local machine store using the certificate store name provided in this structure. If this option is specified, the library will always search for a local machine store before searching for the store by that name for the current user.
CREDENTIAL_STORE_FILENAME	The certificate store name is a file that contains the certificate and private key that will be used.

lpszUserName

A pointer to a string which specifies the certificate owner's username. A value of NULL specifies that no username is required. Currently this parameter is not used and any value specified will be ignored.

lpszPassword

A pointer to a string which specifies the certificate owner's password. A value of NULL specifies

that no password is required. This parameter is only used if a PKCS12 (PFX) certificate file is specified and that certificate has been secured with a password. This value will be ignored the current user or local machine certificate store is specified.

lpszCertStore

A pointer to a string which specifies the name of the certificate store to open. A certificate store is a collection of certificates and their private keys, typically organized by how they are used. If this value is NULL or points to an empty string, the default certificate store "MY" will be used.

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as VeriSign and Thawte act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. This corresponds to the "Personal" store that is displayed by the certificate manager utility and is the default store used by the library.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as VeriSign and Thawte are installed as part of the operating system and periodically updated by Microsoft.

lpszCertName

A pointer to a null terminated string which specifies the name of the certificate to use. The function will first search the certificate store for a certificate with a matching "friendly name"; this is a name for the certificate that is assigned by the user. Note that the name must match completely, but the comparison is not case sensitive. If no matching certificate is found, the function will then attempt to find a certificate that has a matching common name (also called the certificate subject). This comparison is less stringent, and the first partial match will be returned. If this second search fails, the function will return an error indicating that the certificate could not be found.

lpvReserved

Pointer reserved for future use. Set it to NULL when using this function.

lppCredentials

Pointer to an [LPSECURITYCREDENTIALS](#) pointer. The memory for the credentials structure will be allocated by this function and must be released by calling the **HttpDeleteSecurityCredentials** function when it is no longer needed. The pointer value must be set to NULL before the function is called. It is important to note that this is a pointer to a pointer variable, not a pointer to the SECURITYCREDENTIALS structure itself.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **HttpGetLastError**.

Remarks

The structure that is created by this function may be used as client credentials when establishing a secure connection. This is particularly useful for programming languages other than C/C++ which may not support C structures or pointers. The pointer to the SECURITYCREDENTIALS structure can

be declared as an unsigned integer variable which is passed by reference to this function, and then passed by value to the **HttpAsyncConnect** or **HttpConnect** functions.

Example

```
LPSECURITYCREDENTIALS lpSecCred = NULL;
HttpCreateSecurityCredentials(SEcurity_PROTOCOL_DEFAULT,
                             0,
                             NULL,
                             NULL,
                             lpzCertStore,
                             lpzCertName,
                             NULL,
                             &lpSecCred);

hClient = HttpConnect(lpzHostName,
                     HTTP_PORT_SECURE,
                     HTTP_TIMEOUT,
                     HTTP_OPTION_SECURE | HTTP_OPTION_KEEPALIVE,
                     HTTP_VERSION_11,
                     lpSecCred);
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cshttpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

HttpDeleteFile Function

```
INT WINAPI HttpDeleteFile(  
    HCLIENT hClient,  
    LPCTSTR lpszFileName  
);
```

The **HttpDeleteFile** function deletes the specified file from the server.

Parameters

hClient

Handle to the client session.

lpszFileName

Points to a string that specifies the name of the remote file to delete. The file pathing and name conventions must be that of the server.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

This function uses the DELETE command to delete the specified file from the server. The server must be configured to support this command, and client must have the appropriate permission to delete the file, or an error will be returned.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cshttpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[HttpGetFile](#), [HttpPutFile](#)

HttpDeleteFormField Function

```
INT WINAPI HttpDeleteFormField(  
    HFORM hForm,  
    LPCTSTR lpszFieldName  
);
```

The **HttpDeleteFormField** function deletes the specified field from the form.

Parameters

hForm

Handle to the virtual form.

lpszFieldName

Points to a string that specifies the name of the field to delete.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cshttpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[HttpAddFormField](#), [HttpAddFormFile](#), [HttpClearForm](#), [HttpCreateForm](#), [HttpSubmitForm](#)

HttpDeleteHeaders Function

```
BOOL WINAPI HttpDeleteHeaders(  
    HCLIENT hClient,  
    UINT nHeaderType  
);
```

Delete all of the response or request headers for the current session.

Parameters

hClient

Handle to the client session.

nHeaderType

Specifies the type of header to delete. It may be one of the following values:

Constant	Description
HTTP_HEADERS_REQUEST	Delete all of the request headers that have been set for the next request sent to the server. This will clear all of the header values that were set using the HttpSetRequestHeader function.
HTTP_HEADERS_RESPONSE	Delete all of the headers that were set in response to the previous request. A call to the HttpGetResponseHeader function to obtain a specific header value will fail after this function returns.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpDeleteHeaders** function will release the memory allocated for the request or response headers for the current session. This function is typically used to clear all of the current request headers so that the application may create a new set of headers when a persistent connection is being used. The memory allocated for the request and response headers is normally released when the session handle is closed by calling the **HttpDisconnect** function.

Whenever a request for a resource is sent to the server, the response headers from the previous request are automatically cleared. It is not necessary for an application to call the **HttpDeleteHeaders** function to delete the response headers prior to each request.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cshttp10.lib

See Also

[HttpGetFirstHeader](#), [HttpGetNextHeader](#), [HttpGetResponseHeader](#), [HttpSetRequestHeader](#)

HttpDeleteSecurityCredentials Function

```
VOID WINAPI HttpDeleteSecurityCredentials(  
    LPSECURITYCREDENTIALS *LppCredentials  
);
```

The **HttpDeleteSecurityCredentials** function deletes an existing **SECURITYCREDENTIALS** structure.

Parameters

lppCredentials

Pointer to an **LPSECURITYCREDENTIALS** pointer. On exit from the function, the pointer will be NULL.

Return Value

None.

Example

```
if (lpSecCred)  
    HttpDeleteSecurityCredentials(&lpSecCred);  
HttpUninitialize();
```

Remarks

This function can be used to release the memory allocated to the client or server credentials after a secure connection has been terminated.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cshttpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[HttpCreateSecurityCredentials](#), [HttpUninitialize](#)

HttpDestroyForm Function

```
INT WINAPI HttpDestroyForm(  
    HFORM hForm  
);
```

The **HttpDestroyForm** function destroys the specified form, releasing the memory allocated for it.

Parameters

hForm

Handle to the form.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cshttpv10.lib

See Also

[HttpAddFormField](#), [HttpAddFormFile](#), [HttpClearForm](#), [HttpCreateForm](#), [HttpDeleteFormField](#), [HttpSubmitForm](#)

HttpDisableEvents Function

```
INT WINAPI HttpDisableEvents(  
    HCLIENT hClient  
);
```

The **HttpDisableEvents** function disables the event notification mechanism, preventing subsequent event notification messages from being posted to the application's message queue.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

This function affects both event notification and event callbacks. Any outstanding events in the message queue should be ignored by the client application.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

HttpDisableTrace Function

```
BOOL WINAPI HttpDisableTrace();
```

The **HttpDisableTrace** function disables the logging of socket function calls to the trace log.

Parameters

None.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cshttpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[HttpEnableTrace](#)

HttpDisconnect Function

```
INT WINAPI HttpDisconnect(  
    HCLIENT hClient  
);
```

The **HttpDisconnect** function terminates the connection with the server, closing the socket and releasing the memory allocated for the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cshttpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

HttpDownloadFile Function

```
BOOL WINAPI HttpDownloadFile(  
    LPCTSTR lpszLocalFile,  
    LPCTSTR lpszFileURL,  
    UINT nTimeout  
    DWORD dwOptions  
    LPHTTPTRANSFERSTATUS lpStatus  
    HTTPEVENTPROC lpEventProc  
    DWORD_PTR dwParam  
);
```

The **HttpDownloadFile** function downloads the specified file from the server to the local system.

Parameters

lpszLocalFile

A pointer to a string that specifies the file on the local system that will be created, overwritten or appended to. The file pathing and name conventions must be that of the local host.

lpszFileURL

A pointer to a string that specifies the complete URL of the file to be downloaded. The URL must follow the conventions for the File Transfer Protocol and may specify either a standard or secure connection, alternate port number, username, password and optional working directory.

nTimeout

The number of seconds that the client will wait for a response before failing the operation. A value of zero specifies that the default timeout period of sixty seconds will be used.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
HTTP_OPTION_NOCACHE	This instructs the server to not return a cached copy of the resource. When connected to an HTTP 1.0 or earlier server, this directive may be ignored.
HTTP_OPTION_PROXY	This option specifies the client should use the default proxy configuration for the local system. If the system is configured to use a proxy server, then the connection will be automatically established through that proxy; otherwise, a direct connection to the server is established. The local proxy configuration can be changed using the system Control Panel.
HTTP_OPTION_TUNNEL	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established.
HTTP_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server

	certificate will not be validated and the connection will always be permitted. This option only affects connections using either the SSL or TLS protocols.
HTTP_OPTION_SECURE	This option specifies the client should attempt to establish a secure connection with the server. Note that the server must support secure connections using either the SSL or TLS protocol.

lpStatus

A pointer to an HTTPTRANSFERSTATUS structure which contains information about the status of the current file transfer. If this information is not required, a NULL pointer may be specified as the parameter.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **HttpEventProc** callback function. If this parameter is NULL, the callback for the specified event is disabled.

dwParam

A user-defined integer value that is passed to the callback function.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpDownloadFile** function provides a convenient way for an application to download a file in a single function call. Based on the connection information specified in the URL, it will connect to the server, authenticate the session and then download the file to the local system. The URL must be complete, and specify either a standard or secure HTTP scheme:

```
[http|https]://[username : password] @] remotehost [:remoteport] / [path / ...] [filename]
```

If no user name and password is provided, then the client session will be authenticated as an anonymous user. The URL scheme will always determine if the connection is secure, not the option. In other words, if the "http" scheme is used and the HTTP_OPTION_SECURE option is specified, that option will be ignored. To establish a secure connection, the "https" scheme must be specified.

The *lpStatus* parameter can be used by the application to determine the final status of the transfer, including the total number of bytes copied, the amount of time elapsed and other information related to the transfer process. If this information isn't needed, then this parameter may be specified as NULL.

The *lpEventProc* parameter specifies a pointer to a function which will be periodically called during the file transfer process. This can be used to check the status of the transfer by calling **HttpGetTransferStatus** and then update the program's user interface. For example, the callback function could calculate the percentage for how much of the file has been transferred and then update a progress bar control. The *dwParam* parameter is used in conjunction with the event handler and specifies a user-defined value that is passed to the callback function. One common use in a C++ program is to pass the *this* pointer as the value, and then cast it back to an object pointer inside the callback function. If no event handler is required, then a NULL pointer can be specified as the value for *lpEventProc* and the *dwParam* parameter will be ignored.

The **HttpDownloadFile** function is designed to provide a simpler interface for downloading a file. However, complex connections such as those using a specific proxy server or a secure connection which uses a client certificate will require the program to establish the connection using **HttpConnect** or **HttpProxyConnect** and then use **HttpGetFile** to download the file.

Example

```
HTTPTRANSFERSTATUS httpStatus;
LPCTSTR lpszLocalFile = _T("c:\\temp\\database.mdb");
LPCTSTR lpszFileURL = _T("http://www.example.com/updates/database.mdb");
BOOL bResult;

// Download the file using the specified URL
bResult = HttpDownloadFile(lpszLocalFile,
                          lpszFileURL,
                          HTTP_OPTION_PASSIVE,
                          &httpStatus,
                          NULL, 0);

if (!bResult)
{
    TCHAR szError[128];

    // Display a message box that describes the error
    HttpGetErrorString(HttpGetLastError(), szError, 128);
    MessageBox(NULL, szError, NULL, MB_ICONEXCLAMATION|MB_TASKMODAL);
    return;
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cshttpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

HttpDownloadFileEx Function

```
BOOL WINAPI HttpDownloadFileEx(  
    LPCTSTR lpszLocalFile,  
    LPCTSTR lpszFileURL,  
    UINT nTimeout  
    DWORD dwOptions  
    LPHTTPTRANSFERSTATUSEX lpStatus  
    HTTPEVENTPROC lpEventProc  
    DWORD_PTR dwParam  
);
```

The **HttpDownloadFileEx** function downloads the specified file from the server to the local system. This version of the function is designed to support files that are larger than 4GB.

Parameters

lpszLocalFile

A pointer to a string that specifies the file on the local system that will be created, overwritten or appended to. The file pathing and name conventions must be that of the local host.

lpszFileURL

A pointer to a string that specifies the complete URL of the file to be downloaded. The URL must follow the conventions for the File Transfer Protocol and may specify either a standard or secure connection, alternate port number, username, password and optional working directory.

nTimeout

The number of seconds that the client will wait for a response before failing the operation. A value of zero specifies that the default timeout period of sixty seconds will be used.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
HTTP_OPTION_NOCACHE	This instructs the server to not return a cached copy of the resource. When connected to an HTTP 1.0 or earlier server, this directive may be ignored.
HTTP_OPTION_PROXY	This option specifies the client should use the default proxy configuration for the local system. If the system is configured to use a proxy server, then the connection will be automatically established through that proxy; otherwise, a direct connection to the server is established. The local proxy configuration can be changed using the system Control Panel.
HTTP_OPTION_TUNNEL	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established.

HTTP_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using either the SSL or TLS protocols.
HTTP_OPTION_SECURE	This option specifies the client should attempt to establish a secure connection with the server. Note that the server must support secure connections using either the SSL or TLS protocol.

lpStatus

A pointer to an HTTPTRANSFERSTATUSEX structure which contains information about the status of the current file transfer. If this information is not required, a NULL pointer may be specified as the parameter.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **HttpEventProc** callback function. If this parameter is NULL, the callback for the specified event is disabled.

dwParam

A user-defined integer value that is passed to the callback function.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpDownloadFileEx** function provides a convenient way for an application to download a file in a single function call. Based on the connection information specified in the URL, it will connect to the server, authenticate the session and then download the file to the local system. The URL must be complete, and specify either a standard or secure HTTP scheme:

```
[http|https]://[username : password] @] remotehost [:remoteport] / [path / ...] [filename]
```

If no user name and password is provided, then the client session will be authenticated as an anonymous user. The URL scheme will always determine if the connection is secure, not the option. In other words, if the "http" scheme is used and the HTTP_OPTION_SECURE option is specified, that option will be ignored. To establish a secure connection, the "https" scheme must be specified.

The *lpStatus* parameter can be used by the application to determine the final status of the transfer, including the total number of bytes copied, the amount of time elapsed and other information related to the transfer process. If this information isn't needed, then this parameter may be specified as NULL.

The *lpEventProc* parameter specifies a pointer to a function which will be periodically called during the file transfer process. This can be used to check the status of the transfer by calling **HttpGetTransferStatus** and then update the program's user interface. For example, the callback function could calculate the percentage for how much of the file has been transferred and then update a progress bar control. The *dwParam* parameter is used in conjunction with the event handler and specifies a user-defined value that is passed to the callback function. One common use in a C++ program is to pass the *this* pointer as the value, and then cast it back to an object pointer inside the callback function. If no event handler is required, then a NULL pointer can be

specified as the value for *lpEventProc* and the *dwParam* parameter will be ignored.

The **HttpDownloadFileEx** function is designed to provide a simpler interface for downloading a file. However, complex connections such as those using a specific proxy server or a secure connection which uses a client certificate will require the program to establish the connection using **HttpConnect** or **HttpProxyConnect** and then use **HttpGetFile** to download the file.

Example

```
HTTPTRANSFERSTATUSEX httpStatus;
LPCTSTR lpszLocalFile = _T("c:\\temp\\database.mdb");
LPCTSTR lpszFileURL = _T("http://www.example.com/updates/database.mdb");
BOOL bResult;

// Download the file using the specified URL
bResult = HttpDownloadFileEx(lpszLocalFile,
                             lpszFileURL,
                             HTTP_OPTION_PASSIVE,
                             &httpStatus,
                             NULL, 0);

if (!bResult)
{
    TCHAR szError[128];

    // Display a message box that describes the error
    HttpGetErrorString(HttpGetLastError(), szError, 128);
    MessageBox(NULL, szError, NULL, MB_ICONEXCLAMATION|MB_TASKMODAL);
    return;
}
```

Requirements

HttpEnableCompression Function

```
INT WINAPI HttpEnableCompression(  
    HCLIENT hClient,  
    BOOL bEnable  
);
```

The **HttpEnableCompression** function enables or disables support for data compression.

Parameters

hClient

Handle to the client session.

bEnable

A boolean value which specifies if data compression should be enabled or disabled. A non-zero value enables compression, while a value of zero will disable compression.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpEnableCompression** function is used to indicate to the server whether or not it is acceptable to compress the data that is returned to the client. If compression is enabled, the client will advertise that it will accept compressed data by setting the **Accept-Encoding** request header. The server will decide whether a resource being requested can be compressed. If the data is compressed, the library will automatically expand the data before returning it to the caller.

Enabling compression does not guarantee that the data returned by the server will actually be compressed, it only informs the server that the client is willing to accept compressed data. Whether or not a particular resource is compressed depends on the server configuration, and the server may decide to only compress certain types of resources, such as text files. Disabling compression informs the server that the client is not willing to accept compressed data; this is the default.

If the **HttpSetRequestHeader** function is used to explicitly set the **Accept-Encoding** header to request compressed data and compression is not enabled, the library will not attempt to automatically expand the data returned by the server. In this case, the raw compressed data will be returned to the caller and the application is responsible for processing it. This behavior is by design to maintain backwards compatibility with previous versions of the library that did not have internal support for compression.

To determine if the server compressed the data returned to the client, use the **HttpGetResponseHeader** function to get the value of the **Content-Encoding** header. If the header is defined, the value specifies the compression method used, otherwise the data was not compressed.

Enabling compression is only meaningful when downloading files from a server that supports file compression. It has no effect on file uploads.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

HttpEnableEvents Function

```
INT WINAPI HttpEnableEvents(  
    HCLIENT hClient,  
    HWND hEventWnd,  
    UINT uEventMsg  
);
```

The **HttpEnableEvents** function enables event notifications using Windows messages.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Applications should use the **HttpRegisterEvent** function to register an event handler which is invoked when an event occurs.

Parameters

hClient

Handle to the client session.

hEventWnd

Handle to the event notification window. This window receives a user-defined message which specifies the event that has occurred. If this value is NULL, event notification is disabled.

uEventMsg

An unsigned integer which specifies the user-defined message that is sent when an event occurs. This parameter's value must be greater than the value of WM_USER. If the *hEventWnd* parameter is NULL, this value must be specified as WM_NULL.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

When a message is posted to the notification window, the low word of the *lParam* parameter contains the event identifier. The high word of *lParam* contains the low word of the error code, if an error has occurred. The *wParam* parameter contains the client handle. One or more of the following event identifiers may be sent:

Constant	Description
HTTP_EVENT_CONNECT	The connection to the server has completed. The high word of the <i>lParam</i> parameter should be checked, since this notification message will be posted if an error has occurred.
HTTP_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
HTTP_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.

HTTP_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
HTTP_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
HTTP_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.
HTTP_EVENT_COMMAND	A command has been issued by the client and the server response has been received and processed. This event can be used to log the result codes and messages returned by the server in response to actions taken by the client.
HTTP_EVENT_PROGRESS	The client is in the process of sending or receiving data from the server. This event is called periodically during a transfer so that the client can update any user interface components such as a status control or progress bar.
HTTP_EVENT_REDIRECT	This event is generated when a the server indicates that the requested resource has been moved to a new location. The new resource location may be on the same server, or it may be located on another server. Check the value of the Location header field to determine where the resource has been moved to.

As noted, some events are only generated when the client is asynchronous mode. These events depend on the Windows Sockets asynchronous notification mechanism.

If event notification is disabled by specifying a NULL window handle, there may still be outstanding events in the message queue that must be processed. Since event handling has been disabled, these events should be ignored by the client application.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cshttpv10.lib

HttpEnableTrace Function

```
BOOL WINAPI HttpEnableTrace(  
    LPCTSTR lpszTraceFile,  
    DWORD dwTraceFlags  
);
```

The **HttpEnableTrace** function enables the logging of Windows Sockets function calls to a file.

Parameters

lpszTraceFile

A pointer to a string which specifies the name of the trace log file. If this parameter is NULL or an empty string, the default file name **cstrace.log** is used. The file is stored in the directory specified by the TEMP environment variable, if it is defined; otherwise, the current working directory is used.

dwTraceFlags

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
TRACE_INFO	All function calls are written to the trace file. This is the default value.
TRACE_ERROR	Only those function calls which fail are recorded in the trace file.
TRACE_WARNING	Only those function calls which fail or return values which indicate a warning are recorded in the trace file.
TRACE_HEXDUMP	All functions calls are written to the trace file, plus all the data that is sent or received is displayed, in both ASCII and hexadecimal format.
TRACE_PROCESS	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for multithreaded applications that are using worker threads.

Return Value

If the function succeeds, the return value is non-zero. A return value of zero indicates an error. Failure typically indicates that the tracing library **cstrcv10.dll** cannot be loaded on the local system.

Remarks

When trace logging is enabled, the file is opened, appended to and closed for each socket function call. This makes it possible for an application to append its own logging information, however care should be taken to ensure that the file is closed before the next network operation is performed. To limit the size of the log files, enable and disable logging only around those sections of code that you wish to trace.

Note that the TRACE_HEXDUMP trace level generates very large log files since it includes all of the data exchanged between your application and the server.

Trace function logging is managed on a per-thread basis, not for each client handle. This means that all SocketTools libraries and components share the same settings in the current thread. If you

are using multiple SocketTools libraries or components in your application, you only need to enable logging once.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cshttpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

HttpEnumTasks Function

```
INT WINAPI HttpEnumTasks(  
    UINT * lpTasks,  
    INT nMaxTasks,  
    DWORD dwOptions  
);
```

Return a list of active, suspended or finished asynchronous tasks.

Parameters

lpTasks

A pointer to an array of unsigned integer values that will contain unique task identifiers when the function returns. If this parameter is NULL, the function will return the number of tasks.

nMaxTasks

An integer value that specifies the maximum number of task identifiers that may be copied into the *lpTasks* array. If the *lpTasks* parameter is NULL, this value must be zero.

dwOptions

An unsigned integer that specifies the type of asynchronous tasks that may be returned by this function. It may be a combination of the following values:

Constant	Description
HTTP_TASK_DEFAULT	The list of asynchronous task IDs should include both active and suspended tasks. This option is the same as specifying both the HTTP_TASK_ACTIVE and HTTP_TASK_SUSPENDED options.
HTTP_TASK_ACTIVE	The list of asynchronous task IDs should include those tasks which are currently active. An active task represents a background connection to a server that is in the process of performing the requested action, such as uploading or downloading a file.
HTTP_TASK_SUSPENDED	The list of asynchronous task IDs should include those tasks which have been suspended. A suspended task represents a background connection that has been established, but the worker thread is not scheduled for execution.
HTTP_TASK_FINISHED	The list of asynchronous task IDs should include those tasks which have completed recently.

Return Value

If the function is successful, the return value is the number of task identifiers copied into the provided array. If there are no tasks which match the requested criteria, the return value is zero. A return value of HTTP_ERROR indicates an error has occurred. To get extended error information, call the **HttpGetLastError** function.

Remarks

The **HttpEnumTasks** function can be used to obtain a list of numeric identifiers that represent the asynchronous tasks that have been started or those that have completed. These task IDs are used by other functions to reference the background worker thread that has been created and obtain

status information for the task. For example, the **HttpTaskDone** function can be used to determine if a particular task has completed, and the **HttpTaskWait** function can be used to wait for a task to complete and return an error status code if the background operation failed.

There is an internal limit of 128 asynchronous tasks per process that may be active at any one time. When a task completes, the status information about that task is maintained for period of time after the task has completed.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

HttpEventProc Function

```
VOID CALLBACK HttpEventProc(  
    HCLIENT hClient,  
    UINT nEvent,  
    DWORD dwError,  
    DWORD_PTR dwParam  
);
```

The **HttpEventProc** function is an application-defined callback function that processes events generated by the client.

Parameters

hClient

Handle to the client session.

nEvent

An unsigned integer which specifies which event occurred. For a complete list of events, refer to the **HttpRegisterEvent** function.

dwError

An unsigned integer which specifies any error that occurred. If no error occurred, then this parameter will be zero.

dwParam

A user-defined integer value which was specified when the event callback was registered.

Return Value

None.

Remarks

An application must register this callback function by passing its address to the **HttpRegisterEvent** function. This callback function is also used by asynchronous tasks to notify the application when the task has started and completed. The **HttpEventProc** function is a placeholder for the application-defined function name.

If the callback function is invoked by an asynchronous task, it will execute in the context of the worker thread that is managing the client session. You must ensure that any access to global or static variables are synchronized, otherwise the results may be unpredictable. It is recommended that you do not declare any static variables within the callback function itself.

If the application has a graphical user interface, you should never attempt to directly modify a UI control from within the callback function for an asynchronous task. Controls should only be modified by the same UI thread that created their window. One common approach to resolve this issue is to post a user-defined message to the main window to signal that the user interface needs to be updated. The message handler would then process the user-defined message and update the user interface as needed.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cshttp10.lib

Unicode: Implemented as Unicode and ANSI versions.

Copyright © 2023 Catalyst Development Corporation. All rights reserved.

HttpFreezeEvents Function

```
INT WINAPI HttpFreezeEvents(  
    HCLIENT hClient,  
    BOOL bFreeze  
);
```

The **HttpFreezeEvents** function is used to suspend and resume event handling by the client.

Parameters

hClient

Handle to the client session.

bFreeze

A non-zero value specifies that event handling should be suspended by the client. A zero value specifies that event handling should be resumed.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

This function should be used when the application does not want to process events, such as when a modal dialog is being displayed. When events are suspended, all client events are queued. If events are re-enabled at a later point, those queued events will be sent to the application for processing. Note that only one of each event will be generated. For example, if the client has suspended event handling, and four read events occur, once event handling is resumed only one of those read events will be posted to the client. This prevents the application from being flooded by a potentially large number of queued events.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

HttpGetBearerToken Function

```
INT WINAPI HttpGetBearerToken(  
    HCLIENT hClient,  
    LPTSTR lpszBearerToken,  
    INT nMaxLength  
);
```

The **HttpGetBearerToken** function returns the OAuth 2.0 bearer token used to authenticate the client session with a web service.

Parameters

hClient

Handle to the client session.

lpszBearerToken

A pointer to a string buffer which will contain the bearer token when the function returns. The string will be null terminated and the buffer must be large enough to accommodate the entire bearer token or the function will fail. This parameter cannot be a NULL pointer.

nMaxLength

The maximum number of characters that may be copied into the string buffer. This value must be greater than zero.

Return Value

If the function succeeds, the return value is the length of the bearer token string. A return value of zero indicates that no bearer token has been specified. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

This function returns the bearer token which was previously set by a call to **HttpSetBearerToken**. Bearer tokens can be very long strings and do not contain any human readable information. For Google services, these tokens are usually about 180 characters in length. For Microsoft services, their bearer tokens are typically 1,200 characters in length. It is recommended that you provide a buffer size of at least 2,000 characters.

Your application should not store the bearer tokens provided by a web service. These tokens are short-lived and typically only valid for about an hour. If the token has expired, the authorization to access the resource will fail and it must be refreshed. The refresh tokens used to acquire a new bearer token should be stored and they are typically valid for a period of months.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cshttpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

HttpGetCookie Function

```
BOOL WINAPI HttpGetCookie(  
    HCLIENT hClient,  
    LPCTSTR lpszCookieName,  
    LPTSTR lpszCookieValue,  
    INT nCookieValue,  
    LPTSTR lpszCookiePath,  
    INT nCookiePath,  
    LPTSTR lpszCookieDomain,  
    INT nCookieDomain,  
    LPSYSTEMTIME lpCookieExpires,  
    LPDWORD lpdwCookieFlags  
);
```

The **HttpGetCookie** function returns information about a cookie set by the server.

Parameters

hClient

Handle to the client session.

lpszCookieName

A pointer to a string which specifies the name of the cookie to return information about.

lpszCookieValue

A pointer to a string buffer that will contain the value of the cookie. If this information is not required, a NULL pointer may be specified.

nCookieValue

The maximum number of characters that may be copied into the buffer specified by the *lpszCookieValue* parameter, including the terminating null character.

lpszCookiePath

A pointer to a string buffer that will contain the cookie path. If this information is not required, a NULL pointer may be specified.

nCookiePath

The maximum number of characters that may be copied into the buffer specified by the *lpszCookiePath* parameter, including the terminating null character.

lpszCookieDomain

A pointer to a string buffer that will contain the cookie domain. If this information is not required, a NULL pointer may be specified.

nCookieDomain

The maximum number of characters that may be copied into the buffer specified by the *lpszCookieDomain* parameter, including the terminating null character.

lpCookieExpires

A pointer to a [SYSTEMTIME](#) structure which specifies the date and time that the cookie expires. If this information is not required, a NULL pointer may be specified.

lpdwCookieFlags

One or more bit flags which specify status information about the cookie. A value of zero indicates that there are no special status flags for the cookie. This parameter may be NULL if the

information is not required. The following values are currently defined:

Constant	Description
HTTP_COOKIE_SECURE	This flag specifies that the cookie should only be provided to the server if the connection is secure.
HTTP_COOKIE_SESSION	This flag specifies that the cookie should only be used for the current application session and should not be stored permanently on the local system.

Return Value

If the function succeeds, the return value is non-zero. If the specified cookie does not exist or function fails, the return value is zero. To get extended error information, call **HttpGetLastError**.

Remarks

The Hypertext Transfer Protocol uses special tokens called "cookies" to maintain persistent state information between requests for a resource. These cookies are exchanged between the client and server by setting specific header fields. When a server wants the client to use a cookie, it will include a header field named Set-Cookie in the response header when the client requests a resource. The client can then take this cookie and store it, either temporarily in memory or permanently in a file on the local system. The next time that the client requests a resource from that server, it can send the cookie back to the server by setting the Cookie header field. The **HttpGetCookie** function searches for a cookie set by the server in the Set-Cookie header field. The **HttpSetCookie** function creates or modifies the Cookie header field for the next resource requested by the client.

There are two general types of cookies that are used by servers. Session cookies exist only for the duration of the client session; they are stored in memory and not saved in any kind of permanent storage. When the client application terminates, session cookies are deleted and no longer used. Persistent cookies are stored on the local system and are used by the client until their expiration time. It is the responsibility of the client application to store persistent cookies; applications may use a flat text file, a database or any other storage method available.

In addition to the cookie name and value, the server may return additional information about the cookie which the client should use to determine if it should send the cookie back to the server:

The *cookie path* specifies a path for the resources where the cookie should be used. For example, a path of "/" indicates that the cookie should be provided for all resources requested from the server. A path of "/data" would mean that the cookie should be included if the resource is found in the /data folder or a sub-folder, such as /data/projections.asp. However, the cookie would not be provided if the resource /info/status.asp was requested, since it is not in the /data path.

The *cookie domain* specifies the domain for which the cookie should be used. Matches are made by comparing the name of the server against the domain name specified in the cookie. If the domain is example.com, then any server in the example.com domain would match; for example, both shipping.example.com and orders.example.com would match the domain value. However, if the cookie domain was orders.example.com, then the cookie would only be sent if the resource was requested from orders.example.com, not if the resource was located on shipping.example.com or www.example.com.

The *cookie expiration* specifies the date and time that the cookie should be deleted and no longer sent when a resource is requested from the server. This is only valid for persistent cookies, since session cookies are automatically deleted when the client

application terminates. The time is always expressed as Coordinated Universal Time.

The *cookie flags* provide additional information about the cookie. In some cases, a cookie should only be submitted to the server if the resource is requested using a secure connection. In this case, the bit flag HTTP_COOKIE_SECURE will be set.

It is the responsibility of the client application to determine if a cookie meets the criteria required to be submitted to the server. If the application wishes to send the cookie, it can use the **HttpSetCookie** function and specify the cookie name and value.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

HttpGetData Function

```
INT WINAPI HttpGetData(  
    HCLIENT hClient,  
    LPCTSTR lpszResource,  
    LPVOID lpvBuffer,  
    LPDWORD lpdwLength,  
    DWORD dwOptions  
);
```

The **HttpGetData** function requests a resource from the server and copies the data to the specified buffer.

Parameters

hClient

Handle to the client session.

lpszResource

A pointer to a string that specifies the resource on the server. This may be the name of a file on the server, or it may specify the name of a script that will be executed and the output returned to the caller. This string may specify a valid URL for the current server that the client is connected to.

lpvBuffer

A pointer to a byte buffer which will contain the data transferred from the server, or a pointer to a global memory handle which will reference the data when the function returns.

lpdwLength

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the *lpvBuffer* parameter. If the *lpvBuffer* parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the actual length of the file that was downloaded.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
HTTP_TRANSFER_DEFAULT	The default transfer mode. The resource data is downloaded to the local system exactly as it is stored on the server. If you are requesting a text-based resource, the data may use a different end-of-line character sequence. For example, the end-of-line character may be a single linefeed character instead of a carriage return and linefeed pair.
HTTP_TRANSFER_CONVERT	If the resource being downloaded from the server is textual, the data is automatically converted so that the end of line character sequence is compatible with the Windows platform. Individual carriage return or linefeed characters are converted to carriage return/linefeed character sequences.

HTTP_TRANSFER_COMPRESS	This option informs the server that the client is willing to accept compressed data. If the server supports compression for the specified resource, then the data will be automatically expanded before being returned to the caller. This option is selected by default if compression has been enabled using the HttpEnableCompression function.
HTTP_TRANSFER_ERRORDATA	This option causes the client to accept error data from the server if the request fails. If this option is specified, an error response from the server will not cause the function to fail. Instead, the response is returned to the client and the function will succeed. If this option is used, your application should call HttpGetResultCode to obtain the HTTP status code returned by the server. This will enable you to determine if the operation was successful.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpGetData** function is used to retrieve a resource from the server and copy it into a local buffer. The function may be used in one of two ways, depending on the needs of the application. The first method is to pre-allocate a buffer large enough to store the contents of the file. In this case, the *lpvBuffer* parameter will point to the buffer that was allocated and the value that the *lpdwLength* parameter points to should be initialized to the size of that buffer.

The second method that can be used is have the *lpvBuffer* parameter point to a global memory handle which will contain the file data when the function returns. In this case, the value that the *lpdwLength* parameter points to must be initialized to zero. It is important to note that the memory handle returned by the function must be freed by the application, otherwise a memory leak will occur. See the example code below.

If compression has been enabled and the server returns compressed data, it will be automatically expanded before being returned to the caller. This will result in a difference between the value returned in the *lpdwLength* parameter, which contains the actual number of bytes copied into the buffer, and the values reported by **HttpGetTransferStatus**. For example, if the server returns 5,000 bytes of compressed data that expands into 15,000 bytes, this function will return 15,000 as the number of bytes copied into the buffer. However, the **HttpGetTransferStatus** function will return the content length as the original 5,000 bytes of compressed data. For this reason, you should always use the value returned in the *lpdwLength* parameter to determine the amount of data that has been copied into the buffer.

This function will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the HTTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **HttpEnableEvents**, or by registering a callback function using the **HttpRegisterEvent** function.

To determine the current status of a file transfer while it is in progress, use the **HttpGetTransferStatus** function.

Example

```
HGLOBAL hgblBuffer = (HGLOBAL)NULL;
LPBYTE lpBuffer = (LPBYTE)NULL;
DWORD cbBuffer = 0;

// Return the file data into block of global memory allocated by
// the GlobalAlloc function; the handle to this memory will be
// returned in the hgblBuffer parameter
nResult = HttpGetData(hClient,
                    lpszResource,
                    &hgblBuffer,
                    &cbBuffer,
                    HTTP_TRANSFER_DEFAULT);

if (nResult != HTTP_ERROR)
{
    // Lock the global memory handle, returning a pointer to the
    // resource data
    lpBuffer = (LPBYTE)GlobalLock(hgblBuffer);

    // After the data has been used, the handle must be unlocked
    // and freed, otherwise a memory leak will occur
    GlobalUnlock(hgblBuffer);
    GlobalFree(hgblBuffer);
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

HttpGetEncodingType Function

```
INT WINAPI HttpGetEncodingType(  
    HCLIENT hClient  
);
```

The **HttpGetEncodingType** function determines which content-encoding option is enabled.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is one of the following values:

Value	Constant	Description
0	HTTP_ENCODING_NONE	No encoding will be applied to the content of a request, and no Content-Type header will be generated.
1	HTTP_ENCODING_URL	URL encoding will be applied to the content of a request, and a Content-Type header will be generated with the value "application/x-www-form-urlencoded"
2	HTTP_ENCODING_XML	URL encoding will be applied to the content of a request, EXCEPT that spaces will not be replaced by '+'. This encoding type is intended for use with XML parsers that do not recognize '+' as a space. A Content-Type header will be generated with the value "application/x-www-form-urlencoded".

If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cshttpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

HttpGetErrorString Function

```
INT WINAPI HttpGetErrorString(  
    DWORD dwErrorCode,  
    LPTSTR lpszDescription,  
    INT cbDescription  
);
```

The **HttpGetErrorString** function is used to return a description of a specific error code. Typically this is used in conjunction with the **HttpGetLastError** function for use with warning dialogs or as diagnostic messages.

Parameters

dwErrorCode

The error code for which a description is returned.

lpszDescription

A pointer to the buffer that will contain a description of the specified error code. This buffer should be at least 128 characters in length.

cbDescription

The maximum number of characters that may be copied into the description buffer.

Return Value

If the function succeeds, the return value is the length of the description string. If the function fails, the return value is zero, meaning that no description exists for the specified error code. Typically this indicates that the error code passed to the function is invalid.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `cshttpv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

[HttpGetLastError](#), [HttpSetLastError](#)

HttpGetFile Function

```
INT WINAPI HttpGetFile(  
    HCLIENT hClient,  
    LPCTSTR lpszLocalFile,  
    LPCTSTR lpszRemoteFile,  
    DWORD dwOptions,  
    DWORD dwOffset  
);
```

The **HttpGetFile** function transfers the specified file on the server to the local system.

Parameters

hClient

Handle to the client session.

lpszLocalFile

A pointer to a string that specifies the file on the local system that will be created, overwritten or appended to. The file pathing and name conventions must be that of the local system.

lpszRemoteFile

A pointer to a string that specifies the resource on the server. This may be the name of a file on the server, or it may specify the name of a script that will be executed and the output returned to the caller. This string may specify a valid URL for the current server that the client is connected to.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
HTTP_TRANSFER_DEFAULT	The default transfer mode. The resource data is downloaded to the local system exactly as it is stored on the server. If you are requesting a text-based resource, the data may use a different end-of-line character sequence. For example, the end-of-line character may be a single linefeed character instead of a carriage return and linefeed pair.
HTTP_TRANSFER_CONVERT	If the resource being downloaded from the server is textual, the data is automatically converted so that the end of line character sequence is compatible with the Windows platform. Individual carriage return or linefeed characters are converted to carriage return/linefeed character sequences.
HTTP_TRANSFER_COMPRESS	This option informs the server that the client is willing to accept compressed data. If the server supports compression for the specified resource, then the data will be automatically expanded before being returned to the caller. This option is selected by default if compression has been enabled using the HttpEnableCompression function. This option is

	ignored if the <i>dwOffset</i> parameter is non-zero.
HTTP_TRANSFER_ERRORDATA	This option causes the client to accept error data from the server if the request fails. If this option is specified, an error response from the server will not cause the function to fail. Instead, the response is returned to the client and the function will succeed. If this option is used, your application should call HttpGetResultCode to obtain the HTTP status code returned by the server. This will enable you to determine if the operation was successful.

dwOffset

Specifies a byte offset into the file. If this value is greater than zero, the server must support the ability to specify a byte range with the request to download the file, otherwise this function will fail.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

Enabling compression does not guarantee that the data returned by the server will actually be compressed, it only informs the server that the client is willing to accept compressed data. Whether or not a particular resource is compressed depends on the server configuration, and the server may decide to only compress certain types of resources, such as text files. To determine if the server compressed the data returned to the client, use the **HttpGetResponseHeader** function to get the value of the **Content-Encoding** header after this function returns. If the header is defined, the value specifies the compression method used, otherwise the data was not compressed.

To download large files that are over 4GB, use the **HttpGetFileEx** function.

This function will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the HTTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **HttpEnableEvents**, or by registering a callback function using the **HttpRegisterEvent** function.

To determine the current status of a file transfer while it is in progress, use the **HttpGetTransferStatus** function.

Example

```
LPCTSTR lpszLocalFile = _T("index.html");
LPCTSTR lpszRemoteFile = _T("http://sockettools.com/");

if (HttpGetFile(hClient, lpszLocalFile, lpszRemoteFile) == HTTP_ERROR)
{
    dwError = HttpGetLastError();
    _tprintf(stderr, "Unable to download %s, error 0x%lx\n", lpszRemoteFile,
dwError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cshttpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[HttpEnableEvents](#), [HttpGetData](#), [HttpGetFileEx](#), [HttpGetText](#), [HttpGetTransferStatus](#), [HttpPutFile](#), [HttpRegisterEvent](#)

HttpGetFileEx Function

```
INT WINAPI HttpGetFileEx(  
    HCLIENT hClient,  
    LPCTSTR lpszLocalFile,  
    LPCTSTR lpszRemoteFile,  
    DWORD dwOptions,  
    ULARGE_INTEGER uiOffset  
);
```

The **HttpGetFileEx** function transfers the specified file on the server to the local system. This version of the function is designed to support files that are larger than 4GB.

Parameters

hClient

Handle to the client session.

lpszLocalFile

A pointer to a string that specifies the file on the local system that will be created, overwritten or appended to. The file pathing and name conventions must be that of the local host.

lpszRemoteFile

A pointer to a string that specifies the resource on the server. This may be the name of a file on the server, or it may specify the name of a script that will be executed and the output returned to the caller. This string may specify a valid URL for the current server that the client is connected to.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
HTTP_TRANSFER_DEFAULT	The default transfer mode. The resource data is downloaded to the local system exactly as it is stored on the server. If you are requesting a text-based resource, the data may use a different end-of-line character sequence. For example, the end-of-line character may be a single linefeed character instead of a carriage return and linefeed pair.
HTTP_TRANSFER_CONVERT	If the resource being downloaded from the server is textual, the data is automatically converted so that the end of line character sequence is compatible with the Windows platform. Individual carriage return or linefeed characters are converted to carriage return/linefeed character sequences.
HTTP_TRANSFER_COMPRESS	This option informs the server that the client is willing to accept compressed data. If the server supports compression for the specified resource, then the data will be automatically expanded before being returned to the caller. This option is selected by default if compression has been enabled using the

	HttpEnableCompression function. This option is ignored if the <i>uiOffset</i> parameter is non-zero.
HTTP_TRANSFER_ERRORDATA	This option causes the client to accept error data from the server if the request fails. If this option is specified, an error response from the server will not cause the function to fail. Instead, the response is returned to the client and the function will succeed. If this option is used, your application should call HttpGetResultCode to obtain the HTTP status code returned by the server. This will enable you to determine if the operation was successful.

uiOffset

Specifies a byte offset into the file. If this value is greater than zero, the server must support the ability to specify a byte range with the request to download the file, otherwise this function will fail.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

Enabling compression does not guarantee that the data returned by the server will actually be compressed, it only informs the server that the client is willing to accept compressed data. Whether or not a particular resource is compressed depends on the server configuration, and the server may decide to only compress certain types of resources, such as text files. To determine if the server compressed the data returned to the client, use the **HttpGetResponseHeader** function to get the value of the **Content-Encoding** header after this function returns. If the header is defined, the value specifies the compression method used, otherwise the data was not compressed.

This function will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the HTTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **HttpEnableEvents**, or by registering a callback function using the **HttpRegisterEvent** function.

To determine the current status of a file transfer while it is in progress, use the **HttpGetTransferStatusEx** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cshttp10.lib

Unicode: Implemented as Unicode and ANSI versions.

HttpGetFileSize Function

```
INT WINAPI HttpGetFileSize(  
    HCLIENT hClient,  
    LPCTSTR lpszFileName,  
    LPDWORD lpdwFileSize  
);
```

The **HttpGetFileSize** function returns the size of the specified file on the server.

Parameters

hClient

Handle to the client session.

lpszFileName

Points to a string that specifies the name of the remote file.

lpdwFileSize

Points to an unsigned integer that will contain the size of the specified file in bytes.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

This function uses the HEAD command to retrieve header information about the file without downloading the contents of the file itself. This requires that the server support at least version 1.0 of the protocol standard, or an error will be returned.

The server may not return a file size for some resources. This is typically the case with scripts that generate dynamic content because the server has no way of determining the size of the output generated by the script without actually executing it. The server may also not provide a file size for HTML documents which use server side includes (SSI) because that content is also dynamically created by the server. If the request to the server was successful and the file exists, but the server does not return a file size, the function will succeed but the file size returned to the caller will be zero.

When a request is made to the server for information about the file, the library will attempt to keep the connection alive, even if the HTTP_OPTION_KEEPALIVE option has not been specified for the session. This allows an application to request the file size and then download the file without having to write additional code to re-establish the connection. However, it is possible that the attempt to keep the connection open will fail. In that case, an error will be returned and the client handle will no longer be valid. If this happens, the *lpdwFileSize* parameter may still contain a valid value. If the library was able to determine the file size, but was not able to maintain the connection to the server, the returned file size will be greater than zero even if the function returns an error.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cshttp10.lib

Unicode: Implemented as Unicode and ANSI versions.

HttpGetFileSizeEx Function

```
INT WINAPI HttpGetFileSizeEx(  
    HCLIENT hClient,  
    LPCTSTR lpszFileName,  
    LPULARGE_INTEGER lpuiFileSize  
);
```

The **HttpGetFileSizeEx** function returns the size of the specified file on the server. This version of the function is designed to support files that are larger than 4GB.

Parameters

hClient

Handle to the client session.

lpszFileName

Points to a string that specifies the name of the remote file.

lpdwFileSize

Points to a ULARGE_INTEGER structure that will contain the size of the specified file in bytes.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

This function uses the HEAD command to retrieve header information about the file without downloading the contents of the file itself. This requires that the server support at least version 1.0 of the protocol standard, or an error will be returned.

The server may not return a file size for some resources. This is typically the case with scripts that generate dynamic content because the server has no way of determining the size of the output generated by the script without actually executing it. The server may also not provide a file size for HTML documents which use server side includes (SSI) because that content is also dynamically created by the server. If the request to the server was successful and the file exists, but the server does not return a file size, the function will succeed but the file size returned to the caller will be zero.

When a request is made to the server for information about the file, the library will attempt to keep the connection alive, even if the HTTP_OPTION_KEEPALIVE option has not been specified for the session. This allows an application to request the file size and then download the file without having to write additional code to re-establish the connection. However, it is possible that the attempt to keep the connection open will fail. In that case, an error will be returned and the client handle will no longer be valid. If this happens, the *lpdwFileSize* parameter may still contain a valid value. If the library was able to determine the file size, but was not able to maintain the connection to the server, the returned file size will be greater than zero even if the function returns an error.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cshttp10.lib

Unicode: Implemented as Unicode and ANSI versions.

HttpGetFileTime Function

```
INT WINAPI HttpGetFileTime(  
    HCLIENT hClient,  
    LPCTSTR lpszFileName,  
    LPSYSTEMTIME lpFileTime,  
    BOOL bLocalize  
);
```

The **HttpGetFileTime** function returns the modification time for the specified file on the server.

Parameters

hClient

Handle to the client session.

lpszFileName

Points to a string that specifies the name of the remote file.

lpFileTime

Points to a [SYSTEMTIME](#) structure that will be set to the current modification time for the remote file.

bLocalize

A boolean flag which specifies if the file time is localized to the current timezone. If this value is non-zero, then the file time is adjusted to that the time is local to the current system. If this value is zero, the file time is returned in UTC time.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpGetFileTime** function can be used to determine the date and time that a file was last modified on the server. The time may either be localized to the current system, or it may be returned as UTC time.

This function uses the HEAD command to retrieve header information about the file without downloading the contents of the file itself. This requires that the server support at least version 1.0 of the protocol standard, or an error will be returned.

The server may not return a modification time for some resources. If the request to the server was successful and the file exists, but the server does not return a modification time, the function will succeed but all of the members of the SYSTEMTIME structure will be zero.

When a request is made to the server for information about the file, the library will attempt to keep the connection alive, even if the HTTP_OPTION_KEEPALIVE option has not been specified for the session. This allows an application to request the modification time and then download the file without having to write additional code to re-establish the connection. However, it is possible that the attempt to keep the connection open will fail. In that case, an error will be returned and the client handle will no longer be valid. If this happens, the SYSTEMTIME structure may still contain a valid value. If the library was able to determine the modification time, but was not able to maintain the connection to the server, the members of the SYSTEMTIME structure will specify a valid date and time.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cshttpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[HttpCommand](#), [HttpGetFileSize](#)

HttpGetFirstCookie

```
DWORD WINAPI HttpGetFirstCookie(  
    HCLIENT hClient,  
    LPTSTR lpszCookieName,  
    LPINT lpnNameLen,  
    LPTSTR lpszCookieValue,  
    LPINT lpnValueLen  
);
```

The **HttpGetFirstCookie** function returns the first cookie set by the server.

Parameters

hClient

Handle to the client session.

lpszCookieName

A pointer to a string buffer which will contain the name of the first cookie set by the server.

lpnNameLen

A pointer to an integer which specifies the maximum number of characters which may be copied into the buffer, including the terminating null character. When the function returns, this value is updated to specify the actual length of the cookie name string.

lpszCookieValue

A pointer to a string buffer which will contain the name of the first cookie value set by the server. If the cookie value is not required, this parameter may be NULL.

lpnValueLen

A pointer to an integer which specifies the maximum number of characters which may be copied into the buffer, including the terminating null character. When the function returns, this value is updated to specify the actual length of the cookie value string. If the *lpszCookieValue* parameter is NULL, this parameter should also be NULL.

Return Value

If the function succeeds, the return value is a 32-bit token which will be passed to the **HttpGetNextCookie** function to retrieve the next cookie. If there are no cookies or the function fails, the return value is zero. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpGetFirstCookie** function is used to enumerate the cookies set by the server after a resource has been requested. To get information about a specific cookie, use the **HttpGetCookie** function.

Example

```
TCHAR szCookieName[MAXCOOKIENAME];  
TCHAR szCookieValue[MAXCOOKIEVALUE];  
INT nNameLen, nValueLen;  
DWORD dwCookie;  
  
// Initialize the nNameLen and nValueLen variables to  
// the maximum number of characters that can be copied  
// into the string buffers  
nNameLen = MAXCOOKIENAME;
```

```

nValueLen = MAXCOOKIEVALUE;

// Get the first cookie set by the server
dwCookie = HttpGetFirstCookie(hClient,
                             szCookieName,
                             &nNameLen,
                             szCookieValue,
                             &nValueLen);

while (dwCookie != 0)
{
    // The szCookieName and szCookieValue strings contain the
    // the name and value for a cookie set by the server

    // Re-initialize the nNameLen and nValueLen variables
    // to the maximum length of the strings
    nNameLen = MAXCOOKIENAME;
    nValueLen = MAXCOOKIEVALUE;

    // Get the next cookie set by the server
    dwCookie = HttpGetNextCookie(hClient,
                                 dwCookie,
                                 szCookieName,
                                 &nNameLen,
                                 szCookieValue,
                                 &nValueLen);
};

```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cshttp10.lib

HttpGetFirstHeader Function

```
BOOL WINAPI HttpGetFirstHeader(  
    HCLIENT hClient,  
    UINT nHeaderType,  
    LPTSTR lpszHeader,  
    LPINT lpcchHeader  
    LPTSTR lpszValue,  
    LPINT lpcchValue  
);
```

The **HttpGetFirstHeader** function returns the name and value of the first request or response header.

Parameters

hClient

Handle to the client session.

nHeaderType

Specifies the type of header to return. It may be one of the following values:

Constant	Description
HTTP_HEADERS_REQUEST	Return the first header set by the client before a resource has been requested. Request headers typically specify information that the server needs to complete the request, such as the name of the host that has the resource, or what types of resources are acceptable to the client.
HTTP_HEADERS_RESPONSE	Return the first header set by the server after a request has been submitted to the server. The response headers typically contain information about the resource, such as its size, the content type and the date it was last modified.

lpszHeader

A pointer to a string buffer that will contain the name of the header field when the function returns.

lpcchHeader

A pointer to an integer which specifies the maximum number of characters which may be copied into the buffer, including the terminating null character. When the function returns, this value is updated to specify the actual length of the header name string.

lpszValue

A pointer to a string buffer that will contain the name of the header value when the function returns.

lpcchValue

A pointer to an integer which specifies the maximum number of characters which may be copied into the buffer, including the terminating null character. When the function returns, this value is updated to specify the actual length of the header value string.

Return Value

If the function succeeds, the return value is non-zero. If the header field does not exist or the client handle is invalid, the function returns a value of zero. To get extended error information, call **HttpGetLastError**.

Remarks

Use this function together with **HttpGetNextHeader** to enumerate all request or response headers.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cshttpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

HttpGetFormProperties Function

```
INT WINAPI HttpGetFormProperties(  
    HFORM hForm,  
    LPHTTPFORMPROPERTIES lpFormProp  
);
```

The **HttpGetFormProperties** function returns information about the specified form.

Parameters

hForm

Handle to the virtual form.

lpFormProp

Points to a HTTPFORMPROPERTIES structure which will contain information about the specified form.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cshttpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[HttpCreateForm](#), [HttpSetFormProperties](#), [HttpSubmitForm](#), [HTTPFORMPROPERTIES](#)

HttpGetLastError Function

```
DWORD WINAPI HttpGetLastError();
```

Parameters

None.

Return Value

The return value is the last error code value for the current thread. Functions set this value by calling the **HttpSetLastError** function. The Return Value section of each reference page notes the conditions under which the function sets the last error code.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. You should call the **HttpGetLastError** function immediately when a function's return value indicates that an error has occurred. That is because some functions call **HttpSetLastError(0)** when they succeed, clearing the error code set by the most recently failed function.

Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or HTTP_ERROR. Those functions which call **HttpSetLastError** when they succeed are noted on the function reference page.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cshttpv10.lib

See Also

[HttpGetErrorString](#), [HttpSetLastError](#)

HttpGetFirstCookie

```
DWORD WINAPI HttpGetNextCookie(  
    HCLIENT hClient,  
    DWORD dwCookie,  
    LPTSTR lpszCookieName,  
    LPINT lpnNameLen,  
    LPTSTR lpszCookieValue,  
    LPINT lpnValueLen  
);
```

The **HttpGetNextCookie** function returns the next cookie set by the server.

Parameters

hClient

Handle to the client session.

dwCookie

An unsigned integer value which specifies a cookie token returned by a previous call to either **HttpGetFirstCookie** or **HttpGetNextCookie**.

lpszCookieName

A pointer to a string buffer which will contain the name of the first cookie set by the server.

lpnNameLen

A pointer to an integer which specifies the maximum number of characters which may be copied into the buffer, including the terminating null character. When the function returns, this value is updated to specify the actual length of the cookie name string.

lpszCookieValue

A pointer to a string buffer which will contain the name of the first cookie value set by the server. If the cookie value is not required, this parameter may be NULL.

lpnValueLen

A pointer to an integer which specifies the maximum number of characters which may be copied into the buffer, including the terminating null character. When the function returns, this value is updated to specify the actual length of the cookie value string. If the *lpszCookieValue* parameter is NULL, this parameter should also be NULL.

Return Value

If the function succeeds, the return value is a 32-bit token which will be passed to the **HttpGetNextCookie** function to retrieve the next cookie. If there are no more cookies or the function fails, the return value is zero. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpGetNextCookie** function is used to enumerate the cookies set by the server after a resource has been requested. To get information about a specific cookie, use the **HttpGetCookie** function.

Example

```
TCHAR szCookieName[MAXCOOKIENAME];  
TCHAR szCookieValue[MAXCOOKIEVALUE];  
INT nNameLen, nValueLen;  
DWORD dwCookie;
```

```

// Initialize the nNameLen and nValueLen variables to
// the maximum number of characters that can be copied
// into the string buffers
nNameLen = MAXCOOKIENAME;
nValueLen = MAXCOOKIEVALUE;

// Get the first cookie set by the server
dwCookie = HttpGetFirstCookie(hClient,
                              szCookieName,
                              &nNameLen,
                              szCookieValue,
                              &nValueLen);

while (dwCookie != 0)
{
    // The szCookieName and szCookieValue strings contain the
    // the name and value for a cookie set by the server

    // Re-initialize the nNameLen and nValueLen variables
    // to the maximum length of the strings
    nNameLen = MAXCOOKIENAME;
    nValueLen = MAXCOOKIEVALUE;

    // Get the next cookie set by the server
    dwCookie = HttpGetNextCookie(hClient,
                                 dwCookie,
                                 szCookieName,
                                 &nNameLen,
                                 szCookieValue,
                                 &nValueLen);
};

```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cshttpv10.lib

See Also

[HttpGetCookie](#), [HttpGetFirstCookie](#), [HttpGetResponseHeader](#), [HttpSetCookie](#),
[HttpSetRequestHeader](#)

HttpGetNextHeader Function

```
BOOL WINAPI HttpGetNextHeader(  
    HCLIENT hClient,  
    UINT nHeaderType,  
    LPTSTR lpszHeader,  
    LPINT lpcchHeader,  
    LPTSTR lpszValue,  
    LPINT lpcchValue  
);
```

The **HttpGetNextHeader** function returns the name and value of the next request or response header.

Parameters

hClient

Handle to the client session.

nHeaderType

Specifies the type of header to return. It may be one of the following values:

Constant	Description
HTTP_HEADERS_REQUEST	Return the first header set by the client before a resource has been requested. Request headers typically specify information that the server needs to complete the request, such as the name of the host that has the resource, or what types of resources are acceptable to the client.
HTTP_HEADERS_RESPONSE	Return the first header set by the server after a request has been submitted to the server. The response headers typically contain information about the resource, such as its size, the content type and the date it was last modified.

lpszHeader

A pointer to a string buffer that will contain the name of the header field when the function returns.

lpcchHeader

A pointer to an integer which specifies the maximum number of characters which may be copied into the buffer, including the terminating null character. When the function returns, this value is updated to specify the actual length of the header name string.

lpszValue

A pointer to a string buffer that will contain the name of the header value when the function returns.

lpcchValue

A pointer to an integer which specifies the maximum number of characters which may be copied into the buffer, including the terminating null character. When the function returns, this value is updated to specify the actual length of the header value string.

Return Value

If the function succeeds, the return value is non-zero. If the header field does not exist or the client handle is invalid, the function returns a value of zero. To get extended error information, call **HttpGetLastError**.

Remarks

Use this function iteratively after **HttpGetFirstHeader** to enumerate all request or response headers.

Unlike the **HttpGetResponseHeader** function, which returns a single header name and value, the **HttpGetFirstHeader** and **HttpGetNextHeader** functions will return multiple headers that have the same common name.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cshttpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[HttpGetResponseHeader](#), [HttpSetRequestHeader](#), [HttpGetFirstHeader](#)

HttpGetOption Function

```
INT WINAPI HttpGetOption(  
    HCLIENT hClient,  
    DWORD dwOption,  
    LPBOOL lpbEnabled  
);
```

The **HttpGetOption** function determines whether a specified HTTP option is enabled.

Parameters

hClient

Handle to the client session.

dwOption

An unsigned integer which specifies the option that is to be checked. It may be one of the following values:

Constant	Description
HTTP_OPTION_NOCACHE	This instructs the server to not return a cached copy of the resource. When connected to an HTTP 1.0 or earlier server, this directive may be ignored.
HTTP_OPTION_KEEPALIVE	This instructs the server to maintain a persistent connection between requests. This can improve performance because it eliminates the need to establish a separate connection for each resource that is requested.
HTTP_OPTION_REDIRECT	This option specifies the client should automatically handle resource redirection. If the server indicates that the requested resource has moved to a new location, the client will close the current connection and request the resource from the new location. Note that it is possible that the redirected resource will be located on a different server.
HTTP_OPTION_ERRORDATA	This option specifies the client should return the content of an error response from the server, rather than returning an error code. Note that this option will disable automatic resource redirection, and should not be used with HTTP_OPTION_REDIRECT.
HTTP_OPTION_NOUSERAGENT	This option specifies the client should not include a User-Agent header with any requests made during the session. The user agent is a string which is used to identify the client application to the server.
HTTP_OPTION_TUNNEL	This option specifies that a tunneled TCP

	connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established.
HTTP_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using either the SSL or TLS protocols.
HTTP_OPTION_SECURE	This option specifies the client should attempt to establish a secure connection with the server. Note that the server must support secure connections using either the SSL or TLS protocol. The client will default to using TLS 1.2 or later for secure connections.
HTTP_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
HTTP_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
HTTP_OPTION_FREETHREAD	This option specifies the handle returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the handle is synchronized across multiple threads.
HTTP_OPTION_HIRES_TIMER	This option specifies the elapsed time for data transfers should be returned in milliseconds instead of seconds. This will return more accurate transfer times for smaller amounts of data over fast network connections.

lpbEnabled

A pointer to an integer which will be set to a non-zero value when the function returns if the specified option has been enabled. If the option has not been enabled, a zero value will be

returned in the variable.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**. Note that the value returned in the *lpbEnabled* parameter is only valid if the function succeeds.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cshttpv10.lib

See Also

[HttpAsyncConnect](#), [HttpSetOption](#)

HttpGetPriority Function

```
INT WINAPI HttpGetPriority(  
    HCLIENT hClient  
);
```

The **HttpGetPriority** function returns a value which specifies the priority of file transfers.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the current file transfer priority. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpGetPriority** function can be used to determine the current priority assigned to file transfers performed by the client. It may be one of the following values:

Constant	Description
HTTP_PRIORITY_NORMAL	The default priority which balances resource utilization and transfer speed. It is recommended that most applications use this priority.
HTTP_PRIORITY_BACKGROUND	This priority significantly reduces the memory, processor and network resource utilization for the transfer. It is typically used with worker threads running in the background when the amount of time required perform the transfer is not critical.
HTTP_PRIORITY_LOW	This priority lowers the overall resource utilization for the transfer and meters the bandwidth allocated for the transfer. This priority will increase the average amount of time required to complete a file transfer.
HTTP_PRIORITY_HIGH	This priority increases the overall resource utilization for the transfer, allocating more memory for internal buffering. It can be used when it is important to transfer the file quickly, and there are no other threads currently performing file transfers at the time.
HTTP_PRIORITY_CRITICAL	This priority can significantly increase processor, memory and network utilization while attempting to transfer the file as quickly as possible. If the file transfer is being performed in the main UI thread, this priority can cause the application to appear to become non-responsive. No events will be generated during the transfer.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cshttpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[HttpSetPriority](#)

HttpGetRequestHeader Function

```
BOOL WINAPI HttpGetRequestHeader(  
    HCLIENT hClient,  
    LPCTSTR lpszHeader,  
    LPTSTR lpszValue,  
    INT nMaxLength  
);
```

The **HttpGetRequestHeader** function returns the value of the specified request header field.

Parameters

hClient

Handle to the client session.

lpszHeader

Pointer to a string which specifies the header value to be returned.

lpszValue

Pointer to a buffer which will contain the null-terminated string value of the specified header field.

nMaxLength

Maximum number of characters that may be copied into the buffer, including the terminating null character.

Return Value

If the function succeeds, the return value is non-zero. If the header field does not exist or the client handle is invalid, the function returns a value of zero. To get extended error information, call **HttpGetLastError**.

Remarks

When a resource is requested from the server, it consists of two parts. The first part is the command issued to the server, along with the name of the resource and any optional encoded parameters. The second part consists of one or more header fields which can be used to provide additional information to the server. For example, here is what the command and header may look like for a simple request:

```
GET /test HTTP/1.0  
Host: api.sockettools.com  
Accept: text/*
```

The first line consists of the command, the resource and the protocol version. The subsequent lines are the header, which is similar to the headers used in email messages. The Host field specifies the name of the server the resource is being requested from, and the Accept field specifies the type of resources that are acceptable to the client; in this case, any type of text file.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cshttpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[HttpGetResponseHeader](#), [HttpSetRequestHeader](#)

Copyright © 2023 Catalyst Development Corporation. All rights reserved.

HttpGetResponseHeader Function

```
BOOL WINAPI HttpGetResponseHeader(  
    HCLIENT hClient,  
    LPCTSTR lpszHeader,  
    LPTSTR lpszValue,  
    INT nMaxLength  
);
```

The **HttpGetResponseHeader** function returns the value of the specified response header field.

Parameters

hClient

Handle to the client session.

lpszHeader

Pointer to a string which specifies the header value to be returned.

lpszValue

Pointer to a buffer which will contain the null-terminated string value of the specified header field.

nMaxLength

Maximum number of characters that may be copied into the buffer, including the terminating null character.

Return Value

If the function succeeds, the return value is non-zero. If the header field does not exist or the client handle is invalid, the function returns a value of zero. To get extended error information, call **HttpGetLastError**.

Remarks

When a resource is returned by the server, it consists of three parts. The first part consists of a single line that indicates the result of the request. The second part is one or more header fields which provides specific information about the resource, such as its size in bytes. The third part consists of the resource data itself, such as the HTML document or image data. For example, this is what the response to a request for a simple HTML document can look like:

```
HTTP/1.0 200 OK  
Date: Mon, 5 Jan 2004 20:18:33 GMT  
Content-Type: text/html  
Last-Modified: Mon, 5 Jan 2004 19:34:19 GMT  
Content-Length: 115
```

```
<html>  
<head>  
<title>Simple Document</title>  
</head>  
<body>  
This is a simple HTML document.  
</body>  
</html>
```

The first line consists of the protocol version, a numeric response code and some text describing the result. The subsequent lines are the header, which is similar to the headers used in email messages. For example, the Date field specifies the date the resource was requested, the Content-

Type field specifies what type of resource was requested, and the Content-Length field specifies the size of the resource in bytes. The end of the header block is indicated by an empty line (two carriage-return/linefeed sequences), and is followed by the resource itself, in this case a simple HTML document.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cshttpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[HttpGetCookie](#), [HttpGetFirstCookie](#), [HttpGetFirstHeader](#), [HttpGetNextCookie](#), [HttpGetNextHeader](#), [HttpGetRequestHeader](#), [HttpSetRequestHeader](#)

HttpGetResultCode Function

```
INT WINAPI HttpGetResultCode(  
    HCLIENT hClient  
);
```

The **HttpGetResultCode** function reads the result code returned by the server in response to a command. The result code is a three-digit numeric code, and indicates if the operation succeeded, failed or requires additional action by the client.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the result code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

Result codes are three-digit numeric values returned by the server. They may be broken down into the following ranges:

Value	Description
100-199	Positive preliminary result. This indicates that the requested action is being initiated, and the client should expect another reply from the server before proceeding.
200-299	Positive completion result. This indicates that the server has successfully completed the requested action.
300-399	Positive intermediate result. This indicates that the requested action cannot complete until additional information is provided to the server.
400-499	Transient negative completion result. This indicates that the requested action did not take place, but the error condition is temporary and may be attempted again.
500-599	Permanent negative completion result. This indicates that the requested action did not take place.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cshttp10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[HttpCommand](#), [HttpGetResultString](#)

HttpGetResultString Function

```
INT WINAPI HttpGetResultString(  
    HCLIENT hClient,  
    LPTSTR lpszResult,  
    INT nMaxLength  
);
```

The **HttpGetResultString** function returns the last message sent by the server along with the result code.

Parameters

hClient

Handle to the client session.

lpszResult

A pointer to the buffer that will contain the result string returned by the server.

nMaxLength

The maximum number of characters that may be copied into the result string buffer, including the terminating null character.

Return Value

If the function succeeds, the return value is the length of the result string. If a value of zero is returned, this means that no result string was sent by the server. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpGetResultString** function is most useful when an error occurs because the server will typically include a brief description of the cause of the error. This can then be parsed by the application or displayed to the user. The result string is updated each time the client sends a command to the server and then calls **HttpGetResultCode** to obtain the result code for the operation.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cshttp10.lib

Unicode: Implemented as Unicode and ANSI versions.

[HttpCommand](#), [HttpGetResultCode](#)

HttpGetSecurityInformation Function

```
BOOL WINAPI HttpGetSecurityInformation(  
    HCLIENT hClient,  
    LPSECURITYINFO lpSecurityInfo  
);
```

The **HttpGetSecurityInformation** function returns security protocol, encryption and certificate information about the current client connection.

Parameters

hClient

Handle to the client session.

lpSecurityInfo

A pointer to a [SECURITYINFO](#) structure which contains information about the current client connection. The *dwSize* member of this structure must be initialized to the size of the structure before passing the address of the structure to this function.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **HttpGetLastError**.

Remarks

This function is used to obtain security related information about the current client connection to the server. It can be used to determine if a secure connection has been established, what security protocol was selected, and information about the server certificate. Note that a secure connection has not been established, the *dwProtocol* structure member will contain the value `SECURITY_PROTOCOL_NONE`.

Example

The following example notifies the user if the connection is secure or not:

```
SECURITYINFO securityInfo;  
  
securityInfo.dwSize = sizeof(SECURITYINFO);  
if (HttpGetSecurityInformation(hClient, &securityInfo))  
{  
    if (securityInfo.dwProtocol == SECURITY_PROTOCOL_NONE)  
    {  
        MessageBox(NULL, _T("The connection is not secure"),  
                    _T("Connection"), MB_OK);  
    }  
    else  
    {  
        if (securityInfo.dwCertStatus == SECURITY_CERTIFICATE_VALID)  
        {  
            MessageBox(NULL, _T("The connection is secure"),  
                        _T("Connection"), MB_OK);  
        }  
        else  
        {  
            MessageBox(NULL, _T("The server certificate not valid"),  
                        _T("Connection"), MB_OK);  
        }  
    }  
}
```

```
}  
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cshttpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[HttpProxyConnect](#), [HttpSetOption](#), [SECURITYINFO](#)

HttpGetStatus Function

```
INT WINAPI HttpGetStatus(  
    HCLIENT hClient  
);
```

The **HttpGetStatus** function returns the current status of the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the client status code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpGetStatus** function returns a numeric code which identifies the current state of the client session. The following values may be returned:

Value	Constant	Description
1	HTTP_STATUS_IDLE	The client is current idle and not sending or receiving data.
2	HTTP_STATUS_CONNECT	The client is establishing a connection with the server.
3	HTTP_STATUS_READ	The client is reading data from the server.
4	HTTP_STATUS_WRITE	The client is writing data to the server.
5	HTTP_STATUS_DISCONNECT	The client is disconnecting from the server.
6	HTTP_STATUS_GETDATA	The client is downloading data from the server.
7	HTTP_STATUS_PUTDATA	The client is uploading data to the server.
8	HTTP_STATUS_POSTDATA	The client is posting data to a script on the server.

In a multithreaded application, any thread in the current process may call this function to obtain status information for the specified client session. To obtain status information about a file transfer, use the **HttpGetTransferStatus** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cshttpv10.lib

See Also

[HttpIsBlocking](#), [HttpIsReadable](#), [HttpIsWritable](#), [HttpGetTransferStatus](#)

HttpGetTaskError Function

```
DWORD WINAPI HttpGetTaskError(  
    UINT nTaskId  
);
```

Return the last error code for the specified asynchronous task.

Parameters

nTaskId

The task identifier.

Return Value

If the asynchronous task has completed successfully, this function returns a value of zero. A non-zero return value indicates an error has occurred.

Remarks

The **HttpGetTaskError** function returns the last error code associated with the specified asynchronous task. If the task completed successfully, the return value will be zero. If the task is still active, the function will return the error `ST_ERROR_TASK_ACTIVE`. If the task has been suspended, the function will return `ST_ERROR_TASK_SUSPENDED`. Any other value indicates that the task completed, but the operation has failed and the error code will specify the cause of the failure.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `cshttpv10.lib`

See Also

[HttpTaskAbort](#), [HttpTaskResume](#), [HttpTaskSuspend](#), [HttpTaskWait](#)

HttpGetTaskId Function

```
UINT WINAPI HttpGetTaskId(  
    HCLIENT hClient  
);
```

Return the asynchronous task identifier associated with the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is non-zero integer value that specifies a unique asynchronous task identifier. If the client handle is not associated with an asynchronous task, the function will return a value of zero.

Remarks

The **HttpGetTaskId** function will return the task ID that is associated with a client session. This is a unique unsigned integer value that references the worker thread that was created to manage the asynchronous client session. This function should only be called within an event handler that is invoked by a background task that has been started using a function such as **HttpAsyncGetFile**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cshttpv10.lib

See Also

[HttpTaskAbort](#), [HttpTaskDone](#), [HttpTaskResume](#), [HttpTaskSuspend](#), [HttpTaskWait](#)

HttpGetText Function

```
INT WINAPI HttpGetText(  
    HCLIENT hClient,  
    LPCTSTR lpszResource,  
    LPTSTR lpszBuffer,  
    INT nMaxLength  
);
```

The **HttpGetText** function copies the contents of a text file on the server, or the text output from a script, to the specified string buffer.

Parameters

hClient

Handle to the client session.

lpszResource

A pointer to a string that specifies the resource that will be transferred to the local system. This may be the name of a file on the server, or it may specify the name of a script that will be executed and the output returned to the caller. This string may specify a valid URL for the current server that the client is connected to.

lpszBuffer

A pointer to a string buffer which will contain the contents of the text file when the function returns. This buffer should be large enough to store the contents of the file, including a terminating null character. This parameter cannot be NULL.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer. This value must be larger than zero. If this value is smaller than the actual size of the text file, the data returned will be truncated.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpGetText** function is used to download a text file or retrieve the text output from a script and store the contents in a string buffer. Because binary data can include embedded null characters which would truncate the string, this function should only be used with text files or script output that is known to be textual. For example, it is safe to use this function when a resource returns HTML or XML data, but should not be used if it returns an image or executable file.

This function has been included as a convenience for applications that need to retrieve relatively small amounts of textual data and manipulate the contents as a string. If the Unicode version of this function is called, the text is automatically converted to a Unicode string. If the maximum amount of data being returned is unknown or the amount of text is very large, it is recommended that you use the **HttpGetData** or **HttpGetFile** functions.

If you use the **HttpGetFileSize** function to determine how large the string buffer should be prior to calling this function, it is important to be aware that the actual number of characters may differ based on the end-of-line conventions used by the host operating system. For example, if you call

HttpGetFileSize to obtain the size of a text file on a UNIX system, the value will not be large enough to store the complete file because UNIX uses a single linefeed (LF) character to indicate the end-of-line, while a Windows system will use a carriage-return and linefeed (CRLF) pair. To accommodate this difference, you should always allocate extra memory for the string buffer to store the additional end-of-line characters.

HTTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **HttpEnableEvents**, or by registering a callback function using the **HttpRegisterEvent** function.

To determine the current status of a file transfer while it is in progress, use the **HttpGetTransferStatus** function.

Example

```
LPTSTR lpszBuffer = (LPTSTR)calloc(MAXFILESIZE, sizeof(TCHAR));

if (lpszBuffer == NULL)
    return;

nResult = HttpGetText(hClient, lpszRemoteFile, lpszBuffer, MAXFILESIZE);
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cshttpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

HttpGetTimeout Function

```
INT WINAPI HttpGetTimeout(  
    HCLIENT hClient  
);
```

The **HttpGetTimeout** function returns the number of seconds the client will wait for a response from the server. Once the specified number of seconds has elapsed, the function will fail and return to the caller.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the timeout period in seconds. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The timeout value is only used with blocking client connections. A value of zero indicates that the default timeout period of 20 seconds should be used.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cshttpv10.lib

See Also

[HttpConnect](#), [HttpProxyConnect](#), [HttpSetTimeout](#)

HttpGetTransferStatus Function

```
INT WINAPI HttpGetTransferStatus(  
    HCLIENT hClient,  
    LPHTTPTRANSFERSTATUS lpStatus  
);
```

The **HttpGetTransferStatus** function returns information about the current data transfer in progress.

Parameters

hClient

Handle to the client session.

lpStatus

A pointer to an **HTTPTRANSFERSTATUS** structure which contains information about the status of the current data transfer.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpGetTransferStatus** function returns information about the current data transfer, including the average number of bytes transferred per second and the estimated amount of time until the transfer completes. If there is no data currently being transferred, this function will return the status of the last successful transfer made by the client.

In a multithreaded application, any thread in the current process may call this function to obtain status information for the specified client session.

If the option HTTP_OPTION_HIRES_TIMER has been specified when connecting to the server, the values of the *dwTimeElapsed* and *dwTimeEstimated* members of the **HTTPTRANSFERSTATUS** structure will be in milliseconds instead of seconds. You can use this option to obtain more accurate elapsed times when uploading or downloading small amounts of data over a fast network connection.

If you are uploading or downloading large files which exceed 4GB, you should use the **HttpGetTransferStatusEx** function which returns the size as a 64-bit value.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

See Also

[HttpEnableEvents](#), [HttpGetTransferStatusEx](#), [HttpRegisterEvent](#), [HTTPTRANSFERSTATUS](#), [HTTPTRANSFERSTATUSEX](#)

HttpGetTransferStatusEx Function

```
INT WINAPI HttpGetTransferStatusEx(  
    HCLIENT hClient,  
    LPHTTPTRANSFERSTATUSEX lpStatus  
);
```

The **HttpGetTransferStatusEx** function returns information about the current data transfer in progress. This version of the function is designed to support files that are larger than 4GB.

Parameters

hClient

Handle to the client session.

lpStatus

A pointer to an **HTTPTRANSFERSTATUSEX** structure which contains information about the status of the current data transfer.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpGetTransferStatusEx** function returns information about the current data transfer, including the average number of bytes transferred per second and the estimated amount of time until the transfer completes. If there is no data currently being transferred, this function will return the status of the last successful transfer made by the client.

In a multithreaded application, any thread in the current process may call this function to obtain status information for the specified client session.

If the option HTTP_OPTION_HIRES_TIMER has been specified when connecting to the server, the values of the *dwTimeElapsed* and *dwTimeEstimated* members of the **HTTPTRANSFERSTATUSEX** structure will be in milliseconds instead of seconds. You can use this option to obtain more accurate elapsed times when uploading or downloading small amounts of data over a fast network connection.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

See Also

HttpInitialize Function

```
BOOL WINAPI HttpInitialize(  
    LPCTSTR lpszLicenseKey,  
    LPINITDATA lpData  
);
```

The **HttpInitialize** function initializes the library and validates the specified license key at runtime.

Parameters

lpszLicenseKey

Pointer to a string that specifies the runtime license key to be validated. If this parameter is NULL, the library will validate the development license installed on the local system.

lpData

Pointer to an INITDATA data structure. This parameter may be NULL if the initialization data for the library is not required.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **HttpGetLastError**. All other client functions will fail until a license key has been successfully validated.

Remarks

This must be the first function that an application calls before using any of the other functions in the library. When a NULL license key is specified, the library will only function on the development system. Before redistributing the application to an end-user, you must insure that this function is called with a valid license key.

If the *lpData* argument is specified, it must point to an INITDATA structure which has been initialized by setting the *dwSize* member to the size of the structure. All other structure members should be set to zero. If the function is successful, then the INITDATA structure will be filled with identifying information about the library.

Although it is only required that **HttpInitialize** be called once for the current process, it may be called multiple times; however, each call must be matched by a corresponding call to **HttpUninitialize**.

This function dynamically loads other system libraries and allocates thread local storage. If you are calling the functions in this library from within another DLL, it is important that you do not call the **HttpInitialize** or **HttpUninitialize** functions from the **DllMain** function because it can result in deadlocks or access violation errors. If the DLL is linked with the C runtime library (CRT), it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cshtpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

HttpIsBlocking Function

```
BOOL WINAPI HttpIsBlocking(  
    HCLIENT hClient  
);
```

The **HttpIsBlocking** function is used to determine if the client is currently performing a blocking operation.

Parameters

hClient

Handle to the client session.

Return Value

If the client is performing a blocking operation, the function returns a non-zero value. If the client is not performing a blocking operation, or the client handle is invalid, the function returns zero.

Remarks

Because a blocking operation can allow the application to be re-entered (for example, by pressing a button while the operation is being performed), it is possible that another blocking function may be called while it is in progress. Since only one thread of execution may perform a blocking operation at any one time, an error would occur. The **HttpIsBlocking** function can be used to determine if the client is already blocked, and if so, take some other action (such as warning the user that they must wait for the operation to complete).

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `cshttpv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

See Also

[HttpCancel](#), [HttpIsConnected](#), [HttpIsReadable](#), [HttpIsWritable](#), [HttpRead](#), [HttpWrite](#)

HttpIsConnected Function

```
BOOL WINAPI HttpIsConnected(  
    HCLIENT hClient  
);
```

The **HttpIsConnected** function is used to determine if the client is currently connected to a server.

Parameters

hClient

Handle to the client session.

Return Value

If the client is connected to a server, the function returns a non-zero value. If the client is not connected, or the client handle is invalid, the function returns zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `cshttpv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

[HttpIsBlocking](#), [HttpIsReadable](#), [HttpIsWritable](#)

HttpIsReadable Function

```
BOOL WINAPI HttpIsReadable(  
    HCLIENT hClient,  
    INT nTimeout,  
    LPDWORD lpdwAvail  
);
```

The **HttpIsReadable** function is used to determine if data is available to be read from the server.

Parameters

hClient

Handle to the client session.

nTimeout

Timeout for server response, in seconds. A value of zero specifies that the connection should be polled without blocking the current thread.

lpdwAvail

A pointer to an unsigned integer which will contain the number of bytes available to read. This parameter may be NULL if this information is not required.

Return Value

If the client can read data from the server within the specified timeout period, the function returns a non-zero value. If the client cannot read any data, the function returns zero.

Remarks

On some platforms, this value will not exceed the size of the receive buffer (typically 64K bytes). Because of differences between TCP/IP stack implementations, it is not recommended that your application exclusively depend on this value to determine the exact number of bytes available. Instead, it should be used as a general indicator that there is data available to be read.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cshttp10.lib

See Also

[HttpGetStatus](#), [HttpIsBlocking](#), [HttpIsConnected](#), [HttpIsWritable](#), [HttpRead](#)

HttpIsWritable Function

```
BOOL WINAPI HttpIsWritable(  
    HCLIENT hClient,  
    INT nTimeout  
);
```

The **HttpIsWritable** function is used to determine if data can be written to the server.

Parameters

hClient

Handle to the client session.

nTimeout

Timeout for server response, in seconds. A value of zero specifies that the connection should be polled without blocking the current thread.

Return Value

If the client can write data to the server within the specified timeout period, the function returns a non-zero value. If the client cannot write any data, the function returns zero.

Remarks

Although this function can be used to determine if some amount of data can be sent to the remote process it does not indicate the amount of data that can be written without blocking the client. In most cases, it is recommended that large amounts of data be broken into smaller logical blocks, typically some multiple of 512 bytes in length.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `cshttpv10.lib`

HttpOpenFile Function

```
INT WINAPI HttpOpenFile(  
    HCLIENT hClient,  
    LPCTSTR lpszFileName,  
    DWORD dwOffset  
);
```

The **HttpOpenFile** function opens the specified file on the server.

Parameters

hClient

Handle to the client session.

lpszFileName

Points to a string that specifies the name of the remote file to open.

dwOffset

Specifies a byte offset into the file. If this value is greater than zero, the server must support the ability to specify a byte range with the request to open the file, otherwise this function will fail.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

Only one file may be opened at a time for each client session. Use the **HttpCloseFile** function to close the file on the server.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cshttpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

HttpOpenFileEx Function

```
INT WINAPI HttpOpenFileEx(  
    HCLIENT hClient,  
    LPCTSTR lpszFileName,  
    ULARGE_INTEGER uiOffset  
);
```

The **HttpOpenFileEx** function opens the specified file on the server. This version of the function is designed to support files that are larger than 4GB.

Parameters

hClient

Handle to the client session.

lpszFileName

Points to a string that specifies the name of the remote file to open.

uiOffset

Specifies a byte offset into the file. If this value is greater than zero, the server must support the ability to specify a byte range with the request to open the file, otherwise this function will fail.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

Only one file may be opened at a time for each client session. Use the **HttpCloseFile** function to close the file on the server.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cshttpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[HttpCloseFile](#)

HttpPatchData Function

```
INT WINAPI HttpPatchData(  
    HCLIENT hClient,  
    LPCTSTR lpszResource,  
    LPCTSTR lpszPatchData,  
    LPVOID lpvResult,  
    LPDWORD lpcbResult,  
    DWORD dwOptions  
);
```

The **HttpPatchData** function submits patch data to the server and returns the result in a buffer provided by the caller.

Parameters

hClient

Handle to the client session.

lpszResource

A pointer to a string that specifies the resource name that the patch data will be submitted to. Typically this is the name of a script on the server.

lpszPatchData

A pointer to a string that specifies the patch data that will be submitted to the server.

lpvResult

A pointer to a byte buffer which will contain the data returned by the server, or a pointer to a global memory handle which will reference the data when the function returns.

lpcbResult

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the *lpvResult* parameter. If the *lpvResult* parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the actual number of bytes of data that was returned.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
HTTP_PATCH_DEFAULT	The default post mode. The contents of the buffer will be submitted without encoding. The data returned by the server is copied to the result buffer exactly as it is returned from the server.
HTTP_PATCH_CONVERT	If the data being returned from the server is textual, it is automatically converted so that the end of line character sequence is compatible with the Windows platform. Individual carriage return or linefeed characters are converted to carriage return/linefeed character sequences. Note that this option does not have any effect on the form data being submitted to the server, only on the data

returned by the server.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpPatchData** function is used to submit XML or JSON formatted patch data to a service, and then returns a copy of the response from the server into a local buffer. This function will not perform any encoding and will not automatically define the type of patch data being submitted. Your application is responsible for specifying the content type for the patch data, and ensuring that the XML or JSON data that is being submitted to the server is formatted correctly.

This function sends a PATCH command to the server, which is similar to a POST or PUT request. It is used to make partial updates to a resource, rather than creating or replacing it entirely. The format of the patch data is specific to the service being used. If the resource being patched does not exist, the behavior is defined by the server. If enough information is provided, it may choose to create the resource just as if a PUT command was used, or it may return an error.

Your application should use the **HttpSetRequestHeader** function to define the Content-Type header prior to calling the **HttpPatchData** function. One of the most common formats used is the JSON Merge Patch which is defined in RFC 7396. The value for the Content-Type header for this patch format is "application/merge-patch+json". Refer to your service API documentation to determine what patch formats are acceptable, along with any additional header values that must be defined.

The function may be used in one of two ways, depending on the needs of the application. The first approach is to pre-allocate a buffer large enough to store the resulting output of the script. In this case, the *lpvResult* parameter will point to the buffer that was allocated by the client and the value that the *lpcbResult* parameter points to should be initialized to the size of that buffer.

The second approach is to have the *lpvResult* parameter point to a global memory handle which will contain the data when the function returns. In this case, the value that the *lpcbResult* parameter points to must be initialized to zero. It is important to note that the memory handle returned by the function must be freed by the application, otherwise a memory leak will occur. See the example code below.

This function will cause the current thread to block until the post completes, a timeout occurs or the operation is canceled. During the transfer, the HTTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **HttpEnableEvents**, or by registering a callback function using the **HttpRegisterEvent** function.

To determine the current status of the transaction while it is in progress, use the **HttpGetTransferStatus** function.

Example

```
HGLOBAL hgb1Buffer = (HGLOBAL)NULL;  
LPBYTE lpBuffer = (LPBYTE)NULL;  
DWORD cbBuffer = 0;  
  
// Store the script output into block of global memory allocated by  
// the GlobalAlloc function; the handle to this memory will be  
// returned in the hgb1Buffer parameter. Since the output from the  
// script is textual, the HTTP_PATCH_CONVERT option is used
```

```
nResult = HttpPatchData(hClient,
                        lpszResource,
                        lpszPatchData,
                        &hgblBuffer,
                        &cbBuffer,
                        HTTP_PATCH_CONVERT);

if (nResult != HTTP_ERROR)
{
    // Lock the global memory handle, returning a pointer to the
    // output data from the script
    lpBuffer = (LPBYTE)GlobalLock(hgblBuffer);

    // After the data has been used, the handle must be unlocked
    // and freed, otherwise a memory leak will occur
    GlobalUnlock(hgblBuffer);
    GlobalFree(hgblBuffer);
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cshttpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

HttpPostData Function

```
INT WINAPI HttpPostData(  
    HCLIENT hClient,  
    LPCTSTR lpszResource,  
    LPVOID lpvBuffer,  
    DWORD cbBuffer,  
    LPVOID lpvResult,  
    LPDWORD lpcbResult,  
    DWORD dwOptions  
);
```

The **HttpPostData** function submits the contents of the specified buffer to a script on the server and returns the result in a buffer provided by the caller.

Parameters

hClient

Handle to the client session.

lpszResource

A pointer to a string that specifies the resource that the data will be posted to on the server. Typically this is the name of a script that will be executed. This string may specify a valid URL for the current server that the client is connected to.

lpvBuffer

A pointer to the data that will be provided to the script. This parameter may be NULL if the script does not require any additional data from the client.

cbBuffer

The number of bytes to copy from the buffer. If this *lpvBuffer* parameter is NULL, this value should be zero.

lpvResult

A pointer to a byte buffer which will contain the data returned by the server, or a pointer to a global memory handle which will reference the data when the function returns.

lpcbResult

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the *lpvBuffer* parameter. If the *lpvResult* parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the actual number of bytes of data that was returned.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
HTTP_POST_DEFAULT	The default post mode. The contents of the buffer are encoded and sent as standard form data. The data returned by the server is copied to the result buffer exactly as it is returned from the server.
HTTP_POST_CONVERT	If the data being returned from the server is textual, it is

	automatically converted so that the end of line character sequence is compatible with the Windows platform. Individual carriage return or linefeed characters are converted to carriage return/linefeed character sequences. Note that this option does not have any effect on the form data being submitted to the server, only on the data returned by the server.
HTTP_POST_MULTIPART	The contents of the buffer being sent to the server consists of multipart form data and will be sent as-is without any encoding.
HTTP_POST_ERRORDATA	This option causes the client to accept error data from the server if the request fails. If this option is specified, an error response from the server will not cause the function to fail. Instead, the response is returned to the client and the function will succeed.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpPostData** function is used to submit data to a script that executes on the server and then copy the output from that script into a local buffer. If you are submitting XML or JSON formatted data to the server, it is recommended that you use the **HttpPostXml** or **HttpPostJson** functions instead to ensure that the correct content type and encoding is automatically selected.

The function may be used in one of two ways, depending on the needs of the application. The first method is to pre-allocate a buffer large enough to store the resulting output of the script. In this case, the *lpvResult* parameter will point to the buffer that was allocated by the client and the value that the *lpcbResult* parameter points to should be initialized to the size of that buffer.

The second method that can be used is have the *lpvResult* parameter point to a global memory handle which will contain the data when the function returns. In this case, the value that the *lpcbResult* parameter points to must be initialized to zero. It is important to note that the memory handle returned by the function must be freed by the application, otherwise a memory leak will occur. See the example code below.

It is common for servers to return additional information about a failed request in their response to the client. If you need to process this information, use the HTTP_POST_ERRORDATA option which causes the error message to be returned in the *lpvResult* buffer provided by the caller. If this option is used, your application should call **HttpGetResultCode** to obtain the HTTP status code returned by the server. This will enable you to determine if the operation was successful.

This function will cause the current thread to block until the post completes, a timeout occurs or the operation is canceled. During the transfer, the HTTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **HttpEnableEvents**, or by registering a callback function using the **HttpRegisterEvent** function.

To determine the current status of the transaction while it is in progress, use the **HttpGetTransferStatus** function.

Example

```
HGLOBAL hgblBuffer = (HGLOBAL)NULL;
LPBYTE lpBuffer = (LPBYTE)NULL;
DWORD cbBuffer = 0;

// Store the script output into block of global memory allocated by
// the GlobalAlloc function; the handle to this memory will be
// returned in the hgblBuffer parameter. Since the output from the
// script is textual, the HTTP_POST_CONVERT option is used

nResult = HttpPostData(hClient,
                      lpszResource,
                      lpParameters,
                      cbParameters,
                      &hgblBuffer,
                      &cbBuffer,
                      HTTP_POST_CONVERT);

if (nResult != HTTP_ERROR)
{
    // Lock the global memory handle, returning a pointer to the
    // output data from the script
    lpBuffer = (LPBYTE)GlobalLock(hgblBuffer);

    // After the data has been used, the handle must be unlocked
    // and freed, otherwise a memory leak will occur
    GlobalUnlock(hgblBuffer);
    GlobalFree(hgblBuffer);
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cshttpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

HttpPostFile Function

```
INT WINAPI HttpPostFile(  
    HCLIENT hClient,  
    LPCTSTR lpszFileName,  
    LPCTSTR lpszResource,  
    LPCTSTR lpszFieldName,  
    DWORD dwOptions,  
    DWORD dwReserved  
);
```

The **HttpPostFile** function posts the contents of the specified file to a script executed on the server.

Parameters

hClient

Handle to the client session.

lpszFileName

A pointer to a string that specifies the file that will be transferred from the local system. The file pathing and name conventions must be that of the local host.

lpszResource

A pointer to a string that specifies the resource on the server that the file data will be posted to. Typically this is the name of a script that is responsible for processing and storing the file data.

lpszFieldName

A pointer to a string that corresponds to the form field name that the script expects. If this parameter is NULL or an empty string, a default field name of "File1" is used.

dwOptions

An unsigned integer that specifies one or more options. This parameter may be any one of the following values:

Constant	Description
HTTP_TRANSFER_DEFAULT	This option specifies the default transfer mode should be used. If the remote file exists, it will be overwritten with the contents of the uploaded file.

dwReserved

A reserved parameter. This value should always be zero.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpPostFile** function is similar to the **HttpPutFile** function in that it can be used to upload the contents of a local file to a server. However, instead of using the PUT command, the POST command is used to send the file data to a script that is executed on the server. This method has the advantage of not requiring any special configuration settings on the server, however it does require that the script be able to process multipart/form-data as defined in RFC 2388.

To support uploading files from a form on a webpage, the FILE input type is used along with the

action that specifies the script that will accept the file data and process it. For example, the HTML code could look like this:

```
<form action="/cgi-bin/upload.cgi" method="post" enctype="multipart/form-data">  
<input type="file" name="datafile" size="20">  
<input type="submit">  
</form>
```

In this example, the script `/cgi-bin/upload.cgi` is responsible for processing the file data that is posted by the client, and the form field name "datafile" is used. The user can select a file, and when the Submit button is clicked, the file data is posted to the script. To simulate this using the **HttpPostFile** function, the *lpszFileName* parameter should be set to the name of the local file that will be posted to the server. The *lpszResource* parameter should be the name of the script, in this case `/cgi-bin/upload.cgi`. The *lpszFieldName* parameter should be specified as the string "datafile" to match the name of the field used by the form.

Note that the **HttpPostFile** function always submits the file contents as multipart/form-data with the content type set to application/octet-stream. The script that accepts the posted data must be able to parse the multipart header block and correctly process 8-bit data. If the script assumes that the data will be posted using a specific encoding type such as base64 then the file data may not be accepted or may be corrupted by the script.

This function will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the `HTTP_EVENT_PROGRESS` event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **HttpEnableEvents**, or by registering a callback function using the **HttpRegisterEvent** function.

To determine the current status of a file transfer while it is in progress, use the **HttpGetTransferStatus** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `cshttpv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

HttpPostJson Function

```
INT WINAPI HttpPostJson(  
    HCLIENT hClient,  
    LPCTSTR lpszResource,  
    LPCTSTR lpszJsonData,  
    LPVOID lpvResult,  
    LPDWORD lpcbResult,  
    DWORD dwOptions  
);
```

The **HttpPostJson** function submits JSON formatted data to the server and returns the result in a buffer provided by the caller.

Parameters

hClient

Handle to the client session.

lpszResource

A pointer to a string that specifies the resource name that the JSON data will be submitted to. Typically this is the name of a script on the server.

lpszJsonData

A pointer to a string that specifies the JSON data that will be submitted to the server.

lpvResult

A pointer to a byte buffer which will contain the data returned by the server, or a pointer to a global memory handle which will reference the data when the function returns.

lpcbResult

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the *lpvResult* parameter. If the *lpvResult* parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the actual number of bytes of data that was returned.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
HTTP_POST_DEFAULT	The default post mode. The contents of the buffer will be submitted without encoding and should use the standard JSON format. The data returned by the server is copied to the result buffer exactly as it is returned from the server.
HTTP_POST_CONVERT	If the data being returned from the server is textual, it is automatically converted so that the end of line character sequence is compatible with the Windows platform. Individual carriage return or linefeed characters are converted to carriage return/linefeed character sequences. Note that this option does not have any effect on the form data being submitted to the server, only on the data

	returned by the server.
HTTP_POST_ERRORDATA	This option causes the client to accept error data from the server if the request fails. If this option is specified, an error response from the server will not cause the function to fail. Instead, the response is returned to the client and the function will succeed.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpPostJson** function is used to submit JSON formatted data to a script that executes on the server and then copy the output from that script into a local buffer. This function automatically sets the correct content type and encoding required for submitting JSON data to a server, however it does not parse the JSON data itself to ensure that it is well-formed. Your application is responsible for ensuring that the JSON data that is being submitted to the server is formatted correctly.

The function may be used in one of two ways, depending on the needs of the application. The first method is to pre-allocate a buffer large enough to store the resulting output of the script. In this case, the *lpvResult* parameter will point to the buffer that was allocated by the client and the value that the *lpcbResult* parameter points to should be initialized to the size of that buffer.

The second method that can be used is have the *lpvResult* parameter point to a global memory handle which will contain the data when the function returns. In this case, the value that the *lpcbResult* parameter points to must be initialized to zero. It is important to note that the memory handle returned by the function must be freed by the application, otherwise a memory leak will occur. See the example code below.

If the content type for the request has not been explicitly specified, it will be automatically updated by this function to use the "application/json" content type. You can override the default content type for the request by calling the **HttpSetRequestHeader** function prior to calling this function. Most servers require you to explicitly specify what type of data is being submitted by the client and will reject requests which do not correctly identify the content type.

It is common for servers to return additional information about a failed request in their response to the client. If you need to process this information, use the HTTP_POST_ERRORDATA option which causes the error message to be returned in the *lpvResult* buffer provided by the caller. If this option is used, your application should call **HttpGetResultCode** to obtain the HTTP status code returned by the server. This will enable you to determine if the operation was successful.

This function will cause the current thread to block until the post completes, a timeout occurs or the operation is canceled. During the transfer, the HTTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **HttpEnableEvents**, or by registering a callback function using the **HttpRegisterEvent** function.

To determine the current status of the transaction while it is in progress, use the **HttpGetTransferStatus** function.

Example

```
HGLOBAL hgb1Buffer = (HGLOBAL)NULL;
LPBYTE lpBuffer = (LPBYTE)NULL;
```

```

DWORD cbBuffer = 0;

// Store the script output into block of global memory allocated by
// the GlobalAlloc function; the handle to this memory will be
// returned in the hgblBuffer parameter. Since the output from the
// script is textual, the HTTP_POST_CONVERT option is used

nResult = HttpPostJson(hClient,
                      lpszResource,
                      lpszJsonData,
                      &hgblBuffer,
                      &cbBuffer,
                      HTTP_POST_CONVERT);

if (nResult != HTTP_ERROR)
{
    // Lock the global memory handle, returning a pointer to the
    // output data from the script
    lpBuffer = (LPBYTE)GlobalLock(hgblBuffer);

    // After the data has been used, the handle must be unlocked
    // and freed, otherwise a memory leak will occur
    GlobalUnlock(hgblBuffer);
    GlobalFree(hgblBuffer);
}

```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cshttpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

HttpPostXml Function

```
INT WINAPI HttpPostXml(  
    HCLIENT hClient,  
    LPCTSTR lpszResource,  
    LPCTSTR lpszXmlData,  
    LPVOID lpvResult,  
    LPDWORD lpcbResult,  
    DWORD dwOptions  
);
```

The **HttpPostXml** function submits XML formatted data to the server and returns the result in a buffer provided by the caller.

Parameters

hClient

Handle to the client session.

lpszResource

A pointer to a string that specifies the resource name that the XML data will be submitted to. Typically this is the name of a script on the server.

lpszXmlData

A pointer to a string that specifies the XML data that will be submitted to the server.

lpvResult

A pointer to a byte buffer which will contain the data returned by the server, or a pointer to a global memory handle which will reference the data when the function returns.

lpcbResult

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the *lpvResult* parameter. If the *lpvResult* parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the actual number of bytes of data that was returned.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
HTTP_POST_DEFAULT	The default post mode. The contents of the buffer will be submitted without encoding and should use the standard XML format. The data returned by the server is copied to the result buffer exactly as it is returned from the server.
HTTP_POST_CONVERT	If the data being returned from the server is textual, it is automatically converted so that the end of line character sequence is compatible with the Windows platform. Individual carriage return or linefeed characters are converted to carriage return/linefeed character sequences. Note that this option does not have any effect on the form data being submitted to the server, only on the data

	returned by the server.
HTTP_POST_ERRORDATA	This option causes the client to accept error data from the server if the request fails. If this option is specified, an error response from the server will not cause the function to fail. Instead, the response is returned to the client and the function will succeed.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpPostXml** function is used to submit XML formatted data to a script that executes on the server and then copy the output from that script into a local buffer. This function automatically sets the correct content type and encoding required for submitting XML data to a server, however it does not parse the XML data itself to ensure that it is well-formed. Your application is responsible for ensuring that the XML data that is being submitted to the server is formatted correctly.

The function may be used in one of two ways, depending on the needs of the application. The first method is to pre-allocate a buffer large enough to store the resulting output of the script. In this case, the *lpvResult* parameter will point to the buffer that was allocated by the client and the value that the *lpcbResult* parameter points to should be initialized to the size of that buffer.

The second method that can be used is have the *lpvResult* parameter point to a global memory handle which will contain the data when the function returns. In this case, the value that the *lpcbResult* parameter points to must be initialized to zero. It is important to note that the memory handle returned by the function must be freed by the application, otherwise a memory leak will occur. See the example code below.

If the content type for the request has not been explicitly specified, it will be automatically updated by this function to use the "text/xml" content type. You can override the default content type for the request by calling the **HttpSetRequestHeader** function prior to calling this function. Most servers require you to explicitly specify what type of data is being submitted by the client and will reject requests which do not correctly identify the content type.

It is common for servers to return additional information about a failed request in their response to the client. If you need to process this information, use the HTTP_POST_ERRORDATA option which causes the error message to be returned in the *lpvResult* buffer provided by the caller. If this option is used, your application should call **HttpGetResultCode** to obtain the HTTP status code returned by the server. This will enable you to determine if the operation was successful.

This function will cause the current thread to block until the post completes, a timeout occurs or the operation is canceled. During the transfer, the HTTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **HttpEnableEvents**, or by registering a callback function using the **HttpRegisterEvent** function.

To determine the current status of the transaction while it is in progress, use the **HttpGetTransferStatus** function.

Example

```
HGLOBAL hgb1Buffer = (HGLOBAL)NULL;
LPBYTE lpBuffer = (LPBYTE)NULL;
```

```

DWORD cbBuffer = 0;

// Store the script output into block of global memory allocated by
// the GlobalAlloc function; the handle to this memory will be
// returned in the hgblBuffer parameter. Since the output from the
// script is textual, the HTTP_POST_CONVERT option is used

nResult = HttpPostXml(hClient,
                    lpszResource,
                    lpszXmlData,
                    &hgblBuffer,
                    &cbBuffer,
                    HTTP_POST_CONVERT);

if (nResult != HTTP_ERROR)
{
    // Lock the global memory handle, returning a pointer to the
    // output data from the script
    lpBuffer = (LPBYTE)GlobalLock(hgblBuffer);

    // After the data has been used, the handle must be unlocked
    // and freed, otherwise a memory leak will occur
    GlobalUnlock(hgblBuffer);
    GlobalFree(hgblBuffer);
}

```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cshttpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

HttpProxyConnect Function

```
HCLIENT WINAPI HttpProxyConnect(  
    UINT nProxyType,  
    LPCTSTR LpszProxyHost,  
    UINT nProxyPort,  
    LPCTSTR LpszProxyUser,  
    LPCTSTR LpszProxyPassword,  
    LPCTSTR LpszRemoteHost,  
    UINT nRemotePort,  
    UINT nTimeout,  
    DWORD dwOptions,  
    DWORD dwVersion,  
    LPSECURITYCREDENTIALS LpCredentials  
);
```

The **HttpProxyConnect** function is used to establish a synchronous connection with a proxy server.

Parameters

nProxyType

An unsigned integer which specifies the type of proxy that the client is connecting to. The supported proxy server types are as follows:

Constant	Description
HTTP_PROXY_NONE	A direct connection will be established with the server. When this value is specified the proxy parameters are ignored.
HTTP_PROXY_STANDARD	A standard connection is established through the specified proxy server, and all resource requests will be specified using a complete URL. This proxy type should be used with standard connections.
HTTP_PROXY_SECURE	A secure connection is established through the specified proxy server. This proxy type should be used with secure connections and the HTTP_OPTION_SECURE option should also be set via the <i>dwOptions</i> parameter.
HTTP_PROXY_WINDOWS	The configuration options for the current system should be used. If the system is configured to use a proxy server, then the connection will be automatically established through that proxy; otherwise, a direct connection to the server is established. These settings are the same proxy server settings configured in Windows.

lpszProxyHost

A pointer to a string which specifies the proxy server host name or IP address. This argument is ignored if the proxy type is set to HTTP_PROXY_NONE or HTTP_PROXY_WINDOWS and no proxy configuration has been specified for the local system.

nProxyPort

The port number that the proxy server is listening for connections on. A value of zero specifies

that the default port number 80 should be used. Note that in most cases, a proxy server is not configured to use the default port. This argument is ignored if the proxy type is set to HTTP_PROXY_NONE or HTTP_PROXY_WINDOWS and no proxy configuration has been specified for the local system.

lpzProxyUser

A pointer to a string which specifies the user name that will be used to authenticate the client session to the proxy server. If the server does not require user authentication, then a NULL pointer may be passed in this argument.

lpzProxyPassword

A pointer to a string which specifies the password that will be used to authenticate the client session to the proxy server. If the server does not require user authentication, then a NULL pointer may be passed in this argument.

lpzRemoteHost

A pointer to a string which specifies the name of the server to connect to through the proxy server. This may be a fully-qualified domain name or an IP address.

nRemotePort

The port number the server is listening on. A value of zero specifies that the default port number 80 should be used. For standard connections, the default port number is 80. For secure connections, the default port number is 443.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
HTTP_OPTION_NOCACHE	This instructs the server to not return a cached copy of the resource. When connected to an HTTP 1.0 or earlier server, this directive may be ignored.
HTTP_OPTION_KEEPALIVE	This instructs the server to maintain a persistent connection between requests. This can improve performance because it eliminates the need to establish a separate connection for each resource that is requested. If the server does not support the keep-alive option, the client will automatically reconnect when each resource is requested. Although it will not provide any performance benefits, this allows the option to be used with all servers.
HTTP_OPTION_REDIRECT	This option specifies the client should automatically handle resource redirection. If the server indicates that the requested resource has moved to a new location, the client will close the current connection and request the resource from

	the new location. Note that it is possible that the redirected resource will be located on a different server.
HTTP_OPTION_ERRORDATA	This option specifies the client should return the content of an error response from the server, rather than returning an error code. Note that this option will disable automatic resource redirection, and should not be used with HTTP_OPTION_REDIRECT.
HTTP_OPTION_SECURE	This option specifies the client should attempt to establish a secure connection with the server. Note that the server must support secure connections using either the SSL or TLS protocol.
HTTP_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
HTTP_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
HTTP_OPTION_FREETHREAD	This option specifies the handle returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the handle is synchronized across multiple threads.
HTTP_OPTION_HIRES_TIMER	This option specifies the elapsed time for data transfers should be returned in milliseconds instead of seconds. This will return more accurate transfer times for smaller amounts of data over fast network connections.

dwVersion

The requested protocol version used when sending requests to the server. The high word should specify the major version, and the low word should specify the minor version number. The HTTPVERSION macro can be used to create version value.

lpCredentials

Pointer to credentials structure [SECURITYCREDENTIALS](#). This parameter is only used if the HTTP_OPTION_SECURE option is specified for the connection. This parameter may be NULL, in

which case no client credentials will be provided to the server. If client credentials are required, the fields *dwSize*, *lpszCertStore*, and *lpszCertName* must be defined, while other fields may be left undefined. Set *dwSize* to the size of the **SECURITYCREDENTIALS** structure.

Return Value

If the function succeeds, the return value is a handle to the client session. If the function fails, the return value is **INVALID_CLIENT**. To get extended error information, call **HttpGetLastError**.

Remarks

If the **HTTP_PROXY_WINDOWS** proxy type is specified, then the proxy configuration for the local system is used. If no proxy server has been defined, then the proxy-related parameters will be ignored and the function will establish a connection directly to the server.

The username and password information is only used when connecting to a server which supports version 1.1 or later of the protocol.

The *dwOptions* argument can be used to specify the threading model that is used by the library when a connection is established. By default, the handle is initially attached to the thread that created it. From that point on, until the it is released, only the owner may call functions using that handle. The ownership of the handle may be transferred from one thread to another using the **HttpAttachThread** function.

Specifying the **HTTP_OPTION_FREETHREAD** option enables any thread to call any function using the handle, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the handle is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same handle.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `cshttpv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

HttpPutData Function

```
INT WINAPI HttpPutData(  
    HCLIENT hClient,  
    LPCTSTR lpszRemoteFile,  
    LPVOID lpvBuffer,  
    DWORD dwLength,  
    DWORD dwReserved  
);
```

The **HttpPutData** function copies the contents of the specified buffer and stores it in a file on the server.

Parameters

hClient

Handle to the client session.

lpszRemoteFile

A pointer to a string that specifies the file on the server that will be created. This string may specify a valid URL for the current server that the client is connected to.

lpvBuffer

A pointer to a buffer which will contain the data to be transferred from the client and stored in a file on the server.

dwLength

The number of bytes to copy from the buffer.

dwReserved

A reserved parameter. This value should always be zero.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpPutData** function is used to store the contents of the specified buffer in a file on the server. Not all servers permit files to be created using this method, and some may require that specific configuration changes be made to the server in order to support this functionality. Consult your server's technical reference documentation to see if it supports the PUT command, and if so, what must be done to enable it. It may be required that the client authenticate itself using the **HttpAuthenticate** function prior to uploading the data.

This function is designed for uploading the contents of a buffer to be stored as a file on the server. If you need to use the PUT command to as part of a RESTful API where the PUT command is used to submit data to the server, use the **HttpPutDataEx** function. That function will return the success or failure responses back to the client.

This function will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the HTTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **HttpEnableEvents**, or by registering a callback function using the **HttpRegisterEvent** function.

To determine the current status of a transfer while it is in progress, use the

HttpGetTransferStatus function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cshttpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[HttpEnableEvents](#), [HttpGetData](#), [HttpGetFile](#), [HttpGetTransferStatus](#), [HttpPostData](#), [HttpPutDataEx](#), [HttpPutFile](#), [HttpRegisterEvent](#)

HttpPutDataEx Function

```
INT WINAPI HttpPutDataEx(  
    HCLIENT hClient,  
    LPCTSTR lpszResource,  
    LPVOID lpvBuffer,  
    DWORD cbBuffer,  
    LPVOID lpvResult,  
    LPDWORD lpcbResult,  
    DWORD dwOptions  
);
```

The **HttpPutDataEx** function submits the contents of the specified buffer to the server using the PUT command and returns the server's response to the command.

Parameters

hClient

Handle to the client session.

lpszResource

A pointer to a string which specifies the resource path on the server. This string may specify a valid URL for the current server that the client is connected to.

lpvBuffer

A pointer to a buffer which will contain the data to be transferred from the client and submitted to the server. This parameter may not be NULL.

cbBuffer

The number of bytes to copy from the buffer. This value must be larger than zero.

lpvResult

A pointer to a byte buffer which will contain the data returned by the server, or a pointer to a global memory handle which will reference the data when the function returns.

lpcbResult

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the *lpvResult* parameter. If the *lpvResult* parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the actual number of bytes of data that was returned.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
HTTP_PUT_DEFAULT	The default mode. The contents of the buffer are sent unmodified and the data returned by the server is copied to the result buffer exactly as it is returned from the server. This option should be used if the server is expected to return binary data in the response to the PUT request.
HTTP_PUT_CONVERT	If the data being returned from the server is textual, it is automatically converted so that the end of line character

	sequence is compatible with the Windows platform. Individual carriage return or linefeed characters are converted to carriage return/linefeed character sequences. Note that this option does not have any effect on the data being submitted to the server, only on the data returned by the server.
HTTP_PUT_ERRORDATA	This option causes the client to accept error data from the server if the request fails. If this option is specified, an error response from the server will not cause the function to fail. Instead, the response is returned to the client and the function will succeed.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpPutDataEx** function is used to submit data to the server using the PUT command. This is typically used with RESTful APIs and is similar in functionality to the POST command. However, the data that is submitted will be sent to the server as-is and will not be encoded.

The function may be used in one of two ways, depending on the needs of the application. The first method is to pre-allocate a buffer large enough to store the response from the server. In this case, the *lpvResult* parameter will point to the buffer allocated by the client and the value that the *lpcbResult* parameter points to should be initialized to the size of that buffer.

The second method is to have the *lpvResult* parameter point to a global memory handle which will reference the data when the function returns. In this case, the value that the *lpcbResult* parameter points to must be initialized to zero. It is important to note that the memory handle returned by the function must be freed by the application, otherwise a memory leak will occur.

If the Unicode version of this function is called and the server returns a text response to the PUT request, it is the application's responsibility to convert the contents of the *lpvResult* buffer to UTF-16 text. If the server returns text, most likely it will use UTF-8 encoding.

If the content type for the request has not been explicitly specified, it will be automatically updated by this function to use the "application/octet-stream" content type. You can override the default content type for the request by calling the **HttpSetRequestHeader** function prior to calling this function. Most servers require you to explicitly specify what type of data is being submitted by the client and will reject requests which do not correctly identify the content type.

It is common for servers to return additional information about a failed request in their response to the client. If you need to process this information, use the HTTP_PUT_ERRORDATA option which causes the error message to be returned in the *lpvResult* buffer provided by the caller. If this option is used, your application should call **HttpGetResultCode** to obtain the HTTP status code returned by the server. This will enable you to determine if the operation was successful.

This function will cause the current thread to block until the data transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the HTTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **HttpEnableEvents**, or by registering a callback function using the **HttpRegisterEvent** function.

To determine the current status of a data transfer while it is in progress, use the

`HttpGetTransferStatus` function.

Example

```
HGLOBAL hgb1Response = (HGLOBAL)NULL;
LPBYTE lpResponse = (LPBYTE)NULL;
DWORD cbResponse = 0;

// Store the response into block of global memory allocated by
// the GlobalAlloc function; the handle to this memory will be
// returned in the hgb1Buffer parameter. Since the response from
// the server is textual, the HTTP_PUT_CONVERT option is used

nResult = HttpPutDataEx(hClient,
                        lpszResource,
                        lpRequest,
                        cbRequest,
                        &hgb1Response,
                        &cbResponse,
                        HTTP_PUT_CONVERT);

if (nResult != HTTP_ERROR)
{
    // Lock the global memory handle, returning a pointer to the
    // response from the server
    lpResponse = (LPBYTE)GlobalLock(hgb1Response);

    // After the data has been used, the handle must be unlocked
    // and freed, otherwise a memory leak will occur
    GlobalUnlock(hgb1Response);
    GlobalFree(hgb1Response);
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `cshttpv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

HttpPutFile Function

```
INT WINAPI HttpPutFile(  
    HCLIENT hClient,  
    LPCTSTR lpszLocalFile,  
    LPCTSTR lpszRemoteFile,  
    DWORD dwOptions  
    DWORD dwOffset  
);
```

The **HttpPutFile** function transfers the specified file on the local system to the server.

Parameters

hClient

Handle to the client session.

lpszLocalFile

A pointer to a string that specifies the file that will be transferred from the local system. The file pathing and name conventions must be that of the local system.

lpszRemoteFile

A pointer to a string that specifies the file on the server that will be created, overwritten or appended to. This string may specify a valid URL for the current server that the client is connected to.

dwOptions

An unsigned integer that specifies one or more options. This parameter may be any one of the following values:

Constant	Description
HTTP_TRANSFER_DEFAULT	This option specifies the default transfer mode should be used. If the remote file exists, it will be overwritten with the contents of the uploaded file.

dwOffset

Specifies a byte offset into the file. If this value is greater than zero, the server must support the ability to specify a byte range with the request to open the file, otherwise this function will fail.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpPutFile** function is used to transfer a file from the local system to a server. Not all servers permit files to be uploaded and some may require that specific configuration changes be made to the server in order to support this functionality. Consult your server's technical reference documentation to see if it supports the PUT command, and if so, what must be done to enable it. It may be required that the client authenticate itself using the **HttpAuthenticate** function prior to uploading the file.

To upload large files that are over 4GB, use the **HttpPutFileEx** function.

This function will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the HTTP_EVENT_PROGRESS event will be

periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **HttpEnableEvents**, or by registering a callback function using the **HttpRegisterEvent** function.

To determine the current status of a file transfer while it is in progress, use the **HttpGetTransferStatus** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cshttpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

HttpPutFileEx Function

```
INT WINAPI HttpPutFileEx(  
    HCLIENT hClient,  
    LPCTSTR lpszLocalFile,  
    LPCTSTR lpszRemoteFile,  
    DWORD dwOptions  
    ULARGE_INTEGER uiOffset  
);
```

The **HttpPutFileEx** function transfers the specified file on the local system to the server. This version of the function is designed to support files that are larger than 4GB.

Parameters

hClient

Handle to the client session.

lpszLocalFile

A pointer to a string that specifies the file that will be transferred from the local system. The file pathing and name conventions must be that of the local host.

lpszRemoteFile

A pointer to a string that specifies the file on the server that will be created, overwritten or appended to. The file naming conventions must be that of the host operating system.

dwOptions

An unsigned integer that specifies one or more options. This parameter may be any one of the following values:

Constant	Description
HTTP_TRANSFER_DEFAULT	This option specifies the default transfer mode should be used. If the remote file exists, it will be overwritten with the contents of the uploaded file.

uiOffset

Specifies a byte offset into the file. If this value is greater than zero, the server must support the ability to specify a byte range with the request to open the file, otherwise this function will fail.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpPutFileEx** function is used to transfer a file from the local system to a server. Not all servers permit files to be uploaded and some may require that specific configuration changes be made to the server in order to support this functionality. Consult your server's technical reference documentation to see if it supports the PUT command, and if so, what must be done to enable it. It may be required that the client authenticate itself using the **HttpAuthenticate** function prior to uploading the file.

This function will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the HTTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification

must be enabled, either by calling **HttpEnableEvents**, or by registering a callback function using the **HttpRegisterEvent** function.

To determine the current status of a file transfer while it is in progress, use the **HttpGetTransferStatusEx** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cshttpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

HttpPutText Function

```
INT WINAPI HttpPutText(  
    HCLIENT hClient,  
    LPCTSTR lpszRemoteFile,  
    LPCTSTR lpszBuffer  
);
```

The **HttpPutText** function creates a text file on the server using the contents of a string buffer.

Parameters

hClient

Handle to the client session.

lpszRemoteFile

A pointer to a string that specifies the text file on the server that will be created or overwritten. This string may specify a valid URL for the current server that the client is connected to.

lpszBuffer

A pointer to a string that contains the text that will be stored in the file.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpPutText** function is used to create a text file on the server from the contents of a string. If the specified file already exists on the server, its contents will be overwritten. Not all servers permit files to be created using this method, and some may require that specific configuration changes be made to the server in order to support this functionality. Consult your server's technical reference documentation to see if it supports the PUT command, and if so, what must be done to enable it. It may be required that the client authenticate itself using the **HttpAuthenticate** command prior to uploading the data.

If the Unicode version of this function is called, the string will be automatically converted to UTF-8 and then uploaded to the server. If you wish to upload UTF-16 Unicode or ANSI text to the server, you must use the **HttpPutData** function. This function should never be used to upload binary data.

This function will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the HTTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **HttpEnableEvents**, or by registering a callback function using the **HttpRegisterEvent** function.

To determine the current status of a file transfer while it is in progress, use the **HttpGetTransferStatus** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cshtpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[HttpEnableEvents](#), [HttpGetText](#), [HttpGetTransferStatus](#), [HttpPutData](#), [HttpPutFile](#),
[HttpRegisterEvent](#)

HttpPutTextEx Function

```
INT WINAPI HttpPutTextEx(  
    HCLIENT hClient,  
    LPCTSTR lpszResource,  
    LPCTSTR lpszBuffer,  
    LPVOID lpvResult,  
    LPDWORD lpcbResult,  
    DWORD dwOptions  
);
```

The **HttpPutTextEx** function submits the contents of a string buffer to the server using the PUT command and returns the server's response to the command.

Parameters

hClient

Handle to the client session.

lpszResource

A pointer to a string which specifies the resource path on the server. This string may specify a valid URL for the current server that the client is connected to.

lpszBuffer

A pointer to a string that contains the text that will be submitted to the server. This parameter cannot be NULL and may not specify an empty string.

lpvResult

A pointer to a byte buffer which will contain the data returned by the server, or a pointer to a global memory handle which will reference the data when the function returns.

lpcbResult

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the *lpvResult* parameter. If the *lpvResult* parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the actual number of bytes of data that was returned.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
HTTP_PUT_DEFAULT	The default mode. automatically converted so that the end of line character sequence is compatible with the Windows platform. Individual carriage return or linefeed characters are converted to carriage return/linefeed character sequences. Note that this option does not have any effect on the data being submitted to the server, only on the data returned by the server.
HTTP_PUT_ERRORDATA	This option causes the client to accept error data from the server if the request fails. If this option is specified, an error response from the server will not cause the function to fail.

Instead, the response is returned to the client and the function will succeed.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpPutTextEx** function is used to submit the contents of a null terminated string to the server using the PUT command. This is typically used with RESTful APIs and is similar in functionality to the POST command. However, the text that is submitted will not be encoded in the same way that the **HttpPostData** function submits data.

If the Unicode version of this function is called, the text will be converted to UTF-8 and then submitted to the server. If you wish to submit the contents of the string as UTF-16 Unicode text, or the payload contains binary data, you must use the **HttpPutDataEx** function. This function should never be used to upload binary data. If the server returns a text response and the Unicode version of this function is called, it is the application's responsibility to convert the contents of the *lpvResult* buffer to UTF-16 text. If the server returns text, most likely it will use UTF-8 encoding.

If the content type for the request has not been explicitly specified, it will be automatically updated by this function to use the "text/plain" content type. You can override the default content type for the request by calling the **HttpSetRequestHeader** function prior to calling this function. Most servers require you to explicitly specify what type of data is being submitted by the client and will reject requests which do not correctly identify the content type.

It is common for servers to return additional information about a failed request in their response to the client. If you need to process this information, use the HTTP_PUT_ERRORDATA option which causes the error message to be returned in the *lpvResult* buffer provided by the caller. If this option is used, your application should call **HttpGetResultCode** to obtain the HTTP status code returned by the server. This will enable you to determine if the operation was successful.

This function will cause the current thread to block until the data transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the HTTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **HttpEnableEvents**, or by registering a callback function using the **HttpRegisterEvent** function.

To determine the current status of a data transfer while it is in progress, use the **HttpGetTransferStatus** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cshttp10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

HttpRead Function

```
INT WINAPI HttpRead(  
    HCLIENT hClient,  
    LPBYTE lpBuffer,  
    INT cbBuffer  
);
```

The **HttpRead** function reads the specified number of bytes from the client socket and copies them into the buffer. The data may be of any type, and is not terminated with a null character.

Parameters

hClient

Handle to the client session.

lpBuffer

Pointer to the buffer in which the data will be copied.

cbBuffer

The maximum number of bytes to read and copy into the specified buffer. This value must be greater than zero.

Return Value

If the function succeeds, the return value is the number of bytes actually read. A return value of zero indicates that the server has closed the connection and there is no more data available to be read. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

When **HttpRead** is called and the client is in non-blocking mode, it is possible that the function will fail because there is no available data to read at that time. This should not be considered a fatal error. Instead, the application should simply wait to receive the next asynchronous notification that data is available.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cshttpv10.lib

See Also

[HttpIsBlocking](#), [HttpIsReadable](#), [HttpIsWritable](#), [HttpWrite](#)

HttpRegisterEvent Function

```
INT WINAPI HttpRegisterEvent(  
    HCLIENT hClient,  
    UINT nEventId,  
    HTTPEVENTPROC LpEventProc,  
    DWORD_PTR dwParam  
);
```

The **HttpRegisterEvent** function registers an event handler for the specified event.

Parameters

hClient

Handle to the client session.

nEventId

An unsigned integer which specifies which event should be registered with the specified callback function. One of the following values may be used:

Constant	Description
HTTP_EVENT_CONNECT	The connection to the server has completed.
HTTP_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
HTTP_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
HTTP_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
HTTP_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
HTTP_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.
HTTP_EVENT_COMMAND	A command has been issued by the client and the server response has been received and processed. This event can be used to log the result codes and messages returned by the server in response to actions taken by the client.
HTTP_EVENT_PROGRESS	The client is in the process of sending or receiving a file on the data channel. This event is called periodically during a transfer so that the client can update any user interface components such as

	a status control or progress bar.
HTTP_EVENT_REDIRECT	This event is generated when a the server indicates that the requested resource has been moved to a new location. The new resource location may be on the same server, or it may be located on another server. Check the value of the Location header field to determine where the resource has been moved to.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **HttpEventProc** callback function. If this parameter is NULL, the callback for the specified event is disabled.

dwParam

A user-defined integer value that is passed to the callback function. If the application targets the x86 (32-bit) platform, this parameter must be a 32-bit unsigned integer. If the application targets the x64 (64-bit) platform, this parameter must be a 64-bit unsigned integer.

Remarks

The **HttpRegisterEvent** function associates a callback function with a specific event. The event handler is an **HttpEventProc** function that is invoked when the event occurs. Arguments are passed to the function to identify the client session, the event type and the user-defined value specified when the event handler is registered. If the event occurs because of an error condition, the error code will be provided to the handler.

This function is typically used to register an event handler that is invoked while a file is being uploaded or downloaded. The HTTP_EVENT_PROGRESS event will only be generated periodically during the transfer to ensure the application is not flooded with event notifications. It is guaranteed that at least one HTTP_EVENT_PROGRESS notification will occur at the beginning of the transfer, and one at the end of the transfer when it has completed.

The callback function specified by the *lpEventProc* parameter must be declared using the **__stdcall** calling convention. This ensures the arguments passed to the event handler are pushed on to the stack in the correct order. Failure to use the correct calling convention will corrupt the stack and cause the application to terminate abnormally.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cshttpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[HttpDisableEvents](#), [HttpEnableEvents](#), [HttpEventProc](#), [HttpFreezeEvents](#), [HttpGetTransferStatus](#)

HttpSetBearerToken Function

```
INT WINAPI HttpSetBearerToken(  
    HCLIENT hClient,  
    LPTSTR lpszBearerToken  
);
```

The **HttpSetBearerToken** function sets the OAuth 2.0 bearer token used to authenticate the client session with a web service.

Parameters

hClient

Handle to the client session.

lpszBearerToken

A pointer to a null terminated string buffer which contains the bearer token used to authorize client requests. If this parameter is NULL or a zero length string, the current bearer token will be cleared and no client authentication will be performed.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

Using OAuth 2.0 requires you to understand the process of how to request the bearer (access) token. Obtaining a bearer token requires registering your application with the web service provider, getting a unique client ID associated with your application and then requesting the token using the appropriate scope for the service. Obtaining the initial token will typically involve interactive confirmation on the part of the user, requiring they grant permission to your application to access the service.

Your application should not store a bearer token for later use. They have a relatively short lifespan, typically about an hour, and are designed to be used with that session. You should specify offline access as part of the OAuth 2.0 scope if necessary and store the refresh token provided by the service. The refresh token has a much longer validity period and can be used to obtain a new bearer token when needed.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cshttpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[HttpAuthenticate](#), [HttpGetBearerToken](#), [HttpRequestHeader](#)

HttpSetCookie Function

```
BOOL WINAPI HttpSetCookie(  
    HCLIENT hClient,  
    LPCTSTR lpszCookieName,  
    LPCTSTR lpszCookieValue  
);
```

The **HttpSetCookie** function sends the specified cookie to the server when a resource is requested.

Parameters

hClient

Handle to the client session.

lpszCookieName

Pointer to a string which specifies the name of the cookie that will be sent to the server when the next resource is requested.

lpszCookieValue

Pointer to a string which specifies the value of the cookie. To delete a cookie that has been previously set, this parameter should be NULL or point to an empty string.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpSetCookie** function submits the cookie name and value to the server when a resource is requested or data is posted to a script. For more information about cookies and how they are used, refer to the **HttpGetCookie** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cshttpv10.lib

See Also

[HttpGetCookie](#), [HttpGetFirstCookie](#), [HttpGetNextCookie](#), [HttpSetRequestHeader](#)

HttpSetEncodingType Function

```
INT WINAPI HttpSetEncodingType(  
    HCLIENT hClient  
    INT nEncodingType  
);
```

The **HttpSetEncodingType** function specifies the type of encoding to be applied to the content of a HTTP request.

Parameters

hClient

Handle to the client session.

nEncodingType

Specifies the content encoding type; currently-supported values are:

Constant	Description
HTTP_ENCODING_NONE	No encoding will be applied to the content of a request, and no Content-Type header will be generated.
HTTP_ENCODING_URL	URL encoding will be applied to the content of a request, and a Content-Type header will be generated with the value "application/x-www-form-urlencoded"
HTTP_ENCODING_XML	URL encoding will be applied to the content of a request, EXCEPT that spaces will not be replaced by '+'. This encoding type is intended for use with XML parsers that do not recognize '+' as a space. A Content-Type header will be generated with the value "application/x-www-form-urlencoded".

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpSetEncodingType** function explicitly sets the type of encoding used when optional parameter data is submitted with a request for a resource. By default, data is URL encoded and the content type will be designated as application/x-www-form-urlencoded.

If an application specifies HTTP_ENCODING_NONE, then the parameter data is not encoded and there is no content type header created by default. The client application can create its own Content-Type header field by calling the **HttpRequestHeader** function if necessary.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cshttpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

HttpSetFormProperties Function

```
INT WINAPI HttpSetFormProperties(  
    HFORM hForm,  
    LPHTTPFORMPROPERTIES LpFormProp  
);
```

The **HttpSetFormProperties** function updates the properties of the specified form.

Parameters

hForm

Handle to the virtual form.

LpFormProp

Points to a HTTPFORMPROPERTIES structure which specifies the new properties for the form.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cshttpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[HttpCreateForm](#), [HttpGetFormProperties](#), [HttpSubmitForm](#), [HTTPFORMPROPERTIES](#)

HttpSetLastError Function

```
VOID WINAPI HttpSetLastError(  
    DWORD dwErrorCode  
);
```

The **HttpSetLastError** function sets the last error code for the current thread. This function is typically used to clear the last error by specifying a value of zero as the parameter.

Parameters

dwErrorCode

Specifies the last error code for the current thread.

Return Value

None.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or HTTP_ERROR. Those functions which call **HttpSetLastError** when they succeed are noted on the function reference page.

Applications can retrieve the value saved by this function by using the **HttpGetLastError** function. The use of **HttpGetLastError** is optional; an application can call the function to determine the specific reason for a function failure.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cshttpv10.lib

See Also

HttpSetOption Function

```
INT WINAPI HttpSetOption(  
    HCLIENT hClient,  
    DWORD dwOption,  
    BOOL bEnabled  
);
```

The **HttpSetOption** function enables or disables the specified option.

Parameters

hClient

Handle to the client session.

dwOption

An unsigned integer which specifies one of the following options:

Constant	Description
HTTP_OPTION_NOCACHE	This instructs the server to not return a cached copy of the resource. When connected to an HTTP 1.0 or earlier server, this directive may be ignored.
HTTP_OPTION_KEEPALIVE	This instructs the server to maintain a persistent connection between requests. This can improve performance because it eliminates the need to establish a separate connection for each resource that is requested. If the server does not support the keep-alive option, the client will automatically reconnect when each resource is requested. Although it will not provide any performance benefits, this allows the option to be used with all servers.
HTTP_OPTION_REDIRECT	This option specifies the client should automatically handle resource redirection. If the server indicates that the requested resource has moved to a new location, the client will close the current connection and request the resource from the new location. Note that it is possible that the redirected resource will be located on a different server.
HTTP_OPTION_NOUSERAGENT	This option specifies the client should not include a User-Agent header with any requests made during the session. The user agent is a string which is used to identify the client application to the server.
HTTP_OPTION_ERRORDATA	This option specifies the client should return the content of an error response from the server, rather than returning an error code. Note that this option will disable automatic resource redirection, and should not be used with HTTP_OPTION_REDIRECT.
HTTP_OPTION_FREETHREAD	This option specifies the handle returned by this

	function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the handle is synchronized across multiple threads.
HTTP_OPTION_HIRES_TIMER	This option specifies the elapsed time for data transfers should be returned in milliseconds instead of seconds. This will return more accurate transfer times for smaller amounts of data over fast network connections.

bEnabled

An integer value which determines if the option should be enabled or disabled. A non-zero value specifies that the option should be enabled, while a zero value specifies that the option should be disabled.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpSetOption** function can only enable or disable the options listed above. Other options are only available when the connection is initially established. For example, you cannot use this function to enable security options after the connection has been made.

If you use HTTP_OPTION_FREETHREAD to permit any thread to reference a client handle allocated in another thread, your application is responsible for ensuring it does not attempt to submit requests using the same handle on different threads at the same time. If two different threads attempt to perform an operation using the same handle, there is no guarantee as to which thread will complete the operation first.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cshttp10.lib

HttpSetPriority Function

```
INT WINAPI HttpSetPriority(  
    HCLIENT hClient,  
    INT nPriority  
);
```

The **HttpSetPriority** function specifies the priority for file transfers.

Parameters

hClient

Handle to the client session.

nPriority

An integer value which specifies the new priority for file transfers. It may be one of the following values:

Constant	Description
HTTP_PRIORITY_NORMAL	The default priority which balances resource utilization and transfer speed. It is recommended that most applications use this priority.
HTTP_PRIORITY_BACKGROUND	This priority significantly reduces the memory, processor and network resource utilization for the transfer. It is typically used with worker threads running in the background when the amount of time required perform the transfer is not critical.
HTTP_PRIORITY_LOW	This priority lowers the overall resource utilization for the transfer and meters the bandwidth allocated for the transfer. This priority will increase the average amount of time required to complete a file transfer.
HTTP_PRIORITY_HIGH	This priority increases the overall resource utilization for the transfer, allocating more memory for internal buffering. It can be used when it is important to transfer the file quickly, and there are no other threads currently performing file transfers at the time.
HTTP_PRIORITY_CRITICAL	This priority can significantly increase processor, memory and network utilization while attempting to transfer the file as quickly as possible. If the file transfer is being performed in the main UI thread, this priority can cause the application to appear to become non-responsive. No events will be generated during the transfer.

Return Value

If the function succeeds, the return value is the previous file transfer priority. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpSetPriority** function can be used to control the processor usage, memory and network

bandwidth allocated for file transfers. The default priority balances resource utilization and transfer speed while ensuring that a single-threaded application remains responsive to the user. Lower priorities reduce the overall resource utilization at the expense of transfer speed. For example, if you create a worker thread to download a file in the background and want to ensure that it has a minimal impact on the process, the `HTTP_PRIORITY_BACKGROUND` value can be used.

Higher priority values increase the memory allocated for the transfers and increases processor utilization for the transfer. The `HTTP_PRIORITY_CRITICAL` priority maximizes transfer speed at the expense of system resources. It is not recommended that you increase the file transfer priority unless you understand the implications of doing so and have thoroughly tested your application. If the file transfer is being performed in the main UI thread, increasing the priority may interfere with the normal processing of Windows messages and cause the application to appear to become non-responsive. It is also important to note that when the priority is set to `HTTP_PRIORITY_CRITICAL`, normal progress events will not be generated during the transfer.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `cshttpv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

See Also

[HttpGetPriority](#)

HttpSetRequestHeader Function

```
BOOL WINAPI HttpSetRequestHeader(  
    HCLIENT hClient,  
    LPCTSTR lpszHeader,  
    LPCTSTR lpszValue  
);
```

The **HttpSetRequestHeader** function sets the value of the specified request header field.

Parameters

hClient

Handle to the client session.

lpszHeader

Points to a string which specifies the request header field name.

lpszValue

Points to a string which specifies the value of the request header field.

Return Value

If the function succeeds, the return value is non-zero. If the client handle is invalid, the function returns a value of zero. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpSetRequestHeader** function defines a header field and value that is submitted to the server when a resource is requested. If the header field has already been defined, it will be replaced by the new value. There are a number of header fields which are automatically created by the library, and others that are conditionally created depending on whether or not certain options are specified. The following header fields are automatically created by the library:

Header Field	Description
Accept	This header specifies the types of resources that are acceptable to the client. By default, all resource data types are accepted by the client.
Authorization	This header is automatically created if the client uses the <code>HttpAuthenticate</code> function to authenticate a client session.
Connection	This header determines if the connection is maintained after a resource has been requested, or if the connection should be immediately closed. The value of this header depends on whether the <code>HTTP_OPTION_KEEPALIVE</code> option has been specified.
Content-Length	This header defines the length of the data that is being posted to the server or the size of a file being uploaded to the server.
Content-Type	This header defines the content type for data posted to the server. This header is created if URL encoding is specified. The specific type of encoding used can be set by calling the <code>HttpSetEncodingType</code> function.
Host	This header specifies the name of the server that the client has

	connected to. This is automatically generated when any resource is requested.
Pragma	This header is used to control caching performed by the server. If the option HTTP_OPTION_NOCACHE has been specified, this header will automatically be defined with the value "no-cache".
Proxy-Authorization	This header is automatically created if a proxy connection has been established and a username and password is required to authenticate the client session.

Request headers are generated by functions that send resource requests. In some cases, header values are supplied by the requesting function only if the application has not previously defined the header. For others, the requesting function overrides what the application may have defined.

If you use this function to set the Authorization header to a custom value for this client session, you must not call the **HttpAuthenticate** function. The **HttpAuthenticate** function will always override any custom Authorization header value and replace it with the credentials token generated from the username and password provided.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cshttpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

HttpSetTimeout Function

```
INT WINAPI HttpSetTimeout(  
    HCLIENT hClient,  
    INT nTimeout  
);
```

The **HttpSetTimeout** function sets the number of seconds the client will wait for a response from the server. Once the specified number of seconds has elapsed, the function will fail and return to the caller.

Parameters

hClient

Handle to the client session.

nTimeout

The number of seconds to wait for a blocking operation to complete.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The timeout value is only used with blocking client connections.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cshttpv10.lib

See Also

[HttpGetTimeout](#), [HttpIsBlocking](#), [HttpIsReadable](#), [HttpIsWritable](#)

HttpSubmitForm Function

```
INT WINAPI HttpSubmitForm(  
    HCLIENT hClient,  
    HFORM hForm,  
    LPVOID lpvResult,  
    LPDWORD lpcbResult,  
    DWORD dwOptions  
);
```

The **HttpSubmitForm** function submits the contents of the specified form to a script on the server and returns the result in a buffer provided by the caller.

Parameters

hClient

Handle to the client session.

hForm

Handle to the virtual form which contains the data to be submitted to the server.

lpvResult

A pointer to a byte buffer which will contain the data returned by the server, or a pointer to a global memory handle which will reference the data when the function returns.

lpcbResult

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the *lpvBuffer* parameter. If the *lpvResult* parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the actual number of bytes of data that was returned.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
HTTP_SUBMIT_DEFAULT	The default post mode. The contents of the buffer are encoded and sent as standard form data. The data returned by the server is copied to the result buffer exactly as it is returned from the server.
HTTP_SUBMIT_CONVERT	If the data being returned from the server is textual, it is automatically converted so that the end of line character sequence is compatible with the Windows platform. Individual carriage return or linefeed characters are converted to carriage return/linefeed character sequences. Note that this option does not have any effect on the form data being submitted to the server, only on the data returned by the server.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpSubmitForm** function is used to submit form data to a script that executes on the server and then copy the output from that script into a local buffer. The function may be used in one of two ways, depending on the needs of the application. The first method is to pre-allocate a buffer large enough to store the resulting output of the script. In this case, the *lpvResult* parameter will point to the buffer that was allocated by the client and the value that the *lpcbResult* parameter points to should be initialized to the size of that buffer.

The second method that can be used is have the *lpvResult* parameter point to a global memory handle which will contain the data when the function returns. In this case, the value that the *lpcbResult* parameter points to must be initialized to zero. It is important to note that the memory handle returned by the function must be freed by the application, otherwise a memory leak will occur. See the example code below.

This function will cause the current thread to block until the post completes, a timeout occurs or the operation is canceled. During the transfer, the HTTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **HttpEnableEvents**, or by registering a callback function using the **HttpRegisterEvent** function.

To determine the current status of a transaction while it is in progress, use the **HttpGetTransferStatus** function.

Example

```
HFORM hForm = INVALID_FORM;
HGLOBAL hgblResult = (HGLOBAL)NULL;
DWORD cbResult = 0;
INT nResult = 0;

hForm = HttpCreateForm(_T("/login.php"), HTTP_METHOD_POST, HTTP_FORM_ENCODED);

if (hForm == INVALID_FORM)
    return;

HttpAddFormField(hForm, _T("UserName"), lpszUserName, (DWORD)-1L, 0);
HttpAddFormField(hForm, _T("Password"), lpszPassword, (DWORD)-1L, 0);

nResult = HttpSubmitForm(hClient, hForm, &hgblResult, &cbResult, 0);
HttpDestroyForm(hForm);

if (hgblResult != NULL)
{
    LPBYTE lpBuffer = (LPBYTE)GlobalLock(hgblResult);

    // lpBuffer points to data returned by the server after the form
    // data was submitted

    GlobalUnlock(hgblResult);
    GlobalFree(hgblResult);
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cshttpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[HttpRegisterEvent](#)

HttpTaskAbort Function

```
BOOL WINAPI HttpTaskAbort(  
    UINT nTaskId,  
    DWORD dwMilliseconds  
);
```

Abort the specified asynchronous task.

Parameters

nTaskId

The task identifier.

dwMilliseconds

An unsigned integer that specifies the number of milliseconds to wait for the background task to abort.

Return Value

If the function succeeds and the worker thread has terminated, the return value is non-zero. A return value of zero indicates that the worker thread is still running or an error has occurred. To get extended error information, call the **HttpGetLastError** function.

Remarks

The **HttpTaskAbort** function signals the background worker thread associated with the task ID to abort the current operation and terminate as soon as possible. If the *dwMilliseconds* parameter has a value of zero, the function returns immediately after the background thread has been signaled. If the *dwMilliseconds* parameter is non-zero, the function will wait that amount of time for the background thread to terminate.

This function should never be called from within the event handler for an asynchronous task because it can cause the process to deadlock. To abort a file transfer within an event handler, use the **HttpCancel** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cshttp10.lib

See Also

[HttpTaskDone](#), [HttpTaskResume](#), [HttpTaskSuspend](#), [HttpTaskWait](#)

HttpTaskDone Function

```
BOOL WINAPI HttpTaskDone(  
    UINT nTaskId  
);
```

Determine if an asynchronous task has completed.

Parameters

nTaskId

The task identifier.

Return Value

If the asynchronous task has completed, this function returns a non-zero value. A return value of zero indicates that the worker thread is still running or an error has occurred. To get extended error information, call the **HttpGetLastError** function.

Remarks

The **HttpTaskDone** function is used to determine if the specified asynchronous task has completed. If you use this function to poll the status of a background task from within the main UI thread, you must ensure that Windows messages are processed so that the application remains responsive to the end-user. To check if a background transfer has completed, it is recommended that you use a timer to periodically call this function rather than calling it repeatedly within a loop.

To determine if the task completed successfully, the **HttpGetTaskError** function will return the last error code associated with the task. A return value of zero indicates success, while a non-zero return value specifies an error code that indicates the cause of the failure. The last error code for the task can also be retrieved using the **HttpTaskWait** function, which causes the application to wait for the asynchronous task to complete.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cshttpv10.lib

See Also

[HttpGetTaskError](#), [HttpTaskAbort](#), [HttpTaskResume](#), [HttpTaskSuspend](#), [HttpTaskWait](#)

HttpTaskResume Function

```
BOOL WINAPI HttpTaskResume(  
    UINT nTaskId  
);
```

Resume execution of an asynchronous task.

Parameters

nTaskId

The task identifier.

Return Value

If the asynchronous task has resumed, this function returns a non-zero value. A return value of zero indicates that an error has occurred. To get extended error information, call the **HttpGetLastError** function.

Remarks

The **HttpTaskResume** function resumes execution of the background worker thread that was previously suspended using the **HttpTaskSuspend** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cshttpv10.lib

See Also

[HttpTaskAbort](#), [HttpTaskDone](#), [HttpTaskSuspend](#), [HttpTaskWait](#)

HttpTaskSuspend Function

```
BOOL WINAPI HttpTaskSuspend(  
    UINT nTaskId  
);
```

Suspend execution of an asynchronous task.

Parameters

nTaskId

The task identifier.

Return Value

If the asynchronous task has resumed, this function returns a non-zero value. A return value of zero indicates that an error has occurred. To get extended error information, call the **HttpGetLastError** function.

Remarks

The **HttpTaskSuspend** function will suspend execution of the background worker thread associated with the task. Once the task has been suspended, it will no longer be scheduled for execution, however the client session will remain active and the task may be resumed using the **HttpTaskResume** function. Note that if a task is suspended for a long period of time, the background operation may fail because it has exceeded the timeout period imposed by the server.

This function should never be called from within the event handler for an asynchronous task because it can cause the process to deadlock.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cshttpv10.lib

See Also

[HttpTaskAbort](#), [HttpTaskDone](#), [HttpTaskResume](#), [HttpTaskWait](#)

HttpTaskWait Function

```
BOOL WINAPI HttpTaskWait(  
    UINT nTaskId,  
    DWORD dwMilliseconds,  
    DWORD dwReserved,  
    LPDWORD lpdwElapsed,  
    LPDWORD lpdwError  
);
```

Wait for an asynchronous task to complete.

Parameters

nTaskId

The task identifier.

dwMilliseconds

An unsigned integer that specifies the number of milliseconds to wait for the background task to complete.

dwReserved

An unsigned integer reserved for future use. This value should always be zero.

lpdwElapsed

A pointer to an unsigned integer that will contain elapsed time in milliseconds when the function returns. If this information is not required, this parameter may be NULL.

lpdwError

A pointer to an unsigned integer that will contain the error code associated with the completed task. If this information is not required, this parameter may be NULL.

Return Value

If the function succeeds and the worker thread has terminated, the return value is non-zero. A return value of zero indicates that the worker thread is still running or an error has occurred. To get extended error information, call the **HttpGetLastError** function.

Remarks

The **HttpTaskWait** function waits for the specified task to complete. If the task is active and the *dwMilliseconds* parameter is non-zero, this function will cause the current working thread to block until the task completes or the amount of time exceeds the number of milliseconds specified by the caller. If the *dwMilliseconds* parameter is zero, then this function will poll the status of the task and return immediately to the caller.

If the specified task has already completed at the time this function is called, the function will return immediately without causing the current thread to block. If the *lpdwElapsed* parameter is not NULL, it will contain the number of milliseconds that it took for the task to complete. If the *lpdwError* parameter is not NULL, it will contain the last error code value that was set by the worker thread before it terminated. If this value is zero, that means that the background operation was successful and no error occurred. A non-zero value will indicate that the background operation has failed.

You should not call this function from the main UI thread with a long timeout period to wait for a background task to complete. Windows messages will not be processed while this function is blocked waiting for the background task to complete, and this can cause your application to

appear non-responsive to the end-user. If you have a GUI application and you need to periodically check to see if a task has completed, create a timer to periodically call the **HttpTaskDone** function. When it returns a non-zero value (indicating that the task has completed), you can safely call **HttpTaskWait** to obtain the elapsed time and last error code without blocking the current thread.

This function should never be called from within the event handler for an asynchronous task because it can cause the process to deadlock.

Example

```
UINT nTaskId;

// Begin a file transfer in the background

nTaskId = HttpAsyncGetFile(hClient,
                          lpszLocalFile,
                          lpszRemoteFile,
                          HTTP_TRANSFER_DEFAULT,
                          0,
                          NULL,
                          0);

if (nTaskId != 0)
{
    DWORD dwError = NO_ERROR;
    DWORD dwElapsed = 0;

    // Wait for the transfer to complete
    HttpTaskWait(nTaskId, INFINITE, &dwElapsed, &dwError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstoools10.h

Import Library: cshttpv10.lib

See Also

[HttpTaskDone](#), [HttpTaskResume](#), [HttpTaskSuspend](#), [HttpTaskWait](#)

HttpUninitialize Function

```
VOID WINAPI HttpUninitialize();
```

The **HttpUninitialize** function terminates the use of the library.

Parameters

There are no parameters.

Return Value

None.

Remarks

An application is required to perform a successful **HttpInitialize** call before it can call any of the other library functions. When it has completed the use of library, the application must call **HttpUninitialize** to allow the library to free any resources allocated on behalf of the process. Any pending blocking or asynchronous calls in this process are canceled without posting any notification messages, and all sockets that were opened by the process are closed.

There must be a call to **HttpUninitialize** for every successful call to **HttpInitialize** made by a process. In a multithreaded environment, operations for all threads in the client are terminated.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cshttpv10.lib

HttpUploadFile Function

```
BOOL WINAPI HttpUploadFile(  
    LPCTSTR lpszLocalFile,  
    LPCTSTR lpszFileURL,  
    UINT nTimeout  
    DWORD dwOptions  
    LPHTTPTRANSFERSTATUS lpStatus  
    HTTPEVENTPROC lpEventProc  
    DWORD_PTR dwParam  
);
```

The **HttpUploadFile** function uploads the specified file from the local system to the server.

Parameters

lpszLocalFile

A pointer to a string that specifies the file on the local system that will be uploaded to the server. The file pathing and name conventions must be that of the local host.

lpszFileURL

A pointer to a string that specifies the complete URL of the file that will be created or overwritten on the server. The URL must follow the conventions for the Hypertext Transfer Protocol and may specify either a standard or secure connection, alternate port number, username, password and optional working directory.

nTimeout

The number of seconds that the client will wait for a response before failing the operation. A value of zero specifies that the default timeout period of sixty seconds will be used.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
HTTP_OPTION_NOCACHE	This instructs the server to not return a cached copy of the resource. When connected to an HTTP 1.0 or earlier server, this directive may be ignored.
HTTP_OPTION_PROXY	This option specifies the client should use the default proxy configuration for the local system. If the system is configured to use a proxy server, then the connection will be automatically established through that proxy; otherwise, a direct connection to the server is established. The local proxy configuration can be changed using the system Control Panel.
HTTP_OPTION_TUNNEL	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established.

HTTP_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using either the SSL or TLS protocols.
HTTP_OPTION_SECURE	This option specifies the client should attempt to establish a secure connection with the server. Note that the server must support secure connections using either the SSL or TLS protocol.

lpStatus

A pointer to an HTTPTRANSFERSTATUS structure which contains information about the status of the current file transfer. If this information is not required, a NULL pointer may be specified as the parameter.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **HttpEventProc** callback function. If this parameter is NULL, the callback for the specified event is disabled.

dwParam

A user-defined integer value that is passed to the callback function.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpUploadFile** function provides a convenient way for an application to upload a file in a single function call. Based on the connection information specified in the URL, it will connect to the server, authenticate the session and then upload the file to the server. The URL must be complete, and specify either a standard or secure HTTP scheme:

```
[http|https]://[username : password] @] remotehost [:remoteport] / [path / ...] [filename]
```

If no user name and password is provided, then the client session will be authenticated as an anonymous user. The URL scheme will always determine if the connection is secure, not the option. In other words, if the "http" scheme is used and the HTTP_OPTION_SECURE option is specified, that option will be ignored. To establish a secure connection, the "https" scheme must be specified.

Not all web servers permit files to be uploaded and some may require that specific configuration changes be made to the server in order to support this functionality. Consult your server's technical reference documentation to see if it supports the PUT command, and if so, what must be done to enable it. It may be required that the URL specify a username and password to upload a file.

The *lpStatus* parameter can be used by the application to determine the final status of the transfer, including the total number of bytes copied, the amount of time elapsed and other information related to the transfer process. If this information isn't needed, then this parameter may be specified as NULL.

The *lpEventProc* parameter specifies a pointer to a function which will be periodically called during the file transfer process. This can be used to check the status of the transfer by calling

HttpGetTransferStatus and then update the program's user interface. For example, the callback function could calculate the percentage for how much of the file has been transferred and then update a progress bar control. The *dwParam* parameter is used in conjunction with the event handler and specifies a user-defined value that is passed to the callback function. One common use in a C++ program is to pass the *this* pointer as the value, and then cast it back to an object pointer inside the callback function. If no event handler is required, then a NULL pointer can be specified as the value for *lpEventProc* and the *dwParam* parameter will be ignored.

The **HttpUploadFile** function is designed to provide a simpler interface for uploading a file. However, complex connections such as those using a specific proxy server or a secure connection which uses a client certificate will require the program to establish the connection using **HttpConnect** or **HttpProxyConnect** and then use **HttpPutFile** to upload the file. If the server does not support the PUT command, you may be able to upload files using the **HttpPostFile** function. Refer to that function for more information.

Example

```
HTTPTRANSFERSTATUS httpStatus;
LPCTSTR lpszLocalFile = _T("c:\\temp\\database.mdb");
LPCTSTR lpszFileURL =
_T("http://update:secret@www.example.com/updates/database.mdb");
BOOL bResult;

// Upload the file using the specified URL
bResult = HttpUploadFile(lpszLocalFile,
                        lpszFileURL,
                        HTTP_OPTION_PASSIVE,
                        &httpStatus,
                        NULL, 0);

if (!bResult)
{
    TCHAR szError[128];

    // Display a message box that describes the error
    HttpGetErrorString(HttpGetLastError(), szError, 128);
    MessageBox(NULL, szError, NULL, MB_ICONEXCLAMATION|MB_TASKMODAL);
    return;
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstoools10.h

Import Library: cshttpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

HttpUploadFileEx Function

```
BOOL WINAPI HttpUploadFileEx(  
    LPCTSTR lpszLocalFile,  
    LPCTSTR lpszFileURL,  
    UINT nTimeout  
    DWORD dwOptions  
    LPHTTPTRANSFERSTATUSEX lpStatus  
    HTTPEVENTPROC lpEventProc  
    DWORD_PTR dwParam  
);
```

The **HttpUploadFileEx** function uploads the specified file from the local system to the server. This version of the function is designed to support files that are larger than 4GB.

Parameters

lpszLocalFile

A pointer to a string that specifies the file on the local system that will be uploaded to the server. The file pathing and name conventions must be that of the local host.

lpszFileURL

A pointer to a string that specifies the complete URL of the file that will be created or overwritten on the server. The URL must follow the conventions for the Hypertext Transfer Protocol and may specify either a standard or secure connection, alternate port number, username, password and optional working directory.

nTimeout

The number of seconds that the client will wait for a response before failing the operation. A value of zero specifies that the default timeout period of sixty seconds will be used.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
HTTP_OPTION_NOCACHE	This instructs the server to not return a cached copy of the resource. When connected to an HTTP 1.0 or earlier server, this directive may be ignored.
HTTP_OPTION_PROXY	This option specifies the client should use the default proxy configuration for the local system. If the system is configured to use a proxy server, then the connection will be automatically established through that proxy; otherwise, a direct connection to the server is established. The local proxy configuration can be changed using the system Control Panel.
HTTP_OPTION_TUNNEL	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is

	established.
HTTP_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using either the SSL or TLS protocols.
HTTP_OPTION_SECURE	This option specifies the client should attempt to establish a secure connection with the server. Note that the server must support secure connections using either the SSL or TLS protocol.

lpStatus

A pointer to an HTTPTRANSFERSTATUSEX structure which contains information about the status of the current file transfer. If this information is not required, a NULL pointer may be specified as the parameter.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **HttpEventProc** callback function. If this parameter is NULL, the callback for the specified event is disabled.

dwParam

A user-defined integer value that is passed to the callback function.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpUploadFileEx** function provides a convenient way for an application to upload a file in a single function call. Based on the connection information specified in the URL, it will connect to the server, authenticate the session and then upload the file to the server. The URL must be complete, and specify either a standard or secure HTTP scheme:

```
[http|https]://[username : password] @ remotehost [:remoteport] / [path / ...] [filename]
```

If no user name and password is provided, then the client session will be authenticated as an anonymous user. The URL scheme will always determine if the connection is secure, not the option. In other words, if the "http" scheme is used and the HTTP_OPTION_SECURE option is specified, that option will be ignored. To establish a secure connection, the "https" scheme must be specified.

Not all web servers permit files to be uploaded and some may require that specific configuration changes be made to the server in order to support this functionality. Consult your server's technical reference documentation to see if it supports the PUT command, and if so, what must be done to enable it. It may be required that the URL specify a username and password to upload a file.

The *lpStatus* parameter can be used by the application to determine the final status of the transfer, including the total number of bytes copied, the amount of time elapsed and other information related to the transfer process. If this information isn't needed, then this parameter may be specified as NULL.

The *lpEventProc* parameter specifies a pointer to a function which will be periodically called during

the file transfer process. This can be used to check the status of the transfer by calling **HttpGetTransferStatus** and then update the program's user interface. For example, the callback function could calculate the percentage for how much of the file has been transferred and then update a progress bar control. The *dwParam* parameter is used in conjunction with the event handler and specifies a user-defined value that is passed to the callback function. One common use in a C++ program is to pass the *this* pointer as the value, and then cast it back to an object pointer inside the callback function. If no event handler is required, then a NULL pointer can be specified as the value for *lpEventProc* and the *dwParam* parameter will be ignored.

The **HttpUploadFileEx** function is designed to provide a simpler interface for uploading a file. However, complex connections such as those using a specific proxy server or a secure connection which uses a client certificate will require the program to establish the connection using **HttpConnect** or **HttpProxyConnect** and then use **HttpPutFileEx** to upload the file. If the server does not support the PUT command, you may be able to upload files using the **HttpPostFile** function. Refer to that function for more information.

Example

```
HTTPTRANSFERSTATUSEX httpStatus;
LPCTSTR lpszLocalFile = _T("c:\\temp\\database.mdb");
LPCTSTR lpszFileURL =
_T("http://update:secret@www.example.com/updates/database.mdb");
BOOL bResult;

// Upload the file using the specified URL
bResult = HttpUploadFileEx(lpszLocalFile,
                           lpszFileURL,
                           HTTP_OPTION_PASSIVE,
                           &httpStatus,
                           NULL, 0);

if (!bResult)
{
    TCHAR szError[128];

    // Display a message box that describes the error
    HttpGetErrorString(HttpGetLastError(), szError, 128);
    MessageBox(NULL, szError, NULL, MB_ICONEXCLAMATION|MB_TASKMODAL);
    return;
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cshttpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

HttpValidateUrl Function

```
BOOL WINAPI HttpValidateUrl(  
    LPCTSTR lpszURL  
);
```

The **HttpValidateUrl** function determines if a string represents a valid HTTP URL.

Parameters

lpszURL

A pointer to a string that specifies the URL to validate.

Return Value

If the specified URL is valid and the host name can be resolved to an IP address, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpValidateUrl** function will check the value of a string to ensure that it represents a complete, valid URL using either a standard or secure HTTP scheme. This function will not establish a connection with the server to verify that it exists, it will only attempt to resolve the host name to an IP address. If the remote host is specified as an IP address, this function will check to make sure that the address is formatted correctly. Note that if you wish to specify an IPv6 address, you must enclose the address in brackets.

To establish a connection with a server using a URL, use the **HttpConnectUrl** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cshttpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[HttpConnectUrl](#)

HttpVerifyFile Function

```
BOOL WINAPI HttpVerifyFile(  
    HCLIENT hClient,  
    LPCTSTR lpszLocalFile,  
    LPCTSTR lpszRemoteFile,  
    DWORD dwReserved  
);
```

The **HttpVerifyFile** function attempts to verify that the size of a file on the local system is the same as the specified file on the server.

Parameters

hClient

Handle to the client session.

lpszLocalFile

A pointer to a string that specifies the name of file on the local system.

lpszRemoteFile

A pointer to a string that specifies the name of the file on the server.

dwReserved

A reserved parameter. This value should always be zero.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpVerifyFile** function will attempt to verify that the contents of the local and remote files are identical by comparing the size of the files. This function is provided for compatibility with the File Transfer Protocol API, and should not be considered a reliable method for comparing files. Web servers may not consistently return file size information for dynamically created content such as HTML pages which use server-side includes.

It is not recommended that you use this function with text files because of the different end-of-line conventions used by different operating systems. For example, a text file on a Windows system uses a carriage-return and linefeed pair to indicate the end of a line of text. However, on a UNIX system, a single linefeed is used to indicate the end of a line. This can cause the **HttpVerifyFile** function to indicate the files are not identical, even though the only difference is in the end-of-line characters that are used.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cshttpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

HttpWrite Function

```
INT WINAPI HttpWrite(  
    HCLIENT hClient,  
    LPBYTE lpBuffer,  
    INT cbBuffer  
);
```

The **HttpWrite** function sends the specified number of bytes to the server.

Parameters

hClient

Handle to the client session.

lpBuffer

The pointer to the buffer which contains the data that is to be sent to the server.

cbBuffer

The number of bytes to send from the specified buffer.

Return Value

If the function succeeds, the return value is the number of bytes actually written. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The return value may be less than the number of bytes specified by the *cbBuffer* parameter. In this case, the data has been partially written and it is the responsibility of the client application to send the remaining data at some later point. For non-blocking clients, the client must wait for an asynchronous notification message before it resumes sending data.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cshttp10.lib

Hypertext Transfer Protocol Data Structures

- HTTPFORMPROPERTIES
- HTTPTRANSFERSTATUS
- HTTPTRANSFERSTATUSEX
- INITDATA
- SECURITYCREDENTIALS
- SECURITYINFO
- SYSTEMTIME

HTTPFORMPROPERTIES Structure

This structure is used by the **HttpGetFormProperties** and **HttpSetFormProperties** function to return and modify the properties of the specified form.

```
typedef struct _HTTPFORMPROPERTIES
{
    UINT    nFormMethod;
    UINT    nFormType;
    LPCTSTR lpszFormAction;
    DWORD   dwReserved1;
    DWORD   dwReserved2;
} HTTPFORMPROPERTIES, *LPHTTPFORMPROPERTIES;
```

Members

nFormMethod

An unsigned integer value which specifies how the form data will be submitted to the server. It may be one of the following values:

Constant	Description
HTTP_METHOD_GET	The form data should be submitted using the GET command. This method should be used when the amount of form data is relatively small. If the total amount of form data exceeds 2048 bytes, it is recommended that the POST method be used instead.
HTTP_METHOD_POST	The form data should be submitted using the POST command. This is the preferred method of submitting larger amounts of form data. If the total amount of form data exceeds 2048 bytes, it is recommended that the POST method be used.

nFormType

An unsigned integer value which specifies the type of form and how the data will be encoded when it is submitted to the server. It may be one of the following values:

Constant	Description
HTTP_FORM_ENCODED	The form data should be submitted as URL encoded values. This is typically used when the GET method is used to submit the data to the server.
HTTP_FORM_MULTIPART	The form data should be submitted as multipart form data. This is typically used when the POST method is used to submit a file to the server. Note that the script must understand how to process multipart form data if this form type is specified.

lpszFormAction

A pointer to a string which specifies the name of the resource that the form data will be submitted to. Typically this is the name of a script that is executed on the server.

dwReserved1

A reserved structure member.

dwReserved2

A reserved structure member.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Unicode: Implemented as Unicode and ANSI versions.

HTTPTRANSFERSTATUS Structure

This structure is used by the **HttpGetTransferStatus** function to return information about a data transfer in progress.

```
typedef struct _HTTPTRANSFERSTATUS
{
    DWORD    dwBytesTotal;
    DWORD    dwBytesCopied;
    DWORD    dwBytesPerSecond;
    DWORD    dwTimeElapsed;
    DWORD    dwTimeEstimated;
} HTTPTRANSFERSTATUS, *LPHTTPTRANSFERSTATUS;
```

Members

dwBytesTotal

The total number of bytes that will be transferred. If the data is being downloaded from the server to the local host, this is the size of the requested resource. If the data is being uploaded from the local host to the server, it is the size of the local file or memory buffer. If the size of the resource cannot be determined, this value will be zero.

dwBytesCopied

The total number of bytes that have been copied.

dwBytesPerSecond

The average number of bytes that have been copied per second.

dwTimeElapsed

The number of seconds that have elapsed since the file transfer started.

dwTimeEstimated

The estimated number of seconds until the data transfer is completed. This is based on the average number of bytes transferred per second.

Remarks

If the option `HTTP_OPTION_HIRES_TIMER` has been specified when connecting to the server, the values returned in the *dwTimeElapsed* and *dwTimeEstimated* members will be in milliseconds instead of seconds. You can use this option to obtain more accurate elapsed times when uploading or downloading small amounts of data over a fast network connection.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

HTTPTRANSFERSTATUSEX Structure

This structure is used by the **HttpGetTransferStatusEx** function to return information about a data transfer in progress. This structure is designed for use with extended functions that support files larger than 4GB.

```
typedef struct _HTTPTRANSFERSTATUSEX
{
    ULARGE_INTEGER uiBytesTotal;
    ULARGE_INTEGER uiBytesCopied;
    DWORD          dwBytesPerSecond;
    DWORD          dwTimeElapsed;
    DWORD          dwTimeEstimated;
} HTTPTRANSFERSTATUSEX, *LPHTTPTRANSFERSTATUSEX;
```

Members

uiBytesTotal

The total number of bytes that will be transferred. If the data is being downloaded from the server to the local host, this is the size of the requested resource. If the data is being uploaded from the local host to the server, it is the size of the local file or memory buffer. If the size of the resource cannot be determined, this value will be zero.

uiBytesCopied

The total number of bytes that have been copied.

dwBytesPerSecond

The average number of bytes that have been copied per second.

dwTimeElapsed

The number of seconds that have elapsed since the file transfer started.

dwTimeEstimated

The estimated number of seconds until the data transfer is completed. This is based on the average number of bytes transferred per second.

Remarks

If the option `HTTP_OPTION_HIRES_TIMER` has been specified when connecting to the server, the values returned in the *dwTimeElapsed* and *dwTimeEstimated* members will be in milliseconds instead of seconds. You can use this option to obtain more accurate elapsed times when uploading or downloading small amounts of data over a fast network connection.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

INITDATA Structure

This structure contains information about the SocketTools library when the initialization function returns.

```
typedef struct _INITDATA
{
    DWORD        dwSize;
    DWORD        dwVersionMajor;
    DWORD        dwVersionMinor;
    DWORD        dwVersionBuild;
    DWORD        dwOptions;
    DWORD_PTR    dwReserved1;
    DWORD_PTR    dwReserved2;
    TCHAR        szDescription[128];
} INITDATA, *LPINITDATA;
```

Members

dwSize

Size of this structure. This structure member must be set to the size of the structure prior to calling the initialization function. Failure to do so will cause the function to fail.

dwVersionMajor

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the major version number for the library.

dwVersionMinor

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the minor version number for the library.

dwVersionBuild

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the build number for the library.

dwOptions

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

dwReserved1

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

dwReserved2

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

szDescription

A null terminated string which describes the library.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Unicode: Implemented as Unicode and ANSI versions.

SECURITYCREDENTIALS Structure

The **SECURITYCREDENTIALS** structure specifies the information needed by the library to specify additional security credentials, such as a client certificate or private key, when establishing a secure connection.

```
typedef struct _SECURITYCREDENTIALS
{
    DWORD    dwSize;
    DWORD    dwProtocol;
    DWORD    dwOptions;
    DWORD    dwReserved;
    LPCTSTR  lpszHostName;
    LPCTSTR  lpszUserName;
    LPCTSTR  lpszPassword;
    LPCTSTR  lpszCertStore;
    LPCTSTR  lpszCertName;
    LPCTSTR  lpszKeyFile;
} SECURITYCREDENTIALS, *LPSECURITYCREDENTIALS;
```

Members

dwSize

Size of this structure. If the structure is being allocated dynamically, this member must be set to the size of the structure and all other unused structure members must be initialized to a value of zero or NULL.

dwProtocol

A bitmask of supported security protocols. The value of this structure member is constructed by using a bitwise operator with any of the following values:

Constant	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_SSL	Either SSL 2.0 or SSL 3.0 should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, TLS will be excluded from the list of supported protocols. Both SSL 2.0 and 3.0 have been deprecated and will never be used unless explicitly specified. It is not recommended that you enable either of these protocols for secure connections because it will cause most servers to reject your connection request, even if a version of TLS is also specified.
SECURITY_PROTOCOL_TLS	Either the TLS 1.0, 1.1 or 1.2 protocol should be used when establishing a secure connection. The correct protocol is automatically selected, based on

	what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers that reject any attempt to use the older SSL protocol and require that only TLS be used.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This is the recommended version of TLS to use with secure connections.

dwOptions

A value which specifies one or options. This member is constructed by using a bitwise operator with any of the following values:

Constant	Description
CREDENTIAL_STORE_CURRENT_USER	The library will attempt to open a store for the current user using the certificate store name provided in this structure. If no options are specified, then this is the default behavior.
CREDENTIAL_STORE_LOCAL_MACHINE	The library will attempt to open a local machine store using the certificate store name provided in this structure. If this option is specified, the library will always search for a local machine store before searching for the store by that name for the current user.
CREDENTIAL_STORE_FILENAME	The certificate store name is a file that contains the certificate and private key that

will be used.

dwReserved

This structure member is reserved for future use and should always be initialized to zero.

lpszHostName

A pointer to a null terminated string which specifies the hostname that will be used when validating the server certificate. If this member is NULL, then the server certificate will be validated against the hostname used to establish the connection.

lpszUserName

A pointer to a null terminated string which identifies the owner of client certificate. Currently this member is not used by the library and should always be initialized as a NULL pointer.

lpszPassword

A pointer to a null terminated string which specifies the password needed to access the certificate. Currently this member is only used if the CREDENTIAL_STORE_FILENAME option has been specified. If there is no password associated with the certificate, then this member should be initialized as a NULL pointer.

lpszCertStore

A pointer to a null terminated string which specifies the name of the certificate store to open. A certificate store is a collection of certificates and their private keys, typically organized by how they are used. If this value is NULL or points to an empty string, the default certificate store "MY" will be used.

Store Name	Description
------------	-------------

CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as VeriSign and Thawte act as certification authorities.
----	---

MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. This corresponds to the "Personal" store that is displayed by the certificate manager utility and is the default store used by the library.
----	--

ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as VeriSign and Thawte are installed as part of the operating system and periodically updated by Microsoft.
------	--

lpszCertName

A pointer to a null terminated string which specifies the name of the certificate to use. The library will first search the certificate store for a certificate with a matching "friendly name"; this is a name for the certificate that is assigned by the user. Note that the name must match completely, but the comparison is not case sensitive. If no matching certificate is found, the library will then attempt to find a certificate that has a matching common name (also called the certificate subject). This comparison is less stringent, and the first partial match will be returned. If this second search fails, the library will return an error indicating that the certificate could not be found. If the SECURITY_PROTOCOL_SSH protocol has been specified, this member should be NULL.

lpszKeyFile

A pointer to a null terminated string which specifies the name of the file which contains the private key required to establish the connection. This member is only used for SSH connections

and should always be NULL when establishing a secure connection using SSL or TLS.

Remarks

A client application only needs to create this structure if the server requires that the client provide a certificate as part of the process of negotiating the secure session. If a certificate is required, note that it must have a private key associated with it. Attempting to use a certificate that does not have a private key will result in an error during the connection process indicating that the client credentials could not be established.

If you are using a local certificate store, with the certificate and private key stored in the registry, you can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU:" for the current user, or "HKLM:" for the local machine. For example, a certificate store name of "HKLM:MY" would specify the personal certificate store for the local machine, rather than the current user. If neither prefix is specified, then it will default to the certificate store for the current user. You can manage these certificates using the CertMgr.msc Microsoft Management Console (MMC) snap-in.

It is possible to load the certificate from a file rather than from current user's certificate store. The *dwOptions* member should be set to CREDENTIAL_STORE_FILENAME and the *lpzCertStore* member should specify the name of the file that contains the certificate and its private key. The file must be in Private Information Exchange (PFX) format, also known as PKCS#12. These certificate files typically have an extension of .pfx or .p12. Note that if a password was specified when the certificate file was created, it must be provided in the *lpzPassword* member or the library will be unable to access the certificate.

Note that the *lpzUserName* and *lpzPassword* members are values which are used to access the certificate store or private key file. They are not the credentials which are used when establishing the connection with the remote host or authenticating the client session.

The TLS 1.1 and TLS 1.2 protocols are only supported on Windows 7, Windows Server 2008 R2 and later versions of the platform. If these options are specified and the application is running on Windows XP or Windows Vista, the protocol version will be downgraded to TLS 1.0 for backwards compatibility with those platforms.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include ctools10.h

Unicode: Implemented as Unicode and ANSI versions.

SECURITYINFO Structure

This structure contains information about a secure connection that has been established.

```
typedef struct _SECURITYINFO
{
    DWORD        dwSize;
    DWORD        dwProtocol;
    DWORD        dwCipher;
    DWORD        dwCipherStrength;
    DWORD        dwHash;
    DWORD        dwHashStrength;
    DWORD        dwKeyExchange;
    DWORD        dwCertStatus;
    SYSTEMTIME   stCertIssued;
    SYSTEMTIME   stCertExpires;
    LPCTSTR      lpszCertIssuer;
    LPCTSTR      lpszCertSubject;
    LPCTSTR      lpszFingerprint;
} SECURITYINFO, *LPSECURITYINFO;
```

Members

dwSize

Specifies the size of the data structure. This member must always be initialized to **sizeof(SECURITYINFO)** prior to passing the address of this structure to the function. Note that if this member is not initialized, an error will be returned indicating that an invalid parameter has been passed to the function.

dwProtocol

A numeric value which specifies the protocol that was selected to establish the secure connection. One of the following values will be returned:

Constant	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_SSL	Either SSL 2.0 or SSL 3.0 should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, TLS will be excluded from the list of supported protocols. Both SSL 2.0 and 3.0 have been deprecated and will never be used unless explicitly specified. It is not recommended that you enable either of these protocols for secure connections because it will cause most servers to reject your connection request, even if a version of TLS is also specified.
SECURITY_PROTOCOL_TLS	Either the TLS 1.0, 1.1 or 1.2 protocol should be used when establishing a secure connection. The

	<p>correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers that reject any attempt to use the older SSL protocol and require that only TLS be used.</p>
SECURITY_PROTOCOL_TLS10	<p>The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.</p>
SECURITY_PROTOCOL_TLS11	<p>The TLS 1.1 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.</p>
SECURITY_PROTOCOL_TLS12	<p>The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This is the recommended version of TLS to use with secure connections.</p>

dwCipher

A numeric value which specifies the cipher that was selected when establishing the secure connection. One of the following values will be returned:

Constant	Description
SECURITY_CIPHER_RC2	The RC2 block cipher was selected. This is a variable key length cipher which supports keys between 40 and 128 bits, in 8-bit increments.
SECURITY_CIPHER_RC4	The RC4 stream cipher was selected. This is a variable key length cipher which supports keys between 40 and 128 bits, in 8-bit increments.
SECURITY_CIPHER_RC5	The RC5 block cipher was selected. This is a variable key length cipher which supports keys up to 2040 bits, in 8-bit increments.
SECURITY_CIPHER_DES	The DES (Data Encryption Standard) block cipher was selected. This is a fixed key length cipher, using 56-bit

	keys.
SECURITY_CIPHER_DES3	The Triple DES block cipher was selected. This cipher encrypts the data three times using different keys, effectively providing a 168-bit length key.
SECURITY_CIPHER_DESX	A variant of the DES block cipher which XORs an extra 64-bits of the key before and after the plaintext has been encrypted, increasing the key size to 184 bits.
SECURITY_CIPHER_AES	The Advanced Encryption Standard cipher (also known as the Rijndael cipher) is a fixed block size cipher which use a key size of 128, 192 or 256 bits. This cipher is supported on Windows XP SP3 and later versions of the operating system.
SECURITY_CIPHER_SKIPJACK	The Skipjack block cipher was selected. This is a fixed key length cipher, using 80-bit keys.
SECURITY_CIPHER_BLOWFISH	The Blowfish block cipher was selected. This is a variable key length cipher up to 448 bits, using a 64-bit block size.

dwCipherStrength

A numeric value which specifies the strength (the length of the cipher key in bits) of the cipher that was selected. Typically this value will be 128 or 256. 40-bit and 56-bit key lengths are considered weak encryption, and subject to brute force attacks. 128-bit and 256-bit key lengths are considered to be secure, and are the recommended key length for secure communications.

dwHash

A numeric value which specifies the hash algorithm which was selected. One of the following values will be returned:

Constant	Description
SECURITY_HASH_MD5	The MD5 algorithm was selected. Its use has been deprecated and is no longer considered to be cryptographically secure.
SECURITY_HASH_SHA1	The SHA-1 algorithm was selected. Its use has been deprecated and is no longer considered to be cryptographically secure.
SECURITY_HASH_SHA256	The SHA-256 algorithm was selected.
SECURITY_HASH_SHA384	The SHA-384 algorithm was selected.
SECURITY_HASH_SHA512	The SHA-512 algorithm was selected.

dwHashStrength

A numeric value which specifies the strength (the length in bits) of the message digest that was selected.

dwKeyExchange

A numeric value which specifies the key exchange algorithm which was selected. One of the following values will be returned:

--	--

Constant	Description
SECURITY_KEYEX_RSA	The RSA public key algorithm was selected.
SECURITY_KEYEX_KEA	The Key Exchange Algorithm (KEA) was selected. This is an improved version of the Diffie-Hellman public key algorithm.
SECURITY_KEYEX_DH	The Diffie-Hellman key exchange algorithm was selected.
SECURITY_KEYEX_ECDH	The Elliptic Curve Diffie-Hellman key exchange algorithm was selected. This is a variant of the Diffie-Hellman algorithm which uses elliptic curve cryptography. This key exchange algorithm is only supported on Windows XP SP3 and later versions of the operating system.

dwCertStatus

A numeric value which specifies the status of the certificate returned by the secure server. This member only has meaning for connections using the SSL or TLS protocols. One of the following values will be returned:

Constant	Description
SECURITY_CERTIFICATE_VALID	The certificate is valid.
SECURITY_CERTIFICATE_NOMATCH	The certificate is valid, but the domain name does not match the common name in the certificate.
SECURITY_CERTIFICATE_EXPIRED	The certificate is valid, but has expired.
SECURITY_CERTIFICATE_REVOKED	The certificate has been revoked and is no longer valid.
SECURITY_CERTIFICATE_UNTRUSTED	The certificate or certificate authority is not trusted on the local system.
SECURITY_CERTIFICATE_INVALID	The certificate is invalid. This typically indicates that the internal structure of the certificate has been damaged.

stCertIssued

A structure which contains the date and time that the certificate was issued by the certificate authority. If the issue date cannot be determined for the certificate, the SYSTEMTIME structure members will have zero values. This member only has meaning for connections using the SSL or TLS protocols.

stCertExpires

A structure which contains the date and time that the certificate expires. If the expiration date cannot be determined for the certificate, the SYSTEMTIME structure members will have zero values. This member only has meaning for connections using the SSL or TLS protocols.

lpszCertIssuer

A pointer to a string which contains information about the organization that issued the certificate. This string consists of one or more comma-separated tokens. Each token consists of an identifier, followed by an equal sign and a value. If the certificate issuer could not be determined, this member may be NULL. This member only has meaning for connections using the SSL or TLS protocols.

lpszCertSubject

A pointer to a string which contains information about the organization that the certificate was issued to. This string consists of one or more comma-separated tokens. Each token consists of an identifier, followed by an equal sign and a value. If the certificate subject could not be determined, this member may be NULL. This member only has meaning for connections using the SSL or TLS protocols.

lpszFingerprint

A pointer to a string which contains a sequence of hexadecimal values that uniquely identify the server. This member is only used when a connection has been established using the Secure Shell (SSH) protocol.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Unicode: Implemented as Unicode and ANSI versions.

SYSTEMTIME Structure

The **SYSTEMTIME** structure represents a date and time using individual members for the month, day, year, weekday, hour, minute, second, and millisecond.

```
typedef struct _SYSTEMTIME
{
    WORD wYear;
    WORD wMonth;
    WORD wDayOfWeek;
    WORD wDay;
    WORD wHour;
    WORD wMinute;
    WORD wSecond;
    WORD wMilliseconds;
} SYSTEMTIME, *LPSYSTEMTIME;
```

Members

wYear

Specifies the current year. The year value must be greater than 1601.

wMonth

Specifies the current month. January is 1, February is 2 and so on.

wDayOfWeek

Specifies the current day of the week. Sunday is 0, Monday is 1 and so on.

wDay

Specifies the current day of the month

wHour

Specifies the current hour.

wMinute

Specifies the current minute

wSecond

Specifies the current second.

wMilliseconds

Specifies the current millisecond.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include windows.h.

Hypertext Transfer Protocol Server Library

Implements a server that enables the application to access documents using the Hypertext Transfer Protocol.

Reference

- [Functions](#)
- [Data Structures](#)
- [Error Codes](#)

Library Information

File Name	CSHTSV10.DLL
Version	10.0.1468.2518
LibID	39B2930E-60DC-42D6-B388-6D6CD768DBE7
Import Library	CSHTSV10.LIB
Dependencies	None
Standards	RFC 1945, RFC 2616, RFC 3875

Overview

This library provides an interface for implementing an embedded, lightweight server that can be used to provide access to documents and other resources using the Hypertext Transfer Protocol. The server can accept connections from any standard web browser, third-party applications or programs developed using the SocketTools HTTP client API.

The application specifies an initial server configuration and then responds to events that are generated when the client sends a request to the server. An application may implement only minimal handlers for most events, in which case the default actions are performed for most standard HTTP commands. However, an application may also use the event mechanism to filter specific commands or to extend the protocol by providing custom implementations of existing commands or add entirely new commands.

The server includes support for CGI scripting, virtual hosting, client authentication and the creation of virtual directories and files. The server also supports secure connections using SSL/TLS. Secure connections require that a valid SSL certificate be installed on the system.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). If you are using Visual C++ 6.0 it is required that you have Service Pack 6 (SP6) installed. You should install all updates for your development tools and have the current Windows SDK installed. The minimum recommended version of Visual Studio is Visual Studio 2010.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are using Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. It is recommended that you install the current service pack and all critical updates available for your version of the operating system.

This library provides an implementation of a multithreaded server which should only be used with

languages that support the creation of multithreaded applications. It is important that you do not link against static libraries which were not built with support for threading.

This product includes both 32-bit and 64-bit libraries. Native 64-bit CPU support requires the 64-bit version of Windows 7 or later versions of the Windows operating system.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

Hypertext Transfer Protocol Server Functions

Function	Description
HttpAddVirtualHost	Add a new virtual host to the server virtual host table
HttpAddVirtualHostAlias	Add an alternate host name for an existing virtual host
HttpAddVirtualPath	Add a new virtual path for the specified host
HttpAddVirtualUser	Add a new virtual user for the specified host
HttpAuthenticateClient	Authenticate the client and assign access rights for the session
HttpCheckVirtualPath	Determine if the client has permission to access the specified virtual path
HttpCreateServerCredentials	Create a new server security credentials structure
HttpDeleteAllClientHeaders	Delete all of the request or response headers for the specified client session
HttpDeleteClientHeader	Delete a request or response header for the specified client session
HttpDeleteServerCredentials	Delete a previously created security credentials structure
HttpDeleteVirtualHost	Delete a virtual host associated with the specified server
HttpDeleteVirtualPath	Delete a virtual path from the specified virtual host
HttpDeleteVirtualUser	Delete a virtual user from the specified virtual host
HttpDisconnectClient	Disconnect the specific client session, closing the control channel and aborting any file transfer
HttpEnableClientAccess	Enable or disable access rights for the specified client session
HttpEnableCommand	Enable or disable a specific server command
HttpEnumServerClients	Returns a list of active client sessions established with the specified server
HttpGetActiveClient	Return the client ID for the active client session associated with the current thread
HttpGetAllClientHeaders	Return all client request or response headers in a string buffer
HttpGetClientAccess	Return the access rights that have been granted to the client session
HttpGetClientAddress	Return the IP address of the specified client session
HttpGetClientCredentials	Return the credentials for the specified client session
HttpGetClientDirectory	Return the root document directory for a client session
HttpGetClientHeader	Return the value of a request or response header for the specified client session
HttpGetClientIdleTime	Return the idle timeout period for the specified client
HttpGetClientLocalPath	Return the full local path for the specified virtual path
HttpGetClientServer	Return the handle to the server that created the specified client session
HttpGetClientThreadId	Returns the thread ID associated with the specified client session
HttpGetClientUserName	Return the user name associated with the specified client session

HttpGetClientVariable	Return the value of a CGI environment variable for the specified client
HttpGetClientVirtualHost	Return the name of the virtual host the client used to establish the connection
HttpGetClientVirtualHostId	Return the virtual host ID associated with the specified client session
HttpGetClientVirtualPath	Return the virtual path for a local file on the server
HttpGetCommandFile	Return the full path to the local file name or directory specified by the client
HttpGetCommandLine	Return the complete command line issued by the client
HttpGetCommandName	Return the name of the command that was issued by the client
HttpGetCommandQuery	Return the query parameters included with the command
HttpGetCommandResource	Return the path for the resource requested by the client
HttpGetCommandResult	Return the result code and a description of the last command processed by the server
HttpGetCommandUrl	Return the complete URL of the resource requested by the client
HttpGetProgramExitCode	Return the exit code of the last program executed by the client
HttpGetProgramName	Return the name of the CGI program executed by the client
HttpGetProgramOutput	Return a copy of the standard output from a CGI program executed by the client
HttpGetProgramText	Return a copy of the standard output from a CGI program in a string buffer
HttpGetServerAddress	Return the IP address for the server
HttpGetServerDirectory	Return the full path to the root directory assigned to the specified server
HttpGetServerError	Return information about the last server error that occurred
HttpGetServerIdentity	Return the identity and version information for the specified server
HttpGetServerLogFile	Return the current log file format and full path for the file
HttpGetServerMemoryUsage	Return the amount of memory allocated for the server and all client sessions
HttpGetServerName	Return the host name assigned to the server or specified client session
HttpGetServerOptions	Return the configuration options for the specified server
HttpGetServerPriority	Return the current priority assigned to the specified server
HttpGetServerStackSize	Return the initial size of the stack allocated for threads created by the server
HttpGetServerTransferInfo	Return information about the current file transfer
HttpGetServerUuid	Return the UUID assigned to the specified server
HttpGetServerUuidString	Return the UUID assigned to the server as a printable string
HttpGetVirtualHostId	Return the virtual host ID associated with the specified hostname
HttpGetVirtualHostName	Return the hostname associated with the specified virtual host ID

HttpIsClientAuthenticated	Determine if the specified client session has been authenticated
HttpIsCommandEnabled	Determine if the specified command is currently enabled or disabled
HttpReceiveRequest	Receive the request that was sent by the client to the server
HttpRedirectRequest	Redirect the request from the client to another URL
HttpRegisterHandler	Register a CGI program for use and associate it with a file name extension
HttpRegisterProgram	Register a CGI program for use and associate it with a virtual path on the server
HttpRenameServerLogFile	Rename or delete the current log file being updated by the server
HttpRequireAuthentication	Send a response to the client indicating that authentication is required
HttpSendErrorResponse	Send a customized error response to the specified client
HttpSendResponse	Send a response from the server to the specified client
HttpSendResponseData	Send additional data to the client in response to a command
HttpServerAsyncNotify	Enable or disable asynchronous notification of changes in server status
HttpServerDisableTrace	Disable logging of network function calls
HttpServerEnableTrace	Enable logging of network function calls to a file
HttpServerInitialize	Initialize the library and validate the specified license key at runtime
HttpServerProc	Callback function used to process server events
HttpServerRestart	Restart the server, terminating all active client sessions
HttpServerResume	Resume accepting client connections on the specified server
HttpServerStart	Start the server and begin accepting client connections
HttpServerStop	Stop the server and terminate all active client connections
HttpServerSuspend	Suspend accepting client connections on the specified server
HttpServerThrottle	Limit the number of active client connections, connections per address and connection rate
HttpServerUninitialize	Terminate use of the library by the application
HttpSetClientAccess	Change the access rights associated with the specified client session
HttpSetClientHeader	Create or change the value of a request or response header for the client session
HttpSetClientIdleTime	Change the idle timeout period for the specified client session
HttpSetClientVariable	Create or change the value of a CGI environment variable for the specified client
HttpSetCommandFile	Change the name of the local file or directory that is the target of the current command
HttpSetServerError	Set the last error code for the specified server session
HttpSetServerIdentity	Change the identity and version information for the specified server
HttpSetServerLogFile	Change the current log format, level of detail and file name

HttpSetServerName	Change the hostname assigned to the specified server or client session
HttpSetServerPriority	Change the priority assigned to the specified server
HttpSetServerStackSize	Change the initial size of the stack allocated for threads created by the server.

HttpAddVirtualHost Function

```
UINT WINAPI HttpAddVirtualHost(  
    HSERVER hServer,  
    LPCTSTR lpszHostName,  
    UINT nHostPort,  
    LPCTSTR lpszDirectory  
);
```

Add a new virtual host to the server virtual host table.

Parameters

hServer

The server handle.

lpszHostName

A pointer to a string which specifies the hostname that will be added to the virtual host table. This parameter must specify a valid hostname and cannot be a NULL pointer or a zero-length string.

nHostPort

An integer value which specifies the port number for the virtual host. This value must be zero or the same value as the original port number that the server was configured to use.

lpszDirectory

A pointer to a NULL terminated string which specifies the root document directory for the virtual host. If this parameter is NULL or a zero-length string, the virtual host will use the same root directory that was specified when the server was started. This parameter may contain environment variables enclosed in % symbols.

Return Value

If the function is successful, it will return a non-zero integer value that identifies the virtual host. If the function fails, it will return `INVALID_VIRTUAL_HOST` and the last error code will be updated to indicate the cause of the failure.

Remarks

Virtual hosting is a method for sharing multiple domain names on a single instance of a server. The client provides the server with the hostname that it has used to establish the connection, and that name is compared against a table of virtual hosts configured for the server. If the hostname matches a virtual host, the client will use the root directory and any virtual paths that have been assigned to that host.

When the server is first started, a default virtual host with an ID of zero is automatically created and is identified as `VIRTUAL_HOST_DEFAULT`. This virtual host uses the same hostname, port number and root directory that the server instance was created with. The application should treat all other host IDs as opaque values and never make assumptions about how they are allocated.

The *nHostPort* parameter should always be specified with a value of zero, or the same port number that the server was configured to use. Port-based virtual hosting is currently not supported and this parameter is included for future use.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cshtsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[HttpAddVirtualHostAlias](#), [HttpAddVirtualPath](#), [HttpAddVirtualUser](#), [HttpDeleteVirtualHost](#)

HttpAddVirtualHostAlias Function

```
BOOL WINAPI HttpAddVirtualHostAlias(  
    HSERVER hServer,  
    UINT nHostId,  
    LPCTSTR lpszHostAlias  
);
```

Add an alternate host name for an existing virtual host.

Parameters

hServer

The server handle.

nHostId

An integer value which identifies the virtual host.

lpszHostAlias

A pointer to a string which specifies the alias for the virtual host. The alias must be a valid domain name that uniquely identifies the host. This parameter cannot be a NULL pointer or specify an empty string.

Return Value

If the function succeeds, the return value is non-zero. If the server handle is invalid or the virtual host ID does not specify a valid host, the function will return zero. If the function fails, the last error code will be updated to indicate the cause of the failure.

Remarks

The **HttpAddVirtualHostAlias** function adds an alias for an existing virtual host. This enables a client to establish a connection using a number of different domain names which all reference the same virtual host. When the server responds to the client, it will identify itself with the primary domain name assigned to the virtual host rather than the alias provided by the client.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `cshtsv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

See Also

[HttpAddVirtualHost](#), [HttpAddVirtualPath](#)

HttpAddVirtualPath Function

```
BOOL WINAPI HttpAddVirtualPath(  
    HSERVER hServer,  
    UINT nHostId,  
    DWORD dwFileAccess,  
    LPCTSTR lpszVirtualPath,  
    LPCTSTR lpszLocalPath  
);
```

Add a new virtual path for the specified host.

Parameters

hServer

The server handle.

nHostId

An integer value which identifies the virtual host.

dwFileAccess

An integer value which specifies the access clients will be given to the virtual path. For a list of file access permissions, see [User and File Access Constants](#).

lpszVirtualPath

A pointer to a string which specifies the virtual path that will be created. This parameter cannot be a NULL pointer or an empty string. The maximum length of the virtual path is 1024 characters.

lpszLocalPath

A pointer to a string which specifies the local directory or file name that the virtual path will be mapped to. This path must exist and can be no longer than MAX_PATH characters. This parameter cannot be a NULL pointer or an empty string.

Return Value

If the function succeeds, the return value is non-zero. If the server handle is invalid or the virtual host ID does not specify a valid host, the function will return zero. If the function fails, the last error code will be updated to indicate the cause of the failure.

Remarks

The **HttpAddVirtualPath** function maps a virtual path name to a directory or file name on the local system. Virtual paths are assigned to specific hosts and if multiple virtual hosts are created for the server, each can have its own virtual paths which map to different files. To create a virtual path for the default server, the *nHostId* parameter should be specified as VIRTUAL_HOST_DEFAULT.

It is recommended that the *lpszLocalPath* parameter always specify the full path to the local file or directory. If the path is relative, it will be considered relative to the current working directory for the process and expanded to its full path name. The local path can include environment variables surrounded by % symbols. For example, if the value %ProgramData% is included in the path, it will be expanded to the full path for the common application data folder. The local path cannot specify a Windows system folder or the root directory of a mounted drive volume.

The local file or directory does not need to be located in the document root directory for the server or virtual host. It can specify any valid local path that the server process has the appropriate permissions to access. You should exercise caution when creating virtual paths to files or

directories outside of the server root directory. If the *lpszLocalPath* parameter specifies a directory, clients will have access to that directory and all subdirectories using its virtual path.

If you wish to password protect the virtual file or directory, include the HTTP_ACCESS_PROTECTED flag in the file permissions. The default command handlers will recognize this flag and require that the client authenticate itself to grant access to the resource. If the server application implements a custom command handler, it is responsible for checking for the presence of this flag and perform the appropriate checks to ensure that the client session has been authenticated.

If the server was started in restricted mode, the client will be unable to access documents outside of the server root directory and its subdirectories. This restriction also applies to virtual paths that reference documents or other resources outside of the root directory. To allow a client to access a document outside of the server root directory, the **HttpSetClientAccess** function should be used to grant the client HTTP_ACCESS_READ permission.

The **HttpGetClientVirtualPath** function will return the virtual path that is associated with a local file or directory. The **HttpGetClientLocalPath** function will return the full path to a local file or directory that is mapped to a virtual path.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cshtsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[HttpAddVirtualHost](#), [HttpCheckVirtualPath](#), [HttpGetClientLocalPath](#), [HttpGetClientVirtualPath](#), [HttpDeleteVirtualPath](#)

HttpAddVirtualUser Function

```
BOOL WINAPI HttpAddVirtualUser(  
    HSERVER hServer,  
    UINT nHostId,  
    DWORD dwUserAccess,  
    LPCTSTR lpszUserName,  
    LPCTSTR lpszPassword,  
    LPCTSTR lpszDirectory  
);
```

Add a new virtual user for the specified host.

Parameters

hServer

The server handle.

nHostId

An integer value which identifies the virtual host.

dwUserAccess

An integer value which specifies the access clients will be given when authenticated as this user. For a list of user access permissions, see [User and File Access Constants](#).

lpszUserName

A pointer to a string which specifies the user name. The maximum length of a username is 63 characters and it is recommended that names be limited to alphanumeric characters. Whitespace, control characters and certain symbols such as path delimiters and wildcard characters are not permitted. If an invalid character is included in the name, the function will fail with an error indicating the username is invalid. This parameter cannot be NULL and the name must be at least three characters in length. Usernames are not case sensitive.

lpszPassword

A pointer to a string which specifies the user password. The maximum length of a password is 63 characters and is limited to printable characters. Whitespace and control characters are not permitted. If an invalid character is included in the password, the function will fail with an error indicating the password is invalid. This parameter cannot be NULL and must be at least one character in length. Passwords are case sensitive.

lpszDirectory

A pointer to a string which specifies the local directory that is considered to be the virtual user's home directory. This path must exist and can be no longer than MAX_PATH characters. The maximum length of the local path is 260 characters. The directory cannot be located in a Windows system folder or the root directory of a mounted disk volume. If this parameter is NULL or an empty string, the server root directory will be assigned as the user home directory.

Return Value

If the function succeeds, the return value is non-zero. If the server handle is invalid or the virtual host ID does not specify a valid host, the function will return zero. If the function fails, the last error code will be updated to indicate the cause of the failure.

Remarks

The **HttpAddVirtualUser** function adds a virtual user that is associated with the specified virtual

host. If a client attempts to access a protected document and provides credentials, the server will attempt to automatically authenticate the session by searching for virtual user with the same username and password. If a match is found, then the client session is assigned the same access permissions as the virtual user.

If the server is started with the HTTP_SERVER_MULTUSER option, then documents in the virtual user's home directory can be accessed by specifying their username using a specially formatted request URL. For example, if a virtual user named "Thomas" is created, the documents in that user's home directory could be accessed as `http://servername/~thomas/document.html`

All files and subdirectories in the user's home directory are considered to be read-only. A client cannot create files in a user's home directory, even if they are authenticated as that user. In addition, CGI programs and scripts cannot be executed from a user's home directory.

If you wish to modify the information for a user, it is not necessary to delete the username first. If this function is called with a username that already exists, that record is replaced with the values passed to this function.

The virtual users created by this function exist only as long as the server is active. If you wish to maintain a persistent database of users and passwords, you are responsible for its implementation based on the requirements of your specific application. For example, a simple implementation would be to store the user information in a local XML or INI file and then read that configuration file after the server has started, calling this function for each user that is listed.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `cshtsv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

See Also

[HttpAddVirtualHost](#), [HttpDeleteVirtualUser](#)

HttpAuthenticateClient Function

```
BOOL WINAPI HttpAuthenticateClient(  
    HSERVER hServer,  
    UINT nClientId,  
    DWORD dwUserAccess  
);
```

Authenticate the client and assign access rights for the session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

dwUserAccess

An unsigned integer which specifies one or more user access rights. For a list of user access rights that can be granted to the client, see [User and File Access Constants](#).

Return Value

If the the client session could be authenticated, the return value is non-zero. If the server handle and client ID do not specify a valid client session, or the client has already been authenticated, this function will return zero.

Remarks

The **HttpAuthenticateClient** function is used to authenticate a specific client session, typically in response to an HTTP_CLIENT_USERAUTH event that indicates a client has provided authentication credentials as part of the request for a document or other resource.

To enable the server to automatically authenticate a client session, use the **HttpAddVirtualUser** function to add one or more virtual users. The server will search the list of virtual users for a match to the credentials provided by the client and will set the appropriate permissions for the session without requiring a event handler to manually authenticate the session using this function.

If the server was started with the HTTP_SERVER_LOCALUSER option and the client session is not authenticated using this function, the server will attempt to authenticate the client session using the local Windows user database. Although this option can be convenient because it does not require the implementation of an event handler for the HTTP_CLIENT_USERAUTH event, it can be used by clients to attempt to discover valid usernames and passwords for the local system. It is recommended that you use the **HttpAddVirtualUser** function to create virtual users rather than using the local user database.

It is recommended that most applications specify HTTP_ACCESS_DEFAULT as the *dwUserAccess* value for a client session, since this allows the server automatically grant the appropriate access based on the server configuration options.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cshtsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

HttpCreateServerCredentials Function

```
BOOL WINAPI HttpCreateServerCredentials(  
    DWORD dwProtocol,  
    DWORD dwOptions,  
    LPCTSTR lpszUserName,  
    LPCTSTR lpszPassword,  
    LPCTSTR lpszCertStore,  
    LPCTSTR lpszCertName,  
    LPVOID lpvReserved,  
    LPSECURITYCREDENTIALS* lppCredentials  
);
```

The **HttpCreateServerCredentials** function creates a SECURITYCREDENTIALS structure.

Parameters

dwProtocol

A bitmask of supported security protocols. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_SSL	Either SSL 2.0 or SSL 3.0 should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, TLS will be excluded from the list of supported protocols. Both SSL 2.0 and 3.0 have been deprecated and will never be used unless explicitly specified. It is not recommended that you enable either of these protocols for secure connections because it will cause most servers to reject your connection request, even if a version of TLS is also specified.
SECURITY_PROTOCOL_TLS	Either the TLS 1.0, 1.1 or 1.2 protocol should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers that reject any attempt to use the older SSL protocol and require that only TLS be used.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol should be used when establishing a secure connection. This version is

	supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This is the recommended version of TLS to use with secure connections.

dwOptions

A value which specifies one or options. This member is constructed by using a bitwise operator with any of the following values:

Constant	Description
CREDENTIAL_STORE_CURRENT_USER	The library will attempt to open a store for the current user using the certificate store name provided in this structure. If no options are specified, then this is the default behavior.
CREDENTIAL_STORE_LOCAL_MACHINE	The library will attempt to open a local machine store using the certificate store name provided in this structure. If this option is specified, the library will always search for a local machine store before searching for the store by that name for the current user.
CREDENTIAL_STORE_FILENAME	The certificate store name is a file that contains the certificate and private key that will be used.

lpszUserName

A pointer to a string which specifies the certificate owner's username. A value of NULL specifies that no username is required. Currently this parameter is not used and any value specified will be ignored.

lpszPassword

A pointer to a string which specifies the certificate owner's password. A value of NULL specifies

that no password is required. This parameter is only used if a PKCS12 (PFX) certificate file is specified and that certificate has been secured with a password. This value will be ignored the current user or local machine certificate store is specified.

lpszCertStore

A pointer to a string which specifies the name of the certificate store to open. A certificate store is a collection of certificates and their private keys, typically organized by how they are used. If this value is NULL or points to an empty string, the default certificate store "MY" will be used.

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as VeriSign and Thawte act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. This corresponds to the "Personal" store that is displayed by the certificate manager utility and is the default store used by the library.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as VeriSign and Thawte are installed as part of the operating system and periodically updated by Microsoft.

lpszCertName

A pointer to a null terminated string which specifies the name of the certificate to use. The function will first search the certificate store for a certificate with a matching "friendly name"; this is a name for the certificate that is assigned by the user. Note that the name must match completely, but the comparison is not case sensitive. If no matching certificate is found, the function will then attempt to find a certificate that has a matching common name (also called the certificate subject). This comparison is less stringent, and the first partial match will be returned. If this second search fails, the function will return an error indicating that the certificate could not be found.

lpvReserved

Pointer reserved for future use. Set it to NULL when using this function.

lppCredentials

Pointer to an [LPSECURITYCREDENTIALS](#) pointer. The memory for the credentials structure will be allocated by this function and must be released by calling the **HttpDeleteServerCredentials** function when it is no longer needed. The pointer value must be set to NULL before the function is called. It is important to note that this is a pointer to a pointer variable, not a pointer to the SECURITYCREDENTIALS structure itself.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **HttpGetServerError**.

Remarks

The structure that is created by this function may be used as client credentials when establishing a secure connection. This is particularly useful for programming languages other than C/C++ which may not support C structures or pointers. The pointer to the SECURITYCREDENTIALS structure can

be declared as an unsigned integer variable which is passed by reference to this function, and then passed by value to the **HttpServerStart** function.

Example

```
// Create the server credentials that identifies the certificate
// that will be used for secure connections
LPSECURITYCREDENTIALS lpSecCred = NULL;

HttpCreateServerCredentials(SEcurity_PROTOCOL_DEFAULT,
                           0,
                           NULL,
                           NULL,
                           lpCertStore,
                           lpCertName,
                           NULL,
                           &lpSecCred);

// Start the server
hServer = HttpServerStart(lpLocalHost,
                          HTTP_PORT_SECURE,
                          HTTP_SERVER_SECURE,
                          &httpConfig,
                          lpEventHandler,
                          0,
                          lpSecCred);
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cshtsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

HttpCheckVirtualPath Function

```
BOOL WINAPI HttpCheckVirtualPath(  
    HSERVER hServer,  
    UINT nClientId,  
    LPCTSTR lpszVirtualPath,  
    DWORD dwFileAccess  
);
```

Determine if the client has permission to access the specified virtual path.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszVirtualPath

A pointer to a string which specifies the virtual path that should be checked. This path must be absolute and cannot be a NULL pointer or an empty string. The maximum length of the virtual path is 1024 characters.

dwFileAccess

An unsigned integer value which specifies the access permissions that should be checked. For a list of file access permissions, see [User and File Access Constants](#).

Return Value

If the function succeeds, the return value is non-zero. If the server handle is invalid or the client ID does not specify a valid client, the function will return zero. If the function fails, the last error code will be updated to indicate the cause of the failure.

Remarks

The **HttpCheckVirtualPath** function is used to determine if the client has permission to access the virtual file or directory, based on the value of the *dwFileAccess* parameter. For example, if the *dwFileAccess* parameter has the value HTTP_ACCESS_WRITE, this function will check if the client has write permission for the file or directory. The function will return a non-zero value if the client does have the requested permission, or zero if it does not.

Applications that implement their own custom handlers for standard HTTP commands should use this function to ensure that the client has the appropriate permissions to access the requested resource. Failure to check the access permissions for the client can result in the client being able to access restricted documents and other resources. It is recommended that most applications use the default command handlers.

To obtain the path to the local file or directory that the virtual path is mapped to, use the **HttpGetClientLocalPath** function.

Example

```
TCHAR szPathName[1024];  
  
// Get the current request URL path  
INT cchPathName = HttpGetCommandResource(  
    hServer,
```

```
        nClientId,  
        szPathName,  
        1024);  
  
if (cchPathName == 0)  
{  
    HttpSendErrorResponse(hServer, nClientId, 500, NULL);  
    return;  
}  
  
// Check if the client has write access to that resource  
BOOL bAllowed = HttpCheckVirtualPath(  
    hServer,  
    nClientId,  
    szPathName,  
    HTTP_ACCESS_WRITE);  
  
if (!bAllowed)  
{  
    HttpSendErrorResponse(hServer, nClientId, 403, NULL);  
    return;  
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cshtsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

HttpDeleteAllClientHeaders Function

```
BOOL WINAPI HttpDeleteAllClientHeaders(  
    HSERVER hServer,  
    UINT nClientId,  
    UINT nHeaderType  
);
```

Delete all of the request or response headers for the specified client session.

Parameters

hServer

The server handle.

nClientId

Delete all of the request or response headers for the specified client session.

nHeaderType

Specifies the type of headers to delete. It may be one of the following values:

Constant	Description
HTTP_HEADERS_REQUEST	Delete all of the request headers that were provided by the client. Request header values provide additional information to the server about the type of request being made.
HTTP_HEADERS_RESPONSE	Delete all of the response headers that were created by the server in response to a request made by the client. Response header values provide additional information to the client about the type of information that is being returned by the server.

Return Value

If the function succeeds, the return value is non-zero. If the server handle and client ID do not specify a valid client session, the function will return zero.

Remarks

The **HttpDeleteAllClientHeaders** function is used to delete all of the request or response headers that were set as the result of the client issuing a request for a document or other resource. If this function is used to delete all of the response headers, the server will automatically generate a standard set of response headers when it returns the requested information to the client.

It is not necessary to call this function inside an HTTP_CLIENT_DISCONNECT event handler to delete the header values that were set during the client session. This is done automatically when the client disconnects from the server.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cshtsv10.lib

See Also

[HttpDeleteClientHeader](#), [HttpSetClientHeader](#)

HttpDeleteClientHeader Function

```
BOOL WINAPI HttpDeleteClientHeader(  
    HSERVER hServer,  
    UINT nClientId,  
    UINT nHeaderType,  
    LPCTSTR lpszHeaderName  
);
```

Delete a request or response header for the specified client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

nHeaderType

Specifies the type of header to delete. It may be one of the following values:

Constant	Description
HTTP_HEADERS_REQUEST	Delete a request header that was provided by the client. Request header values provide additional information to the server about the type of request being made.
HTTP_HEADERS_RESPONSE	Delete a response header that was created by the server. Response header values provide additional information to the client about the type of information that is being returned by the server.

lpszHeaderName

A pointer to a string that specifies the name of the header that should be deleted. Header names are not case-sensitive and should not include the colon which acts as a delimiter that separates the header name from its value. This parameter cannot be a NULL pointer or an empty string.

Return Value

If the function succeeds, the return value is non-zero. If the server handle and client ID do not specify a valid client session, the function will return zero. If the function fails, the **HttpGetServerError** function will return more information about the last error that has occurred.

Remarks

The **HttpDeleteClientHeader** function will delete a request or response header for the specified client session. There are a number of required response headers that are always sent to a client and deleting the header using this function will cause the server to automatically generate a new default header value. You should not delete response header values unless you are certain of the impact that it would have on the normal operation of the client.

It is not necessary for you to delete a header value to change the value of an existing header. The **HttpSetClientHeader** function will replace an existing header value with a new value, or create a new header if the header name does not already exist.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cshtsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[HttpDeleteAllClientHeaders](#), [HttpGetClientHeader](#), [HttpSetClientHeader](#)

HttpDeleteServerCredentials Function

```
VOID WINAPI HttpDeleteServerCredentials(  
    LPSECURITYCREDENTIALS* LppCredentials  
);
```

The **HttpDeleteServerCredentials** function deletes an existing **SECURITYCREDENTIALS** structure.

Parameters

lppCredentials

Pointer to an LPSECURITYCREDENTIALS pointer. On exit from the function, the pointer value will be NULL.

Return Value

None.

Example

```
if (lpSecCred != NULL)  
    HttpDeleteServerCredentials(&lpSecCred);
```

Remarks

This function can be used to release the memory allocated for the credentials after the server has been started.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cshtsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

HttpDeleteVirtualHost Function

```
BOOL WINAPI HttpDeleteVirtualHost(  
    HSERVER hServer,  
    UINT nHostId  
);
```

Delete a virtual host associated with the specified server.

Parameters

hServer

The server handle.

nHostId

An integer value which identifies the virtual host.

Return Value

If the function succeeds, the return value is non-zero. If the server handle is invalid or the virtual host ID does not specify a valid host, the function will return zero. If the function fails, the last error code will be updated to indicate the cause of the failure.

Remarks

The **HttpDeleteVirtualHost** function removes a virtual host that was created by a previous call to the **HttpAddVirtualHost** function. All virtual paths and users associated with the specified host are no longer valid. It is not necessary to call this function to delete any of the virtual hosts prior to stopping the server. Part of the normal shutdown process is releasing the resources allocated for each virtual host that was added to the server.

This function cannot be used to delete the virtual host with an ID of zero, which is the default virtual host that is allocated when the server is started.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cshtsv10.lib

See Also

HttpDeleteVirtualPath Function

```
BOOL WINAPI HttpDeleteVirtualPath(  
    HSERVER hServer,  
    UINT nHostId,  
    LPCTSTR lpszVirtualPath  
);
```

Remove a virtual path from the specified host.

Parameters

hServer

The server handle.

nHostId

An integer value which identifies the virtual host.

lpszVirtualPath

A pointer to a string which specifies the virtual path that will be removed. This path must be absolute and cannot be a NULL pointer or an empty string.

Return Value

If the function succeeds, the return value is non-zero. If the server handle is invalid or the virtual host ID does not specify a valid host, the function will return zero. If the function fails, the last error code will be updated to indicate the cause of the failure.

Remarks

This function removes a virtual path that was created by a previous call to the **HttpAddVirtualPath** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cshtsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

HttpDeleteVirtualUser Function

```
BOOL WINAPI HttpDeleteVirtualUser(  
    HSERVER hServer,  
    UINT nHostId,  
    LPCTSTR LpszUserName  
);
```

Remove a virtual user from the specified host.

Parameters

hServer

The server handle.

nHostId

An integer value which identifies the virtual host.

lpszUserName

A pointer to a string which specifies the user that will be removed. This parameter cannot be a NULL pointer or an empty string.

Return Value

If the function succeeds, the return value is non-zero. If the server handle is invalid or the virtual host ID does not specify a valid host, the function will return zero. If the function fails, the last error code will be updated to indicate the cause of the failure.

Remarks

This function removes a virtual user that was created by a previous call to the **HttpAddVirtualUser** function. This function will not match partial usernames and wildcard characters cannot be used to delete multiple users. Usernames are not case sensitive.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cshtsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[HttpAddVirtualHost](#), [HttpAddVirtualUser](#)

HttpDisconnectClient Function

```
BOOL WINAPI HttpDisconnectClient(  
    HSERVER hServer,  
    UINT nClientId  
);
```

Close the control connection for the specified client and release the resources allocated for the session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

Return Value

If the function succeeds, the return value is non-zero. If the server handle and client ID do not specify a valid client session, the function will return zero.

Remarks

The **HttpDisconnectClient** function will close the control channel, disconnecting the client from the server and terminating the client session thread. Resources that we allocated for the client, such as memory and open handles, will be released back to the operating system. If the client was in the process of transferring a file, the transfer will be aborted.

This function sends an internal control message that notifies the server that this session should be terminated. When the session thread is signaled that it should terminate, it will abort any active data transfers and begin to release the resources allocated for that session. To ensure that the client session terminates gracefully, there may be a brief period of time where the session thread is still active after this function has returned.

After this function returns, the application should never use the same client ID with another function. Client IDs are unique to the session over the lifetime of the server, and are not reused.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cshtsv10.lib

HttpEnableClientAccess Function

```
BOOL WINAPI HttpEnableClientAccess(  
    HSERVER hServer,  
    UINT nClientId,  
    DWORD dwUserAccess,  
    BOOL bEnable  
);
```

Enable or disable access rights for the specified client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

dwUserAccess

An unsigned integer which specifies an access right to enable or disable. For a list of user access rights that can be granted to the client, see [User and File Access Constants](#).

bEnable

An integer value which specifies if permission should be granted or revoked for the specified access right. If this value is non-zero, permission is granted to the client to perform the action specified by the *dwUserAccess* parameter. If this value is zero, that permission is revoked.

Return Value

If the function succeeds, the return value is non-zero. If the server handle and client ID do not specify a valid client session, the function will return zero.

Remarks

The **HttpEnableClientAccess** function is used to enable or disable access to specific functionality by the client. The function can only change a single access right and cannot be used to enable or disable multiple access rights in a single function call. To change multiple user access rights for the client, use the **HttpSetClientAccess** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cshtsv10.lib

See Also

[HttpAuthenticateClient](#), [HttpGetClientAccess](#), [HttpSetClientAccess](#)

HttpEnableCommand Function

```
BOOL WINAPI HttpEnableCommand(  
    HSERVER hServer,  
    LPCTSTR LpszCommand,  
    BOOL bEnable  
);
```

Enable or disable a specific server command

Parameters

hServer

The server handle.

lpszCommand

A pointer to a NULL terminated string that specifies the name of the command to be enabled or disabled. The command name is not case-sensitive, but the value must otherwise match the exact name. Partial matches are not recognized by this function. This parameter cannot be NULL.

bEnable

An integer value which specifies if the command should be enabled or disabled. If the value is non-zero, the command is enabled. If the value is zero, the command will be disabled.

Return Value

If the function succeeds, the return value is non-zero. If the server handle is invalid or the command is not recognized, the function will return zero. If the function fails, the **HttpGetServerError** function will return more information about the last error that has occurred.

Remarks

The **HttpEnableCommand** function is used to enable or disable access to a specific command on the server. This function is typically used to enable or disable certain commands for security purposes. For example, the PUT command can be disabled, preventing any client from attempting to upload files directly to the server. The **HttpIsCommandEnabled** function can be used to determine if a command is enabled or not.

The command name provided to this function must match the commands defined in RFC 2616 or related protocol standards. Refer to [Hypertext Transfer Protocol Commands](#) for a complete list of server commands.

Some commands cannot be disabled because they are required to perform essential server functions. For example, the GET and HEAD commands cannot be disabled. If you attempt to disable a required command, this function will return zero and the last error code will be set to ST_ERROR_COMMAND_REQUIRED. Because this function affects all clients connected to the server, it should not be used to limit access to certain commands for specific clients. Instead, use an event handler to filter the commands.

The OPTIONS and TRACE commands are disabled by default for all server instances and must be explicitly enabled using the **EnableCommand** method if you wish permit clients to use them. It is not recommended that you enable these commands if your server is going to be publicly accessible over the Internet. If the server started with the option HTTP_SERVER_READONLY, commands that can be used to create or modify files on the server will be disabled by default.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cshtsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

HttpEnumServerClients Function

```
INT WINAPI HttpEnumServerClients(  
    HSERVER hServer,  
    DWORD dwReserved  
    UINT * lpClients,  
    INT nMaxClients  
);
```

Return a list of active client sessions established with the specified server.

Parameters

hServer

Handle to the server socket.

dwReserved

An unsigned integer value that is reserved for future use. This parameter should always be zero.

lpClients

Pointer to an array of unsigned integers which will contain client IDs that uniquely identifies each client when the function returns. If this parameter is NULL, then the function will return the number of active client connections established with the server.

nMaxClients

Maximum number of client IDs to be returned in the *lpClients* array. If the *lpClients* parameter is NULL, this parameter should have a value of zero.

Return Value

If the function succeeds, the return value is the number of active client connections to the server. If the function fails, the return value is HTTP_ERROR. To get extended error information, call

HttpGetServerError.

Remarks

If the *nMaxClients* parameter is less than the number of active client connections, the function will fail and the last error code will be set to the error ST_ERROR_BUFFER_TOO_SMALL. To dynamically determine the number of active connections, call the function with the *lpClients* parameter with a value of NULL, and the *nMaxClients* parameter with a value of zero.

Example

```
INT nClients = HttpEnumServerClients(hServer, 0, NULL, 0);  
  
if (nClients > 0)  
{  
    UINT *lpClients = NULL;  
  
    // Allocate memory for an array of client IDs  
    lpClients = (UINT *)LocalAlloc(LPTR, nClients * sizeof(UINT));  
  
    if (lpClients == NULL)  
    {  
        // Virtual memory has been exhausted  
        return;  
    }  
  
    nClients = HttpEnumServerClients(hServer, 0, lpClients, nClients);
```

```
if (nClients == HTTP_ERROR)
{
    // Unable to obtain list of connected clients
    return;
}

for (INT nIndex = 0; nIndex < nClients; nIndex++)
{
    TCHAR szUserName[HTTP_MAXUSERNAME];

    if (HttpGetClientUserName(hServer, lpClients[nIndex], szUserName,
HTTP_MAXUSERNAME))
    {
        // Perform some action with the client user name
    }
}

// Free the memory allocated for the client IDs
LocalFree((HLOCAL)lpClients);
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cshtsv10.lib

See Also

[HttpServerStart](#)

HttpGetActiveClient Function

```
UINT WINAPI HttpGetActiveClient(  
    HSERVER hServer  
);
```

Return the client ID for the active client session associated with the current thread.

Parameters

hServer

The server handle.

Return Value

If the function succeeds, the return value is the unique ID associated with the client session for the current thread. If the server handle is invalid or there is no client session active on the current thread, the return value is zero.

Remarks

The **HttpGetActiveClient** function is used to obtain the client ID associated with the current thread. This means this function will only return a client ID if it is called within an event handler or a function called by an event handler. If this function is called by a function that is not executing within the context of an event handler it will return a value of zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cshtsv10.lib

See Also

[HttpEnumServerClients](#)

HttpGetClientAccess Function

```
BOOL WINAPI HttpGetClientAccess(  
    HSERVER hServer,  
    UINT nClientId,  
    LPDWORD LpdwUserAccess  
);
```

Return the access rights that have been granted to the client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpdwUserAccess

A pointer to an unsigned integer which specifies one or more access rights for the client session. For a list of user access permissions that can be granted to the client, see [User and File Access Constants](#). This parameter cannot be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the server handle and client ID do not specify a valid client session, the function will return zero. This function can only be used with authenticated clients. If the client session has not been authenticated, the return value will be zero.

Remarks

The **HttpGetClientAccess** function is used to obtain all of the access rights that are currently granted to the client session. The **HttpEnableClientAccess** function can be used to enable or disable specific permissions, and the **HttpSetClientAccess** function can change multiple access rights at once.

Example

```
DWORD dwUserAccess = 0;  
  
// Check if the client has execute permission  
if (HttpGetClientAccess(hServer, nClientId, &dwUserAccess))  
{  
    if (dwUserAccess & HTTP_ACCESS_EXECUTE)  
    {  
        _tprintf(_T("Client %u can execute programs and scripts\n"), nClientId);  
        return;  
    }  
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cshtsv10.lib

See Also

[HttpAuthenticateClient](#), [HttpEnableClientAccess](#), [HttpSetClientAccess](#)

HttpGetClientAddress Function

```
INT WINAPI HttpGetClientAddress(  
    HSERVER hServer,  
    UINT nClientId,  
    LPTSTR lpszAddress,  
    INT nMaxLength  
);
```

Return the IP address of the specified client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszAddress

A pointer to a string buffer that will contain the client IP address, terminated with a null character. To accommodate both IPv4 and IPv6 addresses, this buffer should be at least 46 characters in length. This parameter cannot be NULL.

nMaxLength

An integer value that specifies the maximum number of characters can be copied into the string buffer, including the terminating null character. This value must be greater than zero. If the buffer size is too small, the function will fail.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If either the server handle or the client ID is invalid, or the buffer is not large enough to store the complete address, the function will return a value of zero.

Remarks

The format and length of IPv4 and IPv6 address strings are very different. An IPv4 address string looks like "192.168.0.20", while an IPv6 address string can look something like "fd7c:2f6a:4f4f:ba34::a32". If your application checks for the format of these address strings, it needs to be aware of the differences. You also need to make sure that you're providing enough space to display or store an address to avoid buffer overruns.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cshtsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[HttpGetServerAddress](#)

HttpGetClientCredentials Function

```
BOOL WINAPI HttpGetClientCredentials(  
    HSERVER hServer,  
    UINT nClientId,  
    LPHTTPCLIENTCREDENTIALS LpCredentials  
);
```

Return the user credentials for the specified client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpCredentials

A pointer to an **HTTPCLIENTCREDENTIALS** structure that will contain information about the user when the function returns. This parameter cannot be NULL.

Return Value

If the user credentials for the client session are available, the return value is non-zero. If the server handle and client ID do not specify a valid client session, or the client has not requested authentication, this function will return zero.

Remarks

The **HttpGetClientCredentials** function is used to obtain the username and password that was provided by the client when it requested authentication. Typically this function is used in an event handler to validate the credentials provided by the client. If the credentials are considered valid, the event handler would then call the **HttpAuthenticateClient** function to specify that the session has been authenticated.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cshtsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[HttpAuthenticateClient](#), [HttpRequireAuthentication](#), [HTTPCLIENTCREDENTIALS](#)

HttpGetClientDirectory Function

```
INT WINAPI HttpGetClientDirectory(  
    HSERVER hServer,  
    UINT nClientId,  
    LPTSTR lpszDirectory,  
    INT nMaxLength  
);
```

Returns the root document directory for the specified client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszDirectory

A pointer to a string buffer that will contain the root directory for the specified client session, terminated with a null character. This buffer should be at least MAX_PATH characters in length. This parameter cannot be NULL.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer, including the terminating null character. This value must be larger than zero or the function will fail.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If the server handle and client ID do not specify a valid client session, the function will return zero.

Remarks

This function returns the full path to the root document directory for the specified client session. If no virtual hosts have been configured, then this path will be the same as the root directory assigned to the server when it was started. If the server has been configured with multiple virtual hosts, this function will return the path to the root directory associated with the hostname provided by the client.

To convert a full path to the virtual path for a specific client session, use the **HttpGetClientVirtualPath** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cshtsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[HttpGetClientVirtualPath](#)

HttpGetClientHeader Function

```
INT WINAPI HttpGetClientHeader(  
    HSERVER hServer,  
    UINT nClientId,  
    UINT nHeaderType,  
    LPCTSTR lpszHeaderName,  
    LPTSTR lpszHeaderValue,  
    INT nMaxLength,  
);
```

Return the value of a request or response header for the specified client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

nHeaderType

Specifies the type of header. It may be one of the following values:

Constant	Description
HTTP_HEADERS_REQUEST	Return the value of a request header that was provided by the client. Request header values provide additional information to the server about the type of request being made.
HTTP_HEADERS_RESPONSE	Return the value of a response header that was created by the server. Response header values provide additional information to the client about the type of information that is being returned by the server.

lpszHeaderName

A pointer to a string that specifies the name of the header field. Header names are not case-sensitive and should not include the colon which acts as a delimiter that separates the header name from its value. This parameter cannot be a NULL pointer or an empty string.

lpszHeaderValue

A pointer to a buffer that will contain the header value, terminated with a null character. To determine the length of the header value, this parameter can be NULL and the *nMaxLength* parameter should be specified with a value of zero.

nMaxLength

An integer that specifies the maximum number of characters that can be copied into the header value buffer, including the terminating null character. If the *lpszHeaderValue* parameter is NULL, this value must be zero.

Return Value

If the function succeeds, the return value is the length of the header value, not including the terminating null character. If the server handle and client ID do not specify a valid client session, or there is no header that matches the given name, the function will return zero. If the

lpzHeaderValue parameter is not NULL and the buffer is not large enough to store the complete header value, the function will return zero and the last error code will be set to ST_ERROR_BUFFER_TOO_SMALL. If the function fails, the **HttpGetServerError** function will return more information about the last error that has occurred.

Remarks

The **HttpGetClientHeader** function will return the value of a request or response header for the specified client session. If the *lpzHeaderName* value matches an existing header field, its value will be copied to the string buffer provided by the caller.

Refer to [Hypertext Transfer Protocol Headers](#) for a list of common request and response headers that are used.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cshtsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

HttpGetClientIdleTime Function

```
UINT WINAPI HttpGetClientIdleTime(  
    HSERVER hServer,  
    UINT nClientId,  
    UINT * lpnElapsed  
);
```

Return the idle timeout period for the specified client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpnElapsed

A pointer to an unsigned integer value that will contain the number of seconds the client session has been idle. This parameter may be NULL if this information is not required.

Return Value

If the function succeeds, the return value is client idle timeout period in seconds. If the server handle and client ID do not specify a valid client session, the function will return zero.

Remarks

The **HttpGetClientIdleTime** function will return the number of seconds that the client may remain idle before being automatically disconnected by the server. The idle time of a client session is based on the last time a command was issued to the server or when a data transfer completed. The server will never disconnect a client that is in the process of sending or receiving data, regardless of the idle timeout period.

The default idle timeout period for a client session is 60 seconds, however the server can be configured to use a different value. The minimum timeout period for a client is 10 seconds, the maximum is 300 seconds (5 minutes). An application can change the timeout period for a specific client session using the **HttpSetClientIdleTime** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cshtsv10.lib

See Also

[HttpSetClientIdleTime](#)

HttpGetClientLocalPath Function

```
INT WINAPI HttpGetClientLocalPath(  
    HSERVER hServer,  
    UINT nClientId,  
    LPCTSTR lpszVirtualPath,  
    LPTSTR lpszLocalPath,  
    INT nMaxLength,  
);
```

Return the full local path for a virtual filename or directory on the server.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszVirtualPath

A pointer to a string that specifies a virtual path on the server. This parameter cannot be NULL.

lpszLocalPath

A pointer to a string buffer that will contain the full local path, terminated with a null-character. This buffer should be at least MAX_PATH characters to accommodate the complete path. This parameter cannot be NULL.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer, including the terminating null character. This value must be greater than zero.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If the server handle and client ID do not specify a valid client session, the function will return zero. If the string buffer is not large enough to contain the complete path, this function will return zero and the last error code will be set to ST_ERROR_BUFFER_TOO_SMALL.

Remarks

The **HttpGetClientLocalPath** function takes a virtual path and returns the full path to the specified file or directory on the local system. The virtual path may be absolute or relative to the root directory for the client session.

To obtain the virtual path for a local file or directory, use the **HttpGetClientVirtualPath** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cshtsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[HttpGetClientVirtualPath](#)

HttpGetClientServer Function

```
HSERVER WINAPI HttpGetClientServer(  
    UINT nClientId  
);
```

The **HttpGetClientServer** function returns a handle to the server that created the specified client session.

Parameters

nClientId

An unsigned integer which uniquely identifies the client session.

Return Value

If the function succeeds, the return value is the handle to the server that created the client session. If the function fails, the return value is `INVALID_SERVER`. To get extended error information, call the **HttpGetServerError** function.

Remarks

The **HttpGetClientServer** function returns the handle to the server that created the client session and is typically used within a notification message handler. If the server is in the process of shutting down, or the client session thread is terminating, this function will fail and return `INVALID_SERVER` indicating that the session ID is invalid.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cstools10.h`

Import Library: `cshtsv10.lib`

See Also

[HttpServerAsyncNotify](#)

HttpGetClientThreadId Function

```
DWORD WINAPI HttpGetClientThreadId(  
    HSERVER hServer,  
    UINT nClientId  
);
```

Returns the thread ID associated with the specified client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

Return Value

If the function succeeds, the return value is a thread ID. If the function fails, the return value is zero. To get extended error information, call the **HttpGetServerError** function.

Remarks

The **HttpGetClientThreadId** function returns a thread ID that can be used to identify the thread that is managing the client session. The thread ID can be used with other Windows API functions such as **OpenThread**. Exercise caution when using thread-related functions, interfering with the normal operation of the thread can have unexpected results. You should never use this function to obtain a thread handle and then call the **TerminateThread** function to terminate a client session. This will prevent the thread from releasing the resources that were allocated for the session and can leave the server in an unstable state. To terminate a client session, use the **HttpDisconnectClient** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `cshtsv10.lib`

See Also

[HttpEnumServerClients](#), [HttpGetActiveClient](#)

HttpGetClientUserName Function

```
INT WINAPI HttpGetClientUserName(  
    HSERVER hServer,  
    UINT nClientId,  
    LPTSTR lpszUserName,  
    INT nMaxLength  
);
```

Return the user name associated with the specified client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszUserName

A pointer to a string buffer that will contain the user name associated with the client session. This buffer must be large enough to store the complete user name, including the terminating null character. This parameter cannot be NULL.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer, including the terminating null character. This parameter must have a value larger than zero.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If the server handle and client ID do not specify a valid client session, the function will return zero.

Remarks

The **HttpGetClientUserName** function returns the user name associated with an authenticated client session. If the client has not authenticated itself, this function will return zero and the *lpszUserName* parameter will be set to an empty string.

The **HttpIsClientAuthenticated** function can be used to determine if the client has provided credentials as part of the request made to the server.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cshtsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[HttpAuthenticateClient](#), [HttpGetClientAccess](#), [HttpIsClientAuthenticated](#)

HttpGetClientVariable Function

```
INT WINAPI HttpGetClientVariable(  
    HSERVER hServer,  
    UINT nClientId,  
    LPCTSTR lpszName,  
    LPTSTR lpszValue,  
    INT nMaxLength,  
);
```

Return the value of a CGI environment variable for the specified client.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszName

A pointer to a string that specifies the name of the environment variable. Variable names are not case-sensitive and should not include the equal sign which acts as a delimiter that separates the variable name from its value. This parameter cannot be a NULL pointer or an empty string.

lpszValue

A pointer to a buffer that will contain the value of the environment variable, terminated with a null character. To determine the length of the header value, this parameter can be NULL and the *nMaxLength* parameter should be specified with a value of zero.

nMaxLength

An integer that specifies the maximum number of characters that can be copied into the value buffer, including the terminating null character. If the *lpszValue* parameter is NULL, this value must be zero.

Return Value

If the function succeeds, the return value is the length of the environment variable value, not including the terminating null character. If the server handle and client ID do not specify a valid client session, or there is no environment variable that matches the given name, the function will return zero. If the *lpszValue* parameter is not NULL and the buffer is not large enough to store the complete header value, the function will return zero and the last error code will be set to `ST_ERROR_BUFFER_TOO_SMALL`. If the function fails, the **HttpGetServerError** function will return more information about the last error that has occurred.

Remarks

The **HttpGetClientVariable** function will return the value of an environment variable that has been defined for the client. Each client session inherits a copy of the process environment block, which is then modified to define various environment variables that are used with CGI programs and scripts. The **HttpSetClientVariable** function can be used to change existing environment variables or create new variables.

The standard CGI environment variables that are defined by the server are not created until the client request has been processed. This means that environment variables such as `REMOTE_ADDR` and `SERVER_NAME` will not be defined inside an `HTTP_CLIENT_CONNECT` event handler.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cshtsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[HttpSetClientVariable](#)

HttpGetClientVirtualHost Function

```
INT WINAPI HttpGetClientVirtualHost(  
    HSERVER hServer,  
    UINT nClientId,  
    LPTSTR lpszHostName,  
    INT nMaxLength  
);
```

Return the name of the virtual host the client used to establish the connection.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszHostName

A pointer to a string buffer that will contain the virtual host name. The string buffer will be null terminated and must be large enough to store the complete hostname. If this parameter is NULL, the function will only return the length of the current command in characters, not including the terminating null character.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer, including the terminating null character. If the maximum length specified is smaller than the actual length of the parameter, this function will fail. If the *lpszHostName* parameter is NULL, this value should be zero.

Return Value

An integer value which specifies the number of characters copied into the buffer, not including the terminating null character. If the function fails, the return value will be zero and the **HttpGetServerError** function can be used to retrieve the last error code.

Remarks

The **HttpGetClientVirtualHost** function is used to obtain the hostname that the client used to establish a connection with the server. This function is typically used within an event handler to determine the hostname associated with the request made by the client. It should not be called inside a HTTP_CLIENT_CONNECT event handler because the virtual host has not been selected at that point. If the virtual hostname is not available at the time this function is called, the function will return zero and the last error code will be set to ST_ERROR_VIRTUAL_HOST_NOT_FOUND.

The **HttpGetClientVirtualHostId** function can be used to obtain the virtual host ID associated with the hostname.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cshtsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

HttpGetClientVirtualHostId Function

```
UINT WINAPI HttpGetClientVirtualHostId(  
    HSERVER hServer,  
    UINT nClientId  
);
```

Return the virtual host ID associated with the specified client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

Return Value

An unsigned integer value which specifies the virtual host ID. If the function fails, the return value will be `INVALID_VIRTUAL_HOST` and the **HttpGetServerError** function can be used to retrieve the last error code.

Remarks

The **HttpGetClientVirtualHostId** function is used to obtain the virtual host ID associated with the hostname the client used to establish a connection with the server. This function should not be called inside a `HTTP_CLIENT_CONNECT` event handler because the virtual host has not been selected at that point. If the virtual host ID is not available at the time this function is called, the function will return `INVALID_VIRTUAL_HOST` and the last error code will be set to `ST_ERROR_VIRTUAL_HOST_NOT_FOUND`.

The **HttpGetClientVirtualHost** function can be used to obtain the hostname that the client used to establish the connection.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `cshtsv10.lib`

See Also

[HttpGetClientVirtualHost](#), [HttpGetCommandUrl](#), [HttpGetVirtualHostId](#), [HttpGetVirtualHostName](#)

HttpGetClientVirtualPath Function

```
INT WINAPI HttpGetClientVirtualPath(  
    HSERVER hServer,  
    UINT nClientId,  
    LPCTSTR lpszLocalPath,  
    LPTSTR lpszVirtualPath,  
    INT nMaxLength,  
);
```

Return the virtual path for a local file on the server.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszLocalPath

A pointer to a string that specifies an absolute path on the local system. This parameter cannot be NULL.

lpszVirtualPath

A pointer to a string buffer that will contain the virtual path, terminated with a null-character. This buffer should be at least MAX_PATH characters to accommodate the complete path. This parameter cannot be NULL.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer, including the terminating null character. This value must be greater than zero.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If the server handle and client ID do not specify a valid client session, the function will return zero. If the string buffer is not large enough to contain the complete path, this function will return zero and the last error code will be set to ST_ERROR_BUFFER_TOO_SMALL.

Remarks

A virtual path for the client is relative to the root directory for the specified client session. These virtual paths are what the client will see as an absolute path on the server. For example, if the server was configured to use "C:\ProgramData\MyServer" as the root directory, and the *lpszLocalPath* parameter was specified as "C:\ProgramData\MyServer\Documents\Research", this function would return the virtual path to that directory as "/Documents/Research".

If the *lpszLocalPath* parameter specifies a file or directory outside of the server root directory, this function will return zero and the last error code will be set to ST_ERROR_INVALID_FILE_NAME. This function can only be used with authenticated clients. If the *nClientId* parameter specifies a client session that has not been authenticated, this function will return zero and the last error code will be ST_ERROR_AUTHENTICATION_REQUIRED.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cshtsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[HttpGetCommandFile](#), [HttpGetClientLocalPath](#)

HttpGetCommandFile Function

```
INT WINAPI HttpGetCommandFile(  
    HSERVER hServer,  
    UINT nClientId,  
    LPTSTR LpszFileName,  
    INT nMaxLength  
);
```

Get the full path to a file name or directory specified by the client.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszFileName

A pointer to a string buffer that will contain the full path to a file name or directory specified by the client when it issued a command. The string buffer will be null terminated and must be large enough to store the complete file path. This parameter cannot be NULL.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer. It is recommended that the buffer be at least MAX_PATH characters in size. If the maximum length specified is smaller than the actual length of the full path, this function will fail.

Return Value

An integer value which specifies the number of characters copied into the buffer, not including the terminating null character. If the function fails, the return value will be zero and the **HttpGetServerError** function can be used to retrieve the last error code.

Remarks

The **HttpGetCommandFile** function is used to obtain the full path to a local file name or directory specified by the client as an argument to a standard HTTP command. For example, if the client sends the GET command to the server, this function will return the complete path to the local file that the client wants to retrieve. This function will only work with those standard commands that perform some action on a file or directory.

This function should always be used to obtain the file name for a command that performs a file or directory operation. It normalizes the path provided by the client and ensures that it specifies a file or directory name in the correct location. The **HttpGetCommandUrl** function can be used to obtain the URL that was provided by the client.

To map a virtual path to a file or directory on the local system, use the **HttpAddVirtualPath** function. To redirect a client to use a different URL to access the resource, use the **HttpRedirectRequest** function.

The **HttpSetCommandFile** function can be used to change the name of the local file or directory that is the target of the command, however using this function to redirect access to a resource can have unintended side-effects, particularly in the case where the URL provided by the client actually resolves to an executable CGI program that handles the request.

If the client has provided a URL that resolves to a CGI program that handles the request, this

function behaves differently than if the URL is resolved to a local file or directory. If the client uses the GET or POST command that results in a program being executed to handle the request, this function will return the path to the server root directory along with any additional path information provided in the URL. In other words, the file name returned by this function will be the same as the PATH_TRANSLATED value passed to the CGI program.

This function should only be called after the client request has been received by the server, typically inside a HTTP_CLIENT_COMMAND or HTTP_CLIENT_EXECUTE event handler. It should not be called inside a HTTP_CLIENT_CONNECT event handler because the server has not processed the client request at that point.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cshtsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

HttpGetCommandLine Function

```
INT WINAPI HttpGetCommandLine(  
    HSERVER hServer,  
    UINT nClientId,  
    LPTSTR lpszCmdLine,  
    INT nMaxLength  
);
```

Return the complete command line issued by the client.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszCmdLine

A pointer to a string buffer that will contain the command, including all arguments. The string buffer will be null terminated and must be large enough to store the complete command line. If this parameter is NULL, the function will return the length of the command line.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer. The internal limit on the maximum length of a command is 1024 characters. If the maximum length specified is smaller than the actual length of the complete command, this function will fail.

Return Value

An integer value which specifies the number of characters copied into the buffer, not including the terminating null character. If the function fails, the return value will be zero and the

HttpGetServerError function can be used to retrieve the last error code. If the last error code has a value of zero then no command has been issued by the client.

Remarks

The **HttpGetCommandLine** function is used to obtain the command that was issued by the client, and is commonly used inside HTTP_CLIENT_COMMAND and HTTP_CLIENT_RESULT event handlers to pre-process and post-process client commands, respectively. When the function returns, the string buffer provided by the caller will contain the complete command, including the resource path and requested HTTP version. Any extraneous whitespace will be removed, however all encoding will be preserved.

To obtain the complete URL associated with the request issued by the client, use the **HttpGetCommandUrl** function. If the command sent by the client is used to perform an action on a file or directory, the **HttpGetCommandFile** function should be called to obtain the full path to the local file rather than using the resource path.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cshtsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

HttpGetCommandName Function

```
INT WINAPI HttpGetCommandName
    HSERVER hServer,
    UINT nClientId,
    LPTSTR LpszCommand,
    INT nMaxLength
);
```

Return the name of the last command issued by the client.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszCommand

A pointer to a string buffer that will contain the command name. The string buffer will be null terminated and must be large enough to store the complete command name. If this parameter is NULL, the function will only return the length of the current command in characters, not including the terminating null character.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer, including the terminating null character. If the maximum length specified is smaller than the actual length of the parameter, this function will fail. If the *lpszCommand* parameter is NULL, this value should be zero.

Return Value

An integer value which specifies the number of characters copied into the buffer, not including the terminating null character. If the function fails, the return value will be zero and the **HttpGetServerError** function can be used to retrieve the last error code. If the last error code is returned as a value of zero, this means that no command has been issued by the client.

Remarks

The **HttpGetCommandName** function is used to obtain the name of the last command that was issued by the client. The command name returned by this function will always be capitalized, regardless of how it was sent by the client. This function is typically used inside HTTP_CLIENT_COMMAND and HTTP_CLIENT_RESULT event handlers to pre-process and post-process client commands, respectively. It should not be called inside a HTTP_CLIENT_CONNECT event handler because the server has not processed the client request at that point.

The **HttpGetCommandUrl** function can be used to return the resource that was requested by the client.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cshtsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

HttpGetCommandQuery Function

```
INT WINAPI HttpGetCommandQuery(  
    HSERVER hServer,  
    UINT nClientId,  
    LPTSTR lpszParameters,  
    INT nMaxLength  
);
```

Return the query parameters included with the command.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszParameters

A pointer to a string buffer that will contain the query parameters when the function returns. The string buffer will be null terminated up to the maximum number of characters specified by the caller. If this parameter is NULL the function will return the length of the query string.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer. If the *lpszParameters* parameter is NULL, this value should be zero.

Return Value

An integer value which specifies the number of characters copied into the buffer, not including the terminating null character. If the function fails, the return value will be zero and the

HttpGetServerError function can be used to retrieve the last error code. If the client did not provide any query parameters, this function will return zero and the last error code will be zero.

Remarks

The **HttpGetCommandQuery** function is used to obtain a copy of the query parameters that were included in the request URL. If there were no query parameters, the string buffer will be empty and the return value will be zero. If the request did include query parameters, they will be returned to the caller in their original, encoded form.

This function should not be called within a HTTP_CLIENT_CONNECT event handler because the client request has not been processed at that point.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cshtsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[HttpGetCommandName](#), [HttpGetCommandResource](#), [HttpReceiveRequest](#)

HttpGetCommandResource Function

```
INT WINAPI HttpGetCommandResource(  
    HSERVER hServer,  
    UINT nClientId,  
    LPTSTR lpszResource,  
    INT nMaxLength  
);
```

Return the URL path for the resource requested by the client.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszResource

A pointer to a string buffer that will contain the URL path provided by the client for the current command. The string buffer will be null terminated and must be large enough to store the complete path. If this parameter is NULL, the function will only return the length of the path.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer, including the terminating null character. If the *lpszResource* parameter is NULL, this value should be zero. If this value is less than the length of the URL, the function will fail.

Return Value

An integer value which specifies the number of characters copied into the buffer, not including the terminating null character. If the function fails, the return value will be zero and the **HttpGetServerError** function can be used to retrieve the last error code.

Remarks

The **HttpGetCommandResource** function returns the URL path that the client provided to access the requested resource. The path will not include the URI scheme, user credentials or query parameters. The **HttpGetCommandFile** function can be used to determine the name of the local file on the server that will be accessed using this URL.

If you require the complete URL, not just the path to the resource, use the **HttpGetCommandUrl** function.

This function should only be called after the client request has been received by the server, typically inside a HTTP_CLIENT_COMMAND event handler. It should not be called inside a HTTP_CLIENT_CONNECT event handler because the server has not processed the client request at that point.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cshtsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

HttpGetCommandResult Function

```
INT WINAPI HttpGetCommandResult(  
    HSERVER hServer,  
    UINT nClientId,  
    LPTSTR lpszResult,  
    INT nMaxLength  
);
```

Return the result code and description for the last command issued by the client.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszResult

A pointer to a string buffer that will contain the description of the result code. The string buffer will be null terminated up to the maximum number of characters specified by the caller. This parameter can be NULL if this information is not required.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer. If the *lpszResult* parameter is NULL, this value should be zero.

Return Value

An integer value which specifies the result code for the last command issued by the client. A return value of zero indicates that the command has not completed and there is no result code available.

Remarks

The **HttpGetCommandResult** function is used to determine the result of the last command that was issued by the client and is typically called in the HTTP_CLIENT_RESULT event handler. This function should only be called after a command has been processed or the **HttpSendResponse** function has been called.

The result code is a three-digit integer value that indicates the success or failure of a command. Whenever a client sends a command to the server, the server must respond with this numeric code and a brief description of the the result. Result codes are generally broken down into the following categories:

Result Code	Description
100-199	Result codes in this range are informational and only used with version 1.1 of the protocol. If the server returns a result code in this range, it means that it has received the request and that the client should proceed.
200-299	Result codes in this range indicate that the server has successfully completed the requested action. In most cases this means that the server has returned the requested data to the client, however if a 204 result code is sent, this indicates that the request has been processed but there is no data available.
300-399	Result codes in this range indicate that the requested resource has been moved to a new location. The most common result codes are 301 and 302. A value of

	301 indicates that the location of the resource has changed permanently and all future requests should be sent to the new URL. A value of 302 indicates that the resource location has changed temporarily. The new location of the resource is sent to the client by setting the Location response header field.
400-499	Result codes in this range indicate an error with the request that was made by the client. These types of errors include invalid commands, requests that can only be issued by authenticated clients, or resources that cannot be accessed on the server. The most common result code in this range is the 404 code which indicates that the requested document could not be found.
500-599	Result codes in this range indicate a server error has occurred while processing a valid request. These types of errors are returned when a command has not been implemented, the execution of a CGI program or script has failed unexpectedly, or an internal server error has occurred.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cshtsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

HttpGetCommandUrl Function

```
INT WINAPI HttpGetCommandUrl(  
    HSERVER hServer,  
    UINT nClientId,  
    LPTSTR lpszCmdUrl,  
    INT nMaxLength  
);
```

Return the complete URL of the resource requested by the client.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszCmdUrl

A pointer to a string buffer that will contain the URL provided by the client for the current command. The string buffer will be null terminated and must be large enough to store the complete URL. If this parameter is NULL, the function will only return the length of the URL.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer, including the terminating null character. If the *lpszCmdUrl* parameter is NULL, this value should be zero. If this value is less than the length of the URL, the function will fail.

Return Value

An integer value which specifies the number of characters copied into the buffer, not including the terminating null character. If the function fails, the return value will be zero and the **HttpGetServerError** function can be used to retrieve the last error code.

Remarks

The **HttpGetCommandUrl** function returns the complete URL that the client provided to access the requested resource. The URL will include any query parameters that were specified by the client, but it will not include any user credentials. The **HttpGetCommandFile** function can be used to determine the name of the local file on the server that will be accessed using this URL.

If you only require the URL path, without the URI scheme or the query parameters, use the **HttpGetCommandResource** function.

This function should only be called after the client request has been received by the server, typically inside a HTTP_CLIENT_COMMAND event handler. It should not be called inside a HTTP_CLIENT_CONNECT event handler because the server has not processed the client request at that point.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cshtsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

HttpGetProgramExitCode Function

```
BOOL WINAPI HttpGetProgramExitCode(  
    HSERVER hServer,  
    UINT nClientId,  
    LPDWORD lpdwExitCode  
);
```

Return the exit code of the last program executed by the client.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpdwExitCode

A pointer to an unsigned integer that will contain the program exit code when the function returns. This parameter cannot be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the server handle and client ID do not specify a valid client session, the function will return zero.

Remarks

The **HttpGetProgramExitCode** function returns the exit code of a registered CGI program or script that was executed. By convention, most programs return an exit code in the range of 0-255, with an exit code of zero indicating success. The exit code is commonly used by programs to communicate status information back to the server application.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cshtsv10.lib

See Also

[HttpGetProgramOutput](#), [HttpRegisterProgram](#)

HttpGetProgramName Function

```
INT WINAPI HttpGetProgramName(  
    HSERVER hServer,  
    UINT nClientId,  
    LPTSTR lpszProgramName,  
    INT nMaxLength  
);
```

Return the name of the CGI program executed by the client.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszProgramName

A pointer to a string buffer that will contain the name of the CGI program executed by the client. This parameter cannot be NULL and should be at least MAX_PATH characters in size.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer, including the terminating null character. This parameter must have a value greater than zero.

Return Value

If the function succeeds, the return value is the length of the executable file name. If the server handle and client ID do not specify a valid client session, the function will return zero. If the client has not executed a CGI program this function will return zero and the last error code will be set to zero.

Remarks

The **HttpGetProgramName** function returns the local file name of the CGI program that was executed in response to a request from the client. This is the full path to the executable that was registered with the server using the **HttpRegisterProgram** function. If the client specified a regular document or directory, this function will return a value of zero, indicating that no CGI program has been executed to handle the request.

To obtain the resource URL that was provided by the client, use the **HttpGetCommandUrl** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cshtsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[HttpGetProgramExitCode](#), [HttpGetProgramOutput](#), [HttpRegisterProgram](#)

HttpGetProgramOutput Function

```
DWORD WINAPI HttpGetProgramOutput(  
    HSERVER hServer,  
    UINT nClientId,  
    LPBYTE lpBuffer,  
    DWORD dwBufferSize  
);
```

Return a copy of the standard output from a CGI program executed by the client.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpBuffer

A pointer to a buffer that will contain the output from the last program executed by the client. If this parameter is NULL, the function will return the number of bytes of data that was output by the program. Note that this output is not null terminated.

dwBufferSize

The maximum number of bytes that can be copied into the buffer. If the *lpBuffer* parameter is NULL, this value should be zero.

Return Value

If the function succeeds, the return value is the number of bytes copied into the specified buffer. If the server handle and client ID do not specify a valid client session, the function will return zero. If the client has not executed any programs, the return value will be zero.

Remarks

The **HttpGetProgramOutput** function is used to obtain a copy of the output generated by a CGI program. To determine the number of bytes of output available to read, call this function with the *lpBuffer* parameter as NULL and the *dwBufferSize* parameter with a value of zero. The return value will be the number of bytes of data that was output by the program. It should be noted that for Unicode builds, the buffer is a byte array, not an array of characters, and will not be null terminated.

This function returns the raw output from the program which may contain a response header block, escape sequences, control characters and embedded nulls. When the application processes the output returned by this function, it should never coerce the buffer pointer to an LPTSTR value because there is no guarantee that the data will be null-terminated. To obtain the output from the program as a string, use the **HttpGetProgramText** function.

This function should only be used within an HTTP_CLIENT_EXECUTE event handler, which occurs after the program has terminated.

Example

```
LPBYTE lpBuffer = NULL; // A pointer to the output buffer  
DWORD cbBuffer = 0;     // Number of bytes in the output buffer  
  
// Determine the number of bytes in the output buffer
```

```
cbBuffer = HttpGetProgramOutput(hServer, nClientId, NULL, 0);

if (cbBuffer > 0)
{
    // Allocate memory for the buffer
    lpBuffer = (LPBYTE)LocalAlloc(LPTR, cbBuffer + 1);

    // Copy the program output to the buffer
    if (lpBuffer != NULL)
        cbBuffer = HttpGetProgramOutput(hServer, nClientId, lpBuffer, cbBuffer +
1);
}

// Free the memory allocated for the buffer when finished
if (lpBuffer != NULL)
{
    LocalFree((HLOCAL)lpBuffer);
    lpBuffer = NULL;
    cbBuffer = 0;
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cshtsv10.lib

See Also

[HttpGetProgramExitCode](#), [HttpGetProgramText](#), [HttpRegisterProgram](#)

HttpGetProgramText Function

```
INT WINAPI HttpGetProgramText(  
    HSERVER hServer,  
    UINT nClientId,  
    LPTSTR lpszBuffer,  
    INT nMaxLength  
);
```

Return a copy of the standard output from a CGI program in a string buffer.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszBuffer

A pointer to a buffer that will contain the output from the last program executed by the client as a string. If this parameter is NULL, the function will return the number of bytes of characters that was output by the program, not including a terminating null character.

nMaxLength

The maximum number of bytes that can be copied into the buffer. If the *lpszBuffer* parameter is NULL, this value should be zero.

Return Value

If the function succeeds, the return value is the number of characters copied into the specified string buffer, not including the terminating null character. If the server handle and client ID do not specify a valid client session, the function will return zero. If the client has not executed any programs, the return value will be zero.

Remarks

The **HttpGetProgramText** function is used to obtain a copy of the output generated by a CGI program. To determine the number of characters of output available to read, call this function with the *lpszBuffer* parameter as NULL and the *nMaxLength* parameter with a value of zero. The return value will be the number of characters that were output by the program. If the application dynamically allocates the string buffer, make sure that it allocates an extra character for the terminating null character.

This function will only return textual output from the program and any non-printable control characters and the escape character will be replaced with a space. To obtain the unfiltered output from the program, use the **HttpGetProgramOutput** function. If the program outputs a response header block, this will be included in the string buffer.

This function should only be used within an HTTP_CLIENT_EXECUTE event handler, which occurs after the program has terminated.

Example

```
LPTSTR lpszBuffer = NULL; // A pointer to the output buffer  
INT cchBuffer = 0; // Number of bytes in the output buffer  
  
// Determine the number of bytes in the output buffer
```

```
cchBuffer = HttpGetProgramText(hServer, nClientId, NULL, 0);

if (cchBuffer > 0)
{
    // Allocate memory for the string buffer
    lpszBuffer = (LPTSTR)LocalAlloc(LPTR, (cchBuffer + 1) * sizeof(TCHAR));

    // Copy the program output to the buffer
    if (lpszBuffer != NULL)
        cchBuffer = HttpGetProgramText(hServer, nClientId, lpszBuffer, cchBuffer
+ 1);
}

// Free the memory allocated for the buffer when finished
if (lpszBuffer != NULL)
{
    LocalFree((HLOCAL)lpszBuffer);
    lpszBuffer = NULL;
    cchBuffer = 0;
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cshtsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

HttpGetServerAddress Function

```
INT WINAPI HttpGetServerAddress(  
    HSERVER hServer,  
    UINT nClientId,  
    LPTSTR lpszAddress,  
    INT nMaxLength  
);
```

Return the IP address of the server.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session. This value may be zero.

lpszAddress

A pointer to a string buffer that will contain the server IP address, terminated with a null character. To accommodate both IPv4 and IPv6 addresses, this buffer should be at least 46 characters in length. This parameter cannot be NULL.

nMaxLength

An integer value that specifies the maximum number of characters can be copied into the string buffer, including the terminating null character. This value must be greater than zero. If the buffer size is too small, the function will fail.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If either the server handle or the client ID is invalid, or the buffer is not large enough to store the complete address, the function will return a value of zero.

Remarks

This function will return the IP address assigned to the specified server as a printable string. If the *nClientId* parameter has a value of zero, this function will return the IP address assigned to the local system. If the HTTP_SERVER_NATROUTER option was specified when the server was started, this function will return the external IP address assigned to the system. If the *nClientId* parameter specifies a valid client session, this function will return the IP address that the client used to establish the connection with the server. To determine the IP address assigned to the client, use the **HttpGetClientAddress** function.

The format and length of IPv4 and IPv6 address strings are very different. An IPv4 address string looks like "192.168.0.20", while an IPv6 address string can look something like "fd7c:2f6a:4f4f:ba34::a32". If your application checks for the format of these address strings, it needs to be aware of the differences. You also need to make sure that you're providing enough space to display or store an address to avoid buffer overruns.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cshtsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[HttpGetClientAddress](#), [HttpGetServerName](#)

HttpGetServerDirectory Function

```
INT WINAPI HttpGetServerDirectory(  
    HSERVER hServer,  
    LPTSTR lpszDirectory,  
    INT nMaxLength  
);
```

Return the full path to the root directory assigned to the specified server.

Parameters

hServer

The server handle.

lpszDirectory

A pointer to a string buffer that will contain the server root directory, terminated with a null character. It is recommended that this buffer be at least MAX_PATH characters in length. This parameter cannot be NULL.

nMaxLength

An integer value that specifies the maximum number of characters can be copied into the string buffer, including the terminating null character. This value must be greater than zero. If the buffer size is too small, the function will fail.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If the server handle is invalid, or the buffer is not large enough to store the complete path, the function will return a value of zero.

Remarks

The **HttpGetServerDirectory** function will return the full path to the root directory assigned to the server instance. The root directory may be specified as part of the server configuration, or if no directory is specified by the application, a temporary root directory will be created and this function can be used to obtain the full path to the directory. When the application specifies a root directory, it may use environment variables such as %AppData% in the path. This function will return the fully resolved path name, with all environment variables expanded.

There is no corresponding function to change the server root directory after the server has started. To change the root directory, you must stop the server using the **HttpServerStop** function and then start another instance of the server with a configuration that specifies the new directory.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cshtsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[HttpGetServerAddress](#), [HttpGetServerIdentity](#), [HttpGetServerName](#)

HttpGetServerError Function

```
DWORD WINAPI HttpGetServerError(  
    HSERVER hServer,  
    LPTSTR lpszError,  
    INT nMaxLength  
);
```

Return the last server error code and a description of the error.

Parameters

hServer

The server handle.

lpszError

A pointer to a string buffer that will contain a description of the error. If the error description is not needed, this parameter may be NULL.

nMaxLength

An integer that specifies the maximum number of characters that can be copied into the error string buffer, including the terminating null character. If the *lpszError* parameter is NULL, this value should be zero.

Return Value

An unsigned integer value that specifies the last error that occurred. A value of zero indicates that there was no error.

Remarks

Error codes are unsigned 32-bit values which are private to each server. You should call the **HttpGetServerError** function immediately when a function's return value indicates that an error has occurred. That is because some functions clear the last error code when they succeed.

If the *hServer* parameter is specified with a value of INVALID_SERVER, this function will return the last error that occurred for the current thread. This value should only be used when the function does not have access to a valid server handle, such as when the **HttpServerStart** function fails.

It is important to note that the error codes returned by this method are different than the command result codes that are defined in RFC 2616, the standard protocol specification for HTTP. This function is used to determine reason that an API function has failed, and should not be used to determine if a command issued by the client was successful. The **HttpSendResponse** function is used to send responses to the client, and the **HttpGetCommandResult** function can be used to determine the result of the last command sent by the client.

Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_SERVER or HTTP_ERROR. Those functions which clear the last error code when they succeed are noted on the function reference page.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cshtsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[HttpGetCommandResult](#), [HttpSendResponse](#), [HttpSetServerError](#)

HttpGetServerIdentity Function

```
INT WINAPI HttpGetServerIdentity(  
    HSERVER hServer,  
    LPTSTR lpszIdentity,  
    INT nMaxLength  
);
```

Return the identity of the specified server.

Parameters

hServer

The server handle.

lpszIdentity

A pointer to a string buffer that will contain the identity of the server when the function returns, terminated with a null character. This parameter cannot be NULL. It is recommended that this buffer be at least 32 characters in length.

nMaxLength

An integer value that specifies the maximum number of characters can be copied into the string buffer, including the terminating null character. This value must be greater than zero. If the buffer size is too small, the function will fail.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If the server handle is invalid, or the buffer is not large enough to store the complete path, the function will return a value of zero.

Remarks

The **HttpGetServerIdentity** function returns the identity string that was specified as part of the server configuration. It is used for informational purposes only and does not affect the operation of the server. Typically the string specifies the name of the application and a version number. The **HttpSetServerIdentity** function can be used to change the identity string associated with the server.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cshtsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[HttpSetServerIdentity](#)

HttpGetServerLogFile Function

```
BOOL WINAPI HttpGetServerLogFile(  
    HSERVER hServer,  
    UINT * lpnLogFormat,  
    UINT * lpnLogLevel,  
    LPTSTR lpszFileName,  
    INT nMaxLength  
);
```

Return the current log file format and the full path to the file.

Parameters

hServer

The server handle.

lpnLogFormat

A pointer to an integer value that will contain the log file format being used when the function returns. If this information is not needed, this parameter may be NULL. The following formats are supported:

Constant	Description
HTTP_LOGFILE_NONE (0)	This value specifies that the server should not create or update a log file.
HTTP_LOGFILE_COMMON (1)	This value specifies that the log file should use the common log format that records a subset of information in a fixed format. This log format usually only provides information about file transfers.
HTTP_LOGFILE_COMBINED (2)	This value specifies that the server should use the combined log file format. This format is similar to the common format, however it includes the client referrer and user agent. This is the format that most Apache web servers use by default.
HTTP_LOGFILE_EXTENDED (3)	This value specifies that the log file should use the standard W3C extended log file format. This is an extensible format that can provide additional information about the client session.

lpnLogLevel

A pointer to an integer value that will contain the level of detail the server uses when generating the log file. The minimum value is 1 and the maximum value is 10. If this information is not needed, this parameter may be NULL.

lpszFileName

A pointer to a string buffer that will contain the full path to the log file. This parameter may be NULL if this information is not required.

nMaxLength

An integer that specifies the maximum number of characters that can be copied into the file name string, including the terminating null character. If the *lpszFileName* parameter is NULL, this value should be zero.

Return Value

An integer value which specifies the current log file format. Refer to the **HTTPSERVERCONFIG** structure definition for a list of supported log file formats. If the server handle is invalid or logging has not been enabled, this function will return a value of zero.

Remarks

If the server is configured with logging enabled, but a log file name is not explicitly provided, then the server will automatically generate one. This function can be used to get the full path to the current log file along with the format that is being used to record client session data. Normally the log file is held open by the server thread while it is active, however you can call the **HttpRenameServerLogFile** function to explicitly rename or delete the log file.

To change the name of the log file, the log file format or level of detail, use the **HttpSetServerLogFile** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cshtsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[HttpRenameServerLogFile](#), [HttpSetServerLogFile](#)

HttpGetServerMemoryUsage Function

```
BOOL WINAPI HttpGetServerMemoryUsage(  
    HSERVER hServer,  
    ULARGE_INTEGER * LpMemUsage  
);
```

Return the amount of memory allocated for the server and all client sessions.

Parameters

hServer

The server handle.

lpMemUsage

A pointer to a ULARGE_INTEGER variable which will specify how much memory has been allocated by the server. This parameter will be initialized to a value of zero by the function and updated with the total number of bytes allocated by the server and all active client sessions when it returns.

Return Value

If the function succeeds, the return value is non-zero and the memory usage value will be updated. If the server handle is invalid, or the server cannot be locked, the return value is zero. Call the **HttpGetServerError** function to determine the cause of the failure.

Remarks

This function returns the amount of memory allocated by the server and all active client sessions. It enumerates all of memory allocations made by the server process and client session threads and returns the total number of bytes allocated for the server process. This value reflects the amount of memory explicitly allocated by this library and does not reflect the total working set size of the process, or memory allocated by any other libraries. To determine the working set size for the process, refer to the Win32 **GetProcessWorkingSetSize** and **GetProcessMemoryInfo** functions.

This function forces the server into a locked state, and all client sessions will block until the function returns. Because this function enumerates all heaps allocated for the server process, it can be an expensive operation, particularly when there are a large number of active clients connected to the server. Frequent use of this function can significantly degrade the performance of the server. It is primarily intended for use as a debugging tool to determine if memory usage is the result of an increase in active client sessions. If the value returned by the function remains reasonably constant, but the amount of memory allocated for the process continues to grow, it could indicate a memory leak in some other area of the application.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cshtsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[HttpGetServerStackSize](#), [HttpSetServerStackSize](#)

HttpGetServerName Function

```
INT WINAPI HttpGetServerName(  
    HSERVER hServer,  
    UINT nClientId,  
    LPTSTR lpszHostName,  
    INT nMaxLength  
);
```

Return the host name assigned to the specified server.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session. This value may be zero.

lpszHostName

A pointer to a string buffer that will contain the server host name, terminated with a null character. It is recommended that this buffer be at least 64 characters in length. This parameter cannot be NULL.

nMaxLength

An integer value that specifies the maximum number of characters can be copied into the string buffer, including the terminating null character. This value must be greater than zero. If the buffer size is too small, the function will fail.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If either the server handle or the client ID is invalid, or the buffer is not large enough to store the complete hostname, the function will return a value of zero.

Remarks

This function will return the host name assigned to the specified server. If the *nClientId* parameter has a value of zero, the function will return the default host name that was specified as part of the server configuration. If no host name was explicitly assigned to the server, then it will return the local system name. If the *nClientId* parameter specifies a client session, then it this function will return the host name that the client used to establish the connection.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cshtsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[HttpGetServerAddress](#)

HttpGetServerOptions Function

```
BOOL WINAPI HttpGetServerOptions(  
    HSERVER hServer,  
    LPDWORD LpdwOptions  
);
```

Return the configuration options for the specified server.

Parameters

hServer

The server handle.

LpdwOptions

A pointer to an unsigned integer that will contain the options that were specified when the server was started. This parameter cannot be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the server handle is invalid, the function will return a value of zero.

Remarks

This function will return the options that were specified when the server was started. For a list of server options see [Server Option Constants](#).

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `cshtsv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

[HttpServerStart](#)

HttpGetServerPriority Function

```
INT WINAPI HttpGetServerPriority(  
    HSERVER hServer  
);
```

Return the current priority assigned to the specified server.

Parameters

hServer

The server handle.

Return Value

If the function succeeds, the return value is the priority for the specified server. If the function fails, the return value is HTTP_PRIORITY_INVALID. To get extended error information, call **HttpGetServerError**.

Remarks

The **HttpGetServerPriority** function can be used to determine the current priority assigned to the server. It will return one of the following values:

Constant	Description
HTTP_PRIORITY_BACKGROUND (0)	This priority significantly reduces the memory, processor and network resource utilization for the server. It is typically used with lightweight services running in the background that are designed for few client connections. The server thread will be assigned a lower scheduling priority and will be frequently forced to yield execution to other threads.
HTTP_PRIORITY_LOW (1)	This priority lowers the overall resource utilization for the server and meters the processor utilization for the server thread. The server thread will be assigned a lower scheduling priority and will occasionally be forced to yield execution to other threads.
HTTP_PRIORITY_NORMAL (2)	The default priority which balances resource and processor utilization. This is the priority that is initially assigned to the server when it is started, and it is recommended that most applications use this priority.
HTTP_PRIORITY_HIGH (3)	This priority increases the overall resource utilization for the server and the thread will be given higher scheduling priority. It is not recommended that this priority be used on a system with a single processor.
HTTP_PRIORITY_CRITICAL (4)	This priority can significantly increase processor, memory and network utilization. The server thread will be given higher scheduling priority and will be more responsive to client connection requests. It is not recommended that this priority be used on a system with a single processor.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cstools10.h

Import Library: cshtsv10.lib

See Also

[HttpServerStart](#), [HttpSetServerPriority](#)

HttpGetServerStackSize Function

```
DWORD WINAPI HttpGetServerStackSize(  
    SOCKET hServer  
);
```

Return the initial size of the stack allocated for threads created by the server.

Parameters

hServer

The server handle.

Return Value

If the function succeeds, the return value is the amount of memory that will be allocated for the stack in bytes. If the function fails, the return value is zero. To get extended error information, call **HttpGetServerError**.

Remarks

The **HttpGetServerStackSize** function returns the initial amount of memory that is committed to the stack for each thread created by the server. By default, the stack size for each thread is set to 256K for 32-bit processes and 512K for 64-bit processes.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `csstools10.h`

Import Library: `cshtsv10.lib`

See Also

HttpGetServerTransferInfo Function

```
BOOL WINAPI HttpGetServerTransferInfo(  
    HSERVER hServer,  
    UINT nClientId,  
    LPHTTPSERVERTRANSFER lpTransferInfo  
);
```

Return information about the current file transfer.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpTransferInfo

A pointer to an **HTTPSERVERTRANSFER** structure that will contain information about the last file transfer. This parameter cannot be NULL, and the *dwSize* member of the structure must be initialized to specify the structure size prior to calling this function.

Return Value

If the function succeeds, the return value is non-zero. If the server handle and client ID do not specify a valid client session, the function will return zero.

Remarks

The **HttpGetServerTransferInfo** function is used to obtain information about the last file transfer that was performed by the server for the specified client. This function is typically called within an event handler to determine how many bytes of data were transferred, the type of file and the full path to the file on the local system.

This function will only return information about a file transfer using the GET or PUT commands, with any other command causing this function to fail.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cshtsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

HttpGetServerUuid Function

```
INT WINAPI HttpGetServerUuid(  
    HSERVER hServer,  
    UUID * LpUuid  
);
```

Return the UUID assigned to the specified server.

Parameters

hServer

The server handle.

lpUuid

A pointer to a UUID structure that will contain the server UUID when the function returns. This parameter cannot be NULL.

Return Value

If the function succeeds, the return value is non-zero. If either the server handle is invalid or the pointer to the UUID structure is NULL, the function will return a value of zero.

Remarks

The **HttpGetServerUuid** function returns the Universally Unique Identifier (UUID) that has been assigned to the server. The UUID may either be generated by the application and assigned as part of the server configuration, or an ephemeral UUID may be automatically generated when the server is started. To obtain a printable string version of the UUID, use the **HttpGetServerUuidString** function.

There is no corresponding function to change the UUID assigned to an active server. The server UUID is assigned when the server is started, and it must be a unique value that is maintained throughout the lifetime of the server. To change the UUID associated with the server, the server must be stopped using the **HttpServerStop** function and another instance of the server started with the new UUID.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cshtsv10.lib

See Also

[HttpGetServerUuidString](#), [HTTPSERVERCONFIG](#)

HttpGetServerUuidString Function

```
INT WINAPI HttpGetServerUuidString(  
    HSERVER hServer,  
    LPTSTR lpszHostUuid,  
    INT nMaxLength  
);
```

Return the UUID assigned to the server as a printable string.

Parameters

hServer

The server handle.

lpszHostUuid

A pointer to a string buffer that will contain the server UUID, terminated with a null character. It is recommended that this buffer be at least 40 characters in length. This parameter cannot be NULL.

nMaxLength

An integer value that specifies the maximum number of characters can be copied into the string buffer, including the terminating null character. This value must be greater than zero. If the buffer size is too small, the function will fail.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If either the server handle or the buffer is not large enough to store the complete UUID string, the function will return a value of zero.

Remarks

The **HttpGetServerUuidString** function returns the Universally Unique Identifier (UUID) that has been assigned to the server. The UUID may either be generated by the application and assigned as part of the server configuration, or an ephemeral UUID may be automatically generated when the server is started. To obtain the numeric UUID value, use the **HttpGetServerUuid** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cshtsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[HttpGetServerUuid](#), [HTTPSERVERCONFIG](#)

HttpGetVirtualHostId Function

```
UINT WINAPI HttpGetVirtualHostId(  
    HSERVER hServer,  
    LPCTSTR lpszHostName,  
    UINT nHostPort  
);
```

Return the virtual host ID associated with the specified hostname.

Parameters

hServer

The server handle.

lpszHostName

A string that specifies the virtual host name.

nHostPort

An integer value which specifies the port number for the virtual host. This value must be zero or the same value as the original port number that the server was configured to use.

Return Value

If the function succeeds, the return value is the host ID that uniquely identifies the virtual host. If the server handle is invalid, or there is no virtual host with the specified name, the function will return VIRTUAL_HOST_UNKNOWN. If the function fails, the last error code will be updated to indicate the cause of the failure.

Remarks

The **HttpGetVirtualHostId** function is used to obtain the unique virtual host ID that is associated with a specific hostname. This function will match both the primary virtual hostname added using the **HttpAddVirtualHost** function, as well as any aliases that were added using the **HttpAddVirtualHostAlias** function. To obtain the virtual host ID associated with the active client session, use the **HttpGetClientVirtualHostId** function.

The *nHostPort* parameter should always be specified with a value of zero, or the same port number that the server was configured to use. Port-based virtual hosting is currently not supported and this parameter is included for future use.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cshtsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

HttpGetVirtualHostName Function

```
INT WINAPI HttpGetVirtualHostName(  
    HSERVER hServer,  
    UINT nHostId,  
    LPTSTR LpszHostName,  
    INT nMaxLength  
);
```

Return the hostname associated with the specified virtual host ID.

Parameters

hServer

The server handle.

nHostId

An integer value which identifies the virtual host.

lpszHostName

A pointer to a string buffer that will contain the virtual host name, terminated with a null character. It is recommended that this buffer be at least 64 characters in length. If this parameter is NULL, the function will return the length of the virtual hostname.

nMaxLength

An integer value that specifies the maximum number of characters can be copied into the string buffer, including the terminating null character. If the *lpszHostName* parameter is NULL this value must be zero.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If either the server handle or the host ID is invalid, or the buffer is not large enough to store the complete hostname, the function will return a value of zero.

Remarks

The **HttpGetVirtualHostName** function returns the primary hostname associated with the specified virtual host ID. This is the same hostname that was specified when the virtual host was added to the server configuration using the **HttpAddVirtualHost** function. To obtain the hostname that was used by the active client session to connect to the server, use the **HttpGetClientVirtualHost** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cshtsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

HttpIsClientAuthenticated Function

```
BOOL WINAPI HttpIsClientAuthenticated(  
    HSERVER hServer,  
    UINT nClientId  
);
```

Determine if the specified client session has been authenticated.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

Return Value

If the client session has been authenticated, this function will return a non-zero value, otherwise it will return zero. If the server handle and client ID are valid, this function will clear the last error code.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cshtsv10.lib

See Also

[HttpAuthenticateClient](#), [HttpGetClientCredentials](#), [HttpRequireAuthentication](#)

HttpIsCommandEnabled Function

```
BOOL WINAPI HttpIsCommandEnabled(  
    HSERVER hServer,  
    LPCTSTR LpszCommand  
);
```

Determine if a specific server command has been enabled or disabled.

Parameters

hServer

The server handle.

lpszCommand

A pointer to a NULL terminated string that specifies the name of the command. The command name is not case-sensitive, but the value must otherwise match the exact command name.

Partial matches are not recognized by this function. This parameter cannot be NULL.

Return Value

If the command is enabled, this function will return a non-zero value. If the command is disabled, the server handle is invalid or the command name does not match a supported command, this function will return zero.

Remarks

The **HttpIsCommandEnabled** function is used to determine whether a specific command is enabled. Typically this function is used in an event handler to make sure the command issued by a client is recognized by the server and enabled for use. Commands can be enabled and disabled using the **HttpEnableCommand** function.

This function does not account for the permissions granted to a specific client session. Clients are assigned access rights when they are authenticated using the **HttpAuthenticateClient** function, and certain commands can be limited by the permissions granted to the client. For example, even if the PUT command is enabled, a client must have the HTTP_ACCESS_WRITE permission to use the command to upload a file to the server. For a list of access rights, see [User Access Constants](#).

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cshtsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[HttpAuthenticateClient](#), [HttpEnableCommand](#), [HttpGetCommandName](#)

HttpReceiveRequest Function

```
BOOL WINAPI HttpReceiveRequest(  
    HSERVER hServer,  
    UINT nClientId,  
    DWORD dwOptions,  
    LPHTTPREQUEST lpRequest,  
    LPVOID lpvBuffer,  
    LPDWORD lpdwLength  
);
```

Receive the request that was sent by the client to the server.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

dwOptions

An unsigned integer which specifies how the client request data will be stored. It may be one of the following values:

Constant	Description
HTTP_REQUEST_DEFAULT (0)	If the <i>lpdwLength</i> parameter points to a integer with a non-zero value, the <i>lpvBuffer</i> parameter is considered to be a pointer to a block of memory that has been allocated to store the request data. This is the same as specifying the HTTP_REQUEST_MEMORY option. If the <i>lpdwLength</i> parameter points to an integer with a value of zero, the <i>lpvBuffer</i> parameter is considered to be a pointer to an HGLOBAL memory handle. This is the same as specifying the HTTP_REQUEST_HGLOBAL option.
HTTP_REQUEST_MEMORY (0x1)	The <i>lpvBuffer</i> parameter is a pointer to a block of memory that has been allocated to store the request data. The maximum number of bytes of data that can stored is determined by the value of the integer that the <i>lpdwLength</i> parameter points to. When the function returns, that value will updated with with actual number of bytes copied into the buffer.
HTTP_REQUEST_STRING (0x2)	The <i>lpvBuffer</i> parameter is a pointer to a string buffer that has been allocated to store the request data. The maximum number of bytes of data that can be copied is determined by the value of the integer that the <i>lpdwLength</i> parameter points to. When the function returns, that value will updated with with actual number of bytes copied into the buffer. If the Unicode version of this function is called, the request data will be converted to a null-terminated Unicode string.

HTTP_REQUEST_HGLOBAL (0x4)	The <i>lpvBuffer</i> parameter is a pointer to an HGLOBAL memory handle. When the function returns, the handle will reference a block of memory that contains the request data submitted by the client. The <i>lpdwLength</i> parameter will contain the number of bytes copied to the buffer.
HTTP_REQUEST_FILE (0x8)	The <i>lpvBuffer</i> parameter is a pointer to a string which specifies the name of a file that will contain the request data. If the file does not exist, it will be created. If it does exist, the contents will be replaced. This option is typically used in conjunction with the PUT command. If the <i>lpdwLength</i> parameter is not NULL, the value it points to will be updated with the actual number of bytes stored in the file.
HTTP_REQUEST_HANDLE (0x10)	The <i>lpvBuffer</i> parameter is a handle to an open file. This option is typically used in conjunction with the POST or PUT commands. If the <i>lpdwLength</i> parameter is not NULL, the value it points to will be updated with the actual number of bytes written to the file. If this option is specified, the request data will be written from the current position in the file and will advance the file pointer by the number of bytes received from the client.

lpRequest

A pointer to a **HTTPREQUEST** structure which contains information about the request from the client. This parameter cannot be NULL. The structure that is passed to this function must have all members set to a value of zero except the *dwSize* member, which must be initialized to the size of the structure.

lpvBuffer

A pointer to the buffer that will contain any request data that was submitted by the client. The *dwOptions* parameter determines if this pointer references a block of memory, a null-terminated string buffer, a global memory handle or a file name. If this parameter is NULL, any data submitted by the client will not be copied.

lpdwLength

A pointer to an unsigned integer that will contain the number of bytes of data submitted by the client when the function returns. If the *lpvBuffer* parameter specifies a memory or string buffer, this value must be initialized to the maximum size of the buffer before the function is called. If the *lpvBuffer* parameter points to a global memory handle, this value must be initialized to zero. If *lpvBuffer* is NULL or specifies a file name, this parameter may be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **HttpGetServerError**.

Remarks

The **HttpReceiveRequest** function is called within a HTTP_CLIENT_COMMAND event handler to process the command issued by the client and return information about the request to the server application. It is only necessary for the application to call this function if it wants to implement its own custom handling for a command. It is recommended that most applications use the default command processing for standard commands such as GET and POST to ensure that the

appropriate security checks are performed and the response conforms to the protocol standard.

This function may only be called once per command issued by the client and the data referenced in the **HTTPREQUEST** structure only remains valid while the client is connected to the server. You should never attempt to directly modify the data referenced by any of the structure members. If you wish to store or modify any of the string values returned in the structure, you should allocate a buffer large enough to store the contents of the string, including the terminating null character, and copy the string into that buffer.

If the HTTP_REQUEST_HGLOBAL option is used to return a copy of the request data in a global memory buffer, the HGLOBAL handle must be freed by the application when the data is no longer needed. Failure to free this handle will result in a memory leak.

If the HTTP_REQUEST_HANDLE option is used to write a copy of the request data to an open file, the handle must reference a disk file that was opened or created using the **CreateFile** function with GENERIC_WRITE access. It cannot be a handle to a device or named pipe. If the function succeeds, the file pointer is advanced by the number of bytes of request data submitted by the client. If the function fails, the file pointer is returned to its original position prior to the function being called.

Example

```
// Initialize the HTTPREQUEST structure
HTTPREQUEST httpRequest;
ZeroMemory(&httpRequest, sizeof(httpRequest));
httpRequest.dwSize = sizeof(httpRequest);

// Return the data in a global memory buffer
HGLOBAL hglobalBuffer = NULL;
DWORD dwLength = 0;

bSuccess = HttpReceiveRequest(hServer,
                             nClientId,
                             HTTP_REQUEST_HGLOBAL,
                             &httpRequest,
                             &hglobalBuffer,
                             &dwLength);

if (bSuccess && hglobalBuffer != NULL)
{
    LPBYTE lpBuffer = (LPBYTE)GlobalLock(hglobalBuffer);

    if (lpBuffer != NULL)
    {
        // Process dwLength bytes of data submitted by the client
    }

    GlobalUnlock(hglobalBuffer);
    GlobalFree(hglobalBuffer);
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cshtsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[HttpSendResponse](#), [HTTPREQUEST](#)

HttpRedirectRequest Function

```
BOOL WINAPI HttpRedirectRequest(  
    HSERVER hServer,  
    UINT nClientId,  
    UINT nMethod,  
    LPCTSTR lpszLocation  
);
```

Redirect the request from the client to another URL.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

nMethod

An integer value that specifies if the redirection is permanent or temporary. The following values may be used:

Constant	Description
HTTP_REDIRECT_PERMANENT (1)	This value is used for permanent redirection, indicating that the client should update any record of the link with the new URL specified by the <i>lpszLocation</i> parameter. This result is cacheable and when the client makes subsequent requests for the resource, it should always use the new URL.
HTTP_REDIRECT_TEMPORARY (2)	This value is used for temporary redirection, indicating that the client should issue a request for the resource using the new URL specified by the <i>lpszLocation</i> parameter, but subsequent requests should continue to use the original URL.
HTTP_REDIRECT_OTHER (3)	This value is used for temporary redirection, however it instructs the client that it should use the GET command to request the redirected resource. This option is typically used to redirect a client after it has used the POST command.

lpszLocation

A pointer to a string that specifies the new location for the requested resource. This value must be a complete URL, including the http:// or https:// scheme. This parameter cannot be NULL or point to zero-length string.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **HttpGetServerError**.

Remarks

The **HttpRedirectRequest** function can be used within a HTTP_CLIENT_COMMAND event

handler to redirect the client to a new location for the resource that it has requested. This redirection can be permanent or temporary, depending on whether the server expects the client to continue to use the original URL when requesting the resource.

If the `HTTP_REDIRECT_TEMPORARY` method is used, the actual status code that is returned to the client depends on the version of the protocol that is being used. If the client has issued the request using HTTP 1.0 then the server will return a 302 code to the client. If the client used HTTP 1.1, the server will return a 307 code to the client that indicates it should use the same command verb (GET, POST, etc.) when requesting the resource at the new location.

If the `HTTP_REDIRECT_OTHER` method is used, the status code that is returned to the client depends on which version of the protocol is being used. For clients who are using HTTP 1.0, the server will return a 302 code to the client just as with the `HTTP_REDIRECT_TEMPORARY` method. If the client is using HTTP 1.1, the server will return a 303 code to the client that indicates it should always use the GET command to request the new resource, regardless if a different command was originally used (POST, PUT, etc.)

This function provides a simplified interface for sending a redirection status code that also implicitly sets the Location response header to the value of the *lpzLocation* parameter. If the server application needs to send alternate redirection codes such as 305 (Use Proxy) then it should use the **HttpSendReponse** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `cshtsv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

HttpRegisterHandler Function

```
BOOL WINAPI HttpRegisterHandler(  
    HSERVER hServer,  
    UINT nHostId,  
    LPCTSTR lpszExtension,  
    LPCTSTR lpszProgramFile,  
    LPCTSTR lpszParameters,  
    LPCTSTR lpszDirectory  
);
```

Register a CGI program for use and associate it with a file name extension.

Parameters

hServer

The server handle.

nHostId

An unsigned integer that identifies the virtual host associated with the program. The value VIRTUAL_HOST_DEFAULT should be used for the default host that is created when the server is first started.

lpszExtension

A pointer to a string which specifies the file name extension that is associated with the CGI program. This parameter cannot be NULL.

lpszProgramFile

A pointer to a string that specifies the full path to the executable program. This parameter cannot be NULL.

lpszParameters

A pointer to a string that specifies additional parameters for the program. This value will be passed to the program as command line arguments. If the program does not require any command line parameters, this value may be NULL or point to an empty string.

lpszDirectory

A pointer to a string that specifies the current working directory for the program. If this parameter is NULL or points to an empty string, the server will use the root document directory for the virtual host.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **HttpGetServerError**.

Remarks

The **HttpRegisterHandler** function registers an executable CGI program and associates it with a file name extension. When the client issues a GET or POST command that specifies a file with that extension, the program will be executed and the output return to the client.

The *lpszProgramFile* string specifies file name of the CGI program. You should not install any executable programs in the server root directory or its subdirectories. A client should never have the ability to directly access the executable file itself. It is permitted to have multiple file name extensions that reference the same program. The only requirement is that the extension be unique for the given host. The program name may contain environment variables surrounded by %

symbols. For example, %ProgramFiles% would be expanded to the **C:\Program Files** folder.

It is important to note that the program specified by *lpszProgramFile* must be an executable file, not a script or batch file. If the program name does not contain a directory path, then the standard Windows pathing rules will be used when searching for an executable file that matches the given name. It is recommended that you always provide a full path to the executable file.

The *lpszParameters* string can specify additional command line parameters that should be passed to the CGI program as arguments. This string can also contain a placeholder named "%1" that will be replaced by the full path to the local script filename. If no placeholder is included in the parameters, or *lpszParameters* is a NULL pointer, the script file name will be passed to the program as its only argument.

The executable program that is registered using this program must be a console application that conforms to the CGI/1.1 specification defined in RFC 3875. Request data submitted by the client as part of a POST will be provided to the program as standard input. The output from the program must be written to standard output. The first lines of output from the program should be any response headers, followed by an empty line. Each line should be terminated with a carriage-return and linefeed (CRLF) sequence. If the CGI program outputs additional data to be processed by the client, it should provide Content-Type and Content-Length response headers.

The application can obtain a copy of the output from the command by calling the **HttpGetProgramOutput** function from within a HTTP_CLIENT_EXECUTE event handler.

When developing a CGI program, it is important to take into consideration the environment that it will be executing in. The program will be started as a child process of the server application, and will inherit the same privileges. This means that it will typically have access to the boot drive, the Windows folders and the system registry. CGI programs must ensure that all query parameters and request data submitted by the client have been validated.

If the server is running on a system with User Account Control (UAC) enabled and does not have elevated privileges, do not register a program that requires elevated privileges or has a manifest that specifies the requestedExecutionLevel as requiring administrative privileges.

Example

```
// Register a handler for VBScript
HttpRegisterHandler(hServer,
    VIRTUAL_HOST_DEFAULT,
    _T("vbs"),
    _T("%SystemRoot%\System32\cscript.exe"),
    _T("/nologo /b \"%1\""),
    NULL);
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cshtsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

HttpRegisterProgram Function

```
BOOL WINAPI HttpRegisterProgram(  
    HSERVER hServer,  
    UINT nHostId,  
    LPCTSTR lpszVirtualPath,  
    LPCTSTR lpszProgramFile,  
    LPCTSTR lpszParameters,  
    LPCTSTR lpszDirectory  
);
```

Register a CGI program for use and associate it with a virtual path on the server.

Parameters

hServer

The server handle.

nHostId

An unsigned integer that identifies the virtual host associated with the program. The value VIRTUAL_HOST_DEFAULT should be used for the default host that is created when the server is first started.

lpszVirtualPath

A pointer to a string which specifies the virtual path to the CGI program. This must be an absolute path, but does not have to specify a pre-existing virtual path or map to the directory structure of the root document directory for the server. This parameter cannot be NULL. The maximum length of the virtual path is 1024 characters.

lpszProgramFile

A pointer to a string that specifies the full path to the executable program. This parameter cannot be NULL.

lpszParameters

A pointer to a string that specifies additional parameters for the program. This value will be passed to the program as command line arguments. If the program does not require any command line parameters, this value may be NULL or point to an empty string.

lpszDirectory

A pointer to a string that specifies the current working directory for the program. If this parameter is NULL or points to an empty string, the server will use the root document directory for the virtual host.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **HttpGetServerError**.

Remarks

The **HttpRegisterProgram** function registers an executable CGI program and associates it with a virtual path. When the client issues a GET or POST command specifying the virtual path associated with the program, the program will be executed and the output return to the client.

The *lpszProgramFile* string specifies file name of the CGI program. You should not install any executable programs in the server root directory or its subdirectories. A client should never have the ability to directly access the executable file itself. It is permitted to have multiple virtual paths

that reference the same executable file. The only requirement is that the virtual path be unique for the given host. The program name may contain environment variables surrounded by % symbols. For example, %ProgramFiles% would be expanded to the **C:\Program Files** folder.

It is important to note that the program specified by *lpszProgramFile* must be an executable file, not a script or batch file. If the program name does not contain a directory path, then the standard Windows pathing rules will be used when searching for an executable file that matches the given name. It is recommended that you always provide a full path to the executable file.

The *lpszParameters* string can specify additional command line parameters that should be passed to the CGI program as arguments. This string can also contain a placeholder named "%1" that will be replaced by the virtual path associated with the program. If *lpszParameters* is NULL or a zero-length string, then no additional parameters are passed to the program.

The executable program that is registered using this program must be a console application that conforms to the CGI/1.1 specification defined in RFC 3875. Request data submitted by the client as part of a POST will be provided to the program as standard input. The output from the program must be written to standard output. The first lines of output from the program should be any response headers, followed by an empty line. Each line should be terminated with a carriage-return and linefeed (CRLF) sequence. If the CGI program outputs additional data to be processed by the client, it should provide Content-Type and Content-Length response headers.

The application can obtain a copy of the output from the command by calling the **HttpGetProgramOutput** function from within a HTTP_CLIENT_EXECUTE event handler.

When developing a CGI program, it is important to take into consideration the environment that it will be executing in. The program will be started as a child process of the server application, and will inherit the same privileges. This means that it will typically have access to the boot drive, the Windows folders and the system registry. CGI programs must ensure that all query parameters and request data submitted by the client have been validated.

If the server is running on a system with User Account Control (UAC) enabled and does not have elevated privileges, do not register a program that requires elevated privileges or has a manifest that specifies the requestedExecutionLevel as requiring administrative privileges.

Example

```
HttpRegisterProgram(hServer,  
                   VIRTUAL_HOST_DEFAULT,  
                   HTTP_METHOD_DEFAULT,  
                   _T("/order/invoice"),  
                   _T("%ProgramData%\MyServer\Programs\invoice.exe"),  
                   NULL,  
                   NULL);
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cshtsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[HttpGetProgramExitCode](#), [HttpGetProgramOutput](#), [HttpRegisterHandler](#)

HttpRenameServerLogFile Function

```
BOOL WINAPI HttpRenameServerLogFile(  
    HSERVER hServer,  
    LPCTSTR lpszFileName  
);
```

Rename or delete the current log file being updated by the server.

Parameters

hServer

The server handle.

lpszFileName

A pointer to a string that specifies the file name the current log file should be renamed to. If this parameter is NULL or an empty string, the current log file will be deleted.

Return Value

If the function succeeds, the return value is non-zero. If the server handle does not specify a valid server, the function will return zero. If logging is not currently enabled for the server, this function will return zero.

Remarks

The **HttpRenameServerLogFile** function is used to rename or delete the current log file. Note that this does not change the current log file name or disable logging by the server. It only changes the file name of the current log file, or removes the log file if the *lpszFileName* parameter is NULL. This can be useful if you want your server to perform log file rotation, archiving the current log file. By renaming the current log file, the server will automatically create a new log file with original file name.

This function must be used to rename or delete the current log file while logging is active because the server holds an open handle on the file. The application should not use the **HttpGetServerLogFile** function to obtain the log file name and then use the **MoveFileEx** or **DeleteFile** functions with that file.

To disable logging, use the **HttpSetServerLogFile** function and specify the logging format as HTTP_LOGFILE_NONE.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cshtsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[HttpGetServerLogFile](#), [HttpSetServerLogFile](#)

HttpRequireAuthentication Function

```
BOOL WINAPI HttpRequireAuthentication(  
    HSERVER hServer,  
    UINT nClientId,  
    UINT nAuthType,  
    LPCTSTR lpszRealm  
);
```

Send a response to the client indicating that authentication is required.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

nAuthType

An integer value that corresponds to a result code, informing the client if the redirection is permanent or temporary. The following values may be used:

Constant	Description
HTTP_AUTH_BASIC (1)	This option specifies the Basic authentication scheme should be used. This option is supported by all clients that support at least version 1.0 of the protocol.

lpszRealm

A pointer to a string that is displayed by a web browser to indicate to the user which username and password they should use. If this parameter is NULL or an empty string, the domain name the client used to establish the connection will be used.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **HttpGetServerError**.

Remarks

The **HttpRequireAuthentication** function can be used within a HTTP_CLIENT_COMMAND event handler to indicate to the client that it must provide a username and password to access the requested resource. The client should respond by issuing another request that includes the required credentials. To determine if a client has included credentials with its request, use the **HttpIsClientAuthenticated** function. The **HttpGetClientCredentials** function will return the username and password that was provided by the client.

Some clients may require that the session be secure if authentication is requested or display warning messages to the user if the connection is not secure. It is recommended that you enable security using the HTTP_OPTION_SECURE option if your application will require clients to authenticate before accessing specific resources.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cshtsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[HttpGetClientCredentials](#), [HttpIsClientAuthenticated](#), [HttpSendResponse](#)

HttpSendErrorResponse Function

```
BOOL WINAPI HttpSendErrorResponse(  
    HSERVER hServer,  
    UINT nClientId,  
    UINT nErrorCode,  
    LPCTSTR lpszMessage  
);
```

Send a customized error response to the specified client.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

nErrorCode

An integer value that specifies the error code that should be sent to the client. This value should correspond to the error result codes defined for HTTP in RFC 2616, which are three-digit values in the range of 400 through 599. The function will fail if an invalid error code is specified.

lpszMessage

A pointer to a string that describes the error. If this parameter is NULL or specifies a zero-length string, a default message will be selected based on the error code.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **HttpGetServerError**.

Remarks

The **HttpSendErrorResponse** function sends a response to the client indicating that an error has occurred, providing a numeric error code and HTML formatted text which may be displayed to the user. The *lpszMessage* parameter should provide a brief description of the error that will be included in the output sent to the client. Note that the message should not contain any special formatting control characters or HTML markup.

This function provides a simplified interface for sending an error response to the client. In some cases, a browser may choose to display its own error message to the user in place of the generic HTML document generated by this function. If you want your application to send a customized HTML document for a specific type of error, you should use the **HttpSendResponse** function.

If you wish to redirect the client to use an alternate URL to access the requested resource, it is recommended that you use the **HttpRedirectRequest** function rather than sending an error response.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cshtsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[HttpRequest](#), [HttpSendResponse](#)

HttpSendResponse Function

```
BOOL WINAPI HttpSendResponse(  
    HSERVER hServer,  
    UINT nClientId,  
    DWORD dwOptions,  
    LPHTTPRESPONSE LpResponse,  
    LPVOID lpvBuffer,  
    DWORD dwLength  
);
```

Send a response from the server to the specified client.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

dwOptions

An unsigned integer which specifies how the client request data will be copied. It may be one of the following values:

Constant	Description
HTTP_RESPONSE_DEFAULT (0)	The <i>lpvBuffer</i> parameter is a pointer to a block of memory that contains the response data. The number of bytes of data that in the buffer is specified by the <i>dwLength</i> parameter. This is the same as specifying the HTTP_RESPONSE_MEMORY option.
HTTP_RESPONSE_MEMORY (0x1)	The <i>lpvBuffer</i> parameter is a pointer to a block of memory that contains the response data. The number of bytes of data that in the buffer is specified by the <i>dwLength</i> parameter. The data will be sent to the client as a stream of bytes. If the server application was compiled using Unicode, it is responsibility of the application to convert any Unicode text to either ANSI or UTF-8, depending on the resource that was requested by the client.
HTTP_RESPONSE_STRING (0x2)	The <i>lpvBuffer</i> parameter is a pointer to a string buffer that contains the response data. The maximum number of bytes of data that will be sent to the client is determined by the <i>dwLength</i> parameter. If the value of the <i>dwLength</i> parameter exceeds the string length, the value will be ignored and the contents of the string will be sent up to the terminating null character. If the Unicode version of this function is called, the string will be converted to a byte array before being sent to the client.
HTTP_RESPONSE_HGLOBAL	The <i>lpvBuffer</i> parameter is an HGLOBAL memory

(0x4)	handle which references a block of memory that contains the response data. The number of bytes of data that in the buffer is specified by the dwLength parameter. The data will be sent to the client as a stream of bytes. It is the responsibility of the application to free the global memory handle after it is no longer needed.
HTTP_RESPONSE_FILE (0x8)	The lpvBuffer parameter is a pointer to a string which specifies the name of a file that contains the response data. If the file does not exist, or does not specify a regular file, this function will fail. The dwLength parameter is ignored. If the content type for the specified file is not explicitly defined in the response, the function will attempt to automatically determine the correct type based on the file name extension and/or the contents of the file.
HTTP_RESPONSE_HANDLE (0x10)	The lpvBuffer parameter is a handle to an open file and the dwLength parameter specifies the number of bytes to be read from the file and send to the client. If this option is specified, the response data will be read from the current position in the file and will advance the file pointer by the number of bytes sent to the client.
HTTP_RESPONSE_DYNAMIC (0x100)	The response data will be generated dynamically. This prevents the content length from being included in the response header, and forces the connection to close, regardless if the client has requested to keep the connection open. This option must be specified if the application wishes to use the HttpSendResponseData function to send additional data to the client.
HTTP_RESPONSE_NOCACHE (0x200)	Informs the client that the data being returned by the server should not be cached. Typically this is used in conjunction with the HTTP_RESPONSE_DYNAMIC option when the data is being generated dynamically.

lpResponse

A pointer to a **HTTPRESPONSE** structure which contains additional information about the response to the client. The structure that is passed by reference to this function must have the **dwSize** member initialized to the size of the structure or the function will fail. This parameter may be NULL, in which case a default response of "200 OK" is sent to the client along with any data specified by the **lpvBuffer** parameter.

lpvBuffer

A pointer to the buffer that will contain any response data that should be sent to the client. The **dwOptions** parameter determines if this pointer references a block of memory, a null-terminated string buffer, a global memory handle or a file name. This parameter may be NULL, in which case no data will be sent to the client. If this function is called in response to a HEAD command being sent by the client, this parameter is ignored.

dwLength

An unsigned integer that specifies the number of bytes of data to be sent to the client. If the *lpvBuffer* parameter is NULL, this value must be zero. If this function is called in response to a HEAD command being sent by the client, this parameter is ignored.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **HttpGetServerError**.

Remarks

The **HttpSendResponse** function is called within a HTTP_CLIENT_COMMAND event handler to respond to the request made by the client. This function may only be called once after a command has been received, and must be called after the **HttpReceiveRequest** function. It is only necessary for the application to call this function if it wants to implement its own custom handling for a command. It is recommended that most applications use the default command processing for standard commands such as GET and POST to ensure that the appropriate security checks are performed and the response conforms to the protocol standard.

If the HTTP_RESPONSE_HANDLE option is used to read a copy of the response data from an open file, the handle must reference a disk file that was opened using the **CreateFile** function with GENERIC_READ access. It cannot be a handle to a device or named pipe. If the *dwLength* parameter is larger than the total number of bytes available to be read from the current position in the file, the function will stop sending data to the client when it reaches the end-of-file. If the function succeeds, the file pointer is advanced by the number of bytes of response data sent to the the client. If the function fails, the file pointer is returned to its original position prior to the function being called.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cshtsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[HttpRecieveRequest](#), [HttpSendResponseData](#), [HTTPRESPONSE](#)

HttpSendResponseData Function

```
INT WINAPI HttpSendResponseData(  
    HSERVER hServer,  
    UINT nClientId,  
    LPBYTE lpBuffer,  
    DWORD dwLength,  
    LPDWORD lpdwResponse  
);
```

Send additional data to the client in response to a command.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpBuffer

A pointer to a buffer that contains the response data that should be sent to the client. This parameter cannot be NULL and must point to a valid byte buffer. If the response contains non-ASCII text characters, it should be UTF-8 encoded.

dwLength

An unsigned integer that specifies the size of the response data sent to the client. This value must be greater than zero and should never exceed the number of bytes stored in the buffer specified by the *lpBuffer* parameter.

lpdwResponse

A pointer to an unsigned integer which will contain the total number of bytes successfully sent to the client in response to the request. This parameter may be NULL, in which case it is ignored.

Return Value

If the function succeeds, the return value is the number of bytes of data sent to the client. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetServerError**.

Remarks

The **HttpSendResponseData** function is called within a HTTP_CLIENT_COMMAND event handler to send data to the client in response to a request. This function can only be used to send dynamically generated content after the **HttpSendResponse** function has been called. The HTTP_RESPONSE_DYNAMIC option must have been specified when responding to the client or this function will fail.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cshtsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

HttpServerAsyncNotify Function

```
BOOL WINAPI HttpServerAsyncNotify(  
    HSERVER hServer,  
    HWND hWnd,  
    UINT uMsg  
);
```

Enable or disable asynchronous notification of changes in server status.

Parameters

hServer

The server handle.

hWnd

A handle to the window whose window procedure will receive the notification message.

uMsg

The user-defined message that will be sent to the notification window.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call the **HttpGetServerError** function.

Remarks

The **HttpServerAsyncNotify** function is used by an application to enable or disable asynchronous notifications. The message window is typically the main UI window and these notifications are used signal to the application that it should update the user interface. If the *hWnd* parameter is not NULL, it must specify a valid window handle and the user-defined message must have a value of **WM_USER** or higher. The application cannot specify a notification message that is reserved by the operating system. The pseudo-handle **HWND_BROADCAST** cannot be specified as the notification window. If the *hWnd* parameter is NULL, notifications for the specified server will be disabled.

When asynchronous notifications are enabled for a server, the server will post the user-defined message to the window whenever there is a change in status or after a client has connected or disconnected from the server. The *wParam* message parameter will contain the notification message and the *lParam* message parameter will contain the handle to the server or the client ID. The following notification messages are defined:

Constant	Description
HTTP_NOTIFY_STARTUP	This notification is sent when the server has started and is preparing to accept client connections. This notification is only sent once, and only if asynchronous notifications are enabled immediately after the HttpServerStart function is called. This message will not be sent once the server has begun accepting client connections or when notification messages are disabled and then subsequently re-enabled at a later time. The <i>lParam</i> message parameter will specify the handle to the server.
HTTP_NOTIFY_LISTEN	This notification is sent when the server is listening for

	<p>client connections. This notification message may be sent to the application multiple times over the lifetime of the server. If the server was suspended, this notification will be sent after the application calls the HttpServerResume function to resume accepting client connections. The <i>lParam</i> message parameter will specify the handle to the server.</p>
HTTP_NOTIFY_SUSPEND	<p>This notification is sent when the server suspends accepting new connections because the application has called the HttpServerSuspend function. This notification message may be sent to the application multiple times over the lifetime of the server. The <i>lParam</i> message parameter will specify the handle to the server.</p>
HTTP_NOTIFY_RESTART	<p>This notification is sent when the server is restarted using the HttpServerRestart function. Note that the server socket handle provided by the <i>lParam</i> message parameter will specify the new socket handle of the restarted server instance, not the original socket handle. The <i>lParam</i> message parameter will specify the handle to the server.</p>
HTTP_NOTIFY_CONNECT	<p>This notification is sent when the server accepts a client connection and the thread that manages the client session has begun processing network events for that client. This message notification will not be sent if the client connection is rejected by the server. The <i>lParam</i> message parameter will specify the unique ID of the client that connected to the server.</p>
HTTP_NOTIFY_DISCONNECT	<p>This notification is sent when the client disconnects from the server and the client socket has been closed. This notification message may not occur for each client session that is forced to terminate as the result of the server being stopped using the HttpServerStop function. The <i>lParam</i> message parameter will specify the unique ID of the client that disconnected from the server.</p>
HTTP_NOTIFY_SHUTDOWN	<p>This notification is sent when the server thread is in the process of terminating. At the time the application processes this notification message, the server handle in <i>lParam</i> will reference the defunct server and cannot be used with other server functions. The <i>lParam</i> message parameter will specify the handle to the server.</p>

If asynchronous notifications are enabled, you should never use those notifications as a replacement for an event handler. When an event occurs, the callback function that handles the event is invoked in the context of the thread that manages the client session. The application should exchange data with the client within that event handler and not in response to a notification message. These notification messages should only be used to update the application

UI in response to changes in the status of the server.

The HTTP_NOTIFY_CONNECT and HTTP_NOTIFY_DISCONNECT notifications are different from the other server notifications because the *lParam* message parameter does not specify the server handle, but rather the unique client ID associated with the session that connected to or disconnected from the server. Use the **HttpGetClientServer** function to obtain a handle to the server that created the client session. Note that at the time the application processes the HTTP_NOTIFY_DISCONNECT notification message, the client session will have already terminated.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include ctools10.h

Import Library: cshtsv10.lib

See Also

[HttpGetClientServer](#), [HttpServerStart](#)

HttpServerDisableTrace Function

```
BOOL WINAPI HttpServerDisableTrace();
```

Disable the logging of network function calls.

Parameters

None.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **HttpGetServerError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cshtsv10.lib

[HttpServerEnableTrace](#)

HttpServerEnableTrace Function

```
BOOL WINAPI HttpServerEnableTrace(  
    LPCTSTR lpszTraceFile,  
    DWORD dwTraceFlags  
);
```

Enable the logging of network function calls to a file.

Parameters

lpszTraceFile

A pointer to a string that specifies the name of the log file. If this parameter is NULL or points to an empty string, a log file is created in the temporary directory for the current user.

dwTraceFlags

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
TRACE_DEFAULT (0)	All function calls are written to the trace file. This is the default value.
TRACE_ERROR (1)	Only those function calls which fail are recorded in the trace file.
TRACE_WARNING (2)	Only those function calls which fail, or return values which indicate a warning, are recorded in the trace file.
TRACE_HEXDUMP (4)	All functions calls are written to the trace file, plus all the data that is sent or received is displayed, in both ASCII and hexadecimal format.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call [HttpGetServerError](#).

Remarks

When trace logging is enabled, the log file is opened, appended to and closed for each socket function call. Using the same file name, you can do the same in your application to add additional information to the file if needed. This can provide an application-level context for the entries made by the library. Make sure that the file is closed after the data has been written. If a file name is not specified by the caller, a file named **cstrace.log** will be created in the temporary directory for the current user.

The TRACE_HEXDUMP option can produce very large files, since all data that is being sent and received by the application is logged. To reduce the size of the file, you can enable and disable logging around limited sections of code that you wish to analyze.

To redistribute an application that includes this debug logging functionality, the **cstrcv10.dll** library must be included as part of the installation package. This library provides the trace logging features, and if it is not available the **HttpServerEnableTrace** function will fail. Note that this is a standard Windows DLL and does not need to be registered, it only needs to be redistributed with your application.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cshtsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[HttpServerDisableTrace](#)

HttpServerInitialize Function

```
BOOL WINAPI HttpServerInitialize(  
    LPCTSTR LpszLicenseKey,  
    LPINITDATA LpData  
);
```

The **HttpServerInitialize** function initializes the library and validates the specified license key at runtime.

Parameters

LpszLicenseKey

Pointer to a string that specifies the runtime license key to be validated. If this parameter is NULL, the library will validate the development license installed on the local system.

LpData

Pointer to an INITDATA data structure. This parameter may be NULL if the initialization data for the library is not required.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **HttpGetServerError**. All other functions will fail until a license key has been successfully validated.

Remarks

This must be the first function that an application calls before using any of the other functions in the library. When a NULL license key is specified, the library will only function on the development system. Before redistributing the application to an end-user, you must insure that this function is called with a valid license key.

If the *LpData* argument is specified, it must point to an INITDATA structure which has been initialized by setting the *dwSize* member to the size of the structure. All other structure members should be set to zero. If the function is successful, then the INITDATA structure will be filled with identifying information about the library.

Although it is only required that **HttpServerInitialize** be called once for the current process, it may be called multiple times; however, each call must be matched by a corresponding call to **HttpServerUninitialize**.

This function dynamically loads other system libraries and allocates thread local storage. If you are calling the functions in this library from within another DLL, it is important that you do not call the **HttpServerInitialize** or **HttpServerUninitialize** functions from the **DllMain** function because it can result in deadlocks or access violation errors. If the DLL is linked with the C runtime library (CRT), it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cshtsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

Copyright © 2023 Catalyst Development Corporation. All rights reserved.

HttpServerProc Function

```
VOID CALLBACK HttpServerProc(  
    HSERVER hServer,  
    UINT nClientId,  
    UINT nEventId,  
    DWORD dwError,  
    DWORD_PTR dwParam  
);
```

The **HttpServerProc** function is an application-defined callback function that processes events generated by the server process.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client that has issued a request to the server.

nEventId

An unsigned integer which specifies which event occurred. For a list of events, see [Server Event Constants](#).

dwError

An unsigned integer which specifies any error that occurred. If no error occurred, then this parameter will be zero. The **HttpGetServerError** function can be used to obtain additional information about the error code.

dwParam

A user-defined integer value which was specified when the server was started. This value is guaranteed to be large enough to store a pointer or handle value on both 32-bit and 64-bit platforms.

Return Value

None.

Remarks

The HTTP_CLIENT_COMMAND event can be used to filter commands issued by the client. If the command performs an operation on a file or directory, the **HttpGetCommandFile** function can be used to obtain the file name on the server that the client specified. It is possible for the application to change the file name using the **HttpSetCommandFile** function to direct the server to use a different file than the one specified by the client. If the file name is changed and the event handler returns a value of zero, the server will perform the default action for the command using the new file name.

The callback function will be called in the context of the thread that is currently managing the client session. You must ensure that any access to global or static variables are synchronized, otherwise the results may be unpredictable. It is recommended that you do not declare any static variables within the callback function itself.

If the application has a graphical user interface, you should never attempt to directly modify a UI control from within an event handler. Controls should only be modified by the same UI thread that created their window. To change the user interface in response to a server event, use the

HttpServerAsyncNotify function to enable asynchronous notifications and update the UI in response to the notification message.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cshtsv10.lib

See Also

[HttpServerAsyncNotify](#), [HttpServerStart](#)

HttpServerRestart Function

```
HSERVER WINAPI HttpServerRestart(  
    HSERVER hServer  
);
```

Restart the server, terminating all active client sessions.

Parameters

hServer

The server handle.

Return Value

If the function succeeds, the return value is the new handle for the specified server. If the function fails, the return value is INVALID_SERVER. To get extended error information, call

HttpGetServerError.

Remarks

The **HttpServerRestart** function will restart the specified server, terminating all active client sessions. The server handle that is returned by the function is the handle for the new server instance, and the old handle value is no longer valid. If the function is unable to restart the server for any reason, the server thread is terminated. The server retains all of the configuration parameters from the previous instance, however the statistical information (such as the number of clients, files transferred, etc.) will be reset.

If an application calls this function from within an event handler, the active client session (the client for which the event handler was invoked) may not get a disconnect notification. It is recommended that this function only be called by the same thread that created the server using the **HttpServerStart** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cshtsv10.lib

See Also

[HttpServerStart](#), [HttpServerStop](#)

HttpServerResume Function

```
BOOL WINAPI HttpServerResume(  
    HSERVER hServer  
);
```

Resume accepting client connections.

Parameters

hServer

Handle to the server.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero.

To get extended error information, call **HttpGetServerError**.

Remarks

The **HttpServerResume** function instructs the server to resume accepting new client connections after the **HttpServerSuspend** function has been called.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cshtsv10.lib

See Also

[HttpServerRestart](#), [HttpServerStart](#), [HttpServerStop](#), [HttpServerSuspend](#), [HttpServerThrottle](#)

HttpServerStart Function

```
HSERVER WINAPI HttpServerStart(  
    LPCTSTR lpszLocalHost,  
    UINT nLocalPort,  
    DWORD dwOptions,  
    LPHTTPSERVERCONFIG lpServerConfig,  
    HTTPSETPROCBASE lpServerProc,  
    DWORD_PTR dwServerParam,  
    LPSECURITYCREDENTIALS lpCredentials  
);
```

The **HttpServerStart** function begins listening for client connections on the specified local address and port number. The server is started in its own thread and manages the client sessions independently of the calling thread. All interaction with the server and its client sessions takes place inside the callback function specified by the caller.

Parameters

lpszLocalHost

A pointer to a string which specifies the local hostname or IP address address that the server should be bound to. If this parameter is NULL or an empty string, then an appropriate address will automatically be used. If a specific address is used, the server will only accept client connections on the network interface that is bound to that address.

nLocalPort

The port number the server should use to accept client connections. If a value of zero is specified, the server will use the standard port number 21 to listen for connections, or port 990 if the server is configured to use implicit SSL. The port number used by the application must be unique and multiple instances of a server cannot use the same port number. It is recommended that a port number greater than 5000 be used for private, application-specific implementations.

dwOptions

An unsigned integer value that specifies the options used when creating an instance of the server. For a list of options, see [Server Option Constants](#).

lpServerConfig

A pointer to an **HTTPSERVERCONFIG** structure that specifies the configuration options for the server. If this parameter is NULL, then default configuration parameters will be used that starts the server in a restrictive mode.

lpServerProc

Specifies the address of the application defined callback function. For more information about the callback function, see the description of the **HttpServerProc** callback function. If this parameter is NULL, a default internal handler is used to process client commands.

dwServerParam

A user-defined integer value that is passed to the callback function. If the *lpServerProc* parameter is NULL, this value should be zero. This value is guaranteed to be large enough to store a pointer or handle value on both 32-bit and 64-bit platforms.

lpCredentials

Pointer to a **SECURITYCREDENTIALS** structure. If this parameter is NULL, the default security credentials for the server host name will be used. If security is enabled for the server, it is recommended that you provide a pointer to this structure with specific information about the

server certificate that should be used. If the security options are not specified in the server configuration, this parameter is ignored.

Return Value

If the function succeeds, the return value is a handle to a server session. If the function fails, the return value is `INVALID_SERVER`. To get extended error information, call **HttpGetServerError**.

Remarks

In most cases, the *lpzLocalHost* parameter should be a NULL pointer or an empty string. On a multihomed system, this will enable the server to accept connections on any appropriately configured network adapter. Specifying a hostname or IP address will limit client connections to that particular address. Note that the hostname or address must be one that is assigned to the local system, otherwise an error will occur.

If an IPv6 address is specified as the local address, the system must have an IPv6 stack installed and configured, otherwise the function will fail.

To listen for connections on any suitable IPv4 interface, specify the special dotted-quad address "0.0.0.0". You can accept connections from clients using either IPv4 or IPv6 on the same socket by specifying the special IPv6 address "::0", however this is only supported on Windows 7 and Windows Server 2008 R2 or later platforms. If no local address is specified, then the server will only listen for connections from clients using IPv4. This behavior is by design for backwards compatibility with systems that do not have an IPv6 TCP/IP stack installed.

The handle returned by this function references the listening socket that was created when the server was started. The service is managed in another thread, and all interaction with the server and active client connections are performed inside the event handler. To disconnect all active connections, close the listening socket and terminate the server thread, call the **HttpServerStop** function.

The host UUID that is defined as part of the server configuration should be generated using the **uuidgen** utility that is included with the Windows SDK. You should not use the UUID that is provided in the example code, it is for demonstration purposes only. If no host UUID is specified in the server configuration, an ephemeral UUID will be generated automatically when the server is started.

If the server is started with security enabled, the *lpCredentials* parameter should be used to provide the server certificate information in a **SECURITYCREDENTIALS** structure. If the pointer is NULL, this function will search for a certificate that matches the hostname provided as part of the server configuration. This requires that the server certificate be installed in the personal certificate store of the current process user, and it must have a private key associated with it. To use a certificate with a different name, or one that is stored in a PFX file, a **SECURITYCREDENTIALS** structure must be defined and passed to this function.

Example

```
HSERVER hServer;  
HTTPSERVERCONFIG httpConfig;  
  
// Initialize the server configuration  
ZeroMemory(&httpConfig, sizeof(HTTPSERVERCONFIG));  
httpConfig.dwSize = sizeof(httpConfig);  
httpConfig.nMaxClients = 100;  
httpConfig.nMaxClientsPerAddress = 8;  
httpConfig.nMaxRequests = 5;  
httpConfig.nLogFormat = HTTP_LOGFILE_EXTENDED;
```

```
httpConfig.nLogLevel = 5;
httpConfig.lpszIdentity = _T("MyProgram");
httpConfig.lpszHostName = _T("server.company.com");
httpConfig.lpszHostUuid = _T("10000000-1000-1000-1000-100000000000");
httpConfig.lpszDirectory = _T("%ProgramData%\MyProgram\Files");
httpConfig.lpszLogFile = _T("%ProgramData%\MyProgram\Server.log");

// Start the server
hServer = HttpServerStart(lpszLocalHost,
                        HTTP_PORT_DEFAULT,
                        HTTP_SERVER_DEFAULT,
                        &httpConfig,
                        lpEventHandler,
                        0,
                        NULL);
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cshtsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[HttpEnumServerClients](#), [HttpServerProc](#), [HttpServerRestart](#), [HttpServerStop](#), [HTTPSERVERCONFIG](#), [SECURITYCREDENTIALS](#)

HttpServerStop Function

```
BOOL WINAPI HttpServerStop(  
    HSERVER hServer  
);
```

Stop the server, terminating all active client sessions and releasing the resources that were allocated for the server.

Parameters

hServer

The server handle.

Return Value

If the function succeeds, the return value is non-zero. If the server handle is invalid, the function will return a value of zero.

Remarks

The **HttpServerStop** function instructs the server to stop accepting client connections, disconnects all active client connections and terminates the thread that is managing the server session. The handle is no longer valid after the server has been stopped and should no longer be used. Note that it is possible that the actual handle value may be re-used at a later point when a new server is started. An application should always consider the server handle to be opaque and never depend on it being a specific value.

If an application calls this function from within an event handler, the active client session (the client for which the event handler was invoked) may not get a disconnect notification. It is recommended that this function only be called by the same thread that created the server using the **HttpServerStart** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `cshtsv10.lib`

See Also

[HttpServerRestart](#), [HttpServerStart](#)

HttpServerSuspend Function

```
BOOL WINAPI HttpServerSuspend(  
    HSERVER hServer  
);
```

Suspend the server and reject new client connections.

Parameters

hServer

Handle to the server.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **HttpGetServerError**.

Remarks

The **HttpServerSuspend** function instructs the server to suspend accepting new client connections. Any incoming client connections will be rejected with an error message indicating that the server is currently unavailable. To resume accepting client connections, call the **HttpServerResume** function. Suspending the server will have no effect on clients that have already established a connection with the server.

It is recommended that you only suspend a server if absolutely necessary, and only for brief periods of time. If you want to limit the number of active client connections or control the connection rate for clients, use the **HttpServerThrottle** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cshtsv10.lib

See Also

[HttpServerRestart](#), [HttpServerResume](#), [HttpServerStart](#), [HttpServerStop](#), [HttpServerThrottle](#)

HttpServerThrottle Function

```
BOOL WINAPI HttpServerThrottle(  
    HSERVER hServer,  
    UINT nMaxClients,  
    UINT nMaxClientsPerAddress,  
    DWORD dwConnectionRate  
);
```

The **HttpServerThrottle** function limits the number of active client connections, connections per address and connection rate.

Parameters

hServer

Handle to the server.

nMaxClients

A value which specifies the maximum number of clients that may connect to the server. A value of zero specifies that there is no fixed limit to the number of client connections.

nMaxClientsPerAddress

A value which specifies the maximum number of clients that may connect to the server from the same IP address. A value of zero specifies that there is no fixed limit to the number of client connections per address. By default, there is a limit of four client connections per address.

dwConnectionRate

A value which specifies a restriction on the rate of client connections, limiting the number of connections that will be accepted within that period of time. A value of zero specifies that there is no restriction on the rate of client connections. The higher this value, the fewer the number of connections that will be accepted within a specific period of time. By default, there is no limit on the client connection rate.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **HttpGetServerError**.

Remarks

The **HttpServerThrottle** function is used to limit the number of connections and the connection rate to minimize the potential impact of a large number of client connections over a short period of time. This can be used to protect the server from a client application that is malfunctioning or a deliberate denial-of-service attack in which the attacker attempts to flood the server with connection attempts.

If the maximum number of client connections or maximum number of connections per address is exceeded, the server will reject subsequent connection attempts until the number of active client sessions drops below the specified threshold. Note that adjusting these values lower than the current connection limits will not affect clients that have already connected to the server. For example, if the **HttpServerStart** function is called with the maximum number of clients set to 100, and then **HttpServerThrottle** is called lowering that value to 75, no existing client connections will be affected by the change. However, the server will not accept any new connections until the number of active clients drops below 75.

Increasing the connection rate value will force the server to slow down the rate at which it will

accept incoming client connection requests. For example, setting this parameter to a value of 1000 would limit the server to accepting one client connection every second, while a value of 250 would allow the server to accept four client connections per second. Note that significantly increasing the amount of time the server must wait to accept client connections can exceed the connection backlog queue, resulting in client connections being rejected.

It is recommended that you always specify conservative connection limits for your server application based on expected usage. Allowing an unlimited number of client connections can potentially expose the system to denial-of-service attacks and should never be done for servers that are accessible over the Internet.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cshtsv10.lib

See Also

[HttpServerRestart](#), [HttpServerResume](#), [HttpServerStart](#), [HttpServerSuspend](#)

HttpServerUninitialize Function

```
VOID WINAPI HttpServerUninitialize();
```

The **HttpServerUninitialize** function terminates the use of the library.

Parameters

There are no parameters.

Return Value

None.

Remarks

An application is required to perform a successful **HttpServerInitialize** call before it can call any of the other library functions. When it has completed the use of library, the application must call **HttpServerUninitialize** to allow the library to free any resources allocated on behalf of the process. Any pending blocking or asynchronous calls in this process are canceled without posting any notification messages, and all sockets that were opened by the process are closed.

There must be a call to **HttpServerUninitialize** for every successful call to **HttpServerInitialize** made by a process. Operations for all threads in the server are terminated.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cshtsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[HttpServerInitialize](#), [HttpServerStart](#), [HttpServerStop](#)

HttpSetClientAccess Function

```
BOOL WINAPI HttpSetClientAccess(  
    HSERVER hServer,  
    UINT nClientId,  
    DWORD dwUserAccess  
);
```

Change the access rights associated with the specified client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

dwUserAccess

An unsigned integer which specifies one or more user access rights. For a list of user access rights that can be granted to the client, see [User and File Access Constants](#).

Return Value

If the function succeeds, the return value is non-zero. If the server handle and client ID do not specify a valid client session, the function will return zero. This function can only be used with authenticated clients. If the client session has not been authenticated, the return value will be zero.

Remarks

The **HttpSetClientAccess** function can change the multiple access rights for a client session. The **HttpEnableClientAccess** function can be used to grant or revoke a specific permission for the client session.

If the *dwUserAccess* parameter has a value of HTTP_ACCESS_DEFAULT, then default permissions will be granted to the client session based on the configuration of the server. This is the recommended value for most clients. It is important to consider the implications of changing the access permissions granted to a client session. For example, if you do not grant clients HTTP_ACCESS_READ permission, it can effectively disable the site because the server will return 403 Forbidden errors for all GET and HEAD requests.

This function should typically be called in the HTTP_CLIENT_CONNECT event handler to assign general permissions to the client, or in the HTTP_CLIENT_COMMAND event handler after the client has issued a request and provided any authentication credentials that are required.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cshtsv10.lib

See Also

[HttpAuthenticateClient](#), [HttpEnableClientAccess](#), [HttpGetClientAccess](#)

HttpSetClientHeader Function

```
BOOL WINAPI HttpSetClientHeader(  
    HSERVER hServer,  
    UINT nClientId,  
    UINT nHeaderType,  
    LPCTSTR lpszHeaderName,  
    LPCTSTR lpszHeaderValue  
);
```

Create or change the value of a request or response header for the client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

nHeaderType

Specifies the type of header to create or modify. It may be one of the following values:

Constant	Description
HTTP_HEADERS_REQUEST	Change a request header that was provided by the client. Request header values provide additional information to the server about the type of request being made.
HTTP_HEADERS_RESPONSE	Change a response header that was created by the server. Response header values provide additional information to the client about the type of information that is being returned by the server.

lpszHeaderName

A pointer to a string that specifies the name of the header that should be created or modified. Header names are not case-sensitive and should not include the colon which acts as a delimiter that separates the header name from its value. This parameter cannot be a NULL pointer or an empty string.

lpszHeaderValue

A pointer to a string that specifies the new value of the header. If this parameter is a NULL pointer or an empty string, it has the same effect as deleting the header value from the list of request or response headers.

Return Value

If the function succeeds, the return value is non-zero. If the server handle and client ID do not specify a valid client session, the function will return zero. If the function fails, the **HttpGetServerError** function will return more information about the last error that has occurred.

Remarks

The **HttpSetClientHeader** function will change the value of a request or response header for the specified client session. If the *lpszHeaderName* value matches an existing header field, its value will be replaced. If the header name is not defined, then a new header will be created with the

given value. You should not change the value of most standard response header values unless you are certain of the impact that it would have on the normal operation of the client.

If you wish to define a custom header value that would be included in the response to a client request, you should prefix the header name with "X-" to avoid potential conflicts with the standard response headers. For example, if you wanted to identify a customer, you could create a header field with the name "X-Customer-ID" and set the value to the customer ID number. The client application would receive this custom header value as part of the response to its request for a document.

Refer to [Hypertext Transfer Protocol Headers](#) for a list of common request and response headers that are used.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cshtsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

HttpSetClientIdleTime Function

```
UINT WINAPI HttpSetClientIdleTime(  
    HSERVER hServer,  
    UINT nClientId,  
    UINT nTimeout  
);
```

Change the idle timeout period for the specified client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

nTimeout

An unsigned integer value that specifies the number of seconds that the client may remain idle. If this value is zero, the default idle timeout period for the server will be used.

Return Value

If the function succeeds, the return value is the previous client idle timeout period in seconds. If the server handle and client ID do not specify a valid client session, the function will return zero.

Remarks

The **HttpSetClientIdleTime** function will change the number of seconds that the client may remain idle before being automatically disconnected by the server. The minimum timeout period for a client is 10 seconds, the maximum is 300 seconds (5 minutes). The idle time of a client session is based on the last time a command was issued to the server or when a data transfer completed.

If the value INFINITE is specified as the timeout period, the client activity timer will be refreshed, extending the idle timeout period for the session. This is typically done inside an event handler to prevent the client from being disconnected due to inactivity.

To obtain the current idle timeout period for a client, along with the amount of time the client has been idle, use the **HttpGetClientIdleTime** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cshtsv10.lib

See Also

[HttpGetClientIdleTime](#)

HttpSetClientVariable Function

```
BOOL WINAPI HttpSetClientVariable(  
    HSERVER hServer,  
    UINT nClientId,  
    LPCTSTR lpszName,  
    LPCTSTR lpszValue  
);
```

Create or change the value of a CGI environment variable for the specified client.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszName

A pointer to a string that specifies the name of the environment variable that should be created or modified. Environment variables are not case-sensitive and should not include the equal sign which acts as a delimiter that separates the variable name from its value. This parameter cannot be a NULL pointer or an empty string.

lpszValue

A pointer to a string that specifies the new value of the environment variable. If this parameter is a NULL pointer or an empty string, it has the same effect as deleting the variable from the environment block for the client session.

Return Value

If the function succeeds, the return value is non-zero. If the server handle and client ID do not specify a valid client session, the function will return zero. If the function fails, the **HttpGetServerError** function will return more information about the last error that has occurred.

Remarks

The **HttpSetClientVariable** function will change the value of a environment variable for the specified client session. If the *lpszName* value matches an existing variable, its value will be replaced. If the variable is not defined, then a new variable will be created with the given value. The value of an environment variable can be obtained using the **HttpGetClientVariable** function.

The server will automatically create a number of different environment variables that will be passed to a program or script executed by the server. These variables are defined in RFC 3875 as part of the Common Gateway Interface (CGI) 1.1 specification. The following variables are defined by the server and should not be modified directly by the application:

Variable Name	Description
AUTH_TYPE	The authorization scheme used by the server to authenticate the client session
CONTENT_LENGTH	The length of the request data provided by the client
CONTENT_TYPE	The MIME type that identifies the type of content provided by the client

DOCUMENT_ROOT	The full path to the local document root directory on the server
GATEWAY_INTERFACE	The version of the Common Gateway Interface that is being used by the server
PATH_INFO	The resource or sub-resource that is to be returned by the program or script
PATH_TRANSLATED	The path information mapped to the server root document directory structure
QUERY_STRING	The URL encoded query parameters passed to the program or script
REMOTE_ADDR	The network address of the client sending the request to the server
REMOTE_HOST	The same value as the REMOTE_ADDR variable
REMOTE_USER	The username specified as part of the authentication credentials provided by the client
REQUEST_METHOD	The method used by the client to request the resource
REQUEST_URI	The URI for the script provided by the client
SCRIPT_FILENAME	The full path to the program or script on the server
SCRIPT_NAME	The path to the program or script specified by the client
SERVER_NAME	The hostname or IP address of the server that the client connected to
SERVER_PORT	The port number that the client used to connect to the server
SERVER_PORT_SECURE	This variable has a value of "1" if the client connection to the server is secure
SERVER_PROTOCOL	The version of the server protocol used
SERVER_SOFTWARE	The server identity string which specifies the application name and version

In addition to the environment variables listed, the server will also create variables that are prefixed with "HTTP_" that are set to the value of request headers that are not otherwise defined. For example, the HTTP_USER_AGENT variable will be set to the value of the User-Agent header provided by the client as part of the request.

Calling the **HttpSetClientVariable** function in response to an HTTP_CLIENT_EXECUTE event notification will have no effect because it occurs after the CGI program or script has completed execution. To create or modify environment variables for the client session, it should be done in response to the HTTP_CLIENT_COMMAND event notification.

This function will not change the environment block for the server process. Each client session is allocated its own private environment block which is inherited by the CGI program. When the client session terminates, the memory allocated for its environment is released.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cshtsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

HttpSetCommandFile Function

```
BOOL WINAPI HttpSetCommandFile(  
    HSERVER hServer,  
    UINT nClientId,  
    LPCTSTR lpszFileName  
);
```

Change the name of the local file or directory that is the target of the current command.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszFileName

A pointer to a string that specifies the new file name. This parameter may be NULL to specify that the original file or directory name should be used.

Return Value

If the function succeeds, the return value is non-zero. If the server handle and client ID do not specify a valid client session, the function will return zero.

Remarks

The **HttpSetCommandFile** function is used by the application to change the target file or directory name for the current command from within an HTTP_EVENT_COMMAND event handler. This can be used to effectively redirect the client to use a different file than the one that was actually requested. For example, if the client issues the GET command to download a file from the server, this function can be used to redirect the command to use a different file name. To obtain the full path to the file or directory that is the target of the current command, use the **HttpGetCommandFile** function.

The *lpszFileName* parameter specifies the path to the new file or directory name. If the path is absolute, then it will be used as-is. If the path is relative, it will be relative to the root directory for the client session. Because the root document directory for the client can depend on the hostname that the client used when connecting to the server, it is recommended that you always use an absolute path. The full path to this file is not limited to the server root directory or its subdirectory, it can specify a file anywhere on the local system. If this parameter is a NULL pointer, or points to an empty string, then the server will revert to using the actual file or directory name specified by the command. This enables the application to effectively undo a previous call to this function to change the target file name.

Typically this function would be used to redirect a client to a file or directory that it may not normally have access to. Exercise caution when using this function to provide access to data that is stored outside of the server root directory. Incorrect use of this function could expose the server to security risks or cause unpredictable behavior by client applications. In most cases it is preferable to use the **HttpAddVirtualPath** function to create a virtual path or file name on the server, or the **HttpRedirectRequest** function to request the client use a different URL to access the resource.

This function should only be called within the context of the HTTP_EVENT_COMMAND event, and only for those commands that perform an action on a file or directory. If the current command

does not target a file or directory, this function will return zero and the last error code will be set to ST_ERROR_INVALID_COMMAND.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cshtsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

HttpSetServerError Function

```
VOID WINAPI HttpSetServerError(  
    HSERVER hServer,  
    DWORD dwError  
);
```

Set the last error code for the specified server session.

Parameters

hServer

The server handle.

dwError

An unsigned integer that specifies an error code.

Return Value

None.

Remarks

Error codes are unsigned 32-bit values which are private to each server session. Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_SERVER or HTTP_ERROR.

If the *hServer* parameter is specified as INVALID_SERVER, this function will set the last error code for the current thread, but will not change the error code associated with any server session. This should only be done if the application does not have access to a valid server handle.

If the *dwError* parameter is specified with a value of zero, this effectively clears the error code for the last function that failed. Those functions which clear the last error code when they succeed are noted on the function reference page.

Applications can retrieve the value saved by this function by using the **HttpGetServerError** function to determine the specific reason for a function failure.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cshtsv10.lib

See Also

[HttpGetCommandResult](#), [HttpGetServerError](#), [HttpSendResponse](#)

HttpSetServerIdentity Function

```
BOOL WINAPI HttpSetServerIdentity(  
    HSERVER hServer,  
    LPCTSTR lpszIdentity  
);
```

Change the identity of the specified server.

Parameters

hServer

The server handle.

lpszIdentity

A pointer to a string that identifies the server. If this parameter is NULL or specifies an empty string, the current identity for the server is reset to a default value. The maximum length of the identity string is 64 characters, including the terminating null character.

Return Value

If the function succeeds, the return value is non-zero. If the server handle is invalid, the function will return a value of zero.

Remarks

The **HttpSetClientIdentity** function changes a string value used by the server to identify itself to clients. The identity string does not have any standard format and is used for informational purposes only. Typically it consists of the application name and a version number. Changing the server identity has no effect on the operation of the server. To obtain the identity string currently associated with the server, use the **HttpGetServerIdentity** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cshtsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[HttpGetServerIdentity](#)

HttpSetServerLogFile Function

```
BOOL WINAPI HttpSetServerLogFile(  
    HSERVER hServer,  
    UINT nLogFormat,  
    UINT nLogLevel,  
    LPCTSTR lpszFileName  
);
```

Change the current log format, level of detail and file name.

Parameters

hServer

The server handle.

nLogFormat

An integer value that specifies the format used when creating or updating the server log file. The following formats are supported:

Constant	Description
HTTP_LOGFILE_NONE (0)	This value specifies that the server should not create or update a log file.
HTTP_LOGFILE_COMMON (1)	This value specifies that the log file should use the common log format that records a subset of information in a fixed format. This log format usually only provides information about GET, PUT and POST requests.
HTTP_LOGFILE_COMBINED (2)	This value specifies that the server should use the combined log file format. This format is similar to the common format, however it includes the client referrer and user agent. This is the format that most Apache web servers use by default.
HTTP_LOGFILE_EXTENDED (3)	This value specifies that the log file should use the standard W3C extended log file format. This is an extensible format that can provide additional information about the client session. This format typically generates the largest logfiles.

nLogLevel

An integer value that specifies the level of detail that should be generated in the log file. The minimum value is 1 and the maximum value is 10. If this parameter is zero, it is the same as specifying a log file format of HTTP_LOGFILE_NONE and will disable logging by the server.

lpszFileName

A pointer to a string that specifies the name of the log file that should be created or appended to. If the server was configured with logging enabled and this parameter is NULL or an empty string, the current log file name will not be changed. If the log file does not exist, it will be created. If it does exist, the contents of the log file will be appended to.

Return Value

If the function succeeds, the return value is non-zero. If the server handle does not specify a valid

server, the function will return zero.

Remarks

The **HttpSetServerLogFile** function can be used to change the current log file name, the format of the log file or the level of detail recorded in the log file. In some situations it may be desirable to delete the current log file contents when changing the format or ensure that a new log file is created. To do this, combine the *nLogFormat* parameter with the constant HTTP_LOGFILE_DELETE.

The higher the value of the *nLogLevel* parameter, the greater the level of detail that is recorded by the server. A log level of 1 instructs the server to only record GET, POST and PUT requests, while a level of 10 instructs the server to record all commands processed by the server. Because a higher level of logging detail can negatively impact the performance of the server, it is recommended that you do not exceed a level of 5 for most applications. A log level of 10 should only be used for debugging purposes.

Example

```
UINT nLogFormat = HTTP_LOGFILE_NONE;
UINT nLogLevel = 0;
UINT nNewLevel = 5;
BOOL bChanged = FALSE;

// Change the level of detail for the current log file if logging
// has been enabled and the current level is a lower value

if (HttpGetServerLogFile(hServer, &nLogFormat, &nLogLevel, NULL, 0))
{
    if (nLogFormat != HTTP_LOGFILE_NONE && nLogLevel < nNewLevel)
        bChanged = HttpSetServerLogFile(hServer, nLogFormat, nNewLevel, NULL);
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstoos10.h

Import Library: cshtsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

HttpSetServerName Function

```
BOOL WINAPI HttpSetServerName(  
    HSERVER hServer,  
    UINT nClientId,  
    LPCTSTR lpszHostName  
);
```

Change the host name assigned to the specified server or client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session. This value may be zero.

lpszHostName

A pointer to a string that specifies the new host name assigned to the server or client session. If this value is NULL or points to an empty string, the current host name will be changed to use the default host name.

Return Value

If the function succeeds, the return value is non-zero. If either the server handle or the client ID is invalid, or the buffer is not large enough to store the complete hostname, the function will return a value of zero.

Remarks

This function will change the host name assigned to the specified client session. If the *nClientId* parameter has a value of zero, the function will change default host name that was assigned to the server as part of the server configuration. If the *nClientId* parameter specifies a valid client session and the *lpszHostName* parameter is NULL, the host name associated with the client session will be changed to the current host name assigned to the server.

When a client connects to the server, it can specify the host name that it used to establish the connection by sending the HOST command. This is typically used with virtual hosting, where one server may accept client connections for multiple domains. The **HttpGetServerName** function will return the host name specified by the client, and **HttpSetServerName** can be used by the application to either explicitly assign a different host name to the client session, or override the host name provided by the client.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cshtsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[HttpGetServerAddress](#), [HttpGetServerName](#)

HttpSetServerPriority Function

```
INT WINAPI HttpSetServerPriority(  
    HSERVER hServer,  
    INT nPriority  
);
```

Change the priority assigned to the specified server.

Parameters

hServer

The server handle.

nPriority

An integer value which specifies the new priority for the server. It may be one of the following values:

Constant	Description
HTTP_PRIORITY_BACKGROUND (0)	This priority significantly reduces the memory, processor and network resource utilization for the server. It is typically used with lightweight services running in the background that are designed for few client connections. The server thread will be assigned a lower scheduling priority and will be frequently forced to yield execution to other threads.
HTTP_PRIORITY_LOW (1)	This priority lowers the overall resource utilization for the server and meters the processor utilization for the server thread. The server thread will be assigned a lower scheduling priority and will occasionally be forced to yield execution to other threads.
HTTP_PRIORITY_NORMAL (2)	The default priority which balances resource and processor utilization. This is the priority that is initially assigned to the server when it is started, and it is recommended that most applications use this priority.
HTTP_PRIORITY_HIGH (3)	This priority increases the overall resource utilization for the server and the thread will be given higher scheduling priority. It is not recommended that this priority be used on a system with a single processor.
HTTP_PRIORITY_CRITICAL (4)	This priority can significantly increase processor, memory and network utilization. The server thread will be given higher scheduling priority and will be more responsive to client connection requests. It is not recommended that this priority be used on a system with a single processor.

Return Value

If the function succeeds, the return value is the previous priority assigned to the server. If the function fails, the return value is HTTP_PRIORITY_INVALID. To get extended error information, call

HttpGetServerError.

Remarks

The **HttpSetServerPriority** function can be used to change the current priority assigned to the specified server. Client connections that are accepted after this function is called will inherit the new priority as their default priority. Previously existing client connections will not be affected by this function.

Higher priority values increase the thread priority and processor utilization for each client session. You should only change the server priority if you understand the impact it will have on the system and have thoroughly tested your application. Configuring the server to run with a higher priority can have a negative effect on the performance of other programs running on the system.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cstools10.h`

Import Library: `cshtsv10.lib`

See Also

[HttpGetServerPriority](#), [HttpServerStart](#)

HttpSetServerStackSize Function

```
BOOL WINAPI HttpSetServerStackSize(  
    SOCKET hServer,  
    DWORD dwStackSize  
);
```

Change the initial size of the stack allocated for threads created by the server.

Parameters

hServer

Handle to the server socket.

dwStackSize

The amount of memory that will be committed to the stack for each thread created by the server. If this value is zero, a default stack size will be used.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **HttpGetServerError**.

Remarks

The **HttpSetServerStackSize** function changes the initial amount of memory that is committed to the stack for each thread created by the server. By default, the stack size for each thread is set to 256K for 32-bit processes and 512K for 64-bit processes. Increasing or decreasing the stack size will only affect new threads that are created by the server, it will not affect those threads that have already been created to manage active client sessions. It is recommended that most applications use the default stack size.

You should not change the stack size unless you understand the impact that it will have on your system and have thoroughly tested your application. Increasing the initial commit size of the stack will remove pages from the total system commit limit, and every page of memory that is reserved for stack cannot be used for any other purpose.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `csstools10.h`

Import Library: `cshtsv10.lib`

Hypertext Transfer Protocol Server Data Structures

- HTTPCLIENTCREDENTIALS
- HTTPREQUEST
- HTTPRESPONSE
- HTTPSERVERCONFIG
- HTTPSERVERTRANSFER
- INITDATA
- SECURITYCREDENTIALS

HTTPCLIENTCREDENTIALS Structure

The **HTTPCLIENTCREDENTIALS** structure defines the credentials used to authenticate a specific user.

```
typedef struct _HTTPCLIENTCREDENTIALS
{
    DWORD dwSize;
    DWORD dwFlags;
    UINT nAuthType;
    UINT nHostPort;
    TCHAR szHostName[HTTP_MAXHOSTNAME];
    TCHAR szUserName[HTTP_MAXUSERNAME];
    TCHAR szPassword[HTTP_MAXPASSWORD];
} HTTPCLIENTCREDENTIALS, *LPHTTPCLIENTCREDENTIALS;
```

Members

dwSize

An unsigned integer value that specifies the size of the structure.

dwFlags

An unsigned integer value is reserved for future use. This value will always be zero.

nAuthType

An unsigned integer value that identifies the authentication method.

nHostPort

The server port number.

szHostName

A pointer to a string that specifies the server host name.

szUserName

A pointer to a string that specifies the user name.

szPassword

A pointer to a string that specifies the user password.

Remarks

When an instance of this structure is passed to the **HttpGetClientCredentials** function, this member must be initialized to the size of the structure and all other members must be initialized with a value of zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Unicode: Implemented as Unicode and ANSI versions.

    DWORD    dwVersion;
    DWORD    dwAccess;
    DWORD    dwLength;
    DWORD    dwReserved;
    UINT     nHostId;
    UINT     nHostPort;
    LPCSTR   lpszCommand;
    LPCSTR   lpszHostName;
    LPCSTR   lpszUserName;
    LPCSTR   lpszPassword;
    LPCSTR   lpszResource;
    LPCSTR   lpszParameters;
    LPCSTR   lpszDirectory;
    LPCSTR   lpszPathInfo;
    LPCSTR   lpszProgram;
    LPCSTR   lpszScriptFile;
    LPCSTR   lpszLocalFile;
    LPCSTR   lpszMediaType;
} HTTPREQUEST, *LPHTTPREQUEST;
```

Members

dwSize

An unsigned integer value that specifies the size of the structure.

dwFlags

An unsigned integer value that provides additional information about the request. It may be one or more of the following values:

Constant	Description
HTTP_REQUEST_FLAG_PROTECTED (0x1)	The resource that the client has requested is protected. The client should only be permitted to access the resource if the client session has been authenticated.
HTTP_REQUEST_FLAG_PROGRAM (0x2)	The resource that the client has requested is a CGI program or an executable script. The output from the program or script should be returned to the client in the response. If this flag is specified, the <i>lpszProgram</i> member of the structure specifies the name of the program that should be executed.
HTTP_REQUEST_FLAG_SCRIPT (0x4)	The resource that the client has requested is an executable script. This flag is set when the request URL is mapped to a registered script handler. The <i>lpszProgram</i> member specifies the name of the program that is responsible for executing the

script, and the *lpszScriptFile* parameter specifies the full path to the script itself.

dwVersion

An unsigned integer value that specifies the protocol version used. It may be one of the following values:

Constant	Description
HTTP_VERSION_09 (0x00009)	The client issued a GET command without specifying a protocol version.
HTTP_VERSION_10 (0x10000)	The client issued a command that specified version 1.0 of the protocol.
HTTP_VERSION_11 (0x10001)	The client issued a command that specified version 1.1 of the protocol.

dwAccess

An unsigned integer value that specifies the access permissions that were assigned to the resource. For a list of file access permissions, see [User and File Access Constants](#).

dwLength

An unsigned integer value that will specify the number of bytes of request data provided by the client. If the client did not submit any data with the request, this member will have a value of zero.

dwReserved

An unsigned integer value that is reserved for future use.

nHostId

An integer value that identifies the virtual host that was specified by the client. This is based on the value of the Host request header included in the request. This value will be zero if a host name is not specified by the client, or does not match one of the virtual hosts that have been created.

nHostPort

An integer value that specifies the port number that the client used to establish the connection. This will be the same port number that was used when starting the server.

lpszCommand

A pointer to a string that specifies the command that was issued by the client. The command will always be in upper case. Refer to [Hypertext Transfer Protocol Commands](#) for a list of standard commands.

lpszHostName

A pointer to a string that identifies the hostname or IP address that the client used to establish the connection. This will typically correspond to the hostname assigned to the server, or to one of the virtual hosts that have been created.

lpszUserName

A pointer to a string that specifies the username provided with the request. This member is only set if the client has included authentication credentials as part of the request. If the client has not provided any credentials, this member will be NULL.

lpszPassword

A pointer to a string that specifies the password provided with the request. This member is only set if the client has included authentication credentials as part of the request. If the client has not provided any credentials, this member will be NULL.

lpszResource

A pointer to a string that specifies the URL path provided by the client.

lpszParameters

A pointer to a string that specifies any query parameters that were included in the request made by the client. If the URL did not include any query parameters, this member will be NULL.

lpszDirectory

A pointer to a string that specifies the full path to the root directory for the virtual host.

lpszPathInfo

A pointer to a string that specifies additional path information provided by the client when referencing an executable CGI program or script in the URL. For example, if a program is mapped to the virtual path "/orders/invoice" and the client requests "/orders/invoice/pdf/10001" this member will be the string "/pdf/10001". If there is no path information associated with the request, this member will be NULL.

lpszProgram

A pointer to a string that specifies the local path to the CGI program that should be executed to process the request made by the client. If this member is NULL, it indicates that the client has provided a URL that maps to a local file or directory.

lpszScriptFile

A pointer to a string that specifies the local path to the script file that will be executed by the handler. If this member is NULL, it indicates that the request URL was not mapped to a registered script handler.

lpszLocalFile

A pointer to a string that specifies the local path to the directory or file name referenced by the URL. If the *lpszPathInfo* member is not NULL, then this member will point to a local file name based on the path information appended to the root directory for the virtual host.

lpszMediaType

A pointer to a string that identifies the request data using the standard Internet media types defined in RFC 2046. It is used to designate the format for various types of content and has two parts, a primary and secondary media type separated by a forward slash. Common examples are "text/plain", "text/html" and "application/octet-stream". If the client did not submit any data with the request, this member will be NULL.

Remarks

This structure is used with the **HttpReceiveRequest** function and all members should be initialized to a value of zero, except for the *dwSize* member which should be initialized to the size of the structure. Failure to properly initialize the structure will cause the function call to fail.

The value of the *lpszLocalFile* member depends on whether the client has requested a static document, or if the URL is mapped to a registered program or script handler. If the request is for a static document, then the *dwFlags* member will not have the HTTP_REQUEST_FLAG_PROGRAM bit flag set and the *lpszLocalFile* member will be the full path to the document. If the URL is mapped to a registered program or script, then the *lpszLocalFile* member will be the full path to the server root directory. If the request URL included additional path information, that will be appended to the root directory.

The value of the *lpzScriptFile* member is only defined if the *dwFlags* member has the HTTP_REQUEST_FLAG_SCRIPT bit flag set. This indicates that the request URL references a file that is an executable script with a handler that was registered using the **HttpRegisterHandler** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Unicode: Implemented as Unicode and ANSI versions.

See Also

[HttpReceiveRequest](#), [HttpSendResponse](#), [HTTPRESPONSE](#)

HTTPRESPONSE Structure

The **HTTPRESPONSE** structure provides additional information about the response to the client.

```
typedef struct _HTTPRESPONSE
{
    DWORD    dwSize;
    DWORD    dwFlags;
    DWORD    dwVersion;
    DWORD    dwReserved;
    UINT     nExpires;
    UINT     nResultCode;
    LPCTSTR  lpszReason;
    LPCTSTR  lpszMediaType;
} HTTPRESPONSE, *LPHTTPRESPONSE;
```

Members

dwSize

An unsigned integer value that specifies the size of the structure.

dwFlags

An unsigned integer value that specifies one or more response flags. This member is reserved for future use and should always have a value of zero.

dwVersion

An unsigned integer value that specifies the protocol version used. It may be one of the following values:

Constant	Description
HTTP_VERSION_DEFAULT (0)	The server should respond to the client using the same version specified in the request.
HTTP_VERISON_10 (0x10000)	The server should respond to the client using version 1.0 of the protocol.
HTTP_VERSION_11 (0x10001)	The server should respond to the client using version 1.1 of the protocol.

dwReserved

An unsigned integer value that is reserved for future use.

nExpires

An integer value that specifies the number of seconds until the client should consider any cached response data to be stale. If this value is zero, the default cache expiration time for the server will be used. The default cache expiration time is 7200 seconds (2 hours). The value of this structure member is ignored if the **HTTP_RESPONSE_NOCACHE** option is specified when the response is sent to the client.

nResultCode

An integer value that specifies the result code that should be sent in response to the client request. The result code is a three-digit number that indicates success or failure. For more information, refer to the **HttpGetCommandResult** function.

lpszReason

A string that describes the result code sent to the client. The description should be brief

and should not contain any formatting characters or HTML markup. This parameter may be NULL, in which case a default description of the result code will be used.

lpzMediaType

A string that specifies the Internet media type for the data that is being sent to the client as defined in RFC 2046. The format for the content type string consists of two parts, a primary and secondary media type separated by a forward slash. Common examples are "text/plain", "text/html" and "application/octet-stream". If this member is NULL, the library will attempt to automatically determine the appropriate media type.

Remarks

This structure is used with the **HttpSendResponse** function and the *dwSize* member must be initialized to size of the structure. Failure to properly initialize the structure will cause the function call to fail.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Unicode: Implemented as Unicode and ANSI versions.

HTTPSERVERCONFIG Structure

The **HTTPSERVERCONFIG** structure provides the configuration information used to create an instance of an HTTP server.

```
typedef struct _HTTPSERVERCONFIG
{
    DWORD    dwSize;
    UINT     nMaxClients;
    UINT     nMaxClientsPerAddress;
    UINT     nMaxRequests;
    UINT     nMaxPostSize;
    UINT     nLogFormat;
    UINT     nLogLevel;
    UINT     nCacheTime;
    UINT     nIdleTime;
    UINT     nExecTime;
    LPCTSTR  lpszIdentity;
    LPCTSTR  lpszHostUuid;
    LPCTSTR  lpszHostName;
    LPCTSTR  lpszRootPath;
    LPCTSTR  lpszTempPath;
    LPCTSTR  lpszLogFile;
} HTTPSERVERCONFIG, *LPHTTPSERVERCONFIG;
```

Members

dwSize

An unsigned integer value that specifies the size of the structure.

nMaxClients

An integer value that specifies the maximum number of active client connections that will be accepted by the server. If the maximum number of clients is reached, any further connections are rejected by the server until one or more clients close their connection to the server or are disconnected. A value of zero specifies the default configuration value of 100 connections should be used.

nMaxClientsPerAddress

An integer value that specifies the maximum number of active client connections per IP address that will be accepted by the server. If the maximum number of clients from the same IP address is reached, any further connections are rejected until one of the clients closes its connection to the server. A value of zero specifies the default configuration value of 8 connections per address should be used.

nMaxRequests

An integer value that specifies the maximum number of a requests a client may make per connection. When a client reaches the maximum number of requests, the server will close the connection and the client must establish a new connection to send another request. If this member has a value of zero, the server will allow 5 requests per connection. The minimum value is 1 and the maximum is 100.

nMaxPostSize

An integer value that specifies the maximum size of the request data that may be submitted by a client with a POST command. If the amount of request data submitted to the server exceeds this limit, the server will return a 413 error to the client and the connection will be closed. If this member has a value of zero, the server will permit the client to submit up to 4 MB (4,194,304

bytes) of data. The minimum value is 100 KB (102,400 bytes) and the maximum value is 100 MB (104,857,600 bytes).

nLogFormat

An integer value that specifies the format used when creating or updating the server log file. The following formats are supported:

Constant	Description
HTTP_LOGFILE_NONE (0)	This value specifies that the server should not create or update a log file.
HTTP_LOGFILE_COMMON (1)	This value specifies that the log file should use the common log format that records a subset of information in a fixed format. This log format usually only provides information about file transfers.
HTTP_LOGFILE_COMBINED (2)	This value specifies that the server should use the combined log file format. This format is similar to the common format, however it includes the client referrer and user agent. This is the format that most Apache web servers use by default.
HTTP_LOGFILE_EXTENDED (3)	This value specifies that the log file should use the standard W3C extended log file format. This is an extensible format that can provide additional information about the client session.

nLogLevel

An integer value that specifies the level of detail that should be generated in the log file. The minimum value is 1 and the maximum value is 10. If the *nLogFormat* member specifies a valid log file format and this value is zero, a default level of detail will be selected based on the format. The common log file format generally contains less information by default, only logging the data transfers between the client and server. The W3C extended log file format defaults to a higher level of detail that includes additional information about the client session. The higher the level of detail, the larger the log file will be.

nCacheTime

An integer value that specifies the amount of time that the client should store a document in its cache before requesting it from the server again. A value of zero specifies that the default value of 7200 seconds (2 hours) should be used.

nIdleTime

An integer value that specifies the maximum number of seconds that a client session may be idle before the server closes the control connection to the client. A value of zero specifies the default value of 60 seconds. If the value is non-zero, the minimum value is 10 seconds and the maximum value is 300 seconds (5 minutes). This value is used to initialize the default idle timeout period for each client session. The server determines if a client is idle based on the time the last command was issued and whether or not a file transfer is in progress.

nExecTime

An unsigned integer value that specifies the maximum number of seconds that an external CGI program is permitted to run on the server. Programs are registered using the **HttpRegisterProgram** function, and are executed when the client sends a request for a resource that is associated with the program. If this value is zero, the default timeout period of 5

seconds will be used. The minimum execution time is 1 second and the maximum time limit is 30 seconds.

lpszIdentity

A pointer to a string that identifies the server. It is used for informational purposes only and has no effect on the operation of the server. If this member is not initialized to a value, then a default identity will be used. The server identity is provided when a client establishes the initial connection and when the client sends the STAT or CSID commands. If this member is defined, it is recommended that you only use printable ASCII characters.

lpszHostUuid

A pointer to a string that specifies a Universally Unique Identifier (UUID) that is used to uniquely identify the server. This value can be used when storing information about the server, and should be generated using a utility such as **uuidgen** which is included with Visual Studio. This structure member may be initialized to an empty string, in which case a temporary UUID will be randomly generated.

lpszHostName

A pointer to a string that specifies the fully-qualified host name for the server. If this structure member is initialized with an empty string, the local host name assigned to the Windows system will be used. This value does not need to correspond to the actual host name associated with the server's IP address. This value is used for informational purposes only and has no effect on the operation of the server.

lpszRootPath

A pointer to a string that specifies the path to the root directory for the server. If this structure member is initialized with an empty string, the current working directory for the process will be used as the root directory. It is recommended that you provide a full path to an existing directory and do not specify the root of a local or network drive. If the path does not exist at the time the server is started, it will be automatically created.

lpszTempPath

A pointer to a string that specifies the path to the temporary directory for the server. If this structure member is initialized with an empty string, the current temporary directory for the process will be used. The temporary directory cannot be the same as the root directory, and it is strongly recommended that you do not specify the root of a local or network drive. If the path does not exist at the time the server is started, it will be automatically created.

lpszLogFile

A pointer to a string that specifies the name of the server log file to create, if a logging format has been specified. If logging is enabled and this member is an empty string, then a default log file name will be created. If the file name does not include a path, then the file is created in the server log directory. If the file name includes a path, the log file will be created using that specific name. If the server is in multi-user mode, then the default location for log files will be the Logs subdirectory in the server root directory. If the server is not in multi-user mode, the default location for log files will be the temporary directory for the current process.

Remarks

When an instance of this structure is passed to the **HttpServerStart** function, the **dwSize** member must be initialized to the size of the structure, otherwise the function will fail with an error indicating that the configuration is invalid.

The **nMaxClients** member limits the total number of client connections and the **nMaxClientsPerAddress** member limits the number of simultaneous connections can originate

from the same address. If either client limit is exceeded, the server will automatically close the connection. For more control over how the server accepts client connections, use the **HttpServerThrottle** function. It is not recommended that you set the maximum clients per address below a value of 4. Lower values can negatively impact the performance of some clients, particularly web browsers.

The **nMaxPostSize** member limits the amount of data that a client can submit to the server using a POST command. The default limit is 4 MB which should be sufficient for most applications. One situation where you may need to increase this value is if you expect the client to upload large files using the POST command. Increasing this limit will potentially increase the amount of virtual memory that the server will allocate. Note that this value does not limit amount of data that can be uploaded using the PUT command.

When specifying the root directory for the server configuration, it is important to consider that a client's default access to files on the system will be limited to these directories and any subdirectories. If a root directory is not specified, then one will be created using the current working directory for the process. The root directory path may include environment variables surrounded by % symbols and these will be expanded.

For servers that are publicly accessible, or where you want files to be accessible across multiple server sessions, you should always populate the **szHostUuid** member with a valid UUID string, and the **lpszRootPath** member should specify an absolute path to an existing directory.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Unicode: Implemented as Unicode and ANSI versions.

See Also

HTTPSERVERTRANSFER Structure

The **HTTPSERVERTRANSFER** structure provides information about the last file transfer performed by a client.

```
typedef struct _HTTPSERVERTRANSFER
{
    DWORD          dwSize;
    DWORD          dwReserved;
    DWORD          dwFileAccess;
    DWORD          dwTimeElapsed;
    ULARGE_INTEGER uiBytesCopied;
    TCHAR          szFileName[MAX_PATH];
} HTTPSERVERTRANSFER, *LPHTTPSERVERTRANSFER;
```

Members

dwSize

An unsigned integer value that specifies the size of the structure.

dwReserved

An unsigned integer value that is reserved for future use. This value will always be zero.

dwFileAccess

An unsigned integer value that specifies the how the local file was accessed. It can be one of the following values:

Constant	Description
HTTP_FILE_READ (0)	The file was opened for reading. This mode indicates that the client issued the GET command to download the contents of a file from the server to the client system. The <i>szFileName</i> member specifies the name of the local file on the server that was downloaded by the client.
HTTP_FILE_WRITE (1)	The file was opened for writing. This mode indicates that the client issued the PUT command to upload the contents of a file from the client system to server. The <i>szFileName</i> member specifies the name of the local file on the server that was created by the client. If a file already existed with the name name, it was replaced.

dwTimeElapsed

The amount of time that it took for the file transfer to complete in milliseconds. This value is limited to the resolution of the system timer, which is typically in the range of 10 to 16 milliseconds. This value may be zero if the transfer occurred over a local network or on the same host using a loopback address.

uiBytesCopied

A 64-bit integer value that specifies the total number of bytes copied during the file transfer. This value is represented by a ULARGE_INTEGER union which provides support for those programming languages that do not have intrinsic support for 64-bit integers. For more information, refer to the Windows SDK documentation. The application should not make the assumption that this is the actual size of the file.

szFileName

A pointer to a string value that will contain the full path to the local file that was transferred. The

dwFileAccess member determines whether the file name represents a file that was downloaded by the client, or uploaded from the client and stored on the server.

Remarks

When an instance of this structure is passed to the **HttpGetServerTransferInfo** function, the *dwSize* member must be initialized to the size of the structure, otherwise the function will fail with an error indicating that the parameter is invalid. All other members should be initialized to a value of zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Unicode: Implemented as Unicode and ANSI versions.

INITDATA Structure

This structure contains information about the SocketTools library when the initialization function returns.

```
typedef struct _INITDATA
{
    DWORD        dwSize;
    DWORD        dwVersionMajor;
    DWORD        dwVersionMinor;
    DWORD        dwVersionBuild;
    DWORD        dwOptions;
    DWORD_PTR    dwReserved1;
    DWORD_PTR    dwReserved2;
    TCHAR        szDescription[128];
} INITDATA, *LPINITDATA;
```

Members

dwSize

Size of this structure. This structure member must be set to the size of the structure prior to calling the initialization function. Failure to do so will cause the function to fail.

dwVersionMajor

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the major version number for the library.

dwVersionMinor

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the minor version number for the library.

dwVersionBuild

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the build number for the library.

dwOptions

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

dwReserved1

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

dwReserved2

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

szDescription

A null terminated string which describes the library.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Unicode: Implemented as Unicode and ANSI versions.

SECURITYCREDENTIALS Structure

The **SECURITYCREDENTIALS** structure specifies the information needed by the library to specify additional security credentials, such as a client certificate or private key, when establishing a secure connection.

```
typedef struct _SECURITYCREDENTIALS
{
    DWORD    dwSize;
    DWORD    dwProtocol;
    DWORD    dwOptions;
    DWORD    dwReserved;
    LPCTSTR  lpszHostName;
    LPCTSTR  lpszUserName;
    LPCTSTR  lpszPassword;
    LPCTSTR  lpszCertStore;
    LPCTSTR  lpszCertName;
    LPCTSTR  lpszKeyFile;
} SECURITYCREDENTIALS, *LPSECURITYCREDENTIALS;
```

Members

dwSize

Size of this structure. If the structure is being allocated dynamically, this member must be set to the size of the structure and all other unused structure members must be initialized to a value of zero or NULL.

dwProtocol

A bitmask of supported security protocols. The value of this structure member is constructed by using a bitwise operator with any of the following values:

Constant	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_SSL	Either SSL 2.0 or SSL 3.0 should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, TLS will be excluded from the list of supported protocols. Both SSL 2.0 and 3.0 have been deprecated and will never be used unless explicitly specified. It is not recommended that you enable either of these protocols for secure connections because it will cause most servers to reject your connection request, even if a version of TLS is also specified.
SECURITY_PROTOCOL_TLS	Either the TLS 1.0, 1.1 or 1.2 protocol should be used when establishing a secure connection. The correct protocol is automatically selected, based on

	what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers that reject any attempt to use the older SSL protocol and require that only TLS be used.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This is the recommended version of TLS to use with secure connections.

dwOptions

A value which specifies one or options. This member is constructed by using a bitwise operator with any of the following values:

Constant	Description
CREDENTIAL_STORE_CURRENT_USER	The library will attempt to open a store for the current user using the certificate store name provided in this structure. If no options are specified, then this is the default behavior.
CREDENTIAL_STORE_LOCAL_MACHINE	The library will attempt to open a local machine store using the certificate store name provided in this structure. If this option is specified, the library will always search for a local machine store before searching for the store by that name for the current user.
CREDENTIAL_STORE_FILENAME	The certificate store name is a file that contains the certificate and private key that

will be used.

dwReserved

This structure member is reserved for future use and should always be initialized to zero.

lpszHostName

A pointer to a null terminated string which specifies the hostname that will be used when validating the server certificate. If this member is NULL, then the server certificate will be validated against the hostname used to establish the connection.

lpszUserName

A pointer to a null terminated string which identifies the owner of client certificate. Currently this member is not used by the library and should always be initialized as a NULL pointer.

lpszPassword

A pointer to a null terminated string which specifies the password needed to access the certificate. Currently this member is only used if the CREDENTIAL_STORE_FILENAME option has been specified. If there is no password associated with the certificate, then this member should be initialized as a NULL pointer.

lpszCertStore

A pointer to a null terminated string which specifies the name of the certificate store to open. A certificate store is a collection of certificates and their private keys, typically organized by how they are used. If this value is NULL or points to an empty string, the default certificate store "MY" will be used.

Store Name	Description
------------	-------------

CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as VeriSign and Thawte act as certification authorities.
----	---

MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. This corresponds to the "Personal" store that is displayed by the certificate manager utility and is the default store used by the library.
----	--

ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as VeriSign and Thawte are installed as part of the operating system and periodically updated by Microsoft.
------	--

lpszCertName

A pointer to a null terminated string which specifies the name of the certificate to use. The library will first search the certificate store for a certificate with a matching "friendly name"; this is a name for the certificate that is assigned by the user. Note that the name must match completely, but the comparison is not case sensitive. If no matching certificate is found, the library will then attempt to find a certificate that has a matching common name (also called the certificate subject). This comparison is less stringent, and the first partial match will be returned. If this second search fails, the library will return an error indicating that the certificate could not be found. If the SECURITY_PROTOCOL_SSH protocol has been specified, this member should be NULL.

lpszKeyFile

A pointer to a null terminated string which specifies the name of the file which contains the private key required to establish the connection. This member is only used for SSH connections

and should always be NULL when establishing a secure connection using SSL or TLS.

Remarks

A client application only needs to create this structure if the server requires that the client provide a certificate as part of the process of negotiating the secure session. If a certificate is required, note that it must have a private key associated with it. Attempting to use a certificate that does not have a private key will result in an error during the connection process indicating that the client credentials could not be established.

If you are using a local certificate store, with the certificate and private key stored in the registry, you can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU:" for the current user, or "HKLM:" for the local machine. For example, a certificate store name of "HKLM:MY" would specify the personal certificate store for the local machine, rather than the current user. If neither prefix is specified, then it will default to the certificate store for the current user. You can manage these certificates using the CertMgr.msc Microsoft Management Console (MMC) snap-in.

It is possible to load the certificate from a file rather than from current user's certificate store. The *dwOptions* member should be set to CREDENTIAL_STORE_FILENAME and the *lpzCertStore* member should specify the name of the file that contains the certificate and its private key. The file must be in Private Information Exchange (PFX) format, also known as PKCS#12. These certificate files typically have an extension of .pfx or .p12. Note that if a password was specified when the certificate file was created, it must be provided in the *lpzPassword* member or the library will be unable to access the certificate.

Note that the *lpzUserName* and *lpzPassword* members are values which are used to access the certificate store or private key file. They are not the credentials which are used when establishing the connection with the remote host or authenticating the client session.

The TLS 1.1 and TLS 1.2 protocols are only supported on Windows 7, Windows Server 2008 R2 and later versions of the platform. If these options are specified and the application is running on Windows XP or Windows Vista, the protocol version will be downgraded to TLS 1.0 for backwards compatibility with those platforms.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include ctools10.h

Unicode: Implemented as Unicode and ANSI versions.

Internet Control Message Protocol Library

Determine if a remote host is reachable and how packets of data are routed to that system.

Reference

- [Functions](#)
- [Data Structures](#)
- [Error Codes](#)

Library Information

File Name	CSICMV10.DLL
Version	10.0.1468.2518
LibID	A8CDC210-0CEC-4A3B-A367-A649CEEA7419
Import Library	CSICMV10.LIB
Dependencies	None
Standards	RFC 792

Overview

The Internet Control Message Protocol (ICMP) is commonly used to determine if a remote host is reachable and how packets of data are routed to that system. Users are most familiar with this protocol as it is implemented in the ping and traceroute command line utilities. The ping command is used to check if a system is reachable and the amount of time that it takes for a packet of data to make a round trip from the local system, to the remote host and then back again. The traceroute command is used to trace the route that a packet of data takes from the local system to the remote host, and can be used to identify potential problems with overall throughput and latency. The library can be used to build in this type of functionality in your own applications, giving you the ability to send and receive ICMP echo datagrams in order to perform your own analysis.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). If you are using Visual C++ 6.0 it is required that you have Service Pack 6 (SP6) installed. You should install all updates for your development tools and have the current Windows SDK installed. The minimum recommended version of Visual Studio is Visual Studio 2010.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are using Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. It is recommended that you install the current service pack and all critical updates available for your version of the operating system.

This product includes both 32-bit and 64-bit libraries. Native 64-bit CPU support requires the 64-bit version of Windows 7 or later versions of the Windows operating system.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location

on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

Internet Control Message Protocol Functions

Function	Description
IcmpCancel	Cancel the current blocking operation
IcmpCloseHandle	Close the current client session
IcmpCreateHandle	Create a new handle for the current client session
IcmpDisableEvents	Disable asynchronous event notification
IcmpDisableTrace	Disable logging of socket-level calls to the trace log
IcmpEcho	Send one or more echo datagrams to the specified host
IcmpEnableEvents	Enable asynchronous event notification
IcmpEnableTrace	Enable logging of socket function calls to a file
IcmpEventProc	Callback function that processes events generated by the client
IcmpFormatAddress	Convert a numeric IP address to a string
IcmpFreezeEvents	Suspend or resume event handling by the calling process
IcmpGetErrorString	Return a description for the specified error code
IcmpGetHostAddress	Return the current host IP address
IcmpGetHostName	Return the current host name
IcmpGetLastError	Return the last error code
IcmpGetPacketSize	Return the ICMP datagram packet size
IcmpGetRecvCount	Return the number of packets received
IcmpGetSendCount	Return the number of packets sent
IcmpGetSequenceId	Return the current sequence identifier
IcmpGetTimeout	Return the number of milliseconds until an operation times out
IcmpGetTimeToLive	Return the current time-to-live for the ICMP datagram
IcmpGetTripTime	Return the current trip time statistics
IcmpInitialize	Initialize the library and validate the specified license key at runtime
IcmpIsBlocking	Determine if the client is blocked, waiting for information
IcmpRecvEcho	Read an ICMP datagram returned by the remote host
IcmpRegisterEvent	Register an event callback function
IcmpReset	Reset the current client state
IcmpResolveAddress	Resolve an IP address into a fully qualified host name
IcmpSendEcho	Send an ICMP datagram to the specified host
IcmpSetHostAddress	Set the IP address of the host to receive the next datagram
IcmpSetHostName	Set the name of the host to receive the next datagram

IcmpSetLastError	Set the last error code
IcmpSetPacketSize	Set the ICMP datagram packet size
IcmpSetSequenceId	Set the sequence identifier for the next datagram
IcmpSetTimeout	Set the number of milliseconds until an operation times out
IcmpSetTimeToLive	Set the time-to-live for the next datagram
IcmpTraceRoute	Trace the route from the local system to a remote host
IcmpUninitialize	Terminate use of the library by the application

IcmpCancel Function

```
INT WINAPI IcmpCancel(  
    HCLIENT hClient  
);
```

The **IcmpCancel** function cancels any outstanding blocking operation in the client, causing the blocking function to fail. The application may then retry the operation or terminate the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is ICMP_ERROR. To get extended error information, call **IcmpGetLastError**.

Remarks

When the **IcmpCancel** function is called, the blocking function will not immediately fail. An internal flag is set which causes the blocking operation to exit with an error. This means that the application cannot cancel an operation and immediately perform some other operation. Instead it must allow the calling stack to unwind, returning back to the blocking operation before making any further function calls.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstoools10.h

Import Library: csicmv10.lib

See Also

[IcmpIsBlocking](#)

IcmpCloseHandle Function

```
INT WINAPI IcmpCloseHandle(  
    HCLIENT hClient  
);
```

The **IcmpCloseHandle** function closes the socket and releases the memory allocated for the client session.

Parameters

hClient

A handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is ICMP_ERROR. To get extended error information, call **IcmpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csicmv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[IcmpCreateHandle](#), [IcmpInitialize](#), [IcmpUninitialize](#)

IcmpCreateHandle Function

```
HCLIENT WINAPI IcmpCreateHandle(  
    UINT nPacketSize,  
    UINT nTimeToLive,  
    DWORD dwTimeout,  
    DWORD dwReserved,  
    HWND hEventWnd,  
    UINT uEventMsg  
);
```

The **IcmpCreateHandle** function creates a client handle for sending and receiving ICMP echo datagrams. If an event notification window is specified, the client will be notified when a network event occurs.

Parameters

nPacketSize

An unsigned integer which specifies the default packet size used when generating ICMP echo datagrams. The minimum packet size is 32 bytes and the maximum size is 65,535 bytes.

nTimeToLive

An unsigned integer which specifies the default time-to-live for ICMP echo datagrams. This determines the maximum number of times that a packet will be routed from one system to another while enroute to its destination. The minimum time-to-live value is 1, the maximum is 255. The recommend value for this parameter is 255, and typical applications should use a time-to-live value of at least 30.

dwTimeout

An unsigned integer which specifies the maximum number of milliseconds to wait before the current operation times out.

dwReserved

A reserved parameter. This value should always be zero.

hEventWnd

The handle to an asynchronous notification window. This window receives messages which notify the client when asynchronous network events occur. If asynchronous event notification is not required, this parameter may be NULL.

uEventMsg

The message identifier that is used when an asynchronous network event occurs. This value should be greater than WM_USER as defined in the Windows header files. If the *hEventWnd* parameter is NULL, this parameter should be specified as WM_NULL.

Return Value

If the function succeeds, the return value is a handle to the client session. If the function fails, the return value is INVALID_CLIENT. To get extended error information, call **IcmpGetLastError**.

Remarks

The **IcmpCreateHandle** function creates a client handle that is used with subsequent calls to the library. This library uses a special type of socket called a raw socket, which is created to send and receive ICMP echo datagrams. Raw socket support is optional under the Windows Sockets specification, and may not be available if a non-standard networking libraries are used or may

only be available to privileged accounts.

If the *hEventWnd* parameter is not NULL, the client operates in asynchronous mode and messages will be posted to the notification window when a network event occurs. When a message is posted to the window, the low word of the *lParam* parameter contains the event identifier. The high word of *lParam* contains the low word of the error code, if an error has occurred. The *wParam* parameter contains the client handle. One or more of the following event identifiers may be sent:

Constant	Description
ICMP_EVENT_ECHO	The client has generated an ICMP echo datagram and has sent it to the specified host. If the datagram is received, the remote host should generate a reply and return it to the sender.
ICMP_EVENT_REPLY	The client has received an ICMP echo reply datagram from the remote host. At this point the client can collect statistical information.
ICMP_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation.
ICMP_EVENT_CANCEL	The current operation has been canceled. The client application may attempt to retry the operation or close the handle.

To cancel asynchronous notification and return the client to a blocking mode, use the **IcmpDisableEvents** function.

The ability to create and send ICMP echo datagrams is limited to privileged users. Non-administrator users will receive an error if they attempt to create a client handle. On Windows NT it is possible to disable this security check by creating or modifying the system registry. Microsoft Knowledge Base article 195445 has additional information and instructions for making this change.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstoools10.h

Import Library: csicmv10.lib

See Also

[IcmpCloseHandle](#), [IcmpInitialize](#), [IcmpUninitialize](#)

IcmpDisableEvents Function

```
INT WINAPI IcmpDisableEvents(  
    HCLIENT hClient  
);
```

The **IcmpDisableEvents** function disables all event notification, including event callbacks. Any pending events are deleted.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is ICMP_ERROR. To get extended error information, call **IcmpGetLastError**.

Remarks

This function affects both event notification and event callbacks. Any outstanding events in the message queue should be ignored by the client application.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstoools10.h

Import Library: csicmv10.lib

See Also

[IcmpEnableEvents](#), [IcmpFreezeEvents](#), [IcmpRegisterEvent](#)

IcmpDisableTrace Function

```
BOOL WINAPI IcmpDisableTrace();
```

The **IcmpDisableTrace** function disables the logging of socket function calls to the trace log file.

Parameters

None.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csicmv10.lib

See Also

[IcmpEnableTrace](#)

IcmpEcho Function

```
INT WINAPI IcmpEcho(  
    LPCTSTR lpszHostName,  
    UINT nIterations,  
    UINT nPacketSize,  
    DWORD dwTimeout,  
    DWORD dwReserved,  
    LPICMPTIME lpTime  
);
```

The **IcmpEcho** function sends one or more ICMP echo datagrams, collecting information about the reliability and latency of a connection between the local and remote host.

Parameters

lpszHostName

A pointer to a string which specifies the fully qualified domain name of the remote host, or the IP address in dotted notation.

nIterations

An unsigned integer value which specifies the number of echo datagrams that will be sent to the remote host. The minimum value for this parameter is 1 and the maximum value is 512.

nPacketSize

An unsigned integer value which specifies the size of the echo datagram in bytes. The minimum size is 1 byte and the maximum size is 65,535 bytes. It is recommended that most applications use the minimum size of 32 bytes for this parameter.

dwTimeout

An unsigned integer which specifies the number of milliseconds the function will wait for a response to an echo datagram.

dwReserved

A reserved parameter. This value should always be zero.

lpTime

A pointer to an [ICMPTIME](#) structure which will contain the minimum, maximum and average round trip times for the echo datagrams sent and received.

Return Value

If the function succeeds, the return value is the number of replies received from the remote host. If the function fails, the return value is `ICMP_ERROR`. To get extended error information, call **IcmpGetLastError**.

Remarks

The **IcmpEcho** function sends a series of ICMP echo datagrams to the specified host, providing a simplified interface for pinging a remote system. If the function returns the same value as the number of iterations, then replies were received for all of the echo datagrams that were sent. This would typically indicate that the client can establish a reliable connection to the server; the values returned in the `ICMPTIME` structure provide information on the latency between the two hosts. Higher average time values would indicate greater latency and reduced throughput between the systems. If the function returns a value less than the specified number of iterations, this indicates that replies were not received for one or more of the echo datagrams. This may indicate that there

are problems routing data between the local and remote host. A return value of zero indicates that there was no response to the echo datagrams. The remote host may not exist or may not be available.

The failure for a host to respond to an ICMP echo datagram may not indicate a problem with the remote system. In some cases, a router between the local and remote host may be malfunctioning or discarding the datagrams. Systems can also be configured to specifically ignore ICMP echo datagrams and not respond to them; this is often a security measure to prevent certain kinds of Denial of Service attacks.

The ability to send ICMP datagrams may be restricted to users with administrative privileges, depending on the policies and configuration of the local system. If you are unable to send or receive any ICMP datagrams, it is recommended that you check the firewall settings and any third-party security software that could impact the normal operation of this component.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csicmv10.lib

IcmpEnableEvents Function

```
INT WINAPI IcmpEnableEvents(  
    HCLIENT hClient,  
    HWND hEventWnd,  
    UINT uEventMsg  
);
```

The **IcmpEnableEvents** function enables event notifications using Windows messages.

This function has been deprecated and is retained for backwards compatibility. Applications should use the **IcmpRegisterEvent** function to register an event handler which is invoked when an event occurs.

Parameters

hClient

Handle to the client session.

hEventWnd

Handle to the event notification window. This window receives a user-defined message which specifies the event that has occurred. If this value is NULL, event notification is disabled.

uEventMsg

An unsigned integer which specifies the user-defined message that is sent when an event occurs. This parameter's value must be greater than the value of WM_USER.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is ICMP_ERROR. To get extended error information, call **IcmpGetLastError**.

Remarks

When a message is posted to the notification window, the low word of the *lParam* parameter contains the event identifier. The high word of *lParam* contains the low word of the error code, if an error has occurred. The *wParam* parameter contains the client handle. One or more of the following event identifiers may be sent:

Constant	Description
ICMP_EVENT_ECHO	The client has generated an ICMP echo datagram and has sent it to the specified host. If the datagram is received, the remote host should generate a reply and return it to the sender.
ICMP_EVENT_REPLY	The client has received an ICMP echo reply datagram from the remote host. At this point the client can collect statistical information.
ICMP_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation.
ICMP_EVENT_CANCEL	The current operation has been canceled. The client application may attempt to retry the operation or close the handle.

To cancel asynchronous notification and return the client to a blocking mode, use the **IcmpDisableEvents** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csicmv10.lib

See Also

[IcmpDisableEvents](#), [IcmpFreezeEvents](#), [IcmpRegisterEvent](#)

IcmpEnableTrace Function

```
BOOL WINAPI IcmpEnableTrace(  
    LPCTSTR lpszTraceFile,  
    DWORD dwTraceFlags  
);
```

The **IcmpEnableTrace** function enables the logging of socket function calls to a file.

Parameters

lpszTraceFile

A pointer to a string which specifies the name of the trace log file. If this parameter is NULL or an empty string, the default file name **cstrace.log** is used. The file is stored in the directory specified by the TEMP environment variable, if it is defined; otherwise, the current working directory is used.

dwTraceFlags

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
TRACE_INFO	All function calls are written to the trace file. This is the default value.
TRACE_ERROR	Only those function calls which fail are recorded in the trace file.
TRACE_WARNING	Only those function calls which fail or return values which indicate a warning are recorded in the trace file.
TRACE_HEXDUMP	All functions calls are written to the trace file, plus all the data that is sent or received is displayed, in both ASCII and hexadecimal format.
TRACE_PROCESS	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for multithreaded applications that are using worker threads.

Return Value

If the function succeeds, the return value is non-zero. A return value of zero indicates an error. Failure typically indicates that the tracing library **cstrcv10.dll** cannot be loaded on the local system.

Remarks

When trace logging is enabled, the file is opened, appended to and closed for each socket function call. This makes it possible for an application to append its own logging information, however care should be taken to ensure that the file is closed before the next network operation is performed. To limit the size of the log files, enable and disable logging only around those sections of code that you wish to trace.

Note that the TRACE_HEXDUMP trace level generates very large log files since it includes all of the data exchanged between your application and the remote host.

Trace function logging is managed on a per-thread basis, not for each client handle. This means that all SocketTools libraries and components share the same settings in the current thread. If you

are using multiple SocketTools libraries or components in your application, you only need to enable logging once.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csicmv10.lib

Unicode: Implemented as Unicode and ANSI versions.

IcmpEventProc Function

```
VOID CALLBACK IcmpEventProc(  
    HCLIENT hClient,  
    UINT nEventId,  
    DWORD dwError,  
    DWORD_PTR dwParam  
);
```

The **IcmpEventProc** function is an application-defined callback function that processes events generated by the calling process.

Parameters

hClient

The handle to the client session.

nEvent

An unsigned integer which specifies which event occurred. For a complete list of events, refer to the **IcmpRegisterEvent** function.

dwError

An unsigned integer which specifies any error that occurred. If no error occurred, then this parameter will be zero.

dwParam

A user-defined integer value which was specified when the event callback was registered.

Return Value

None.

Remarks

An application must register this callback function by passing its address to the **IcmpRegisterEvent** function. The **IcmpEventProc** function is a placeholder for the application-defined function name.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csicmv10.lib

See Also

[IcmpDisableEvents](#), [IcmpEnableEvents](#), [IcmpFreezeEvents](#), [IcmpRegisterEvent](#)

IcmpFormatAddress Function

```
INT WINAPI IcmpFormatAddress(  
    DWORD dwAddress,  
    LPTSTR lpszAddress,  
    INT nMaxLength  
);
```

The **IcmpFormatAddress** function converts a numeric IP address to a string.

Parameters

dwAddress

A unsigned 32-bit integer which specifies the IP address to be converted into a string.

lpszAddress

A pointer to a null-terminated array of characters which will contain the converted IP address in dot-notation. This string should be at least 16 characters in length.

nMaxLength

The maximum number of characters which may be copied in to the string buffer.

Return Value

If the function succeeds, the return value is the length of the string buffer. If the function fails, the return value is zero. To get extended error information, call **IcmpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csicmv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[IcmpGetHostAddress](#), [IcmpGetHostName](#), [IcmpResolveAddress](#)

IcmpFreezeEvents Function

```
INT WINAPI IcmpFreezeEvents(  
    HCLIENT hClient,  
    BOOL bFreeze  
);
```

The **IcmpFreezeEvents** function is used to suspend and resume event handling by the client.

Parameters

hClient

Handle to the client session.

bFreeze

A non-zero value specifies that event handling should be suspended by the client. A zero value specifies that event handling should be resumed.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is ICMP_ERROR. To get extended error information, call **IcmpGetLastError**.

Remarks

This function should be used when the application does not want to process events, such as when a modal dialog is being displayed. When events are suspended, all client events are queued. If events are re-enabled at a later point, those queued events will be sent to the application for processing. Note that only one of each event will be generated. For example, if the client has suspended event handling, and four read events occur, once event handling is resumed only one of those read events will be posted to the client. This prevents the application from being flooded by a potentially large number of queued events.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csicmv10.lib

IcmpGetErrorString Function

```
INT WINAPI IcmpGetErrorString(  
    DWORD dwErrorCode,  
    LPTSTR lpszDescription,  
    INT cbDescription  
);
```

The **IcmpGetErrorString** function is used to return a description of a specific error code. Typically this is used in conjunction with the **IcmpGetLastError** function for use with warning dialogs or as diagnostic messages.

Parameters

dwErrorCode

The error code for which a description is returned.

lpszDescription

A pointer to the buffer that will contain a description of the specified error code. This buffer should be at least 128 characters in length.

cbDescription

The maximum number of characters that may be copied into the description buffer.

Return Value

If the function succeeds, the return value is the length of the description string. If the function fails, the return value is 0, meaning that no description exists for the specified error code. Typically this indicates that the error code passed to the function is invalid.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csicmv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

IcmpGetHostAddress Function

```
INT WINAPI IcmpGetHostAddress(  
    HCLIENT hClient,  
    LPTSTR lpszHostAddress,  
    INT cbHostAddress  
);
```

The **IcmpGetHostAddress** copies the IP address of the current host into the specified buffer as a string using dot-notation.

Parameters

hClient

A handle to the client session.

lpszHostAddress

A pointer to the buffer that will contain the IP address of the current remote host in dot-notation. This buffer should be at least 16 characters in length.

cbHostAddress

The maximum number of characters that may be copied into the buffer, including the terminating null character character.

Return Value

If the function succeeds, the return value is the length of the address string. If the return value is zero, this indicates that no remote host has been specified. If the function fails, the return value is ICMP_ERROR. To get extended error information, call **IcmpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csicmv10.lib

Unicode: Implemented as Unicode and ANSI versions.

IcmpGetHostName Function

```
INT WINAPI IcmpGetHostName(  
    HCLIENT hClient,  
    LPTSTR lpszHostName,  
    INT cbHostName  
);
```

The **IcmpGetHostName** copies the name of the current host into the specified buffer.

Parameters

hClient

A handle to the client session.

lpszHostName

A pointer to the buffer that will contain the name of the current remote host. This buffer should be at least 64 characters in length.

cbHostName

The maximum number of characters that may be copied into the buffer, including the terminating null character character.

Return Value

If the function succeeds, the return value is the length of the host name string. If the return value is zero, this indicates that no remote host has been specified. If the function fails, the return value is ICMP_ERROR. To get extended error information, call **IcmpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csicmv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[IcmpFormatAddress](#), [IcmpGetHostAddress](#), [IcmpResolveAddress](#), [IcmpSetHostAddress](#), [IcmpSetHostName](#)

IcmpGetLastError Function

```
DWORD WINAPI IcmpGetLastError();
```

Parameters

None.

Return Value

The return value is the last error code value for the current thread. Functions set this value by calling the **IcmpSetLastError** function. The Return Value section of each reference page notes the conditions under which the function sets the last error code.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. You should call the **IcmpGetLastError** function immediately when a function's return value indicates that an error has occurred. That is because some functions call **IcmpSetLastError(0)** when they succeed, clearing the error code set by the most recently failed function.

Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or ICMP_ERROR. Those functions which call **IcmpSetLastError** when they succeed are noted on the function reference page.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

IcmpGetPacketSize Function

```
UINT WINAPI IcmpGetPacketSize(  
    HCLIENT hClient  
);
```

The **IcmpGetPacketSize** function returns the size of the ICMP echo datagram that will be sent to the remote host. The minimum packet size is 1 byte, the maximum packet size is 65,535 bytes.

Parameters

hClient

A handle to the client session.

Return Value

If the function succeeds, the return value is the size of the datagram. If the function fails, the return value is ICMP_ERROR. To get extended error information, call **IcmpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csicmv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[IcmpGetRecvCount](#), [IcmpGetSendCount](#), [IcmpGetSequenceId](#), [IcmpGetTimeToLive](#),

IcmpGetRecvCount Function

```
INT WINAPI IcmpGetRecvCount(  
    HCLIENT hClient  
);
```

The **IcmpGetRecvCount** function returns the number of replies sent to the client from the remote host.

Parameters

hClient

A handle to the client session.

Return Value

If the function succeeds, the return value is the number of replies. If the function fails, the return value is ICMP_ERROR. To get extended error information, call **IcmpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csicmv10.lib

Unicode: Implemented as Unicode and ANSI versions.

IcmpGetSendCount Function

```
INT WINAPI IcmpGetSendCount(  
    HCLIENT hClient  
);
```

The **IcmpGetSendCount** function returns the number of datagrams sent to the remote host by the client.

Parameters

hClient

A handle to the client session.

Return Value

If the function succeeds, the return value is the number of datagrams sent by the client. If the function fails, the return value is ICMP_ERROR. To get extended error information, call **IcmpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csicmv10.lib

Unicode: Implemented as Unicode and ANSI versions.

IcmpGetSequenceId Function

```
INT WINAPI IcmpGetSequenceId(  
    HCLIENT hClient  
);
```

The **IcmpGetSequenceId** function returns the sequence identifier for the last ICMP echo datagram received by the client.

Parameters

hClient

A handle to the client session.

Return Value

If the function succeeds, the return value is the sequence identifier. If the function fails, the return value is ICMP_ERROR. To get extended error information, call **IcmpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csicmv10.lib

Unicode: Implemented as Unicode and ANSI versions.

IcmpGetTimeout Function

```
DWORD WINAPI IcmpGetTimeout(  
    HCLIENT hClient  
);
```

The **IcmpGetTimeout** function returns the number of milliseconds the client will wait for a response from the remote host. Once the specified number of milliseconds has elapsed, the function will fail and return to the caller.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the timeout period in milliseconds. If the function fails, the return value is ICMP_ERROR. To get extended error information, call **IcmpGetLastError**.

Remarks

The timeout value is only used with blocking client connections. A value of zero indicates that the default timeout period of 20 seconds should be used.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csicmv10.lib

See Also

[IcmpIsBlocking](#), [IcmpSetTimeout](#)

IcmpGetTimeToLive Function

```
INT WINAPI IcmpGetTimeToLive(  
    HCLIENT hClient  
);
```

The **IcmpGetTimeToLive** function returns the time-to-live for the last ICMP echo datagram received by the client.

Parameters

hClient

A handle to the client session.

Return Value

If the function succeeds, the return value is the time-to-live for the last datagram. If the function fails, the return value is ICMP_ERROR. To get extended error information, call **IcmpGetLastError**.

Remarks

The time-to-live (TTL) value is specified in the IP header of a datagram, and is used to control the number of routers that the datagram is passed through. Each router that handles the datagram decrements the TTL value by one. When it drops to zero, a datagram is returned to the sender, specifying that the TTL has been exceeded. The default value is 255.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csicmv10.lib

See Also

[IcmpGetPacketSize](#), [IcmpGetRecvCount](#), [IcmpGetSendCount](#), [IcmpGetSequenceId](#), [IcmpGetTripTime](#), [IcmpSetSequenceId](#), [IcmpSetTimeToLive](#)

IcmpGetTripTime Function

```
INT WINAPI IcmpGetTripTime(  
    HCLIENT hClient,  
    LPICMP_TIME lpIcmpTime  
);
```

The **IcmpGetTripTime** returns round-trip statistics for the datagrams sent to the current remote host.

Parameters

hClient

A handle to the client session.

lpIcmpTime

A pointer to an [ICMP_TIME](#) data structure which will contain the round-trip statistics for the current remote host.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is `ICMP_ERROR`. To get extended error information, call **IcmpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csicmv10.lib`

IcmpInitialize Function

```
BOOL WINAPI IcmpInitialize(  
    LPCTSTR lpszLicenseKey,  
    LPINITDATA lpData  
);
```

The **IcmpInitialize** function initializes the library and validates the specified license key at runtime.

Parameters

lpszLicenseKey

Pointer to a string that specifies the runtime license key to be validated. If this parameter is NULL, the library will validate the development license installed on the local system.

lpData

Pointer to an INITDATA data structure. This parameter may be NULL if the initialization data for the library is not required.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **IcmpGetLastError**. All other client functions will fail until a license key has been successfully validated.

Remarks

This must be the first function that an application calls before using any of the other functions in the library. When a NULL license key is specified, the library will only function on the development system. Before redistributing the application to an end-user, you must insure that this function is called with a valid license key.

If the *lpData* argument is specified, it must point to an INITDATA structure which has been initialized by setting the *dwSize* member to the size of the structure. All other structure members should be set to zero. If the function is successful, then the INITDATA structure will be filled with identifying information about the library.

Although it is only required that **IcmpInitialize** be called once for the current process, it may be called multiple times; however, each call must be matched by a corresponding call to **IcmpUninitialize**.

This function dynamically loads other system libraries and allocates thread local storage. If you are calling the functions in this library from within another DLL, it is important that you do not call the **IcmpInitialize** or **IcmpUninitialize** functions from the **DllMain** function because it can result in deadlocks or access violation errors. If the DLL is linked with the C runtime library (CRT), it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csicmv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

IcmpIsBlocking Function

```
BOOL WINAPI IcmpIsBlocking(  
    HCLIENT hClient  
);
```

The **IcmpIsBlocking** function is used to determine if the client is currently performing a blocking operation.

Parameters

hClient

Handle to the client session.

Return Value

If the client is performing a blocking operation, the function returns a non-zero value. If the client is not performing a blocking operation, or the client handle is invalid, the function returns zero.

Remarks

Because a blocking operation can allow the application to be re-entered (for example, by pressing a button while the operation is being performed), it is possible that another blocking function may be called while it is in progress. Since only one thread of execution may perform a blocking operation at any one time, an error would occur. The **IcmpIsBlocking** function can be used to determine if the client is already blocked, and if so, take some other action (such as warning the user that they must wait for the operation to complete).

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csicmv10.lib`

See Also

[IcmpCancel](#)

IcmpRecvEcho Function

```
INT WINAPI IcmpRecvEcho(  
    HCLIENT hClient  
);
```

The **IcmpRecvEcho** function reads the reply to an ICMP echo datagram generated by the client. This function should only be called by asynchronous client sessions in response to an event notification that a datagram has been received.

Parameters

hClient

A handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is ICMP_ERROR. To get extended error information, call **IcmpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csicmv10.lib

See Also

IcmpRegisterEvent Function

```
INT WINAPI IcmpRegisterEvent(  
    HCLIENT hClient,  
    UINT nEventId,  
    INETEVENTPROC LpfnEvent,  
    DWORD_PTR dwParam  
);
```

The **IcmpRegisterEvent** function registers a callback function for the specified event.

Parameters

hClient

Handle to client session.

nEventId

An unsigned integer which specifies which event should be registered with the specified callback function. One or more of the following values may be used:

Constant	Description
ICMP_EVENT_ECHO	The client has generated an ICMP echo datagram and has sent it to the specified host. If the datagram is received, the remote host should generate a reply and return it to the sender.
ICMP_EVENT_REPLY	The client has received an ICMP echo reply datagram from the remote host. At this point the client can collect statistical information.
ICMP_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation.
ICMP_EVENT_CANCEL	The current operation has been canceled. The client application may attempt to retry the operation or close the handle.

lpfnEvent

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **IcmpEventProc** callback function. If this parameter is NULL, the callback for the specified event is disabled.

dwParam

A user-defined integer value that is passed to the callback function. If the application targets the x86 (32-bit) platform, this parameter must be a 32-bit unsigned integer. If the application targets the x64 (64-bit) platform, this parameter must be a 64-bit unsigned integer.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is ICMP_ERROR. To get extended error information, call **IcmpGetLastError**.

Remarks

The **IcmpRegisterEvent** function associates a callback function with a specific event. The event

handler is an **IcmpEventProc** function that is invoked when the event occurs. Arguments are passed to the function to identify the client session, the event type and the user-defined value specified when the event handler is registered. If the event occurs because of an error condition, the error code will be provided to the handler.

The callback function specified by the *lpEventProc* parameter must be declared using the **__stdcall** calling convention. This ensures the arguments passed to the event handler are pushed on to the stack in the correct order. Failure to use the correct calling convention will corrupt the stack and cause the application to terminate abnormally.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csicmv10.lib

See Also

[IcmpDisableEvents](#), [IcmpEnableEvents](#), [IcmpEventProc](#), [IcmpFreezeEvents](#)

IcmpReset Function

```
INT WINAPI IcmpReset(  
    HCLIENT hClient  
);
```

The **IcmpReset** function resets the client session, clearing the packet trip statistics, time-to-live, sequence identifier, send and receive counts.

Parameters

hClient

A handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is ICMP_ERROR. To get extended error information, call **IcmpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csicmv10.lib

See Also

[IcmpSetHostAddress](#), [IcmpSetHostName](#), [IcmpSetSequenceId](#), [IcmpSetTimeToLive](#)

IcmpResolveAddress Function

```
INT WINAPI IcmpResolveAddress(  
    DWORD dwAddress,  
    LPTSTR lpszHostName,  
    INT nMaxLength  
);
```

The **IcmpResolveAddress** function resolves a numeric IP address into a fully qualified domain name.

Parameters

dwAddress

The IP address to be resolved, specified as an unsigned 32-bit integer in network byte order.

lpszHostName

A pointer to a buffer that will contain a null-terminated string that specifies the fully qualified domain name for the host. It is recommended that this buffer be at least 64 characters in length.

nMaxLength

The maximum number of characters that can be copied into the string buffer, including the terminating null character.

Return Value

If the function succeeds, the return value is the length of the host name. If the function fails, the return value is ICMP_ERROR. To get extended error information, call **IcmpGetLastError**.

Remarks

The **IcmpResolveAddress** function is used to perform a reverse DNS lookup, converting a numeric IP address into a fully qualified domain name. This is useful for functions like **IcmpTraceRoute**, which return host addresses as numeric values in network byte order. If the reverse DNS lookup fails because there is no PTR record for the given IP address, a printable form of the address in dotted notation will be returned in the string buffer.

Calling this function will cause the thread to block until the IP address is resolved, or until the DNS query times out because there is no reverse record for the address. In some cases, a reverse lookup can take several seconds.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csicmv10.lib

See Also

[IcmpGetHostAddress](#), [IcmpGetHostName](#), [IcmpSetHostAddress](#), [IcmpSetHostName](#), [IcmpTraceRoute](#)

IcmpSendEcho Function

```
INT WINAPI IcmpSendEcho(  
    HCLIENT hClient  
);
```

The **IcmpSendEcho** function sends an ICMP echo datagram to the remote host.

Parameters

hClient

A handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is ICMP_ERROR. To get extended error information, call **IcmpGetLastError**.

Remarks

For asynchronous client sessions, this function returns immediately. Otherwise, the client enters a blocking state and waits for a reply from the remote host. The function returns when a reply has been received, or the operation times-out.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csicmv10.lib

Unicode: Implemented as Unicode and ANSI versions.

IcmpSetHostAddress Function

```
INT WINAPI IcmpSetHostAddress(  
    HCLIENT hClient,  
    DWORD dwAddress  
);
```

The **IcmpSetHostAddress** function specifies the IP address of the host to receive an ICMP echo datagram. If the address specifies a new host, the current client statistics are reset.

Parameters

hClient

A handle to the client session.

dwAddress

The IP address of the remote host as a 32-bit integer value, specified in network byte order.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is ICMP_ERROR. To get extended error information, call **IcmpGetLastError**.

Remarks

To specify a remote host name or an IP address as a string in dot notation, use the **IcmpSetHostName** function instead.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csicmv10.lib

See Also

[IcmpGetHostAddress](#), [IcmpGetHostName](#), [IcmpSetHostName](#)

IcmpSetHostName Function

```
INT WINAPI IcmpSetHostName(  
    HCLIENT hClient,  
    LPCTSTR lpszHostName  
);
```

The **IcmpSetHostName** function specifies the name of the host to receive an ICMP echo datagram. If the name specifies a new host, the current client statistics are reset.

Parameters

hClient

A handle to the client session.

lpszHostName

A pointer to a string which specifies the name, or IP address in dot-notation, of the remote host.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is ICMP_ERROR. To get extended error information, call **IcmpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csicmv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[IcmpGetHostAddress](#), [IcmpGetHostName](#), [IcmpSetHostAddress](#)

IcmpSetLastError Function

```
VOID WINAPI IcmpSetLastError(  
    DWORD dwErrorCode  
);
```

The **IcmpSetLastError** function sets the error code for the current thread. This function is typically used to clear the last error by passing a value of zero as the parameter.

Parameters

dwErrorCode

Specifies the error code for the current thread.

Return Value

None.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or ICMP_ERROR. Those functions which call **IcmpSetLastError** when they succeed are noted on the function reference page.

Applications can retrieve the value saved by this function by using the **IcmpGetLastError** function. The use of **IcmpGetLastError** is optional; an application can call the function to determine the specific reason for a function failure.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csicmv10.lib

See Also

IcmpSetPacketSize Function

```
UINT WINAPI IcmpSetPacketSize(  
    HCLIENT hClient,  
    UINT nPacketSize  
);
```

The **IcmpSetPacketSize** function sets the size of the ICMP datagram packet that is sent to the remote host.

Parameters

hClient

Handle to the client session.

nPacketSize

Size of the ICMP datagram packet in bytes. The minimum packet size is 1 byte and the maximum packet size is 65,535 bytes.

Return Value

If the function succeeds, the return value is the previous ICMP datagram packet size. If the function fails, the return value is zero. To get extended error information, call **IcmpGetLastError**.

Remarks

Note that packet sizes over 512 bytes may not be supported by your networking software or configuration. It is recommended that most applications use the minimum packet size of 32 bytes.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csicmv10.lib

See Also

[IcmpGetPacketSize](#), [IcmpSetSequenceId](#), [IcmpSetTimeToLive](#)

IcmpSetSequenceId Function

```
INT WINAPI IcmpSetSequenceId(  
    HCLIENT hClient,  
    INT nSequenceId  
);
```

The **IcmpSetSequenceId** function sets the sequence identifier for the next ICMP echo datagram sent by the client. The default sequence identifier for the first datagram is one.

Parameters

hClient

A handle to the client session.

nSequenceId

The sequence identifier for the next datagram sent by the client.

Return Value

If the function succeeds, the return value is the previous sequence identifier. If the function fails, the return value is ICMP_ERROR. To get extended error information, call **IcmpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csicmv10.lib

See Also

IcmpSetTimeout Function

```
DWORD WINAPI IcmpSetTimeout(  
    HCLIENT hClient,  
    DWORD dwTimeout  
);
```

The **IcmpSetTimeout** function sets the number of milliseconds the client will wait for a response from the remote host. Once the specified number of milliseconds has elapsed, the function will fail and return to the caller.

Parameters

hClient

Handle to the client session.

dwTimeout

The number of milliseconds until a blocking operation fails.

Return Value

If the function succeeds, the return value is the value of the timeout before the function was called.

If the function fails, the return value is ICMP_ERROR. To get extended error information, call

IcmpGetLastError.

Remarks

The timeout value is only used with blocking client connections.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csicmv10.lib

See Also

[IcmpCreateHandle](#), [IcmpGetTimeout](#)

IcmpSetTimeToLive Function

```
INT WINAPI IcmpSetTimeToLive(  
    HCLIENT hClient,  
    INT nTimeToLive  
);
```

The **IcmpSetTimeToLive** function sets the maximum time-to-live for the next ICMP datagram sent by the client.

Parameters

hClient

A handle to the client session.

nTimeToLive

The time-to-live value for the next ICMP echo datagram.

Return Value

If the function succeeds, the return value is the previous time-to-live value. If the function fails, the return value is ICMP_ERROR. To get extended error information, call **IcmpGetLastError**.

Remarks

The time-to-live (TTL) value is specified in the IP header of a datagram, and is used to control the number of routers that the datagram is passed through. Each router that handles the datagram decrements the TTL value by one. When it drops to zero, a datagram is returned to the sender, specifying that the TTL has been exceeded.

Calling this function changes the default TTL value for all subsequent ICMP datagrams sent by the library, with the default value being 255. Note that not all Windows Sockets implementations support setting the time-to-live value.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csicmv10.lib

See Also

[IcmpGetPacketSize](#), [IcmpGetRecvCount](#), [IcmpGetSendCount](#), [IcmpGetSequenceId](#), [IcmpGetTimeToLive](#), [IcmpGetTripTime](#), [IcmpSetPacketSize](#), [IcmpSetSequenceId](#)

IcmpTraceRoute Function

```
INT WINAPI IcmpTraceRoute(  
    LPCTSTR lpszHostName,  
    UINT nMaxHops,  
    DWORD dwTimeout,  
    DWORD dwReserved,  
    LPICMPTRACE lpTrace,  
    LPDWORD lpdwSize  
);
```

The **IcmpTraceRoute** function sends a series of ICMP echo datagrams to trace the route taken from the local system to the remote host.

Parameters

lpszHostName

A pointer to a string which specifies the fully qualified domain name of the remote host, or the IP address in dotted notation.

nMaxHops

An unsigned integer which specifies the maximum number of routers the datagram will be forwarded through (the number of hops) to the remote host. The minimum value is 1 and the maximum value is 255. It is recommended that most applications specify a value of at least 30.

dwTimeout

An unsigned integer which specifies the number of milliseconds the function will wait for a response to an echo datagram.

dwReserved

A reserved parameter. This value should always be zero.

lpTrace

A pointer to an array of [ICMPTRACE](#) structures which will contain information about each intermediate host between the local and remote system. The number of structures must be at least the same as the maximum number of hops specified by the *nMaxHops* parameter. To determine the total number of bytes that must be allocated for the structure array, this parameter can be passed as NULL and the total size will be returned in the *lpdwSize* parameter.

lpdwSize

A pointer to an unsigned integer which should be initialized to the size of the ICMPTRACE array passed to the function. If the *lpTrace* parameter is NULL, the function will calculate the size of the array buffer that must be allocated and return that value. If both the *lpTrace* and *lpdwSize* parameters are NULL, no statistical information about the intermediate hosts will be collected.

Return Value

If the function succeeds, the return value is the number of intermediate hosts between the local and remote system. If the function fails, the return value is ICMP_ERROR. To get extended error information, call **IcmpGetLastError**.

Remarks

The **IcmpTraceRoute** function sends a series of ICMP echo datagrams to the specified host, adjusting the time-to-live value to determine the intermediate hosts that route the packet. The function returns the number of hops to the remote host.

It is important to note that the failure of an intermediate host to respond to an ICMP echo datagram may not indicate a problem with the remote system. Systems can be configured to specifically ignore ICMP echo datagrams and not respond to them; this is often a security measure to prevent certain kinds of Denial of Service attacks.

The ability to send ICMP datagrams may be restricted to users with administrative privileges, depending on the policies and configuration of the local system. If you are unable to send or receive any ICMP datagrams, it is recommended that you check the firewall settings and any third-party security software that could impact the normal operation of this component.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csicmv10.lib

IcmpUninitialize Function

```
VOID WINAPI IcmpUninitialize();
```

The **IcmpUninitialize** function terminates the use of the library.

Parameters

There are no parameters.

Return Value

None.

Remarks

An application is required to perform a successful **IcmpInitialize** call before it can call any of the other the library functions. When it has completed the use of library, the application must call **IcmpUninitialize** to allow the library to free any resources allocated on behalf of the process. Any pending blocking or asynchronous calls in this process are canceled without posting any notification messages, and all sockets that were opened by the process are closed.

There must be a call to **IcmpUninitialize** for every successful call to **IcmpInitialize** made by a process. In a multithreaded environment, operations for all threads in the client are terminated.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csicmv10.lib

Internet Control Message Protocol Data Structures

- ICMPTIME
- ICMPTRACE
- INITDATA
- INTERNET_ADDRESS
- SYSTEMTIME

ICMPTIME Structure

This structure is used by the [IcmpGetTripTime](#) function to return the round-trip times of an ICMP datagram.

```
typedef struct _ICMPTIME {
    DWORD dwTripAverage;
    DWORD dwTripMaximum;
    DWORD dwTripMinimum;
    DWORD dwTripTime;
} ICMPTIME, *LPICMPTIME;
```

Members

dwTripAverage

The average round-trip time in milliseconds for all datagrams sent to the current host.

dwTripMaximum

The maximum round-trip time in milliseconds for all datagrams sent to current host.

dwTripMinimum

The minimum round-trip time in milliseconds for all datagrams sent to the current host.

dwTripTime

The current round-trip time in milliseconds for the last datagram sent to the current host.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

ICMPTRACE Structure

This structure is used by the [IcmpTraceRoute](#) function to return the route of an ICMP datagram.

```
typedef struct _ICMPTRACE
{
    UINT          nDistance;
    DWORD        dwHostAddress;
    DWORD        dwTripAverage;
    DWORD        dwTripMaximum;
    DWORD        dwTripMinimum;
} ICMPTRACE, *LPICMPTRACE;
```

Members

nDistance

The distance from the local host to the remote host for this route.

dwHostAddress

An unsigned integer which specifies the IP address of the remote host in network byte order.

dwTripAverage

The average round-trip time in milliseconds for all datagrams sent to the specified host.

dwTripMaximum

The maximum round-trip time in milliseconds for all datagrams sent to specified host.

dwTripMinimum

The minimum round-trip time in milliseconds for all datagrams sent to the specified host.

dwTripTime

The current round-trip time in milliseconds for the last datagram sent to the specified host.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

INITDATA Structure

This structure contains information about the SocketTools library when the initialization function returns.

```
typedef struct _INITDATA
{
    DWORD      dwSize;
    DWORD      dwVersionMajor;
    DWORD      dwVersionMinor;
    DWORD      dwVersionBuild;
    DWORD      dwOptions;
    DWORD_PTR  dwReserved1;
    DWORD_PTR  dwReserved2;
    TCHAR      szDescription[128];
} INITDATA, *LPINITDATA;
```

Members

dwSize

Size of this structure. This structure member must be set to the size of the structure prior to calling the initialization function. Failure to do so will cause the function to fail.

dwVersionMajor

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the major version number for the library.

dwVersionMinor

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the minor version number for the library.

dwVersionBuild

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the build number for the library.

dwOptions

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

dwReserved1

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

dwReserved2

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

szDescription

A null terminated string which describes the library.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Unicode: Implemented as Unicode and ANSI versions.

INTERNET_ADDRESS Structure

This structure represents a numeric IPv4 or IPv6 address in network byte order.

```
typedef struct _INTERNET_ADDRESS
{
    INT    ipFamily;
    BYTE  ipNumber[16];
} INTERNET_ADDRESS, *LPINTERNET_ADDRESS;
```

Members

ipFamily

An integer which identifies the type of IP address. It will be one of the following values:

Constant	Description
INET_ADDRESS_UNKNOWN	The address has not been specified or the bytes in the <i>ipNumber</i> array does not represent a valid address. Functions which populate this structure will use this value to indicate that the address cannot be determined.
INET_ADDRESS_IPV4	Specifies that the address is in IPv4 format. The first four bytes of the <i>ipNumber</i> array are significant and contains the IP address. The remaining bytes are not significant and an application should not depend on them having any particular value, including zero.
INET_ADDRESS_IPV6	Specifies that the address is in IPv6 format. All bytes in the <i>ipNumber</i> array are significant. Note that it is possible for an IPv6 address to actually represent an IPv4 address. This is indicated by the first 10 bytes of the address being zero.

ipNumber

A byte array which contains the numeric form of the IP address. This array is large enough to store both IPv4 (32 bit) and IPv6 (128 bit) addresses. The values are stored in network byte order.

Remarks

The **INTERNET_ADDRESS** structure is used by some functions to represent an Internet address in a binary format that is compatible with both IPv4 and IPv6 addresses. Applications that use this structure should consider it to be opaque, and should not modify the contents of the structure directly.

For compatibility with legacy applications that expect an IP address to be 32 bits and stored in an unsigned integer, you can copy the first four bytes of the *ipNumber* array using the **CopyMemory** function or equivalent. Note that if this is done, your application should always check the *ipFamily* member first to make sure that it is actually an IPv4 address.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

SYSTEMTIME Structure

The **SYSTEMTIME** structure represents a date and time using individual members for the month, day, year, weekday, hour, minute, second, and millisecond.

```
typedef struct _SYSTEMTIME
{
    WORD wYear;
    WORD wMonth;
    WORD wDayOfWeek;
    WORD wDay;
    WORD wHour;
    WORD wMinute;
    WORD wSecond;
    WORD wMilliseconds;
} SYSTEMTIME, *LPSYSTEMTIME;
```

Members

wYear

Specifies the current year. The year value must be greater than 1601.

wMonth

Specifies the current month. January is 1, February is 2 and so on.

wDayOfWeek

Specifies the current day of the week. Sunday is 0, Monday is 1 and so on.

wDay

Specifies the current day of the month

wHour

Specifies the current hour.

wMinute

Specifies the current minute

wSecond

Specifies the current second.

wMilliseconds

Specifies the current millisecond.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include windows.h.

Internet Message Access Protocol Library

Manage email messages and mailboxes on a mail server.

Reference

- [Functions](#)
- [Data Structures](#)
- [Error Codes](#)

Library Information

File Name	CSMAPV10.DLL
Version	10.0.1468.2518
LibID	E1419168-2803-4EF6-A0BC-48A71D9EEFD7
Import Library	CSMAPV10.LIB
Dependencies	None
Standards	RFC 3501

Overview

The Internet Message Access Protocol (IMAP) is an application protocol which is used to access a user's email messages which are stored on a mail server. However, unlike the Post Office Protocol (POP) where messages are downloaded and processed on the local system, the messages on an IMAP server are retained on the server and processed remotely. This is ideal for users who need access to a centralized store of messages or have limited bandwidth. For example, traveling salesmen who have notebook computers or mobile users on a wireless network would be ideal candidates for using IMAP.

The SocketTools IMAP library implements the current standard for this protocol, and provides functions to retrieve messages, or just certain parts of a message, create and manage mailboxes, search for specific messages based on certain criteria and so on. The API is designed as a superset of the Post Office Protocol API, so developers who are used to working with the POP3 library will find the IMAP library very easy to integrate into an existing application.

This library supports secure connections using the standard SSL and TLS protocols.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). If you are using Visual C++ 6.0 it is required that you have Service Pack 6 (SP6) installed. You should install all updates for your development tools and have the current Windows SDK installed. The minimum recommended version of Visual Studio is Visual Studio 2010.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are using Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. It is recommended that you install the current service pack and all critical updates available for your version of the operating system.

This product includes both 32-bit and 64-bit libraries. Native 64-bit CPU support requires the 64-bit version of Windows 7 or later versions of the Windows operating system.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

Internet Message Access Protocol Functions

Function	Description
ImapAsyncConnect	Connect asynchronously to the specified server
ImapAttachThread	Attach the specified client handle to another thread
ImapCancel	Cancel the current blocking operation
ImapCheckMailbox	Check the current mailbox for new messages
ImapCloseMessage	Close the current message
ImapCommand	Send a command to the server
ImapConnect	Connect to the specified server
ImapCopyMessage	Copy a message from the current mailbox to another mailbox
ImapCreateMailbox	Create a new mailbox on the server
ImapCreateMessage	Create a new message in the specified mailbox
ImapCreateSecurityCredentials	Allocate a structure to establish client security credentials
ImapDeleteMailbox	Delete the specified mailbox from the server
ImapDeleteMessage	Delete the specified message from the mailbox
ImapDeleteSecurityCredentials	Delete the specified client security credentials
ImapDisableEvents	Disable the event notification mechanism
ImapDisableTrace	Disable logging of socket function calls to the trace log
ImapDisconnect	Disconnect from the current server
ImapEnableEvents	Enable the client event notification mechanism
ImapEnableTrace	Enable logging of socket function calls to a file
ImapEnumMessages	Enumerate the messages in the current mailbox
ImapEventProc	Callback function that processes events generated by the client
ImapExamineMailbox	Select the specified mailbox in read-only mode
ImapExpungeMailbox	Remove messages that have been marked for deletion from the current mailbox
ImapFreezeEvents	Suspend and resume event handling by the client
ImapGetCapability	Return a string which identifies the capabilities of the server
ImapGetCurrentMailbox	Return the name of the currently selected mailbox
ImapGetDeletedMessages	Return the messages that have been marked for deletion
ImapGetErrorString	Return a description for the specified error code
ImapGetFirstMailbox	Return the first mailbox according to specified criteria
ImapGetHeaderValue	Return the value of the specified header field
ImapGetHeaderValueEx	Return the value of a header field in the specified message part
ImapGetIdleThreadId	Return the ID of the thread created to monitor the client session
ImapGetLastError	Return the last error code
ImapGetMailboxDelimiter	Get the path delimiter for the specified mailbox hierarchy

ImapGetMailboxSize	Return the size of the specified mailbox
ImapGetMailboxStatus	Return the status of the specified mailbox
ImapGetMailboxUID	Return the unique identifier for the specified mailbox
ImapGetMessage	Retrieve the specified message from the server
ImapGetMessageCount	Return the number of messages available in the mailbox
ImapGetMessageCountEx	Return the number of messages available in the mailbox
ImapGetMessageFlags	Return the status flags for the specified message
ImapGetMessageHeaders	Retrieve the specified message header from the server
ImapGetMessageHeadersEx	Retrieve the specified message header, UID and flags from the server
ImapGetMessageId	Return the message ID string for the specified message
ImapGetMessageParts	Return the number of MIME message parts in the specified message
ImapGetMessageSender	Return the address of the message sender
ImapGetMessageSize	Return the size of the specified message
ImapGetMessageUid	Return the unique identifier for the specified message
ImapGetNewMessages	Return a list of the new messages in the current mailbox
ImapGetNextMailbox	Return the next mailbox name on the server
ImapGetResultCode	Return the result code from the previous command
ImapGetResultString	Return the result string from the previous command
ImapGetSecurityInformation	Return security information about the current client connection
ImapGetStatus	Return the current status of the client
ImapGetTimeout	Return the number of seconds until an operation times out
ImapGetTransferStatus	Return data transfer statistics
ImapGetUnseenMessages	Return a list of messages from the current mailbox that have not been read
ImapIdle	Enables mailbox status monitoring for the client session
ImapIdleProc	Callback function that receives update notifications from the server
ImapInitialize	Initialize the library and validate the specified license key at runtime
ImapIsBlocking	Determine if the client is blocked, waiting for information
ImapIsConnected	Determine if the client is connected to the server
ImapIsReadable	Determine if data can be read from the server
ImapIsWritable	Determine if data can be written to the server
ImapLogin	Login to the server
ImapOpenMessage	Open the specified message for reading on the server
ImapOpenMessageEx	Open the specified message for reading on the server, with additional options
ImapRead	Read data returned by the server
ImapRegisterEvent	Register an event handler for the specified event
ImapRenameMailbox	Rename the specified mailbox
ImapReselectMailbox	Reselect the current mailbox and return updated status information

ImapSearchMailbox	Search the mailbox according to specified criteria
ImapSelectMailbox	Select the specified mailbox in read-write mode
ImapSetLastError	Set the last error code for the current thread
ImapSetMessageFlags	Set one or more status flags for the specified message
ImapSetTimeout	Set the number of seconds until an operation times out
ImapStoreMessage	Store the contents of a message to the specified file
ImapSubscribeMailbox	Subscribe to the specified mailbox
ImapUndeleteMessage	Undelete the specified message from the current mailbox
ImapUninitialize	Terminate use of the library by the application
ImapUnselectMailbox	Unselect the current mailbox and expunge any deleted messages
ImapUnsubscribeMailbox	Unsubscribe from the specified mailbox
ImapWrite	Write data to the server

ImapAsyncConnect Function

```
HCLIENT WINAPI ImapAsyncConnect(  
    LPCTSTR lpszRemoteHost,  
    UINT nRemotePort,  
    UINT nTimeout,  
    DWORD dwOptions,  
    LPSECURITYCREDENTIALS LpCredentials,  
    HWND hEventWnd,  
    UINT uEventMsg  
);
```

The **ImapAsyncConnect** function is used to establish a connection with the server.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

The application should create a background worker thread and establish a connection by calling **ImapConnect** within that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each client session.

Parameters

lpszHostName

A pointer to a null terminated string which specifies the host name or IP address of the IMAP server.

nRemotePort

The port number the client should use to establish the connection. A value of zero specifies that default port 143 should be used, which is the standard port number assigned to the IMAP service. If the secure port number is specified, an implicit SSL/TLS connection will be established by default.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation

dwOptions

An unsigned integer value which specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
IMAP_OPTION_NONE	No connection options specified. A standard connection to the server will be established using the specified host name and port number.
IMAP_OPTION_IDENTIFY	This option specifies the client should identify itself to the server. If enabled, the client will send the ID command to the server as defined in RFC 2971. This option has no effect if the server does not support the ID command.
IMAP_OPTION_TUNNEL	This option specifies that a tunneled TCP

	<p>connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established.</p>
IMAP_OPTION_TRUSTEDSITE	<p>This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using either the SSL or TLS protocols.</p>
IMAP_OPTION_SECURE	<p>This option specifies that a secure connection should be established with the server and requires that the server support either the SSL or TLS protocol. This option is the same as specifying IMAP_OPTION_SECURE_EXPLICIT, which initiates the secure session using the STARTTLS command.</p>
IMAP_OPTION_SECURE_EXPLICIT	<p>This option specifies the client should attempt to establish a secure connection with the server. The server must support secure connections using either the SSL or TLS protocol and the STARTTLS command.</p>
IMAP_OPTION_SECURE_IMPLICIT	<p>This option specifies the client should attempt to establish a secure connection with the server. The server must support secure connections using either the SSL or TLS protocol, and the secure session must be negotiated immediately after the connection has been established.</p>
IMAP_OPTION_SECURE_FALLBACK	<p>This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.</p>
HTTP_OPTION_PREFER_IPV6	<p>This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.</p>
IMAP_OPTION_FREETHREAD	<p>This option specifies the handle returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access</p>

to the handle is synchronized across multiple threads.

lpCredentials

A pointer to a [SECURITYCREDENTIALS](#) structure which is used to establish the client credentials for a secure connection to the server. The function **ImapCreateSecurityCredentials** can be used to create this structure if necessary. If a standard non-secure connection is being established, or client credentials are not required by the server, this parameter can be NULL.

hEventWnd

The handle to the asynchronous notification window. This window receives messages which notify the client of various asynchronous client events that occur. Specifying this parameter and a message identifier causes the connection to be non-blocking. If this parameter is NULL, then a blocking connection is established.

uEventMsg

The message identifier that is used when an asynchronous client event occurs. This value should be greater than WM_USER as defined in the Windows header files. If the *hEventWnd* parameter is NULL, this parameter should be specified as WM_NULL.

Return Value

If the function succeeds, the return value is a handle to a client session. If the function fails, the return value is INVALID_CLIENT. To get extended error information, call **ImapGetLastError**.

Remarks

When a message is posted to the notification window, the low word of the *lParam* parameter contains the event identifier. The high word of *lParam* contains the low word of the error code, if an error has occurred. The *wParam* parameter contains the client handle. One or more of the following event identifiers may be sent:

Constant	Description
IMAP_EVENT_CONNECT	The connection to the server has completed. The high word of the <i>lParam</i> parameter should be checked, since this notification message will be posted if an error has occurred.
IMAP_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
IMAP_EVENT_READ	Data is available to read by the client. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the calling process is in asynchronous mode.
IMAP_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
IMAP_EVENT_TIMEOUT	The client has timed out while waiting for a response from the server. Note that under some circumstances this event can be generated for a non-blocking connection, such as when the client is establishing a secure connection.

IMAP_EVENT_CANCEL	The client has canceled the current operation.
IMAP_EVENT_COMMAND	The client has processed a command that was sent to the server. The result code and result string can be used to determine if the response to the command. The high word of the IParam parameter should be checked, since this notification message will also be posed if the command cannot be executed.
IMAP_EVENT_PROGRESS	This event notification is sent periodically during lengthy blocking operations, such as retrieving a complete message from the server.

To cancel asynchronous notification and return the client to a blocking mode, use the **ImapDisableEvents** function.

The *dwOptions* argument can be used to specify the threading model that is used by the library when a connection is established. By default, the handle is initially attached to the thread that created it. From that point on, until the it is released, only the owner may call functions using that handle. The ownership of the handle may be transferred from one thread to another using the **ImapAttachThread** function.

Specifying the IMAP_OPTION_FREETHREAD option enables any thread to call any function using the handle, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the handle is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same handle.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmapi10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[ImapConnect](#), [ImapDisableEvents](#), [ImapDisconnect](#), [ImapEnableEvents](#), [ImapInitialize](#), [ImapUninitialize](#)

ImapAttachThread Function

```
DWORD WINAPI ImapAttachThread(  
    HCLIENT hClient  
    DWORD dwThreadId  
);
```

The **ImapAttachThread** function attaches the specified client handle to another thread.

Parameters

hClient

Handle to the client session.

dwThreadId

The ID of the thread that will become the new owner of the handle. A value of zero specifies that the current thread should become the owner of the client handle.

Return Value

If the function succeeds, the return value is the thread ID of the previous owner. If the function fails, the return value is IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

When a client handle is created, it is associated with the current thread that created it. Normally, if another thread attempts to perform an operation using that handle, an error is returned since it does not own the handle. This is used to ensure that other threads cannot interfere with an operation being performed by the owner thread. In some cases, it may be desirable for one thread in a client application to create the client handle, and then pass that handle to another worker thread. The **ImapAttachThread** function can be used to change the ownership of the handle to the new worker thread. By preserving the return value from the function, the original owner of the handle can be restored before the worker thread terminates.

This function should be called by the new thread immediately after it has been created, and if the new thread does not release the handle itself, the ownership of the handle should be restored to the parent thread before it terminates. Under no circumstances should **ImapAttachThread** be used to forcibly release a handle allocated by another thread while a blocking operation is in progress. To cancel an operation, use the **ImapCancel** function and then release the handle after the blocking function exits and control is returned to the current thread.

Note that the *dwThreadId* parameter is presumed to be a valid thread ID and no checks are performed to ensure that the thread actually exists. Specifying an invalid thread ID will orphan the handle until the **ImapUninitialize** function is called.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmapi10.lib

See Also

[ImapCancel](#), [ImapAsyncConnect](#), [ImapConnect](#), [ImapDisconnect](#), [ImapUninitialize](#)

ImapCancel Function

```
INT WINAPI ImapCancel(  
    HCLIENT hClient  
);
```

The **ImapCancel** function cancels any outstanding blocking operation in the client, causing the blocking function to fail. The application may then retry the operation or terminate the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

When the **ImapCancel** function is called, the blocking function will not immediately fail. An internal flag is set which causes the blocking operation to exit with an error. This means that the application cannot cancel an operation and immediately perform some other operation. Instead it must allow the calling stack to unwind, returning back to the blocking operation before making any further function calls.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmapi10.lib

See Also

[ImapIsBlocking](#)

ImapCheckMailbox Function

```
INT WINAPI ImapCheckMailbox(  
    HCLIENT hClient,  
    UINT *LpnMessages,  
    UINT *LpnUnseen  
);
```

The **ImapCheckMailbox** function requests that the server create a checkpoint of the currently selected mailbox, and returns the current number of messages and unseen messages.

Parameters

hClient

Handle to the client session.

lpnMessages

A pointer to an unsigned integer value which will contain the number of messages in the currently selected mailbox when the function returns.

lpnUnseen

A pointer to an unsigned integer value which will contain the number of unseen messages in the currently selected mailbox.

Return Value

If the function succeeds, it returns zero. If an error occurs, the function returns IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

When the client requests a checkpoint, the server may perform implementation-dependent housekeeping for that mailbox, such as updating the mailbox on disk with the current state of the mailbox in memory. On some systems this command has no effect other than to update the client with the current number of messages in the mailbox.

This function actually sends two IMAP commands. The first is the CHECK command, followed by the NOOP command to poll for any new messages that have arrived. In addition to polling the server for new messages, this command can also be used to ensure the idle timer on the server does not expire and force a disconnect from the client.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmapi10.lib

See Also

ImapCloseMessage Function

```
INT WINAPI ImapCloseMessage(  
    HCLIENT hClient  
);
```

The **ImapCloseMessage** function closes the current message.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

The **ImapCloseMessage** function closes the current message. If there is any remaining data left to be read from the message, it will be read and discarded.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmav10.lib

See Also

[ImapCreateMessage](#), [ImapOpenMessage](#), [ImapOpenMessageEx](#)

ImapCommand Function

```
INT WINAPI ImapCommand(  
    HCLIENT hClient,  
    LPCTSTR lpszCommand,  
    LPCTSTR lpszParameter  
);
```

The **ImapCommand** function sends a command to the server. This function is typically used for site-specific commands not directly supported by the API.

Parameters

hClient

Handle to the client session.

lpszCommand

The command which will be executed by the server.

lpszParameter

An optional command parameter. If the command requires more than one parameter, then they should be combined into a single string, with a space separating each parameter. If the command does not accept any parameters, this value may be NULL.

Return Value

If the function succeeds, it returns an IMAP result code. If the command was successful, it returns IMAP_RESULT_OK. A return value of IMAP_RESULT_CONTINUE indicates the command was accepted and the caller should proceed with the next command. If an error occurs, the function returns IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

A list of valid commands can be found in the technical specification for the protocol. The current version of the protocol which is supported by this library is version 4rev1 as defined in RFC 3501.

Use the **ImapGetResultCode** function to determine the result of the command that was sent to the server.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmapi10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[ImapGetResultCode](#), [ImapGetResultString](#)

ImapConnect Function

```
HCLIENT WINAPI ImapConnect(  
    LPCTSTR lpszHostName,  
    UINT nRemotePort,  
    UINT nTimeout,  
    DWORD dwOptions,  
    LPSECURITYCREDENTIALS LpCredentials  
);
```

The **ImapConnect** function is used to establish a connection with the server. It supports connection options beyond those provided beyond **ImapConnect**.

Parameters

lpszHostName

A pointer to a null terminated string which specifies the host name or IP address of the IMAP server.

nRemotePort

The port number the client should use to establish the connection. A value of zero specifies that default port 143 should be used, which is the standard port number assigned to the IMAP service. If the secure port number is specified, an implicit SSL/TLS connection will be established by default.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwOptions

An unsigned integer value which specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
IMAP_OPTION_NONE	No connection options specified. A standard connection to the server will be established using the specified host name and port number.
IMAP_OPTION_IDENTIFY	This option specifies the client should identify itself to the server. If enabled, the client will send the ID command to the server as defined in RFC 2971. This option has no effect if the server does not support the ID command.
IMAP_OPTION_TUNNEL	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established.
IMAP_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the

	connection will always be permitted. This option only affects connections using either the SSL or TLS protocols.
IMAP_OPTION_SECURE	This option specifies that a secure connection should be established with the server and requires that the server support either the SSL or TLS protocol. This option is the same as specifying IMAP_OPTION_SECURE_EXPLICIT, which initiates the secure session using the STARTTLS command.
IMAP_OPTION_SECURE_EXPLICIT	This option specifies the client should attempt to establish a secure connection with the server. Note that the server must support secure connections using either the SSL or TLS protocol.
IMAP_OPTION_SECURE_IMPLICIT	This option specifies the client should attempt to establish a secure connection with the server. The server must support secure connections using either the SSL or TLS protocol, and the secure session must be negotiated immediately after the connection has been established.
IMAP_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
IMAP_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
IMAP_OPTION_FREETHREAD	This option specifies the handle returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the handle is synchronized across multiple threads.

lpCredentials

A pointer to a [SECURITYCREDENTIALS](#) structure which is used to establish the client credentials for a secure connection to the server. The function **ImapCreateSecurityCredentials** can be used to create this structure if necessary. If a standard non-secure connection is being established, or client credentials are not required by the server, this parameter can be NULL.

Return Value

If the function succeeds, the return value is a handle to a client session. If the function fails, the return value is `INVALID_CLIENT`. To get extended error information, call **ImapGetLastError**.

Remarks

To prevent this function from blocking the main user interface thread, the application should create a background worker thread and establish a connection by calling **ImapConnect** in that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each client session.

The *dwOptions* argument can be used to specify the threading model that is used by the library when a connection is established. By default, the handle is initially attached to the thread that created it. From that point on, until the it is released, only the owner may call functions using that handle. The ownership of the handle may be transferred from one thread to another using the **ImapAttachThread** function.

Specifying the `IMAP_OPTION_FREETHREAD` option enables any thread to call any function using the handle, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the handle is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same handle.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csmapi10.lib`

Unicode: Implemented as Unicode and ANSI versions.

[ImapDisconnect](#), [ImapInitialize](#), [ImapLogin](#)

ImapCopyMessage Function

```
INT WINAPI ImapCopyMessage(  
    HCLIENT hClient,  
    UINT nMessageId,  
    LPCTSTR lpszMailbox  
);
```

The **ImapCopyMessage** function copies a message from the current mailbox to the specified mailbox. The message is appended to the mailbox, and the message flags and internal date are preserved.

Parameters

hClient

Handle to the client session.

nMessageId

The message identifier which specifies which message is to be copied to the mailbox. This value must be greater than zero and specify a valid message number.

lpszMailbox

A pointer to a string which specifies the name of the mailbox that the message will be copied to. The mailbox must already exist, and the client must have the appropriate access rights to modify the mailbox.

Return Value

If the function succeeds, it returns a value of zero. If an error occurs, the function returns IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

If the mailbox does not exist, the function will fail. To create a new mailbox, use the **ImapCreateMailbox** function. A message can be copied within the same mailbox, in which case the server may flag it as a new message.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmapi10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[ImapCreateMailbox](#), [ImapGetResultCode](#), [ImapGetResultString](#)

ImapCreateMailbox Function

```
INT WINAPI ImapCreateMailbox(  
    HCLIENT hClient,  
    LPCTSTR lpszMailbox  
);
```

The **ImapCreateMailbox** function creates a new mailbox on the server.

Parameters

hClient

Handle to the client session.

lpszMailbox

A pointer to a string which specifies the new mailbox to be created.

Return Value

If the function succeeds, it returns a value of zero. If an error occurs, the function returns IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

If the mailbox name is suffixed with the server's hierarchy delimiter, this indicates to the server that the client intends to create mailbox names under the specified name in the hierarchy. If superior hierarchical names are specified in the mailbox name, then the server may automatically create them as needed. For example, if the mailbox name "Mail/Office/Projects" is specified and "Mail/Office" does not exist, it may be automatically created by the server.

The special mailbox name INBOX is reserved, and cannot be created. It is recommended that mailbox names only consist of printable ASCII characters, and the special characters "*" and "%" should be avoided.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmapi10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[ImapDeleteMailbox](#), [ImapGetFirstMailbox](#), [ImapGetNextMailbox](#), [ImapRenameMailbox](#)

ImapCreateMessage Function

```
INT WINAPI ImapCreateMessage(  
    HCLIENT hClient,  
    LPCTSTR lpszMailbox,  
    DWORD dwReserved,  
    LPVOID lpMessage,  
    DWORD dwMessageSize,  
    DWORD dwFlags  
);
```

The **ImapCreateMessage** function creates a message, appending it to the contents of the specified mailbox.

Parameters

hClient

Handle to the client session.

lpszMailbox

A pointer to a string which specifies the name of the mailbox that the message will be created in. The mailbox must already exist, and the client must have the appropriate access rights to modify the mailbox.

dwReserved

A reserved parameter. This value should always be zero.

lpMessage

A pointer to the buffer which contains the message to be created.

dwMessageSize

An unsigned integer value which specifies the size of the message in bytes. If this value is zero, then it is assumed that the *lpMessage* parameter points to a string.

dwFlags

An unsigned integer that specifies one or more message flags. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
IMAP_FLAG_NONE	No value.
IMAP_FLAG_ANSWERED	The message has been answered.
IMAP_FLAG_DRAFT	The message is not completed and is marked as a draft copy.
IMAP_FLAG_URGENT	The message is flagged for urgent or special attention.
IMAP_FLAG_SEEN	The message has been read.

Return Value

If the function succeeds, it returns zero. If an error occurs, the function returns IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

If the mailbox does not exist, the function will fail. To create a new mailbox, use the **ImapCreateMailbox** function. If the message is created in the mailbox that is currently selected, the server may flag it as recent.

This function is typically used by applications to store messages which have already been sent to a user. After a message has been delivered using the SMTP protocol, that same message may be created in a mailbox on the IMAP server so that the user has access to those messages.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmav10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

ImapCreateSecurityCredentials Function

```
BOOL WINAPI ImapCreateSecurityCredentials(  
    DWORD dwProtocol,  
    DWORD dwOptions,  
    LPCTSTR lpszUserName,  
    LPCTSTR lpszPassword,  
    LPCTSTR lpszCertStore,  
    LPCTSTR lpszCertName,  
    LPVOID lpvReserved,  
    LPSECURITYCREDENTIALS* lppCredentials  
);
```

The **ImapCreateSecurityCredentials** function creates a **SECURITYCREDENTIALS** structure.

Parameters

dwProtocol

A bitmask of supported security protocols. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_SSL	Either SSL 2.0 or SSL 3.0 should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, TLS will be excluded from the list of supported protocols. Both SSL 2.0 and 3.0 have been deprecated and will never be used unless explicitly specified. It is not recommended that you enable either of these protocols for secure connections because it will cause most servers to reject your connection request, even if a version of TLS is also specified.
SECURITY_PROTOCOL_TLS	Either the TLS 1.0, 1.1 or 1.2 protocol should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers that reject any attempt to use the older SSL protocol and require that only TLS be used.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol should be used when establishing a secure connection. This version is

	supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This is the recommended version of TLS to use with secure connections.

dwOptions

A value which specifies one or options. This member is constructed by using a bitwise operator with any of the following values:

Constant	Description
CREDENTIAL_STORE_CURRENT_USER	The library will attempt to open a store for the current user using the certificate store name provided in this structure. If no options are specified, then this is the default behavior.
CREDENTIAL_STORE_LOCAL_MACHINE	The library will attempt to open a local machine store using the certificate store name provided in this structure. If this option is specified, the library will always search for a local machine store before searching for the store by that name for the current user.
CREDENTIAL_STORE_FILENAME	The certificate store name is a file that contains the certificate and private key that will be used.

lpszUserName

A pointer to a string which specifies the certificate owner's username. A value of NULL specifies that no username is required. Currently this parameter is not used and any value specified will be ignored.

lpszPassword

A pointer to a string which specifies the certificate owner's password. A value of NULL specifies

that no password is required. This parameter is only used if a PKCS12 (PFX) certificate file is specified and that certificate has been secured with a password. This value will be ignored the current user or local machine certificate store is specified.

lpszCertStore

A pointer to a string which specifies the name of the certificate store to open. A certificate store is a collection of certificates and their private keys, typically organized by how they are used. If this value is NULL or points to an empty string, the default certificate store "MY" will be used.

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as VeriSign and Thawte act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. This corresponds to the "Personal" store that is displayed by the certificate manager utility and is the default store used by the library.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as VeriSign and Thawte are installed as part of the operating system and periodically updated by Microsoft.

lpszCertName

A pointer to a null terminated string which specifies the name of the certificate to use. The function will first search the certificate store for a certificate with a matching "friendly name"; this is a name for the certificate that is assigned by the user. Note that the name must match completely, but the comparison is not case sensitive. If no matching certificate is found, the function will then attempt to find a certificate that has a matching common name (also called the certificate subject). This comparison is less stringent, and the first partial match will be returned. If this second search fails, the function will return an error indicating that the certificate could not be found.

lpvReserved

Pointer reserved for future use. Set it to NULL when using this function.

lppCredentials

Pointer to an [LPSECURITYCREDENTIALS](#) pointer. The memory for the credentials structure will be allocated by this function and must be released by calling the **ImapDeleteSecurityCredentials** function when it is no longer needed. The pointer value must be set to NULL before the function is called. It is important to note that this is a pointer to a pointer variable, not a pointer to the SECURITYCREDENTIALS structure itself.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **ImapGetLastError**.

Remarks

The structure that is created by this function may be used as client credentials when establishing a secure connection. This is particularly useful for programming languages other than C/C++ which may not support C structures or pointers. The pointer to the SECURITYCREDENTIALS structure can

be declared as an unsigned integer variable which is passed by reference to this function, and then passed by value to the **ImapAsyncConnect** or **ImapConnect** functions.

Example

```
LPSECURITYCREDENTIALS lpSecCred = NULL;
ImapCreateSecurityCredentials(SEcurity_PROTOCOL_DEFAULT,
                             0,
                             NULL,
                             NULL,
                             lpszCertStore,
                             lpszCertName,
                             NULL,
                             &lpSecCred);

hClient = ImapConnect(lpszHostName,
                     IMAP_PORT_SECURE,
                     IMAP_TIMEOUT,
                     IMAP_OPTION_SECURE,
                     lpSecCred);
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmapi10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

ImapDeleteMailbox Function

```
INT WINAPI ImapDeleteMailbox(  
    HCLIENT hClient,  
    LPCTSTR lpszMailbox  
);
```

The **ImapDeleteMailbox** function deletes a mailbox on the server.

Parameters

hClient

Handle to the client session.

lpszMailbox

A pointer to a string which specifies the mailbox to be deleted.

Return Value

If the function succeeds, it returns value of zero. If an error occurs, the function returns IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

A mailbox cannot be deleted if it contains inferior hierarchical names and has the IMAP_FLAG_NOSELECT attribute. On most systems this is the case when the mailbox name references a directory on the server, and that directory contains other subdirectories or mailboxes. To remove the mailbox, you must first delete any child mailboxes that exist.

If the mailbox that is deleted is the currently selected mailbox, it will be automatically unselected and any messages marked for deletion will be expunged before the mailbox is removed. If the delete operation fails, the client will remain in an unselected state until either the **ImapExamineMailbox** or **ImapSelectMailbox** function is called.

The special mailbox name INBOX is reserved, and cannot be deleted.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmapi10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[ImapCreateMailbox](#), [ImapGetFirstMailbox](#), [ImapGetNextMailbox](#), [ImapRenameMailbox](#)

ImapDeleteMessage Function

```
INT WINAPI ImapDeleteMessage(  
    HCLIENT hClient,  
    UINT nMessageId  
);
```

The **ImapDeleteMessage** function marks the specified message for deletion from the current mailbox.

Parameters

hClient

Handle to the client session.

nMessage

Number of message to delete from the server. This value must be greater than zero. The first message in the mailbox is message number one.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

This function only marks the message for deletion. The message is not actually deleted until the mailbox is expunged or another mailbox is selected. This function will return an error if the current mailbox is in read-only mode, such as if it was selected using the **ImapExamineMailbox** function.

It is important to note that unlike the POP3 protocol, a message that is marked for deletion is still accessible on the IMAP server until the mailbox is expunged. This means, for example, that a deleted message can still be retrieved using the **ImapGetMessage** function.

To determine if a message has been marked for deletion, use the **ImapGetMessageFlags** function and check if the IMAP_FLAG_DELETED bit flag has been set. To list all of the deleted messages in the current mailbox, use the **ImapGetDeletedMessages** function.

To remove the deletion flag from the message, use the **ImapUndeleteMessage** function. To prevent all messages in the current mailbox from being expunged, use the **ImapReselectMailbox** function to reset the current mailbox state.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmapi10.lib

See Also

ImapDeleteSecurityCredentials Function

```
VOID WINAPI ImapDeleteSecurityCredentials(  
    LPSECURITYCREDENTIALS* LppCredentials  
);
```

The **ImapDeleteSecurityCredentials** function deletes an existing **SECURITYCREDENTIALS** structure.

Parameters

lppCredentials

Pointer to an [LPSECURITYCREDENTIALS](#) pointer. On exit from the function, the pointer will be NULL.

Return Value

None.

Example

```
if (lpSecCred)  
    ImapDeleteSecurityCredentials(&lpSecCred);  
  
ImapUninitialize();
```

Remarks

This function can be used to release the memory allocated to the client or server credentials after a secure connection has been terminated.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csmapi10.lib`

Unicode: Implemented as Unicode and ANSI versions.

See Also

[ImapCreateSecurityCredentials](#), [ImapUninitialize](#)

ImapDisableEvents Function

```
INT WINAPI ImapDisableEvents(  
    HCLIENT hClient  
);
```

The **ImapDisableEvents** function disables the event notification mechanism, preventing subsequent event notification messages from being posted to the application's message queue.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

The **ImapDisableEvents** function is used to disable event message posting for the specified client session. Although this will immediately prevent any new events from being generated, it is possible that messages could be waiting in the message queue. Therefore, an application must be prepared to handle client event messages after this function has been called.

This function is automatically called if the client has event notification enabled, and the **ImapDisconnect** function is called. The same issues regarding outstanding event messages also applies in this situation, requiring that the application handle event messages that may reference a client handle that is no longer valid.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmapi10.lib

ImapDisableTrace Function

```
BOOL WINAPI ImapDisableTrace();
```

The **ImapDisableTrace** function disables the logging of socket function calls to the trace log.

Parameters

None.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **ImapGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmavp10.lib

See Also

[ImapEnableTrace](#)

ImapDisconnect Function

```
INT WINAPI ImapDisconnect(  
    HCLIENT hClient  
);
```

The **ImapDisconnect** function terminates the connection with the server, releasing the memory allocated for the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

If a mailbox is selected at the time that **ImapDisconnect** is called, the current mailbox will be unselected and any messages that are marked for deletion will be expunged. To prevent any deleted messages from being removed from the mailbox, use the **ImapUnselectMailbox** function to unselect the current mailbox prior to disconnecting from the server.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmapi10.lib

See Also

[ImapAsyncConnect](#), [ImapConnect](#), [ImapUninitialize](#), [ImapUnselectMailbox](#)

ImapEnableEvents Function

```
INT WINAPI ImapEnableEvents(  
    HCLIENT hClient,  
    HWND hEventWnd,  
    UINT uEventMsg  
);
```

The **ImapDisableEvents** function disables the event notification mechanism, preventing subsequent event notification messages from being posted to the application's message queue.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Applications should use the **ImapRegisterEvent** function to register an event handler which is invoked when an event occurs.

Parameters

hClient

Handle to the client session.

hEventWnd

Handle to the window which will receive the client notification messages. This parameter must specify a valid window handle. If a NULL handle is specified, event notification will be disabled.

uEventMsg

The message that is received when a client event occurs. To avoid conflict with standard Windows messages, this value must be greater than WM_USER (1024) or an error will be returned. If the *hEventWnd* parameter is NULL, this value should be WM_NULL.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

The **ImapEnableEvents** function is used to request that notification messages be posted to the specified window whenever a client event occurs. This allows an application to monitor the status of different client operations, such as a file transfer. The client must create a window message handler, which processes the various events. The *wParam* argument will contain the client handle, the low word of the *lParam* argument will contain the event identifier, and the high word will contain any error code. If no error has occurred, the high word will have a value of zero. The following events may be generated:

Constant	Description
IMAP_EVENT_CONNECT	The connection to the server has completed. The high word of the <i>lParam</i> parameter should be checked, since this notification message will be posted if an error has occurred.
IMAP_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
IMAP_EVENT_READ	Data is available to read by the client. No additional messages will

	be posted until the client has read at least some of the data. This event is only generated if the calling process is in asynchronous mode.
IMAP_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
IMAP_EVENT_TIMEOUT	The client has timed out while waiting for a response from the server. Note that under some circumstances this event can be generated for a non-blocking connection, such as when the client is establishing a secure connection.
IMAP_EVENT_CANCEL	The client has canceled the current operation.
IMAP_EVENT_COMMAND	The client has processed a command that was sent to the server. The result code and result string can be used to determine if the response to the command. The high word of the IParam parameter should be checked, since this notification message will also be posed if the command cannot be executed.
IMAP_EVENT_PROGRESS	This event notification is sent periodically during lengthy blocking operations, such as retrieving a complete message from the server.

It is not required that the client be placed in asynchronous (non-blocking) mode in order to receive event notifications, except for the connect, disconnect, read and write events. To disable event notification, call the **ImapDisableEvents** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmapi10.lib

See Also

[ImapAsyncConnect](#), [ImapDisableEvents](#), [ImapRegisterEvent](#)

ImapEnableTrace Function

```
BOOL WINAPI ImapEnableTrace(  
    LPCTSTR lpszTraceFile,  
    DWORD dwTraceFlags  
);
```

The **ImapEnableTrace** function enables the logging of socket function calls to a file.

Parameters

lpszTraceFile

Name of the trace log file. If this parameter is NULL or empty, the file CSTRACE.LOG is used. The directory for CSTRACE.LOG is given by the TEMP environment variable, if it is defined; otherwise, the directory given by the TMP environment variable is used, if it is defined; otherwise, the current working directory is used.

dwTraceFlags

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Constant	Description
0	TRACE_DEFAULT	All function calls and return values are written to the trace file. The actual data being sent or received will not be logged. This is the default value.
1	TRACE_ERROR	Only those function calls which fail are recorded in the trace file. Those errors which are not fatal and only indicate a warning will not be logged.
2	TRACE_WARNING	Only those function calls which fail, or return values which indicate a warning, are recorded in the trace file.
4	TRACE_HEXDUMP	All functions calls are written to the trace file, plus all the data that is sent or received is displayed, in both ASCII and hexadecimal format.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **ImapGetLastError**.

Remarks

When trace logging is enabled, the logfile is opened, appended to and closed for each socket function call. Using the same logfile name, you can do the same in your application to add additional information to the logfile if needed. This can provide an application-level context for the entries made by the library. Make sure that the logfile is closed after the data has been written.

The TRACE_HEXDUMP option can produce very large logfiles, since all data that is being sent and received by the application is logged. To reduce the size of the file, you can enable and disable logging around limited sections of code that you wish to analyze.

All of the SocketTools networking components that use the Windows Sockets API support logging. If you are using multiple components, you only need to enable tracing once in your application or once per thread in a multithreaded application.

To redistribute an application that includes logging functionality, the **cstrcv10.dll** library must be included as part of the installation package. This library provides the trace logging features, and if it is not available the **ImapEnableTrace** function will fail. Note that the trace logging library is a standard Windows DLL and does not need to be registered, it only needs to be redistributed with your application.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmav10.lib

Unicode: Implemented as Unicode and ANSI versions.

[ImapDisableTrace](#)

ImapEnumMessages Function

```
INT WINAPI ImapEnumMessages(  
    HCLIENT hClient,  
    UINT nFirstMessageId,  
    UINT nLastMessageId,  
    DWORD dwMessageFlags,  
    DWORD dwReserved,  
    LPIMAPMESSAGE lpMessageList,  
    INT nMaxMessages  
);
```

The **ImapEnumMessages** function enumerates the messages in the current mailbox, populating an array of IMAPMESSAGE structures which contain information about each message.

Parameters

hClient

Handle to the client session.

nFirstMessageId

An unsigned integer value which specifies the first message to enumerate. This value must be greater than zero and specify a valid message identifier. The first message in the mailbox has a value of one.

nLastMessageId

An unsigned integer value which specifies the last message to enumerate. This value must be greater than or equal to the value of the *nFirstMessageId* parameter. A special value of 0xFFFFFFFF can be used to specify the last message in the mailbox.

dwMessageFlags

This parameter is used to determine which messages are enumerated. If the value is zero, then all applicable messages will be enumerated. If the value is non-zero, only those messages which have at least one of the specified flags will be returned. More than one flag can be specified by using a bitwise operator. Valid message flags are:

Constant	Description
IMAP_FLAG_ANSWERED	Return only those messages which have been answered.
IMAP_FLAG_DELETED	Return only those messages which have been marked for deletion.
IMAP_FLAG_DRAFT	Return only those messages which have been marked as draft copies.
IMAP_FLAG_URGENT	Return only those messages which have been flagged for urgent or special attention.
IMAP_FLAG_RECENT	Return only those messages which have been recently added to the mailbox.
IMAP_FLAG_SEEN	Return only those messages which have been read.

dwReserved

A reserved parameter. This value should always be set to zero.

lpMessageList

A pointer to an array of [IMAPMESSAGE](#) structures which will contain information about each of the messages returned by the server. This parameter cannot be NULL.

nMaxMessages

An integer value which specifies the maximum size of the IMAPMESSAGE array that was passed to the function. This value must be at least one.

Return Value

If the function succeeds, the return value is the number of messages that were enumerated. If no messages match the specified criteria, the function will return a value of zero. If an error is encountered, the function returns IMAP_ERROR. To get extended error information, call [ImapGetLastError](#).

Remarks

If the message UID is being stored locally by the client to identify the message over multiple sessions, it must also store the mailbox UID. Only the combination of the mailbox name, mailbox UID and message UID can be used to uniquely identify a given message on the server. Although IMAP server implementations are encouraged to maintain persistent message UIDs, they are not required to do so and those values may change if the mailbox UID changes.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmapi10.lib

See Also

[ImapGetMessage](#), [ImapGetMessageCount](#), [ImapGetMessageFlags](#), [ImapGetMessageHeaders](#), [ImapGetMessageSize](#), [ImapGetMessageUid](#)

ImapEventProc Function

```
VOID CALLBACK ImapEventProc(  
    HCLIENT hClient,  
    UINT nEvent,  
    DWORD dwError,  
    DWORD_PTR dwParam  
);
```

The **ImapEventProc** function is an application-defined callback function that processes events generated by the client.

Parameters

hClient

Handle to the client session.

nEvent

An unsigned integer which specifies which event occurred. For a complete list of events, refer to the **ImapRegisterEvent** function.

dwError

An unsigned integer which specifies any error that occurred. If no error occurred, then this parameter will be zero.

dwParam

A user-defined integer value which was specified when the event callback was registered.

Return Value

None.

Remarks

An application must register this callback function by passing its address to the **ImapRegisterEvent** function. The **ImapEventProc** function is a placeholder for the application-defined function name.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmav10.lib

See Also

[ImapDisableEvents](#), [ImapEnableEvents](#), [ImapFreezeEvents](#), [ImapRegisterEvent](#)

ImapExamineMailbox Function

```
INT WINAPI ImapExamineMailbox(  
    HCLIENT hClient,  
    LPCTSTR lpszMailbox,  
    LPIMAPMAILBOX lpMailboxInfo  
);
```

The **ImapExamineMailbox** function selects the specified mailbox for read-only access.

Parameters

hClient

Handle to the client session.

lpszMailbox

A pointer to a string which specifies the new mailbox to be examined.

lpMailboxInfo

A pointer to an [IMAPMAILBOX](#) structure which contains information about the mailbox when the function returns. This parameter may be NULL if the caller does not require any information about the mailbox.

Return Value

If the function succeeds, it returns zero. If an error occurs, the function returns `IMAP_ERROR`. To get extended error information, call **ImapGetLastError**.

Remarks

The **ImapExamineMailbox** function is used to select a mailbox in read-only mode. Messages can be read, but they cannot be modified or deleted from the mailbox and new messages will not lose their status as new messages if they are accessed.

If the client has a different mailbox currently selected, that mailbox will be closed and any messages marked for deletion will be expunged. To prevent deleted messages from being removed from the previous mailbox, use the **ImapUnselectMailbox** function prior to examining the new mailbox.

If an application wishes to update the information returned in the `IMAPMAILBOX` structure for the current mailbox, simply call **ImapExamineMailbox** again with the same mailbox name.

The special case-insensitive mailbox name `INBOX` is used for new messages. Other mailbox names may or may not be case-sensitive depending on the IMAP server's operating system and implementation.

To access a mailbox in read-write mode, use the **ImapSelectMailbox** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csmapi10.lib`

Unicode: Implemented as Unicode and ANSI versions.

See Also

[ImapDeleteMailbox](#), [ImapGetFirstMailbox](#), [ImapGetMailboxStatus](#), [ImapGetNextMailbox](#),

ImapExpungeMailbox Function

```
INT WINAPI ImapExpungeMailbox(  
    HCLIENT hClient,  
    LPIMAPMAILBOX lpMailboxInfo  
);
```

The **ImapExpungeMailbox** function removes all messages marked for deletion from the current mailbox.

Parameters

hClient

Handle to the client session.

lpMailboxInfo

A pointer to an [IMAPMAILBOX](#) structure which contains information about the mailbox when the function returns. This parameter may be NULL if the caller does not require any information about the mailbox.

Return Value

If the function succeeds, it returns zero. If an error occurs, the function returns `IMAP_ERROR`. To get extended error information, call **ImapGetLastError**.

Remarks

The **ImapExpungeMailbox** function causes all messages marked for deletion to be removed from the mailbox. Note that this can cause the mailbox's UID to change, and potentially invalidate the current message UIDs. It is recommended that applications use the information returned in the `IMAPMAILBOX` structure to update any internal state information stored on the local system.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csmapi10.lib`

Unicode: Implemented as Unicode and ANSI versions.

See Also

[ImapCreateMailbox](#), [ImapExamineMailbox](#), [ImapGetFirstMailbox](#), [ImapGetNextMailbox](#), [ImapRenameMailbox](#), [ImapSelectMailbox](#)

ImapFreezeEvents Function

```
INT WINAPI ImapFreezeEvents(  
    HCLIENT hClient,  
    BOOL bFreeze  
);
```

The **ImapFreezeEvents** function is used to suspend and resume event handling by the client.

Parameters

hClient

Handle to the client session.

bFreeze

A non-zero value specifies that event handling should be suspended by the client. A zero value specifies that event handling should be resumed.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

This function should be used when the application does not want to process events, such as when a modal dialog is being displayed. When events are suspended, all client events are queued. If events are re-enabled at a later point, those queued events will be sent to the application for processing. Note that only one of each event will be generated. For example, if the client has suspended event handling, and four events of the same type occur, once event handling is resumed only one of those events will be posted to the client. This prevents the application from being flooded by a potentially large number of queued events.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmapi10.lib

See Also

[ImapDisableEvents](#), [ImapEnableEvents](#), [ImapRegisterEvent](#)

ImapGetCapability Function

```
INT WINAPI ImapGetCapability(  
    HCLIENT hClient,  
    LPTSTR lpszCapability,  
    INT nMaxLength  
);
```

The **ImapGetCapability** function returns a string which identifies the capabilities of the IMAP server.

Parameters

hClient

Handle to the client session.

lpszCapability

A pointer to a null terminated string buffer that will contain one or more tokens separated by spaces which identify the capabilities of the IMAP server.

nMaxLength

The maximum length of the capability string, including the terminating null character.

Return Value

If the function succeeds, it returns the length of the capability string, not including the terminating null character. If an error occurs, the function returns IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

This function returns a string that contains one or more tokens separated by whitespace. Each token identifies a capability of the server. The following table lists some of the common capabilities:

Capability	Description
ACL	The RFC 2086 ACL extension
BINARY	The RFC 3516 binary content extension
CHILDREN	The RFC 3348 child mailbox extension
ID	The RFC 2971 ID extension
IDLE	The RFC 2177 IDLE extension
LOGINDISABLED	The RFC 2595 TLS/SSL extension
LOGINREFERRALS	The RFC 2221 login referrals extension
MAILBOXREFERRALS	The RFC 2193 mailbox referrals extension
MULTIAPPEND	The RFC 3501 MULTIAPPEND extension
NAMESPACE	The RFC 2342 namespace Extension
QUOTA	The RFC 2087 QUOTA extension
STARTTLS	The RFC 2595 TLS/SSL extension
UNSELECT	The RFC 3691 UNSELECT extension

Additional capabilities may be supported by your server. Note that experimental or custom capabilities are always prefixed with the letter X. A list of standard IMAP capabilities is maintained by the Internet Assigned Numbers Authority (IANA) at www.iana.org.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csmapi10.lib`

Unicode: Implemented as Unicode and ANSI versions.

ImapGetCurrentMailbox Function

```
INT WINAPI ImapGetCurrentMailbox(  
    HCLIENT hClient,  
    LPTSTR lpszMailbox,  
    INT nMaxLength  
);
```

The **ImapGetCurrentMailbox** function returns the name of the current mailbox that has been selected.

Parameters

hClient

Handle to the client session.

lpszMailbox

A pointer to a null terminated string buffer that will contain the current mailbox name.

nMaxLength

The maximum length of the mailbox string, including the terminating null character.

Return Value

If the function succeeds, it returns the length of the current mailbox name, not including the terminating null character. If an error occurs, the function returns IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmapi10.lib

Unicode: Implemented as Unicode and ANSI versions.

ImapGetDeletedMessages Function

```
INT WINAPI ImapGetDeletedMessages(  
    HCLIENT hClient,  
    UINT* LpnMessageIds,  
    INT nMaxMessages  
);
```

The **ImapGetDeletedMessages** function returns the message identifiers for those messages that have been marked for deletion in the current mailbox.

Parameters

hClient

Handle to the client session.

lpnMessageIds

A pointer to an array of unsigned integers that will contain the message identifiers of those messages which have been marked for deletion in the current mailbox. This parameter may be NULL, in which case the function will return the number of deleted messages but will not return their identifiers.

nMaxMessages

The maximum number of message identifiers that may be stored in the *lpnMessageIds* array. If the *lpnMessageIds* parameter is NULL, this value should be zero.

Return Value

If the function succeeds, the return value is the number of messages marked for deletion in the current mailbox. If the function fails, the return value is IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

The message identifiers returned by this function are only valid until the mailbox is expunged or another mailbox is selected.

To remove the deleted flag from a message, use the **ImapUndeleteMessage** function. To prevent all messages in the current mailbox from being expunged, use the **ImapReselectMailbox** function to reset the current mailbox state.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmapi10.lib

ImapGetErrorString Function

```
INT WINAPI ImapGetErrorString(  
    DWORD dwErrorCode,  
    LPTSTR lpszDescription,  
    INT nMaxLength  
);
```

The **ImapGetErrorString** function is used to return a description of a specific error code. Typically this is used in conjunction with the **ImapGetLastError** function for use with warning dialogs or as diagnostic messages.

Parameters

dwErrorCode

The error code for which a description should be returned. If this value is zero, then the description of the last error will be returned. If the last error code is zero, indicating no error, then this function will return zero.

lpszDescription

A pointer to the buffer that will contain a description of the specified error code. It is recommended that this buffer be at least 128 characters in length. If a NULL pointer is specified, then no message will be returned but the function will return the length of the error string, not including the terminating null byte.

nMaxLength

The maximum number of characters that may be copied into the description buffer.

Return Value

If the function succeeds, the return value is the length of the description string. If the function fails, the return value is 0, meaning that no description exists for the specified error code. Typically this indicates that the error code passed to the function is invalid.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmapi10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[ImapGetLastError](#), [ImapGetResultCode](#), [ImapGetResultString](#), [ImapSetLastError](#)

ImapGetFirstMailbox Function

```
INT WINAPI ImapGetFirstMailbox(  
    HCLIENT hClient,  
    LPCTSTR lpszReference,  
    LPCTSTR lpszWildcard,  
    DWORD dwOptions,  
    LPVOID lpvReserved,  
    LPTSTR lpszMailbox,  
    INT nMaxLength  
    LPDWORD lpdwFlags  
);
```

The **ImapGetFirstMailbox** function returns the name of the first matching mailbox.

Parameters

hClient

Handle to the client session.

lpszReference

A pointer to a string which specifies the reference name. An empty string or NULL pointer specifies that the default mailbox hierarchy for the current user is returned. If the reference name is provided, this must be the name of a mailbox or a level of the mailbox hierarchy which provides the context in which the mailbox name is interpreted.

lpszWildcard

A pointer to a null terminated string which specifies the mailbox name to match. The wildcard character "*" may be used to match any portion of the mailbox hierarchy, including the delimiter. The wildcard character "%" matches any portion of the mailbox name, but does not match the mailbox delimiter. An empty string or NULL pointer specifies that all mailboxes in the context of the *lpszReference* parameter should be returned.

dwOptions

Specifies one or more options which controls how mailboxes are returned by the function. The options are bit flags which may be combined using a bitwise operator. One or more of the following values may be used:

Constant	Description
IMAP_LIST_DEFAULT	This option specifies that all regular, selectable mailboxes should be returned.
IMAP_LIST_SUBSCRIBED	This option specifies that only subscribed mailboxes should be returned.
IMAP_LIST_FOLDERS	This option specifies that non-selectable mailbox folders should also be returned.
IMAP_LIST_HIDDEN	This option specifies that hidden mailboxes should be returned.
IMAP_LIST_INFERIOR	This option specifies that inferior mailboxes should be returned if an explicit wildcard mask is not specified.

lpvReserved

A reserved parameter. This value should always be set to NULL.

lpszMailbox

A pointer to a string buffer which will contain the first matching mailbox. This parameter cannot be NULL. A minimum buffer size of at least 128 character is recommended.

nMaxLength

Specifies the maximum length of the string buffer. The maximum length of the buffer should be large enough to accommodate most path names on the IMAP server.

lpdwFlags

A pointer to an unsigned integer which will contain the mailbox flags for the first matching mailbox. This parameter may be NULL, in which case the mailbox flags are not returned. Otherwise, one or more of the following bit flags may be returned:

Constant	Description
IMAP_FLAG_NOINFERIORS	The mailbox does not contain any sub-mailboxes. In the IMAP protocol, these are referred to as inferior hierarchical mailbox names.
IMAP_FLAG_NOSELECT	The mailbox cannot be selected or examined. This flag is typically used by servers to indicate that the mailbox name refers to a directory on the server, not a mailbox file.
IMAP_FLAG_MARKED	The mailbox is marked as being of interest to a client. If this flag is used, it typically means that the mailbox contains messages. An application should not depend on this flag being present for any given mailbox. Some IMAP servers do not support marked or unmarked flags for mailboxes.
IMAP_FLAG_UNMARKED	The mailbox is marked as not being of interest to a client. If this flag is used, it typically means that the mailbox does not contain any messages. An application should not depend on this flag being present for any given mailbox. Some IMAP servers do not support marked or unmarked flags for mailboxes.

Return Value

If the function succeeds, it returns the length of the mailbox name. If an error occurs, the function returns IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

The **ImapGetFirstMailbox** function is used to begin enumerating the available mailboxes for the current user on the IMAP server. Subsequent mailbox names are returned by calling **ImapGetNextMailbox** until the function returns IMAP_ERROR with an error code of ST_ERROR_NO_MORE_MAILBOXES.

The function of the *lpszReference* and *lpszWildcard* parameters are implementation dependent and generally are tied to the underlying operating system. On a UNIX based system, it can be helpful to think of the reference name as the directory where mailbox folders are stored, and the mailbox name as the name to search for in that directory and any subdirectories, if applicable. If the reference name is an empty string or NULL pointer, this typically refers to the current user's home directory.

Generally speaking, a reference name should only be specified if you or the user of the application knows the directory structure on the IMAP server. Incorrectly using a reference name can have serious negative side-effects. For example, specifying a reference name of "/" on a UNIX based system could cause the IMAP server to return search every directory on the system for a matching mailbox name. Similarly, the IMAP server may be unable to distinguish between regular files in the user's home directory and mailboxes. For this reason, most IMAP clients require that the user specify the directory on the server where their mailboxes are stored. Typically this is subdirectory named "mail" or "Mail" under the user's home directory. For non-UNIX servers, the mailbox hierarchy may be represented differently, including a flat hierarchy.

Hidden mailboxes are those mailboxes which use the UNIX convention of the name beginning with a period. Therefore, a mailbox named ".secrets" would not normally be returned by the **ImapGetFirstMailbox** and **ImapGetNextMailbox** functions. The IMAP_LIST_HIDDEN option causes all mailboxes to be returned.

The IMAP_LIST_INFERIOR option will return inferior mailboxes (mailboxes located in folders or subdirectories) if a wildcard mask is not specified. If a wildcard mask is specified, this option has no effect and only those mailboxes which match the wildcard will be returned.

Subscribed mailboxes are those which were specified using the **ImapSubscribeMailbox** function. Marked mailboxes are typically those which have some special importance to the user.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmapi10.lib

Unicode: Implemented as Unicode and ANSI versions.

[ImapDeleteMailbox](#), [ImapGetMailboxStatus](#), [ImapGetNextMailbox](#), [ImapRenameMailbox](#), [ImapSelectMailbox](#)

ImapGetHeaderValue Function

```
INT WINAPI ImapGetHeaderValue(  
    HCLIENT hClient,  
    UINT nMessageId,  
    LPCTSTR LpszHeader,  
    LPTSTR LpszValue,  
    INT nMaxLength  
);
```

The **ImapGetHeaderValue** function returns the value of a header field in the specified message.

Parameters

hClient

Handle to the client session.

nMessageId

Number of message to retrieve header value from. This value must be greater than zero. The first message in the mailbox is message number one.

lpszHeader

Pointer to a string which specifies the message header to retrieve. The colon should not be included in this string.

lpszValue

Pointer to a string buffer that will contain the value of the specified message header.

nMaxLength

The maximum number of characters that may be copied into the buffer, including the terminating null character.

Return Value

If the function succeeds, it returns the length of the header field value. If the header field is not present in the message, the function will return a value of zero. If the function fails, the return value is IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

The **ImapGetHeaderValue** function returns the value of header field from the specified message. This allows an application to be able to easily determine the value of a header such as the sender, or the subject of the message. Any header field, including non-standard extensions, may be returned by this function.

To return the value of a header field from a specific part of a multipart MIME message, use the **ImapGetHeaderValueEx** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmapi10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[ImapGetHeaderValueEx](#), [ImapGetMessageHeaders](#), [ImapGetMessageId](#), [ImapGetMessageSender](#)

ImapGetHeaderValueEx Function

```
INT WINAPI ImapGetHeaderValueEx(  
    HCLIENT hClient,  
    UINT nMessageId,  
    UINT nMessagePart,  
    LPVOID lpvReserved,  
    LPCTSTR lpszHeader,  
    LPTSTR lpszValue,  
    INT nMaxLength  
);
```

The **ImapGetHeaderValueEx** function returns the value of a header field from the specified message part.

Parameters

hClient

Handle to the client session.

nMessageId

Number of message to retrieve header value from. This value must be greater than zero. The first message in the mailbox is message number one.

nMessagePart

The message part that the header value will be retrieved from. Message parts start with a value of one. A value of zero specifies that the RFC822 header field for the message will be used.

lpvReserved

A reserved parameter. This value should always be NULL.

lpszHeader

Pointer to a string which specifies the message header to retrieve. The colon should not be included in this string.

lpszValue

Pointer to a string buffer that will contain the value of the specified message header.

nMaxLength

The maximum number of characters that may be copied into the buffer, including the terminating null character.

Return Value

If the function succeeds, it returns the length of the header field value. If the header field is not present in the message, the function will return a value of zero. If the function fails, the return value is IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

The **ImapGetHeaderValueEx** function returns the value of a header field from the specified message part. This allows an application to be able to easily determine the value of a header such as the sender, or the subject of the message. Any header field, including non-standard extensions, may be returned by this function.

To determine if a message is a multipart MIME message, use the **ImapGetMessageParts** function. The return value specifies the number of parts in the message, with a value greater than

one indicating that it is a multipart message.

Note that unlike the SocketTools MIME API which considers the first message part to be zero, the IMAP protocol defines the first message part to be one.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmapi10.lib

Unicode: Implemented as Unicode and ANSI versions.

ImapGetIdleThreadId Function

```
DWORD WINAPI ImapGetIdleThreadId(  
    HCLIENT hClient  
);
```

The **ImapGetIdleThreadId** function returns ID of the thread that is monitoring the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, it returns the ID of the thread that is checking for update notifications from the server. If there is no active thread monitoring the client session, the function will return zero.

Remarks

The worker thread that monitors the client connection in the background can terminate if an IMAP command is sent to the server, if the **ImapCancel** function is called or if the client disconnects from the server. The **ImapGetIdleThreadId** function enables the application to determine if this background thread is still active or not.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmapi10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[ImapIdle](#), [ImapIdleProc](#)

ImapGetLastError Function

```
DWORD WINAPI ImapGetLastError();
```

Parameters

None.

Return Value

The return value is the calling thread's last error code value. Functions set this value by calling the **ImapSetLastError** function. The return value section of each reference page notes the conditions under which the function sets the last error code.

Remarks

You should call the **ImapGetLastError** function immediately when a function's return value indicates that an error has occurred. That is because some functions call **ImapSetLastError(0)** when they succeed, clearing the error code set by the most recently failed function.

Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value error code such as FALSE, NULL, INVALID_CLIENT or IMAP_ERROR. Those functions which call **ImapSetLastError** when they succeed are noted on the function reference page.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmapi10.lib

See Also

[ImapGetErrorString](#), [ImapSetLastError](#)

ImapGetMailboxDelimiter Function

```
INT WINAPI ImapGetMailboxDelimiter(  
    HCLIENT hClient,  
    LPCTSTR lpszMailbox,  
    LPTSTR lpszDelimiter,  
    INT nMaxLength  
);
```

The **ImapGetMailboxDelimiter** function returns the hierarchical path delimiter used for the specified mailbox.

Parameters

hClient

Handle to the client session.

lpszMailbox

A pointer to a null terminated string which specifies the mailbox name. This parameter may be NULL or an empty string, in which case the default delimiter will be returned.

lpszDelimiter

A pointer to a null terminated string buffer that will contain the mailbox delimiter.

nMaxLength

The maximum length of the delimiter string, including the terminating null character.

Return Value

If the function succeeds, it returns the length of the delimiter for the specified mailbox, not including the terminating null character. If an error occurs, the function returns IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

If the IMAP server supports multiple levels of mailboxes, then a special character or sequence of characters are used as delimiters between different levels of the mailbox hierarchy. On most systems, including most UNIX and Windows platforms, the delimiter is the forward slash "/" character.

It is possible that an IMAP server may only support a flat namespace, in which case this function will return a value of zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmapi10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[ImapExamineMailbox](#), [ImapSelectMailbox](#), [ImapUnselectMailbox](#)

ImapGetMailboxSize Function

```
DWORD WINAPI ImapGetMailboxSize(  
    HCLIENT hClient,  
    LPCTSTR lpszMailbox  
);
```

The **ImapGetMailboxSize** function returns the size of the specified mailbox.

Parameters

hClient

Handle to the client session.

lpszMailbox

A pointer to a string which specifies the mailbox name.

Return Value

If the function succeeds, it returns the size of the mailbox. If an error occurs, the function returns IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

The **ImapGetMailboxSize** function may require a significant amount of time to calculate the mailbox size if there are a large number of messages in the mailbox. If the specified mailbox is not currently selected, then the current mailbox is unselected, the new mailbox is selected and the size calculated, and then the original mailbox is re-selected. This will have the side-effect of causing any messages marked for deletion to be expunged from the mailbox.

Because it can potentially result in long delays, it is not recommended that an application calculate the mailbox size unless it is absolutely necessary.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmapi10.lib

Unicode: Implemented as Unicode and ANSI versions.

[ImapCreateMailbox](#), [ImapGetFirstMailbox](#), [ImapGetNextMailbox](#), [ImapRenameMailbox](#)

ImapGetMailboxStatus Function

```
INT WINAPI ImapGetMailboxStatus(  
    HCLIENT hClient,  
    LPCTSTR lpszMailbox,  
    LPIMAPMAILBOXSTATUS lpMailboxStatus  
);
```

The **ImapGetMailboxStatus** function returns status information about the specified mailbox.

Parameters

hClient

Handle to the client session.

lpszMailbox

A pointer to a null terminated string that specifies the mailbox to return information about.

lpMailboxStatus

A pointer to an [IMAPMAILBOXSTATUS](#) structure which contains status information about the specified mailbox.

Return Value

If the function succeeds, it returns zero. If an error occurs, the function returns IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

The **ImapGetMailboxStatus** function enables an application to obtain status information about a mailbox without having to select another mailbox or open a second connection to the IMAP server to examine the mailbox. The information returned is a subset of the information returned when a mailbox is selected.

Note that obtaining status information for a mailbox may be a slow operation. It may require that server open the mailbox in read-only mode internally in order to obtain some of the status information. For this reason, this function should not be used to check for new messages; use the **ImapCheckMailbox** function instead.

Some IMAP servers may return an error if you attempt to obtain status information about the currently selected mailbox. The protocol standard states that clients should not use this method on the currently selected mailbox, and should instead use the information returned by the **ImapSelectMailbox** or **ImapExamineMailbox** functions.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmapi10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[ImapCheckMailbox](#), [ImapExamineMailbox](#), [ImapSelectMailbox](#)

ImapGetMailboxUID Function

```
DWORD WINAPI ImapGetMailboxUID(  
    HCLIENT hClient,  
    LPCTSTR lpszMailbox  
);
```

The **ImapGetMailboxUID** function returns the unique identifier for the specified mailbox.

Parameters

hClient

Handle to the client session.

lpszMailbox

A pointer to a null terminated string that specifies the mailbox name.

Return Value

If the function succeeds, it returns a non-zero value. If no unique identifier is assigned to the mailbox, the function will return zero. If an error occurs, the function returns IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

The **ImapGetMailboxUID** function returns an unsigned 32-bit value which uniquely identifies the mailbox and corresponds to the UIDVALIDITY value returned by the IMAP server. The actual value is determined by the server and should be considered opaque. The protocol specification requires that a mailbox's UID must not change unless the mailbox contents are modified or existing messages in the mailbox have been assigned new UIDs.

An application can use the mailbox UID value in combination with the message UID in order to uniquely identify a message on the server. However, the application must take into consideration that the IMAP server can reassign new message UIDs when the mailbox is modified. If the mailbox and message UIDs are being stored on the local system to track what messages have been retrieved from the server, the application must check the UID of the mailbox whenever it is selected. If the mailbox UID has changed, this means that the UIDs for the messages in that mailbox may have changed. The client should resynchronize with the server, and update it's local copy of that mailbox.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmapi10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[ImapGetCurrentMailbox](#), [ImapGetMailboxStatus](#), [ImapGetMessageUid](#)

ImapGetMessage Function

```
INT WINAPI ImapGetMessage(  
    HCLIENT hClient,  
    UINT nMessageId,  
    UINT nMessagePart,  
    LPVOID lpvMessage,  
    LPDWORD lpdwLength,  
    DWORD dwOptions  
);
```

The **ImapGetMessage** function retrieves a message from the server.

Parameters

hClient

Handle to the client session.

nMessageId

Number of message to retrieve from the server. This value must be greater than zero. The first message in the mailbox is message number one.

nMessagePart

The message part that will be retrieved. A value of zero specifies that the complete message should be returned. If the message is a multipart MIME message, message parts start with a value of one.

lpvMessage

A pointer to a byte buffer which will contain the data transferred from the server, or a pointer to a global memory handle which will reference the data when the function returns.

lpdwLength

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the *lpvMessage* parameter. If the *lpvMessage* parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the actual length of the message that was downloaded.

dwOptions

An unsigned integer value which specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
IMAP_SECTION_DEFAULT	All headers and the complete body of the specified message or message part are to be retrieved. The client application is responsible for parsing the header block. If the message is a MIME multipart message and the complete message is returned, the application is responsible for parsing the individual message parts if necessary.
IMAP_SECTION_HEADER	All headers for the specified message or message part are to be retrieved. The client application is responsible for parsing the header block.

IMAP_SECTION_MIMEHEADER	The MIME headers for the specified message or message are to be retrieved. Only those header fields which are used in MIME messages, such as Content-Type will be returned to the client. This is typically useful when processing the header for a multipart message which contains file attachments. The client application is responsible for parsing the header block.
IMAP_SECTION_BODY	The body of the specified message or message part is to be retrieved. For a MIME formatted message, this may include data that is uuencoded or base64 encoded. The application is responsible for decoding this data.
IMAP_SECTION_PREVIEW	The message header or body is being previewed and should not be marked as read by the server. This prevents the message from having the IMAP_FLAG_SEEN flag from being automatically set when the message data is retrieved.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

The **ImapGetMessage** function is used to retrieve a message from the server and copy it into a local buffer. The function may be used in one of two ways, depending on the needs of the application. The first method is to pre-allocate a buffer large enough to store the contents of the message. In this case, the *lpvMessage* parameter will point to the buffer that was allocated, the value that the *lpdwLength* parameter points to should be initialized to the size of that buffer.

The second method that can be used is have the *lpvMessage* parameter point to a global memory handle which will contain the message data when the function returns. In this case, the value that the *lpdwLength* parameter points to must be initialized to zero. It is important to note that the memory handle returned by the function must be freed by the application, otherwise a memory leak will occur.

This function will cause the current thread to block until the transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the IMAP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **ImapEnableEvents**, or by registering a callback function using the **ImapRegisterEvent** function.

To determine if a message is a multipart MIME message, use the **ImapGetMessageParts** function. The return value specifies the number of parts in the message, with a value greater than one indicating that it is a multipart message. Combining the IMAP_SECTION_HEADER and IMAP_SECTION_BODY options will only return the header and body for the specified message if the *nMessagePart* parameter is zero. Due to a limitation of the IMAP FETCH command, if a message part is specified then only the body of that message part will be returned.

Note that unlike the SocketTools MIME API which considers the first message part to be zero, the IMAP protocol defines the first message part to be one.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmapi10.lib

See Also

[ImapGetMessageCount](#), [ImapGetMessageHeaders](#), [ImapGetMessageParts](#), [ImapStoreMessage](#)

ImapGetMessageCount Function

```
INT WINAPI ImapGetMessageCount(  
    HCLIENT hClient  
);
```

The **ImapGetMessageCount** function returns the number of messages that are available in the currently selected mailbox.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, it returns the number of messages in the currently selected mailbox. If no messages are available, this function will return zero. If the function fails, the return value is `IMAP_ERROR`. To get extended error information, call **ImapGetLastError**.

Remarks

The **ImapGetMessageCount** function does not distinguish between messages that are marked for deletion and those which are not. This is because messages that are marked for deletion on an IMAP server can still be accessed until the mailbox is expunged or unselected. This differs from the POP3 protocol, where messages cannot be accessed once they have been marked for deletion.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csmapi10.lib`

See Also

[ImapDeleteMessage](#), [ImapGetHeaderValue](#), [ImapGetMessage](#), [ImapGetMessageCountEx](#), [ImapGetMessageHeaders](#), [ImapStoreMessage](#)

ImapGetMessageCountEx Function

```
INT WINAPI ImapGetMessageCountEx(  
    HCLIENT hClient,  
    UINT *LpnLastMessage,  
    DWORD *LpdwMailboxSize  
);
```

The **ImapGetMessageCountEx** function returns the number of messages that are available in the currently selected mailbox, and optionally the size of the mailbox in bytes.

Parameters

hClient

Handle to the client session.

lpnLastMessage

Address of a variable that receives the number of the last valid message in the mailbox. If a NULL value is specified, this argument is ignored.

lpdwMailboxSize

Address of a variable that receives the current size of the mailbox. If a NULL value is specified, this argument is ignored.

Return Value

If the function succeeds, it returns the number of messages that are currently available. If no messages are available, this function will return zero. If the function fails, the return value is IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

The **ImapGetMessageCountEx** function is provided for compatibility with the POP3 API. The *lpnLastMessage* parameter will always contain the same value returned by the function since there is no distinction between the message count and the last available message. This is because messages that are marked for deletion on an IMAP server can still be accessed until the mailbox is expunged or unselected. This differs from the POP3 protocol, where messages cannot be accessed once they have been marked for deletion.

If the *lpdwMailboxSize* parameter is specified, this function will call **ImapGetMailboxSize** to determine the size of the currently selected mailbox. Unlike the POP3 protocol, calculating the mailbox size may require a significant amount of time if there are a large number of messages in the mailbox. It is not recommended that an application request the mailbox size unless it is absolutely necessary.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmapi10.lib

Unicode: Implemented as Unicode and ANSI versions.

ImapGetMessageFlags Function

```
BOOL WINAPI ImapGetMessageFlags(  
    HCLIENT hClient,  
    UINT nMessageId,  
    LPDWORD lpdwMessageFlags  
);
```

The **ImapGetMessageFlags** function returns the message flags for the specified message.

Parameters

hClient

Handle to the client session.

nMessageId

Number of message to obtain the message flags for. This value must be greater than zero. The first message in the mailbox is message number one.

lpdwMessageFlags

Pointer to an unsigned integer that will contain the message flags for the specified message. The value may be zero, or one or more of the following values:

Constant	Description
IMAP_FLAG_ANSWERED	The message has been answered.
IMAP_FLAG_DELETED	The message has been marked for deletion.
IMAP_FLAG_DRAFT	The message has not been completed and is marked as a draft copy.
IMAP_FLAG_URGENT	The message has been flagged for urgent or special attention.
IMAP_FLAG_RECENT	The message has been added to the mailbox recently.
IMAP_FLAG_SEEN	The message has been read.

Return Value

If the function succeeds, the return value is non-zero and the *lpdwMessageFlags* parameter contains the status flags for the specified message. If the function fails, the return value is zero. To get extended error information, call **ImapGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmapi10.lib

ImapGetMessageHeaders Function

```
INT WINAPI ImapGetMessageHeaders(  
    HCLIENT hClient,  
    UINT nMessageId,  
    LPVOID lpvHeaders,  
    LPDWORD lpdwLength  
);
```

The **ImapGetMessageHeaders** function retrieves the headers for the specified message from the server.

Parameters

hClient

Handle to the client session.

nMessageId

Number of message to retrieve from the server. This value must be greater than zero. The first message in the mailbox is message number one.

lpvHeaders

A pointer to a byte buffer which will contain the data transferred from the server, or a pointer to a global memory handle which will reference the data when the function returns.

lpdwLength

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the *lpvHeaders* parameter. If the *lpvHeaders* parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the actual length of the message that was downloaded.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

The **ImapGetMessageHeaders** function is used to retrieve a message header block from the server and copy it into a local buffer. The function may be used in one of two ways, depending on the needs of the application. The first method is to pre-allocate a buffer large enough to store the contents of the file. In this case, the *lpvHeaders* parameter will point to the buffer that was allocated, the value that the *lpdwLength* parameter points to should be initialized to the size of that buffer.

The second method that can be used is have the *lpvHeaders* parameter point to a global memory handle which will contain the file data when the function returns. In this case, the value that the *lpdwLength* parameter points to must be initialized to zero. It is important to note that the memory handle returned by the function must be freed by the application, otherwise a memory leak will occur.

This function will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the IMAP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **ImapEnableEvents**, or by registering a callback function using

the **ImapRegisterEvent** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmapi10.lib

See Also

[ImapGetMessage](#), [ImapGetMessageCount](#), [ImapGetMessageParts](#), [ImapStoreMessage](#)

ImapGetMessageHeadersEx Function

```
INT WINAPI ImapGetMessageHeadersEx(  
    HCLIENT hClient,  
    UINT nMessageId,  
    DWORD dwReserved,  
    LPDWORD lpdwMessageUID,  
    LPDWORD lpdwMessageFlags,  
    LPVOID lpvHeaders,  
    LPDWORD lpdwLength  
);
```

The **ImapGetMessageHeadersEx** function retrieves the headers, unique ID and flags for the specified message.

Parameters

hClient

Handle to the client session.

nMessageId

Number of message to retrieve from the server. This value must be greater than zero. The first message in the mailbox is message number one.

dwReserved

A reserved parameter, this value should always be zero.

lpdwMessageUID

A pointer to an unsigned integer which will contain the unique ID assigned to the message by the server when the function returns. This parameter may be NULL if this information is not required.

lpdwMessageFlags

A pointer to an unsigned integer which will contain the message flags when the function returns. This parameter may be NULL if this information is not required, otherwise the value may be zero or one or more of the following bitflags:

Constant	Description
IMAP_FLAG_ANSWERED	The message has been answered.
IMAP_FLAG_DELETED	The message has been marked for deletion.
IMAP_FLAG_DRAFT	The message has not been completed and is marked as a draft copy.
IMAP_FLAG_URGENT	The message has been flagged for urgent or special attention.
IMAP_FLAG_RECENT	The message has been added to the mailbox recently.
IMAP_FLAG_SEEN	The message has been read.

lpvHeaders

A pointer to a byte buffer which will contain the data transferred from the server, or a pointer to a global memory handle which will reference the data when the function returns.

lpdwLength

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the *lpvHeaders* parameter. If the *lpvHeaders* parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the actual length of the message that was downloaded.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

The **ImapGetMessageHeadersEx** function is used to retrieve a message header block from the server and copy it into a local buffer. The function may be used in one of two ways, depending on the needs of the application. The first method is to pre-allocate a buffer large enough to store the contents of the file. In this case, the *lpvHeaders* parameter will point to the buffer that was allocated, the value that the *lpdwLength* parameter points to should be initialized to the size of that buffer.

The second method that can be used is have the *lpvHeaders* parameter point to a global memory handle which will contain the file data when the function returns. In this case, the value that the *lpdwLength* parameter points to must be initialized to zero. It is important to note that the memory handle returned by the function must be freed by the application, otherwise a memory leak will occur.

If the *lpdwMessageUID* and/or *lpdwMessageFlags* parameters are NULL, they will be ignored. Otherwise, the function will always initialize the values to zero and only sets them if the header block for the message can be retrieved.

This function will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the IMAP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **ImapEnableEvents**, or by registering a callback function using the **ImapRegisterEvent** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstoools10.h

Import Library: csmavp10.lib

See Also

ImapGetMessageId Function

```
INT WINAPI ImapGetMessageId(  
    HCLIENT hClient,  
    UINT nMessageId,  
    LPTSTR lpszMessageId,  
    INT nMaxLength  
);
```

The **ImapGetMessageId** function returns the message identifier string for the specified message.

Parameters

hClient

Handle to the client session.

nMessageId

Number of message to retrieve the unique identifier for. This value must be greater than zero. The first message in the mailbox is message number one.

lpszMessageId

Address of a string buffer to receive the message identifier. This should be at least 64 bytes in length.

nMaxLength

The maximum length of the string buffer.

Return Value

If the function succeeds, the return value is the length of the unique identifier string. If the function fails, the return value is IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

The **ImapGetMessageId** function returns the message identifier from the Message-ID header of the specified message. The returned value is a string which can be used to identify a specific message, regardless if the message is moved to a different mailbox.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmapi10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

ImapGetMessageParts Function

```
INT WINAPI ImapGetMessageParts(  
    HCLIENT hClient,  
    UINT nMessageId  
);
```

The **ImapGetMessageParts** function returns the number of parts in a MIME multipart message on the server.

Parameters

hClient

Handle to the client session.

nMessageId

Number of message to retrieve the part count for. This value must be greater than zero. The first message in the mailbox is message number one.

Return Value

If the function succeeds, the return value is the number of parts in the specified message. If the function fails, the return value is IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

The **ImapGetMessageParts** function can be used to determine if a message on the server contains multiple parts. A multipart MIME message typically contains file attachments or multiple representations of the message, such as a version of the message in plain text and another using HTML markup.

If the function returns a value of one, then the message does not contain multiple parts and is a standard RFC822 formatted message. A value greater than one indicates that the message does have multiple parts. The **ImapGetMessageEx** function may be used to retrieve the data for a specific part of the message.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

ImapGetMessageSender Function

```
INT WINAPI ImapGetMessageSender(  
    HCLIENT hClient,  
    UINT nMessageId,  
    LPTSTR lpszAddress,  
    INT nMaxLength  
);
```

The **ImapGetMessageSender** function returns the sender's address for the specified message.

Parameters

hClient

Handle to the client session.

nMessageId

Number of message to retrieve header value from. This value must be greater than zero. The first message in the mailbox is message number one.

lpszAddress

Pointer to a string buffer that will contain the address of the message sender.

nMaxLength

The maximum number of characters that may be copied into the buffer, including the terminating null character.

Return Value

If the function succeeds, it returns the length of the address. If the sender cannot be determined, the function will return a value of zero. If the function fails, the return value is IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

The **ImapGetMessageSender** function returns the email address specified in the Return-Path header field. This allows an application to be able to easily determine the sender, without parsing the header or downloading the contents of the message.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmapi10.lib

Unicode: Implemented as Unicode and ANSI versions.

ImapGetMessageUid Function

```
DWORD WINAPI ImapGetMessageUid(  
    HCLIENT hClient,  
    UINT nMessageId  
);
```

The **ImapGetMessageUid** function returns the unique identifier (UID) for the specified message in the current mailbox.

Parameters

hClient

Handle to the client session.

nMessageId

Number of message to obtain the unique identifier for. This value must be greater than zero. The first message in the mailbox is message number one.

Return Value

If the function succeeds, it returns a non-zero value. If no unique identifier is assigned to the message, the function will return zero. If an error occurs, the function returns IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

The **ImapGetMessageUid** function returns an unsigned integer value which specifies a unique identifier for this message. The actual value is determined by the server and should be considered opaque.

An application can use the message UID value in combination with the mailbox UID in order to uniquely identify a message on the server. However, the application must take into consideration that the IMAP server can reassign new message UIDs when the mailbox is modified. If the mailbox and message UIDs are being stored on the local system to track what messages have been retrieved from the server, the application must check the UID of the mailbox whenever it is selected. If the mailbox UID has changed, this means that the UIDs for the messages in that mailbox may have changed. The client should resynchronize with the server, and update it's local copy of that mailbox.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmapi10.lib

ImapGetNewMessages Function

```
INT WINAPI ImapGetNewMessages(  
    HCLIENT hClient,  
    UINT* lpnMessageIds,  
    INT nMaxMessages  
);
```

The **ImapGetNewMessages** function returns the message identifiers for those messages that have recently been added to the mailbox and have not been read.

Parameters

hClient

Handle to the client session.

lpnMessageIds

A pointer to an array of unsigned integers that will contain the message identifiers of those messages that have recently been added to the mailbox and have not been read. This parameter may be NULL, in which case the function will return the number of new messages but will not return their identifiers.

nMaxMessages

The maximum number of message identifiers that may be stored in the *lpnMessageIds* array. If the *lpnMessageIds* parameter is NULL, this value should be zero.

Return Value

If the function succeeds, the return value is the number of new messages in the current mailbox. If the function fails, the return value is IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

The message identifiers returned by this function are only valid until the mailbox is expunged or another mailbox is selected. Once a message has been read using **ImapGetMessage** or **ImapStoreMessage**, it is no longer considered to be a new message.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmapi10.lib

[ImapGetUnseenMessages](#), [ImapSearchMailbox](#)

ImapGetNextMailbox Function

```
INT WINAPI ImapGetNextMailbox(  
    HCLIENT hClient,  
    LPTSTR lpszMailbox,  
    INT nMaxLength  
    LPDWORD lpdwFlags  
);
```

The **ImapGetNextMailbox** function returns the name of the next matching mailbox.

Parameters

hClient

Handle to the client session.

lpszMailbox

A pointer to a string buffer which will contain the next matching mailbox. This parameter cannot be NULL. A minimum buffer size of at least 128 character is recommended.

nMaxLength

Specifies the maximum length of the string buffer. The maximum length of the buffer should be large enough to accommodate most path names on the IMAP server.

lpdwFlags

A pointer to an unsigned integer which will contain the mailbox flags for the next matching mailbox. This parameter may be NULL, in which case the mailbox flags are not returned. Otherwise, one or more of the following bit flags may be returned:

Constant	Description
IMAP_FLAG_NOINFERIORS	The mailbox does not contain any sub-mailboxes. In the IMAP protocol, these are referred to as inferior hierarchical mailbox names.
IMAP_FLAG_NOSELECT	The mailbox cannot be selected or examined. This flag is typically used by servers to indicate that the mailbox name refers to a directory on the server, not a mailbox file.
IMAP_FLAG_MARKED	The mailbox is marked as being of interest to a client. If this flag is used, it typically means that the mailbox contains messages. An application should not depend on this flag being present for any given mailbox. Some IMAP servers do not support marked or unmarked flags for mailboxes.
IMAP_FLAG_UNMARKED	The mailbox is marked as not being of interest to a client. If this flag is used, it typically means that the mailbox does not contain any messages. An application should not depend on this flag being present for any given mailbox. Some IMAP servers do not support marked or unmarked flags for mailboxes.

Return Value

If the function succeeds, it returns the length of the mailbox name. If an error occurs, the function

returns IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

The **ImapGetNextMailbox** function returns the next matching mailbox name. When the last mailbox has been returned, the next call to this function will result in an error, with the last error code set to ST_ERROR_NO_MORE_MAILBOXES.

Subscribed mailboxes are those which were specified using the **ImapSubscribeMailbox** function. Marked mailboxes are typically those which have some special importance to the user.

For more information about enumerating the available mailboxes on the IMAP server, refer to the **ImapGetFirstMailbox** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmapi10.lib

Unicode: Implemented as Unicode and ANSI versions.

ImapGetResultCode Function

```
INT WINAPI ImapGetResultCode(  
    HCLIENT hClient  
);
```

The **ImapGetResultCode** function reads the result code returned by the server in response to a command. The result code is an integer value, and indicates if the operation succeeded or failed.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the result code. If the function fails, it returns IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

The following result codes may be returned by the IMAP server:

Constant	Description
IMAP_RESULT_UNKNOWN	An unknown result code was returned by the server.
IMAP_RESULT_OK	The previous command completed successfully. The result string contains information about the results of the command.
IMAP_RESULT_NO	The previous command could not be completed. The result string contains information about why the command failed.
IMAP_RESULT_BAD	The previous command could not be completed, the command may be invalid or not supported on the server. The result string contains information about why the command failed.
IMAP_RESULT_CONTINUE	The command has executed and is waiting for additional data from the client.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmapi10.lib

[ImapCommand](#), [ImapGetResultString](#)

ImapGetResultString Function

```
INT WINAPI ImapGetResultString(  
    HCLIENT hClient,  
    LPTSTR lpszResult,  
    INT nMaxLength  
);
```

The **ImapGetResultString** function returns the last message sent by the server along with the result code.

Parameters

hClient

Handle to the client session.

lpszResult

A pointer to the buffer that will contain the result string returned by the server.

nMaxLength

The maximum number of characters that may be copied into the result string buffer, including the terminating null character.

Return Value

If the function succeeds, the return value is the length of the result string. If a value of zero is returned, this means that no result string was sent by the server. If the function fails, the return value is IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

The **ImapGetResultString** function is most useful when an error occurs because the server will typically include a brief description of the cause of the error. This can then be parsed by the application or displayed to the user. The result string is updated each time the client sends a command to the server and then calls **ImapGetResultCode** to obtain the result code for the operation.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmapi10.lib

Unicode: Implemented as Unicode and ANSI versions.

ImapGetSecurityInformation Function

```
BOOL WINAPI ImapGetSecurityInformation(  
    HCLIENT hClient,  
    LPSECURITYINFO lpSecurityInfo  
);
```

The **ImapGetSecurityInformation** function returns security protocol, encryption and certificate information about the current client connection.

Parameters

hClient

Handle to the client session.

lpSecurityInfo

A pointer to a [SECURITYINFO](#) structure which contains information about the current client connection. The *dwSize* member of this structure must be initialized to the size of the structure before passing the address of the structure to this function.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **ImapGetLastError**.

Remarks

This function is used to obtain security related information about the current client connection to the server. It can be used to determine if a secure connection has been established, what security protocol was selected, and information about the server certificate. Note that a secure connection has not been established, the *dwProtocol* structure member will contain the value `SECURITY_PROTOCOL_NONE`.

Example

The following example notifies the user if the connection is secure or not:

```
SECURITYINFO securityInfo;  
  
securityInfo.dwSize = sizeof(SECURITYINFO);  
if (ImapGetSecurityInformation(hClient, &securityInfo))  
{  
    if (securityInfo.dwProtocol == SECURITY_PROTOCOL_NONE)  
    {  
        MessageBox(NULL, _T("The connection is not secure"),  
                    _T("Connection"), MB_OK);  
    }  
    else  
    {  
        if (securityInfo.dwCertStatus == SECURITY_CERTIFICATE_VALID)  
        {  
            MessageBox(NULL, _T("The connection is secure"),  
                        _T("Connection"), MB_OK);  
        }  
        else  
        {  
            MessageBox(NULL, _T("The server certificate not valid"),  
                        _T("Connection"), MB_OK);  
        }  
    }  
}
```

```
}  
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

ImapGetStatus Function

```
INT WINAPI ImapGetStatus(  
    HCLIENT hClient  
);
```

The **ImapGetStatus** function returns the current status of the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the client status code. If the function fails, the return value is IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

The **ImapGetStatus** function returns a numeric code which identifies the current state of the client session. The following values may be returned:

Value	Constant	Description
1	IMAP_STATUS_IDLE	The client is current idle and not sending or receiving data.
2	IMAP_STATUS_CONNECT	The client is establishing a connection with the server.
3	IMAP_STATUS_READ	The client is reading data from the server.
4	IMAP_STATUS_WRITE	The client is writing data to the server.
5	IMAP_STATUS_DISCONNECT	The client is disconnecting from the server.

In a multithreaded application, any thread in the current process may call this function to obtain status information for the specified client session.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmapi10.lib

ImapGetTimeout Function

```
INT WINAPI ImapGetTimeout(  
    HCLIENT hClient  
);
```

The **ImapGetTimeout** function returns the number of seconds the client will wait for a response from the server. Once the specified number of seconds has elapsed, the function will fail and return to the caller.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the timeout period in seconds. If the function fails, the return value is IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

The timeout value is only used with blocking client connections. A value of zero indicates that the default timeout period of 20 seconds should be used.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmav10.lib

ImapGetTransferStatus Function

```
INT WINAPI ImapGetTransferStatus(  
    HCLIENT hClient,  
    LPIMAPTRANSFERSTATUS lpStatus  
);
```

The **ImapGetTransferStatus** function returns information about the current file transfer in progress.

Parameters

hClient

Handle to the client session.

lpStatus

A pointer to an [IMAPTRANSFERSTATUS](#) structure which contains information about the status of the current file transfer.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is `IMAP_ERROR`. To get extended error information, call **ImapGetLastError**.

Remarks

The **ImapGetTransferStatus** function returns information about the current file transfer, including the average number of bytes transferred per second and the estimated amount of time until the transfer completes. If there is no file currently being transferred, this function will return the status of the last successful transfer made by the client.

In a multithreaded application, any thread in the current process may call this function to obtain status information for the specified client session.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csmapi10.lib`

Unicode: Implemented as Unicode and ANSI versions.

ImapGetUnseenMessages Function

```
INT WINAPI ImapGetUnseenMessages(  
    HCLIENT hClient,  
    UINT * lpnMessageIds,  
    INT nMaxMessages  
);
```

The **ImapGetUnseenMessages** function returns the message identifiers for those messages that have not been read.

Parameters

hClient

Handle to the client session.

lpnMessageIds

A pointer to an array of unsigned integers that will contain the message identifiers of those messages that have not been read. This parameter may be NULL, in which case the function will return the number of unseen messages but will not return their identifiers.

nMaxMessages

The maximum number of message identifiers that may be stored in the *lpnMessageIds* array. If the *lpnMessageIds* parameter is NULL, this value should be zero.

Return Value

If the function succeeds, the return value is the number of unseen messages in the current mailbox. If the function fails, the return value is IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

The message identifiers returned by this function are only valid until the mailbox is expunged or another mailbox is selected. Once a message has been read using **ImapGetMessage** or **ImapStoreMessage**, it is no longer considered to be an unseen message.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmapi10.lib

See Also

[ImapGetDeletedMessages](#), [ImapGetMessageCount](#), [ImapGetMessageFlags](#),
[ImapGetNewMessages](#), [ImapSearchMailbox](#)

ImapIdle Function

```
INT WINAPI ImapIdle(  
    HCLIENT hClient,  
    UINT nTimeout,  
    DWORD dwOptions,  
    IMAPIDLEPROC lpfnIdleProc,  
    DWORD_PTR dwParam  
);
```

The **ImapIdle** function enables mailbox status monitoring for the client session, allowing the client to receive notifications from the server whenever a new message arrives or a message is expunged from the currently selected mailbox. This is typically used as an alternative to the client periodically polling the server for status information.

Parameters

hClient

Handle to the client session.

nTimeout

Specifies the timeout period in seconds to wait for a notification from the server. This parameter is only used when the IMAP_IDLE_WAIT option has been specified.

dwOptions

Specifies the options which should be used when enabling idle monitoring. The following options are supported:

Constant	Description
IMAP_IDLE_NOWAIT	The function should return immediately after idle processing has been enabled. When this option is used, the application may continue to perform other functions while the client session is monitored for status updates sent by the server. The client will continue to monitor status changes until an IMAP command issued or the client disconnects from the server.
IMAP_IDLE_WAIT	The function should wait until the server sends a status update, or until the timeout period is reached. The client will stop monitoring status changes when the function returns. If this option is used in a single-threaded application, normal message processing can be impeded, causing the application to appear non-responsive until the timeout period is reached. It is strongly recommended that single-threaded applications with a user interface specify the IMAP_IDLE_NOWAIT option instead.

lpfnIdleProc

A pointer to an [IMAPIDLEPROC](#) callback function that will be invoked whenever the server sends an update notification to the client. This parameter must specify a valid function address and cannot be a NULL pointer.

dwParam

A user-defined value that is passed back to the caller whenever the callback function is invoked. This can be used to provide additional state information to the client. If it is not needed, the

caller should use a value of zero.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is `IMAP_ERROR`. To get extended error information, call **ImapGetLastError**.

Remarks

Many IMAP servers support the ability to asynchronously send status updates to the client, rather than have the client periodically poll the server. The client enables this feature by calling **ImapIdle** and providing the address of a callback function that will be invoked whenever the server sends an update notification to the client. Typically these updates inform the client that a new message has arrived or that a message has been expunged from the mailbox.

The **ImapIdle** function can operate in two modes, based on the options specified by the caller. If the option `IMAP_IDLE_NOWAIT` is specified, the function begins monitoring the client session and returns control immediately to the caller. If the server sends a update notification, the callback function will be invoked with information about the status change. If the option `IMAP_IDLE_WAIT` is specified, the function will block waiting for the server to send a notification message to the client. The function will return when either a message is received or the timeout period is exceeded.

Sending an IMAP command to the server will cause the client to stop monitoring the session for status changes. To explicitly stop monitoring the session, use the **ImapCancel** function. To determine if the current client session is being monitored, use the **ImapGetIdleThreadId** function. A non-zero return value indicates that the client session is idle and being monitored.

This function works by sending the `IDLE` command to the server and starting a worker thread which monitors the connection and looks for untagged responses issued by the server. Callbacks will be invoked for `EXISTS`, `EXPUNGE` and `RECENT` messages. Note that some servers may periodically send untagged `OK` messages to the client, indicating that the connection is still active; these messages are explicitly ignored. Because the monitoring is performed in a different thread, the callback function is invoked in the context of that thread. Client event notifications are disabled while inside the callback function, and the **ImapIdle** function cannot be used to restart monitoring from within a callback function.

Applications should not perform any operation that takes a significant amount of time or updates the user interface from within the callback function. Instead, use flags or send application defined messages to indicate a change in state. For example, if the server sends a notification that a new email message has arrived, the application should not attempt to read the new message and update the user interface from within the callback function. Instead, it could use the **PostMessage** function to send an application-defined message to the UI thread indicating the change in state. The application would have a message handler for that Windows message and update the user interface, indicating that a new message has arrived.

An application should never make an assumption about how a particular server may send update notifications to the client. Servers can be configured to use different intervals at which notifications are sent. For example, a server may send new message notifications immediately, but may periodically notify the client when a message has been expunged. Alternatively, a server may only send notifications at fixed intervals, in which case the client would not be notified of any new messages until the interval period is reached. It is not possible for a client to know what a particular server's update interval is. Applications that require that degree of control should not use **ImapIdle** and should poll the server instead.

Example

```

// Begin monitoring the client session for status changes; when a new
// message arrives or a message is expunged, the UpdateHandler callback
// function will be invoked.
BOOL MonitorUpdates(HWND hwndNotify)
{
    INT nResult;

    nResult = ImapIdle(hClient, 0, IMAP_IDLE_NOWAIT, UpdateHandler, hwndNotify);

    if (nResult == IMAP_ERROR)
    {
        ShowError(ImapGetLastError());
        return FALSE;
    }

    return TRUE;
}

// This function is called whenever the server notifies the client
// that a new message has arrived or a message has been expunged from
// the current mailbox
#define WM_APP_NEWMESSAGE (WM_APP+1)
#define WM_APP_EXPUNGED (WM_APP+2)

VOID CALLBACK UpdateHandler(HCLIENT hClient, UINT nUpdateId, UINT nMessageId,
DWORD_PTR dwParam)
{
    switch (nUpdateId)
    {
    case IMAP_UPDATE_MESSAGE:
        {
            // Send a message indicating that a new message has arrived
            PostMessage((HWND)dwParam, WM_APP_NEWMESSAGE, nMessageId, 0);
        }
        break;

    case IMAP_UPDATE_EXPUNGE:
        {
            // Send a message indicating that a message has been expunged
            PostMessage((HWND)dwParam, WM_APP_EXPUNGED, nMessageId, 0);
        }
        break;
    }
}

```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmapi10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[ImapGetIdleThreadId](#), [ImapIdleProc](#)

ImapIdleProc Function

```
VOID CALLBACK ImapIdleProc(  
    HCLIENT hClient,  
    UINT nUpdateId,  
    UINT nMessageId,  
    DWORD_PTR dwParam  
);
```

The **ImapIdleProc** function is an application-defined callback function that is invoked whenever the server sends a status update to the client. For more information about status monitoring, refer to the **ImapIdle** function.

Parameters

hClient

Handle to the client session.

nUpdateId

An unsigned integer which specifies the type of update notification that has been sent by the server. It may be one of the following values:

Constant	Description
IMAP_UPDATE_UNKNOWN	The server has sent an unrecognized notification message. The value of the <i>nMessageId</i> argument is undefined for this type of notification. This does not necessarily reflect an error condition, as some servers may send additional notification messages beyond the standard EXISTS, EXPUNGE and RECENT messages. Most applications should ignore this type of notification.
IMAP_UPDATE_MESSAGE	The server has sent notification message to the client indicating that a new message has arrived. The <i>nMessageId</i> argument will contain the message number for the new message. Typically this update notification occurs shortly after the new message has been stored in the current mailbox.
IMAP_UPDATE_EXPUNGE	The server has sent a notification message to the client indicating that a message has been removed from the current mailbox. The <i>nMessageId</i> argument will contain the message number for the message that has been removed. It is recommended that the application re-examine the mailbox when this notification is received. Typically this notification is only sent periodically by the server, and may not be sent immediately after a message has been expunged from the mailbox.
IMAP_UPDATE_MAILBOX	The server has sent notification message to the client indicating that the state of the mailbox has changed. The <i>nMessageId</i> argument is not used with this notification. This message is sent periodically by the server and may not be sent immediately after a new message arrives or a

message is flagged as unread. It is recommended that the application re-examine the mailbox when this notification is received.

nMessageId

An unsigned integer which specifies the message number associated with the status change. Note that this argument is not used with the IMAP_UPDATE_MAILBOX notification and will contain a value of zero.

dwParam

A user-defined integer value which was specified when the **ImapIdle** function was called.

Return Value

None.

Remarks

An application must enable this callback function by passing its address to the **ImapIdle** function. The **ImapIdleProc** function is a placeholder for the application-defined function name.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmav10.lib

See Also

[ImapGetIdleThreadId](#), [ImapIdle](#)

ImapInitialize Function

```
BOOL WINAPI ImapInitialize(  
    LPCTSTR lpszLicenseKey,  
    LPINITDATA lpData  
);
```

The **ImapInitialize** function initializes the library and validates the specified license key at runtime.

Parameters

lpszLicenseKey

Pointer to a string that specifies the runtime license key to be validated. If this parameter is NULL, the library will validate the development license installed on the local system.

lpData

Pointer to an INITDATA data structure. This parameter may be NULL if the initialization data for the library is not required.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **ImapGetLastError**. All other client functions will fail until a license key has been successfully validated.

Remarks

This must be the first function that an application calls before using any of the other functions in the library. When a NULL license key is specified, the library will only function on the development system. Before redistributing the application to an end-user, you must insure that this function is called with a valid license key.

If the *lpData* argument is specified, it must point to an INITDATA structure which has been initialized by setting the *dwSize* member to the size of the structure. All other structure members should be set to zero. If the function is successful, then the INITDATA structure will be filled with identifying information about the library.

Although it is only required that **ImapInitialize** be called once for the current process, it may be called multiple times; however, each call must be matched by a corresponding call to **ImapUninitialize**.

This function dynamically loads other system libraries and allocates thread local storage. If you are calling the functions in this library from within another DLL, it is important that you do not call the **ImapInitialize** or **ImapUninitialize** functions from the **DllMain** function because it can result in deadlocks or access violation errors. If the DLL is linked with the C runtime library (CRT), it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmapi10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

ImapIsBlocking Function

```
BOOL WINAPI ImapIsBlocking(  
    HCLIENT hClient  
);
```

The **ImapIsBlocking** function is used to determine if the client is currently performing a blocking operation.

Parameters

hClient

Handle to the client session.

Return Value

If the client is performing a blocking operation, the function returns a non-zero value. If the client is not performing a blocking operation, or the client handle is invalid, the function returns zero.

Remarks

Because a blocking operation can allow the application to be re-entered (for example, by pressing a button while the operation is being performed), it is possible that another blocking function may be called while it is in progress. Since only one thread of execution may perform a blocking operation at any one time, an error would occur. The **ImapIsBlocking** function can be used to determine if the client is already blocked, and if so, take some other action such as warning the user that they must wait for the operation to complete.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmapi10.lib

See Also

[ImapCancel](#), [ImapIsConnected](#), [ImapIsReadable](#), [ImapIsWritable](#)

ImapIsConnected Function

```
BOOL WINAPI ImapIsConnected(  
    HCLIENT hClient  
);
```

The **ImapIsConnected** function is used to determine if the client is currently connected to a server.

Parameters

hClient

Handle to the client session.

Return Value

If the client is connected to a server, the function returns a non-zero value. If the client is not connected, or the client handle is invalid, the function returns zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmapi10.lib

Unicode: Implemented as Unicode and ANSI versions.

[ImapIsBlocking](#), [ImapIsReadable](#), [ImapIsWritable](#)

ImapIsReadable Function

```
BOOL WINAPI ImapIsReadable(  
    HCLIENT hClient,  
    INT nTimeout,  
    LPDWORD lpdwAvail  
);
```

The **ImapIsReadable** function is used to determine if data is available to be read from the server.

Parameters

hClient

Handle to the client session.

nTimeout

Timeout for server response, in seconds. A value of zero specifies that the connection should be polled without blocking the current thread.

lpdwAvail

A pointer to an unsigned integer which will contain the number of bytes available to read. This parameter may be NULL if this information is not required.

Return Value

If the client can read data from the server within the specified timeout period, the function returns a non-zero value. If the client cannot read any data, the function returns zero.

Remarks

On some platforms, this value will not exceed the size of the receive buffer (typically 64K bytes). Because of differences between TCP/IP stack implementations, it is not recommended that your application exclusively depend on this value to determine the exact number of bytes available. Instead, it should be used as a general indicator that there is data available to be read.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmapi10.lib

[ImapGetStatus](#), [ImapIsBlocking](#), [ImapIsConnected](#), [ImapIsWritable](#), [ImapRead](#)

ImapIsWritable Function

```
BOOL WINAPI ImapIsWritable(  
    HCLIENT hClient,  
    INT nTimeout  
);
```

The **ImapIsWritable** function is used to determine if data can be written to the server.

Parameters

hClient

Handle to the client session.

nTimeout

Timeout for server response, in seconds. A value of zero specifies that the connection should be polled without blocking the current thread.

Return Value

If the client can write data to the server within the specified timeout period, the function returns a non-zero value. If the client cannot write any data, the function returns zero.

Remarks

Although this function can be used to determine if some amount of data can be sent to the remote process it does not indicate the amount of data that can be written without blocking the client. In most cases, it is recommended that large amounts of data be broken into smaller logical blocks, typically some multiple of 512 bytes in length.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmapi10.lib

See Also

[ImapGetStatus](#), [ImapIsBlocking](#), [ImapIsConnected](#), [ImapIsReadable](#), [ImapWrite](#)

ImapLogin Function

```
INT WINAPI ImapLogin(  
    HCLIENT hClient,  
    UINT nAuthType,  
    LPCTSTR lpszUserName,  
    LPCTSTR lpszPassword  
);
```

The **ImapLogin** function authenticates the specified user in on the server. This function must be called after the connection has been established, and before attempting to retrieve messages or perform any other function on the server.

Parameters

hClient

Handle to the client session.

nAuthType

Identifies the type of authentication that should be used when the client logs in to the mail server. The following authentication methods are supported:

Constant	Description
IMAP_AUTH_LOGIN	Standard cleartext username and password is sent to the server. This authentication method is supported by all servers. Note that some servers may only support LOGIN authentication if a secure connection has been established.
IMAP_AUTH_PLAIN	Login using the PLAIN authentication mechanism as defined in RFC 4959. This authentication method is supported by most servers, although some may require that client establish a secure connection.
IMAP_AUTH_XOAUTH2	This authentication type will use the XOAUTH2 method to authenticate the client session. This authentication method does not require the user password, instead the <i>lpszPassword</i> parameter must specify the OAuth 2.0 bearer token issued by the service provider. The application must provide a valid access token which has not expired, or this function will fail.
IMAP_AUTH_BEARER	This authentication type will use the OAUTHBEARER method to authenticate the client session as defined in RFC 7628. This authentication method does not require the user password, instead the <i>lpszPassword</i> parameter must specify the OAuth 2.0 bearer token issued by the service provider. The application must provide a valid access token which has not expired, or this function will fail.
IMAP_AUTH_ANONYMOUS	Login using the anonymous Simple Authentication and Security Layer (SASL) mechanism as defined in RFC 4505. If this authentication method is specified, the

<p><i>lpszUserName</i> parameter should specify a name or email address acceptable to the mail server. The <i>lpszPassword</i> parameter is ignored and may be NULL.</p>
--

lpszUserName

A null terminated string which specifies the user name to be used to authenticate the current client session.

lpszPassword

A null terminated string which specifies the password to be used when authenticating the current client session. If you are using the IMAP_AUTH_XOAUTH2 or IMAP_AUTH_BEARER authentication methods, this parameter is not a password, instead it specifies the OAuth 2.0 bearer token provided by the mail service.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

In some cases, the user may be pre-authenticated by the server. In this case, the function will fail with the last error set to ST_ERROR_ALREADY_AUTHENTICATED. If a particular authentication method is not supported by the server, the last error will be set to ST_ERROR_INVALID_AUTHENTICATION_TYPE. For compatibility with the greatest number of servers, it is recommended that you use IMAP_AUTH_LOGIN as the authentication method.

You should only use an OAuth 2.0 authentication method if you understand the process of how to request the access token. Obtaining an access token requires registering your application with the mail service provider (e.g.: Microsoft or Google), getting a unique client ID associated with your application and then requesting the access token using the appropriate scope for the service. Obtaining the initial token will typically involve interactive confirmation on the part of the user, requiring they grant permission to your application to access their mail account.

The IMAP_AUTH_XOAUTH2 and IMAP_AUTH_BEARER authentication methods are similar, but they are not interchangeable. Both use an OAuth 2.0 bearer token to authenticate the client session, but they differ in how the token is presented to the server. It is currently preferable to use the XOAUTH2 method because it is more widely available and some service providers do not yet support the OAUTHBEARER method.

Your application should not store an OAuth 2.0 bearer token for later use. They have a relatively short lifespan, typically about an hour, and are designed to be used with that session. You should specify offline access as part of the OAuth 2.0 scope if necessary and store the refresh token provided by the service. The refresh token has a much longer validity period and can be used to obtain a new bearer token when needed.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmapi10.lib

Unicode: Implemented as Unicode and ANSI versions.

ImapOpenMessage Function

```
INT WINAPI ImapOpenMessage(  
    HCLIENT hClient,  
    UINT nMessageId,  
    DWORD dwReserved  
);
```

The **ImapOpenMessage** function opens the specified message on the server.

Parameters

hClient

Handle to the client session.

nMessageId

Number of message to retrieve. This value must be greater than zero. The first message in the mailbox is message number one.

dwReserved

A reserved parameter. This value should always be zero.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

The **ImapOpenMessage** function uses the FETCH command to access the specified message on the server. The client can then use the the **ImapRead** function to read the contents of the message.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmapi10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[ImapCloseMessage](#), [ImapGetMessage](#), [ImapGetMessageHeaders](#), [ImapOpenMessageEx](#), [ImapRead](#), [ImapStoreMessage](#)

ImapOpenMessageEx Function

```
INT WINAPI ImapOpenMessageEx(  
    HCLIENT hClient,  
    UINT nMessageId,  
    UINT nMessagePart,  
    DWORD dwOffset,  
    LPDWORD lpdwLength,  
    DWORD dwOptions  
);
```

The **ImapOpenMessageEx** function opens a message or a specific part of a multipart message in the current mailbox. The message data may also be limited a specific byte offset and length, which can be useful for previewing the contents.

Parameters

hClient

Handle to the client session.

nMessageId

Number of message to retrieve. This value must be greater than zero. The first message in the mailbox is message number one.

nMessagePart

The message part that will be retrieved. A value of zero specifies that the complete message should be returned. If the message is a multipart MIME message, message parts start with a value of one.

dwOffset

The byte offset into the message. This parameter can be used in conjunction with the *lpdwLength* parameter to return a specific part of a message. A value of zero specifies the beginning of the message.

lpdwLength

A pointer to an unsigned integer value which should be initialized to the maximum number of bytes to be read, and will contain the size of the message when the function returns. To specify the entire message, from the offset specified by the *dwOffset* parameter to the end of the message, initialize the *lpdwLength* parameter to a value of -1. This parameter may be NULL if the message size is not needed.

dwOptions

The low order word of this parameter specifies how the message data will be returned. It may be one of the following values:

Constant	Description
IMAP_SECTION_DEFAULT	All headers and the complete body of the specified message or message part are to be retrieved. The client application is responsible for parsing the header block. If the message is a MIME multipart message and the complete message is returned, the application is responsible for parsing the individual message parts if necessary.

IMAP_SECTION_HEADER	All headers for the specified message or message part are to be retrieved. The client application is responsible for parsing the header block.
IMAP_SECTION_MIMEHEADER	The MIME headers for the specified message or message are to be retrieved. Only those header fields which are used in MIME messages, such as Content-Type will be returned to the client. This is typically useful when processing the header for a multipart message which contains file attachments. The client application is responsible for parsing the header block.
IMAP_SECTION_BODY	The body of the specified message or message part is to be retrieved. For a MIME formatted message, this may include data that is uuencoded or base64 encoded. The application is responsible for decoding this data.
IMAP_SECTION_PREVIEW	The message header or body is being previewed and should not be marked as read by the server. This prevents the message from having the IMAP_FLAG_SEEN flag from being automatically set when the message data is retrieved.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **ImapGetLastError**.

Remarks

The **ImapOpenMessageEx** function uses the FETCH command to access the specified message on the server. The client can then use the **ImapRead** function to read the contents of the message.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmavp10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[ImapCloseMessage](#), [ImapGetMessage](#), [ImapGetMessageHeaders](#), [ImapOpenMessage](#), [ImapRead](#), [ImapStoreMessage](#)

ImapRead Function

```
INT WINAPI ImapRead(  
    HCLIENT hClient,  
    LPBYTE lpBuffer,  
    INT cbBuffer  
);
```

The **ImapRead** function reads the specified number of bytes from the client socket and copies them into the buffer. The data may be of any type, and is not terminated with a null character.

Parameters

hClient

Handle to the client session.

lpBuffer

Pointer to the buffer in which the data will be copied.

cbBuffer

The maximum number of bytes to read and copy into the specified buffer. This value must be greater than zero.

Return Value

If the function succeeds, the return value is the number of bytes actually read. A return value of zero indicates that there is no more data available to be read. If the function fails, the return value is IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

When **ImapRead** is called and the client is in non-blocking mode, it is possible that the function will fail because there is no available data to read at that time. This should not be considered a fatal error. Instead, the application should simply wait to receive the next asynchronous notification that data is available.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmapi10.lib

See Also

[ImapGetMessage](#), [ImapGetMessageHeaders](#), [ImapIsBlocking](#)

ImapRegisterEvent Function

```
INT WINAPI ImapRegisterEvent(  
    HCLIENT hClient,  
    UINT nEvent,  
    IMAPEVENTPROC LpEventProc,  
    DWORD_PTR dwParam  
);
```

The **ImapRegisterEvent** function registers a callback function for the specified event.

Parameters

hClient

Handle to the client session.

nEvent

An unsigned integer which specifies which event should be registered with the specified callback function. One of the following values may be used:

Constant	Description
IMAP_EVENT_CONNECT	The connection to the server has completed.
IMAP_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
IMAP_EVENT_READ	Data is available to read by the client. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the calling process is in asynchronous mode.
IMAP_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
IMAP_EVENT_TIMEOUT	The client has timed out while waiting for a response from the server. Note that under some circumstances this event can be generated for a non-blocking connection, such as when the client is establishing a secure connection.
IMAP_EVENT_CANCEL	The client has canceled the current operation.
IMAP_EVENT_COMMAND	The client has processed a command that was sent to the server. The result code and result string can be used to determine if the response to the command.
IMAP_EVENT_PROGRESS	This event notification is sent periodically during lengthy blocking operations, such as retrieving a complete message from the server.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **ImapEventProc** callback

function. If this parameter is NULL, the callback for the specified event is disabled.

dwParam

A user-defined integer value that is passed to the callback function. If the application targets the x86 (32-bit) platform, this parameter must be a 32-bit unsigned integer. If the application targets the x64 (64-bit) platform, this parameter must be a 64-bit unsigned integer.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

The **ImapRegisterEvent** function associates a callback function with a specific event. The event handler is an **ImapEventProc** function that is invoked when the event occurs. Arguments are passed to the function to identify the client session, the event type and the user-defined value specified when the event handler is registered. If the event occurs because of an error condition, the error code will be provided to the handler.

This function is typically used to register an event handler that is invoked while a message is being retrieved. The IMAP_EVENT_PROGRESS event will only be generated periodically during the transfer to ensure the application is not flooded with event notifications. It is guaranteed that at least one IMAP_EVENT_PROGRESS notification will occur at the beginning of the transfer, and one at the end of the transfer when it has completed.

The callback function specified by the *lpEventProc* parameter must be declared using the **__stdcall** calling convention. This ensures the arguments passed to the event handler are pushed on to the stack in the correct order. Failure to use the correct calling convention will corrupt the stack and cause the application to terminate abnormally.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmapi10.lib

See Also

[ImapDisableEvents](#), [ImapEnableEvents](#), [ImapEventProc](#), [ImapFreezeEvents](#)

ImapRenameMailbox Function

```
INT WINAPI ImapRenameMailbox(  
    HCLIENT hClient,  
    LPCTSTR lpszOldMailbox,  
    LPCTSTR lpszNewMailbox  
);
```

The **ImapRenameMailbox** function renames an existing mailbox.

Parameters

hClient

Handle to the client session.

lpszOldMailbox

A pointer to a string which specifies the mailbox to be renamed.

lpszNewMailbox

A pointer to a string which specifies the new mailbox name.

Return Value

If the function succeeds, it returns zero. If an error occurs, the function returns IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

The **ImapRenameMailbox** function renames an existing mailbox on the server. The new mailbox name cannot exist on the server, or the function will fail.

If the existing mailbox name contains inferior hierarchical names (mailboxes under the specified mailbox) then those mailboxes will also be renamed. For example, if the mailbox "Mail/Pictures" contains two mailboxes, "Personal" and "Work" and it is renamed to "Mail/Images" then the two mailboxes under it would be automatically renamed to "Mail/Images/Personal" and "Mail/Images/Work".

If the mailbox being renamed is the currently selected mailbox, the current mailbox will be unselected and any messages marked for deletion will be expunged. The new mailbox name will then automatically be re-selected. To prevent deleted messages from being removed from the mailbox prior to being renamed, use the **ImapUnselectMailbox** function to unselect the current mailbox before calling **ImapRenameMailbox**. Note that if the rename operation fails, the client may be left in an unselected state.

It is permitted to rename the special mailbox INBOX. In this case, the messages will be moved from the INBOX mailbox to the new mailbox. If the INBOX mailbox is currently selected, the new mailbox will not automatically be selected. INBOX will remain the selected mailbox.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmapi10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[ImapCreateMailbox](#), [ImapDeleteMailbox](#), [ImapGetFirstMailbox](#), [ImapGetNextMailbox](#)

ImapReselectMailbox Function

```
BOOL WINAPI ImapReselectMailbox(  
    HCLIENT hClient,  
    LPIMAPMAILBOX lpMailboxInfo  
);
```

The **ImapReselectMailbox** function reselects the current mailbox and returns updated information about the status of the mailbox.

Parameters

hClient

Handle to the client session.

lpMailboxInfo

A pointer to an [IMAPMAILBOX](#) structure which contains updated information about the mailbox when the function returns. This parameter may be NULL if the caller does not require any information about the mailbox.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is `IMAP_ERROR`. To get extended error information, call **ImapGetLastError**.

Remarks

The **ImapReselectMailbox** function forces the current mailbox to be reselected and returns updated information about the status of the mailbox. Deleted messages are not expunged from the mailbox and remain marked for deletion.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csmapi10.lib`

See Also

[ImapExamineMailbox](#), [ImapSelectMailbox](#), [ImapUnselectMailbox](#)

ImapSearchMailbox Function

```
LONG WINAPI ImapSearchMailbox(  
    HCLIENT hClient,  
    LPCTSTR lpszCriteria,  
    LPCTSTR lpszCharacterSet,  
    DWORD dwReserved,  
    UINT* lpnMessageIds,  
    LONG nMaxMessages  
);
```

The **ImapSearchMailbox** function searches the current mailbox for messages that match the specified criteria, returning matching message identifiers.

Parameters

hClient

Handle to the client session.

lpszCriteria

A pointer to a string which specifies the search criteria.

lpszCharacterSet

A pointer to a string which specifies the character set to use when searching the mailbox. If this parameter is NULL or an empty string, the default UTF-8 character set will be used.

dwReserved

A reserved parameter which should be set to the value 0.

lpnMessageIds

A pointer to an array of unsigned integers that will contain the message identifiers of those messages which match the search criteria in the current mailbox. This parameter may be NULL, in which case the function will return the number of matching messages but will not return their identifiers.

nMaxMessages

The maximum number of message identifiers that may be stored in the *lpnMessageIds* array. If the *lpnMessageIds* parameter is NULL, this value should be zero.

Return Value

If the function succeeds, the return value is the number of messages that meet the search criteria in the current mailbox. If the function fails, the return value is IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

The **ImapSearchMailbox** function is used to search a mailbox for messages which match a given criteria and return a list of the matching message identifiers. The search criteria is composed of one or more search keywords and an optional value to match against. String searches are not case sensitive and partial matches in the message are returned.

The following search keywords are recognized:

Keyword	Description
ANSWERED	Match those messages which have the IMAP_FLAG_ANSWERED flag set.

BCC <i>address</i>	Match those messages which contain the specified address in the BCC header field.
BEFORE <i>date</i>	Match those messages which were added to the mailbox prior to the specified date.
BODY <i>string</i>	Match those messages where the body contains the specified string.
CC <i>address</i>	Match those messages which contain the specified address in the CC header field.
DELETED	Match those messages which have the IMAP_FLAG_DELETED flag set.
DRAFT	Match those messages which have the IMAP_FLAG_DRAFT flag set.
FLAGGED	Match those messages which have the IMAP_FLAG_URGENT flag set.
FROM <i>address</i>	Match those messages which contain the specified address in the FROM header field.
HEADER <i>field string</i>	Match those messages which contain the string in the specified header field. If no string is specified, then all messages which contain the header will be matched.
LARGER <i>size</i>	Match those messages which are larger than the specified size in bytes.
NEW	Match those messages which have the IMAP_FLAG_RECENT flag set, but not the IMAP_FLAG_SEEN flag.
OLD	Match those messages which do not have the IMAP_FLAG_RECENT flag set.
ON <i>date</i>	Match those messages which were added on the specified date.
RECENT	Match those messages which have the IMAP_FLAG_RECENT flag set.
SEEN	Match those messages which have the IMAP_FLAG_SEEN flag set.
SENTBEFORE <i>date</i>	Match those messages whose Date header value is earlier than the specified date.
SENTON <i>date</i>	Match those messages whose Date header value is the same as the specified date.
SENTSINCE <i>date</i>	Match those messages whose Date header value is later than the specified date.
SINCE <i>date</i>	Match those messages added to the mailbox after the specified date.
SMALLER <i>size</i>	Match those messages which are smaller than the specified size in bytes.
SUBJECT <i>string</i>	Match those messages whose Subject header contains the specified string.
TEXT <i>string</i>	Match those messages whose headers or body contains the specified string.
TO <i>address</i>	Match those messages which contain the specified address in the TO header field.
UID <i>sequence</i>	Match those messages with unique identifiers in the sequence set.

UNANSWERED	Match those messages which do not have the IMAP_FLAG_ANSWERED flag set.
UNDELETED	Match those messages which do not have the IMAP_FLAG_DELETED flag set.
UNDRAFT	Match those messages which do not have the IMAP_FLAG_DRAFT flag set.
UNFLAGGED	Match those messages which do not have the IMAP_FLAG_URGENT flag set.
UNSEEN	Match those messages which do not have the IMAP_FLAG_SEEN flag set.

In addition to the listed keywords, the keyword NOT may prefix a keyword to return those messages which do not match the search criteria. For example, "NOT TO user@domain.com" would return those messages which were not addressed to user@domain.com.

If multiple search keywords are specified, the result is the intersection of all those messages which meet the search criteria. For example, a search criteria of "DELETED SINCE 1-Jan-2003" would return all those messages which are marked for deletion and were added to the mailbox after 1 January 2003.

Those search keywords which expect dates must be specified in format *dd-mmm-yyyy* where the month is the three letter abbreviation for the month name. Note that the internal date the message was added to the mailbox is not the same as the value of the Date header field in the message.

The UID keyword expects a one or more unique message identifiers. These values may provided as comma separated list, or a range delimited by a colon. For example, "UID 23000:24000" would return all those messages who have UIDs ranging from 23000 through to 24000.

The message identifiers returned by this function are only valid until the mailbox is expunged or another mailbox is selected.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmapi10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[ImapGetNewMessages](#), [ImapGetUnseenMessages](#)

ImapSelectMailbox Function

```
INT WINAPI ImapSelectMailbox(  
    HCLIENT hClient,  
    LPCTSTR lpszMailbox,  
    LPIMAPMAILBOX lpMailboxInfo  
);
```

The **ImapSelectMailbox** function selects the specified mailbox for read-write access.

Parameters

hClient

Handle to the client session.

lpszMailbox

A pointer to a string which specifies the new mailbox to be selected.

lpMailboxInfo

A pointer to an [IMAPMAILBOX](#) structure which contains information about the mailbox when the function returns. This parameter may be NULL if the caller does not require any information about the mailbox.

Return Value

If the function succeeds, it returns zero. If an error occurs, the function returns IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

The **ImapSelectMailbox** function is used to select a mailbox in read-write mode. If the client has a different mailbox currently selected, that mailbox will be closed and any messages marked for deletion will be expunged. To prevent deleted messages from being removed from the previous mailbox, use the **ImapUnselectMailbox** function prior to selecting the new mailbox.

If an application wishes to update the information returned in the IMAPMAILBOX structure for the current mailbox, simply call **ImapSelectMailbox** again with the same mailbox name. Note that this will not cause any messages marked for deletion to be expunged.

The special case-insensitive mailbox name INBOX is used for new messages. Other mailbox names may or may not be case-sensitive depending on the IMAP server's operating system and implementation.

To access a mailbox in read-only mode, use the **ImapExamineMailbox** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmapi10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

ImapSetLastError Function

```
VOID WINAPI ImapSetLastError(  
    DWORD dwErrorCode  
);
```

The **ImapSetLastError** function sets the last error code for the current thread.

Parameters

dwErrorCode

Specifies the last error code for the caller. A value of zero clears the last error code.

Return Value

None.

Remarks

Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value error code such as FALSE, NULL, INVALID_CLIENT or IMAP_ERROR. Those functions which call **ImapSetLastError** when they succeed are noted on the function reference page.

Applications can retrieve the value saved by this function by using the **ImapGetLastError** function. The use of **ImapGetLastError** is optional. An application can call it to find out the specific reason for a function failure.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmapi10.lib

ImapSetMessageFlags Function

```
INT WINAPI ImapSetMessageFlags(  
    HCLIENT hClient,  
    UINT nMessageId,  
    UINT nMode  
    DWORD dwMessageFlags  
);
```

The **ImapSetMessageFlags** function returns the message flags for the specified message.

Parameters

hClient

Handle to the client session.

nMessageId

Number of message to obtain the message flags for. This value must be greater than zero. The first message in the mailbox is message number one.

nMode

An unsigned integer value which specifies one of the following modes which determines how the message flags are set:

Constant	Description
IMAP_FLAGS_REPLACE	All message flags are replaced with the flags specified by the <i>dwMessageFlags</i> parameter.
IMAP_FLAGS_ADD	The message flags specified by the <i>dwMessageFlags</i> parameter will be set for the message. Message flags that have been previously set will remain unmodified.
IMAP_FLAGS_REMOVE	The message flags specified by the <i>dwMessageFlags</i> parameter will be removed from the message. Message flags that are not specified will remain unmodified.

dwMessageFlags

An unsigned integer value which specifies one or more message flags. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
IMAP_FLAG_ANSWERED	The message has been answered.
IMAP_FLAG_DELETED	The message has been marked for deletion.
IMAP_FLAG_DRAFT	The message has not been completed and is marked as a draft copy.
IMAP_FLAG_URGENT	The message has been flagged for urgent or special attention.
IMAP_FLAG_RECENT	The message has been added to the mailbox recently.
IMAP_FLAG_SEEN	The message has been read.

Return Value

If the function succeeds, it returns IMAP_RESULT_OK. If an error occurs, the function returns IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmapi10.lib

See Also

[ImapDeleteMessage](#), [ImapGetMessageCount](#), [ImapGetMessageFlags](#)

ImapSetTimeout Function

```
INT WINAPI ImapSetTimeout(  
    HCLIENT hClient,  
    INT nTimeout  
);
```

The **ImapSetTimeout** function sets the number of seconds the client will wait for a response from the server. Once the specified number of seconds has elapsed, the function will fail and return to the caller.

Parameters

hClient

Handle to the client session.

nTimeout

The number of seconds to wait for a blocking operation to complete.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

The timeout value is only used with blocking network operations.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmav10.lib

See Also

[ImapConnect](#), [ImapGetTimeout](#), [ImapRead](#)

ImapStoreMessage Function

```
INT WINAPI ImapStoreMessage(  
    HCLIENT hClient,  
    UINT nMessageId,  
    LPCTSTR lpszFileName  
);
```

The **ImapStoreMessage** function retrieves a message from the current mailbox and stores it in a local file or the system clipboard.

Parameters

hClient

Handle to the client session.

nMessageId

Number of the message to retrieve. This value must be greater than zero. The first message in the mailbox is message number one.

lpszFileName

Pointer to a string which specifies the file that the message will be stored in. If an empty string or NULL pointer is passed as an argument, the message is copied to the system clipboard.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

The **ImapStoreMessage** function provides a method of retrieving and storing a message on the local system. The contents of the message is stored as a text file, using the specified file name. This function always causes the caller to block until the entire message has been retrieved, even if the client has been put in asynchronous mode.

If event handling is enabled, the IMAP_EVENT_PROGRESS event will fire periodically during the transfer of the message to the local system. An application can determine how much of the message has been retrieved by calling the **ImapGetTransferStatus** function.

To retrieve the message into a global memory buffer so that it can be passed to the MIME or SMTP libraries, use the **ImapGetMessage** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmapi10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[ImapGetMessage](#), [ImapGetMessageHeaders](#), [ImapGetTransferStatus](#)

ImapSubscribeMailbox Function

```
INT WINAPI ImapSubscribeMailbox(  
    HCLIENT hClient,  
    LPCTSTR lpszMailbox  
);
```

The **ImapSubscribeMailbox** function subscribes the user to the specified mailbox.

Parameters

hClient

Handle to the client session.

lpszMailbox

A pointer to a string which specifies the mailbox to subscribe to.

Return Value

If the function succeeds, it returns zero. If an error occurs, the function returns IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

The **ImapSubscribeMailbox** function adds the specified mailbox to the current user's list of active or subscribed mailboxes. The user will remain subscribed to the mailbox across multiple sessions, until the **ImapUnsubscribeMailbox** function is called to remove the mailbox from the subscription list.

To list those mailboxes which the user has subscribed to, use the **ImapGetFirstMailbox** function and specify the IMAP_LIST_SUBSCRIBED option.

Note that if a user subscribes to a mailbox and that mailbox is later renamed or deleted, the mailbox will not be automatically removed from the user's subscription list. An application must not assume that because a mailbox name is included in the list of subscribed mailboxes, it exists and can be selected. To check if the mailbox exists, use the **ImapGetMailboxStatus** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmapi10.lib

Unicode: Implemented as Unicode and ANSI versions.

ImapUndeleteMessage Function

```
INT WINAPI ImapUndeleteMessage(  
    HCLIENT hClient,  
    UINT nMessageId  
);
```

The **ImapUndeleteMessage** function removes the deletion flag for the specified message.

Parameters

hClient

Handle to the client session.

nMessage

Number of message to undelete from the server. This value must be greater than zero. The first message in the mailbox is message number one.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmav10.lib

See Also

ImapUninitialize Function

```
VOID WINAPI ImapUninitialize();
```

The **ImapUninitialize** function terminates the use of the library.

Parameters

There are no parameters.

Return Value

None.

Remarks

An application is required to perform a successful **ImapInitialize** call before it can call any of the other library functions. When it has completed the use of library, the application must call **ImapUninitialize** to allow the library to free any resources allocated on behalf of the process. Any pending blocking or asynchronous calls in this process are canceled without posting any notification messages, and all sockets that were opened by the process are closed.

There must be a call to **ImapUninitialize** for every successful call to **ImapInitialize** made by a process. In a multithreaded environment, operations for all threads in the client are terminated.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmapi10.lib

See Also

[ImapAsyncConnect](#), [ImapConnect](#), [ImapDisconnect](#), [ImapInitialize](#)

ImapUnselectMailbox Function

```
INT WINAPI ImapUnselectMailbox(  
    HCLIENT hClient,  
    BOOL bExpunge  
);
```

The **ImapUnselectMailbox** function unselects the current mailbox.

Parameters

hClient

Handle to the client session.

bExpunge

A boolean flag which determines if deleted messages will be expunged from the mailbox. A non-zero value specifies that messages that have been marked for deletion will be removed from the mailbox. A zero value specifies that no messages will be removed from the mailbox.

Return Value

If the function succeeds, it returns zero. If an error occurs, the function returns IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmapi10.lib

See Also

ImapUnsubscribeMailbox Function

```
INT WINAPI ImapUnsubscribeMailbox(  
    HCLIENT hClient,  
    LPCTSTR lpszMailbox  
);
```

The **ImapUnsubscribeMailbox** function unsubscribes the user from the specified mailbox.

Parameters

hClient

Handle to the client session.

lpszMailbox

A pointer to a string which specifies the mailbox to unsubscribe from.

Return Value

If the function succeeds, it returns zero. If an error occurs, the function returns IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

The **ImapUnsubscribeMailbox** function removes the specified mailbox from the current user's list of active or subscribed mailboxes.

To list those mailboxes which the user has subscribed to, use the **ImapGetFirstMailbox** function and specify the IMAP_LIST_SUBSCRIBED option.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmapi10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[ImapExamineMailbox](#), [ImapGetFirstMailbox](#), [ImapGetNextMailbox](#), [ImapSelectMailbox](#), [ImapSubscribeMailbox](#), [ImapUnselectMailbox](#)

ImapWrite Function

```
INT WINAPI ImapWrite(  
    HCLIENT hClient,  
    LPBYTE lpBuffer,  
    INT cbBuffer  
);
```

The **ImapWrite** function sends the specified number of bytes to the server.

Parameters

hClient

Handle to the client session.

lpBuffer

The pointer to the buffer which contains the data that is to be sent to the server.

cbBuffer

The number of bytes to send from the specified buffer.

Return Value

If the function succeeds, the return value is the number of bytes actually written. If the function fails, the return value is IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

The return value may be less than the number of bytes specified by the *cbBuffer* parameter. In this case, the data has been partially written and it is the responsibility of the client application to send the remaining data at some later point. For non-blocking clients, the client must wait for the IMAP_EVENT_WRITE asynchronous notification message before it resumes sending data.

The **ImapWrite** function should not be used to send commands to the IMAP server. Use the **ImapCommand** function instead.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmapi10.lib

Internet Message Access Protocol Data Structures

- IMAPMAILBOX
- IMAPMAILBOXSTATUS
- IMAPMESSAGE
- IMAPTRANSFERSTATUS
- INITDATA
- SECURITYCREDENTIALS
- SECURITYINFO
- SYSTEMTIME

IMAPMAILBOX Structure

This structure contains information about a selected mailbox.

```
typedef struct _IMAPMAILBOX
{
    UINT    nMessages;
    UINT    nRecentMessages;
    UINT    nUnseenMessageId;
    DWORD   dwMailboxUID;
    DWORD   dwNextMessageUID;
    DWORD   dwFlags;
    DWORD   dwPermanentFlags;
    DWORD   dwAccessMode;
    DWORD   dwReserved1;
    DWORD   dwReserved2;
} IMAPMAILBOX, *LPIMAPMAILBOX;
```

Members

nMessages

A value specifies the total number of messages in the mailbox.

nRecentMessages

A value which specifies the number of new messages that have recently arrived in the mailbox.

nUnseenMessageId

A value which specifies the message ID of the first unseen message in the mailbox.

dwMailboxUID

A value which specifies a unique identifier for this mailbox which corresponds to the UIDVALIDITY value returned by the IMAP server. The actual value is determined by the server and should be considered opaque. The protocol specification requires that a mailbox's UID must not change unless the mailbox contents are modified or existing messages in the mailbox have been assigned new UIDs.

dwNextMessageUID

A value which specifies the predicted unique identifier that will be assigned to a new message in the mailbox. This corresponds to the UIDNEXT value returned by the IMAP server. The protocol specification requires that as long as the mailbox UID is unchanged, messages that are added to the mailbox will be assigned a UID greater than or equal to the next UID value.

dwFlags

A value which specifies one or more mailbox flags. One or more of the following values may be specified:

Constant	Description
IMAP_FLAG_NOINFERIORS	The mailbox does not contain any child mailboxes. In the IMAP protocol, these are referred to as inferior hierarchical mailbox names.
IMAP_FLAG_NOSELECT	The mailbox cannot be selected or examined. This flag is typically used by servers to indicate that the mailbox name refers to a directory on the server, not a mailbox file.
IMAP_FLAG_MARKED	The mailbox is marked as being of interest to a client. If

	this flag is used, it typically means that the mailbox contains messages. An application should not depend on this flag being present for any given mailbox. Some IMAP servers do not support marked or unmarked flags for mailboxes.
IMAP_FLAG_UNMARKED	The mailbox is marked as not being of interest to a client. If this flag is used, it typically means that the mailbox does not contain any messages. An application should not depend on this flag being present for any given mailbox. Some IMAP servers do not support marked or unmarked flags for mailboxes.

dwPermanentFlags

A value which specifies the message flags that a client can change permanently. If this value is zero, then no permanent flags are defined for the mailbox and the client may assume that all message flags may be set permanently. Otherwise, one or more of the following values may be specified:

Constant	Description
IMAP_FLAG_ANSWERED	The message has been answered.
IMAP_FLAG_DRAFT	The message has not been completed and is marked as a draft copy.
IMAP_FLAG_URGENT	The message has been flagged for urgent or special attention.
IMAP_FLAG_SEEN	The message has been read.

dwAccessMode

A value which specifies the access mode for the mailbox. It may be one of the following values:

Constant	Description
IMAP_ACCESS_READONLY	The mailbox has been selected in read-only mode. Messages may not be created in the mailbox, nor can message flags be modified.
IMAP_ACCESS_READWRITE	The mailbox has been selected in read-write mode. Messages may be modified by the client, and messages marked for deletion can be expunged.

dwReserved1

A reserved value that is undefined.

dwReserved2

A reserved value that is undefined.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmapi10.lib

IMAPMAILBOXSTATUS Structure

This structure contains information about a mailbox.

```
typedef struct _IMAPMAILBOXSTATUS
{
    UINT    nMessages;
    UINT    nRecentMessages;
    UINT    nUnseenMessages;
    DWORD   dwMailboxUID;
    DWORD   dwNextMessageUID;
    DWORD   dwReserved;
} IMAPMAILBOXSTATUS, *LPIMAPMAILBOXSTATUS;
```

Members

nMessages

A value specifies the total number of messages in the mailbox.

nRecentMessages

A value which specifies the number of new messages that have recently arrived in the mailbox.

nUnseenMessages

A value which specifies the number of unread messages in the mailbox.

dwMailboxUID

A value which specifies a unique identifier for this mailbox which corresponds to the UIDVALIDITY value returned by the IMAP server. The actual value is determined by the server and should be considered opaque. The protocol specification requires that a mailbox's UID must not change unless the mailbox contents are modified or existing messages in the mailbox have been assigned new UIDs.

dwNextMessageUID

A value which specifies the predicted unique identifier that will be assigned to a new message in the mailbox. This corresponds to the UIDNEXT value returned by the IMAP server. The protocol specification requires that as long as the mailbox UID is unchanged, messages that are added to the mailbox will be assigned a UID greater than or equal to the next UID value.

dwReserved

A reserved value that is undefined.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

IMAPMESSAGE Structure

This structure contains information about a message.

```
typedef struct _IMAPMESSAGE
{
    UINT    nMessageId;
    DWORD   dwMessageUID;
    DWORD   dwSize;
    DWORD   dwFlags;
    DWORD   dwTimestamp;
    DWORD   dwReserved;
} IMAPMESSAGE, *LPIMAPMESSAGE;
```

Members

nMessageId

An integer value which identifies the message. The message identifier is only valid while the mailbox is selected and no messages marked for deletion have been expunged. To maintain a persistent identifier for the message, use a combination of the mailbox UID and message UID.

dwMessageUID

An integer value which specifies a unique identifier for this message. The actual value is determined by the server and should be considered opaque. If the client application stores the message UID on the local system, it should also store the UID for the mailbox that contains the message. If the mailbox UID changes, the message UID may no longer be valid.

dwSize

Specifies the size of the message in bytes.

dwFlags

A value which specifies one or more message flags. One or more of the following values may be specified:

Constant	Description
IMAP_FLAG_NONE	No value.
IMAP_FLAG_ANSWERED	The message has been answered.
IMAP_FLAG_DELETED	The message has been marked for deletion.
IMAP_FLAG_DRAFT	The message has not been completed and is marked as a draft copy.
IMAP_FLAG_URGENT	The message has been flagged for urgent or special attention.
IMAP_FLAG_RECENT	The message has been added to the mailbox recently.
IMAP_FLAG_SEEN	The message has been read.

dwTimestamp

An integer value which specifies the date and time that the message was created in the mailbox. The value is expressed as the number of seconds since midnight, 1 January 1970 and is the same value that is used for the standard C runtime library time functions. Note that the date and time used is the message's internal date from the mail server, not the value of the Date header field.

dwReserved

A reserved value that is undefined.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmapi10.lib

Copyright © 2023 Catalyst Development Corporation. All rights reserved.

IMAPTRANSFERSTATUS Structure

This structure is used by the [ImapGetTransferStatus](#) function to return information about a file transfer in progress.

```
typedef struct _IMAPTRANSFERSTATUS
{
    UINT    nMessageId;
    DWORD   dwBytesTotal;
    DWORD   dwBytesCopied;
    DWORD   dwBytesPerSecond;
    DWORD   dwTimeElapsed;
    DWORD   dwTimeEstimated;
} IMAPTRANSFERSTATUS, *LPIMAPTRANSFERSTATUS;
```

Members

nMessageId

The message ID of the current message that is being transferred.

dwBytesTotal

The total number of bytes that will be transferred. If the file is being copied from the server to the local host, this is the size of the remote file. If the file is being copied from the local host to the server, it is the size of the local file. If the file size cannot be determined, this value will be zero.

dwBytesCopied

The total number of bytes that have been copied.

dwBytesPerSecond

The average number of bytes that have been copied per second.

dwTimeElapsed

The number of seconds that have elapsed since the file transfer started.

dwTimeEstimated

The estimated number of seconds until the file transfer is completed. This is based on the average number of bytes transferred per second.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

INITDATA Structure

This structure contains information about the SocketTools library when the initialization function returns.

```
typedef struct _INITDATA
{
    DWORD      dwSize;
    DWORD      dwVersionMajor;
    DWORD      dwVersionMinor;
    DWORD      dwVersionBuild;
    DWORD      dwOptions;
    DWORD_PTR  dwReserved1;
    DWORD_PTR  dwReserved2;
    TCHAR      szDescription[128];
} INITDATA, *LPINITDATA;
```

Members

dwSize

Size of this structure. This structure member must be set to the size of the structure prior to calling the initialization function. Failure to do so will cause the function to fail.

dwVersionMajor

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the major version number for the library.

dwVersionMinor

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the minor version number for the library.

dwVersionBuild

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the build number for the library.

dwOptions

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

dwReserved1

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

dwReserved2

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

szDescription

A null terminated string which describes the library.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Unicode: Implemented as Unicode and ANSI versions.

SECURITYCREDENTIALS Structure

The **SECURITYCREDENTIALS** structure specifies the information needed by the library to specify additional security credentials, such as a client certificate or private key, when establishing a secure connection.

```
typedef struct _SECURITYCREDENTIALS
{
    DWORD    dwSize;
    DWORD    dwProtocol;
    DWORD    dwOptions;
    DWORD    dwReserved;
    LPCTSTR  lpszHostName;
    LPCTSTR  lpszUserName;
    LPCTSTR  lpszPassword;
    LPCTSTR  lpszCertStore;
    LPCTSTR  lpszCertName;
    LPCTSTR  lpszKeyFile;
} SECURITYCREDENTIALS, *LPSECURITYCREDENTIALS;
```

Members

dwSize

Size of this structure. If the structure is being allocated dynamically, this member must be set to the size of the structure and all other unused structure members must be initialized to a value of zero or NULL.

dwProtocol

A bitmask of supported security protocols. The value of this structure member is constructed by using a bitwise operator with any of the following values:

Constant	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_SSL	Either SSL 2.0 or SSL 3.0 should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, TLS will be excluded from the list of supported protocols. Both SSL 2.0 and 3.0 have been deprecated and will never be used unless explicitly specified. It is not recommended that you enable either of these protocols for secure connections because it will cause most servers to reject your connection request, even if a version of TLS is also specified.
SECURITY_PROTOCOL_TLS	Either the TLS 1.0, 1.1 or 1.2 protocol should be used when establishing a secure connection. The correct protocol is automatically selected, based on

	what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers that reject any attempt to use the older SSL protocol and require that only TLS be used.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This is the recommended version of TLS to use with secure connections.

dwOptions

A value which specifies one or options. This member is constructed by using a bitwise operator with any of the following values:

Constant	Description
CREDENTIAL_STORE_CURRENT_USER	The library will attempt to open a store for the current user using the certificate store name provided in this structure. If no options are specified, then this is the default behavior.
CREDENTIAL_STORE_LOCAL_MACHINE	The library will attempt to open a local machine store using the certificate store name provided in this structure. If this option is specified, the library will always search for a local machine store before searching for the store by that name for the current user.
CREDENTIAL_STORE_FILENAME	The certificate store name is a file that contains the certificate and private key that

will be used.

dwReserved

This structure member is reserved for future use and should always be initialized to zero.

lpszHostName

A pointer to a null terminated string which specifies the hostname that will be used when validating the server certificate. If this member is NULL, then the server certificate will be validated against the hostname used to establish the connection.

lpszUserName

A pointer to a null terminated string which identifies the owner of client certificate. Currently this member is not used by the library and should always be initialized as a NULL pointer.

lpszPassword

A pointer to a null terminated string which specifies the password needed to access the certificate. Currently this member is only used if the CREDENTIAL_STORE_FILENAME option has been specified. If there is no password associated with the certificate, then this member should be initialized as a NULL pointer.

lpszCertStore

A pointer to a null terminated string which specifies the name of the certificate store to open. A certificate store is a collection of certificates and their private keys, typically organized by how they are used. If this value is NULL or points to an empty string, the default certificate store "MY" will be used.

Store Name	Description
------------	-------------

CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as VeriSign and Thawte act as certification authorities.
----	---

MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. This corresponds to the "Personal" store that is displayed by the certificate manager utility and is the default store used by the library.
----	--

ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as VeriSign and Thawte are installed as part of the operating system and periodically updated by Microsoft.
------	--

lpszCertName

A pointer to a null terminated string which specifies the name of the certificate to use. The library will first search the certificate store for a certificate with a matching "friendly name"; this is a name for the certificate that is assigned by the user. Note that the name must match completely, but the comparison is not case sensitive. If no matching certificate is found, the library will then attempt to find a certificate that has a matching common name (also called the certificate subject). This comparison is less stringent, and the first partial match will be returned. If this second search fails, the library will return an error indicating that the certificate could not be found. If the SECURITY_PROTOCOL_SSH protocol has been specified, this member should be NULL.

lpszKeyFile

A pointer to a null terminated string which specifies the name of the file which contains the private key required to establish the connection. This member is only used for SSH connections

and should always be NULL when establishing a secure connection using SSL or TLS.

Remarks

A client application only needs to create this structure if the server requires that the client provide a certificate as part of the process of negotiating the secure session. If a certificate is required, note that it must have a private key associated with it. Attempting to use a certificate that does not have a private key will result in an error during the connection process indicating that the client credentials could not be established.

If you are using a local certificate store, with the certificate and private key stored in the registry, you can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU:" for the current user, or "HKLM:" for the local machine. For example, a certificate store name of "HKLM:MY" would specify the personal certificate store for the local machine, rather than the current user. If neither prefix is specified, then it will default to the certificate store for the current user. You can manage these certificates using the CertMgr.msc Microsoft Management Console (MMC) snap-in.

It is possible to load the certificate from a file rather than from current user's certificate store. The *dwOptions* member should be set to CREDENTIAL_STORE_FILENAME and the *lpzCertStore* member should specify the name of the file that contains the certificate and its private key. The file must be in Private Information Exchange (PFX) format, also known as PKCS#12. These certificate files typically have an extension of .pfx or .p12. Note that if a password was specified when the certificate file was created, it must be provided in the *lpzPassword* member or the library will be unable to access the certificate.

Note that the *lpzUserName* and *lpzPassword* members are values which are used to access the certificate store or private key file. They are not the credentials which are used when establishing the connection with the remote host or authenticating the client session.

The TLS 1.1 and TLS 1.2 protocols are only supported on Windows 7, Windows Server 2008 R2 and later versions of the platform. If these options are specified and the application is running on Windows XP or Windows Vista, the protocol version will be downgraded to TLS 1.0 for backwards compatibility with those platforms.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cstools10.h

Unicode: Implemented as Unicode and ANSI versions.

SECURITYINFO Structure

This structure contains information about a secure connection that has been established.

```
typedef struct _SECURITYINFO
{
    DWORD        dwSize;
    DWORD        dwProtocol;
    DWORD        dwCipher;
    DWORD        dwCipherStrength;
    DWORD        dwHash;
    DWORD        dwHashStrength;
    DWORD        dwKeyExchange;
    DWORD        dwCertStatus;
    SYSTEMTIME   stCertIssued;
    SYSTEMTIME   stCertExpires;
    LPCTSTR      lpszCertIssuer;
    LPCTSTR      lpszCertSubject;
    LPCTSTR      lpszFingerprint;
} SECURITYINFO, *LPSECURITYINFO;
```

Members

dwSize

Specifies the size of the data structure. This member must always be initialized to **sizeof(SECURITYINFO)** prior to passing the address of this structure to the function. Note that if this member is not initialized, an error will be returned indicating that an invalid parameter has been passed to the function.

dwProtocol

A numeric value which specifies the protocol that was selected to establish the secure connection. One of the following values will be returned:

Constant	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_SSL	Either SSL 2.0 or SSL 3.0 should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, TLS will be excluded from the list of supported protocols. Both SSL 2.0 and 3.0 have been deprecated and will never be used unless explicitly specified. It is not recommended that you enable either of these protocols for secure connections because it will cause most servers to reject your connection request, even if a version of TLS is also specified.
SECURITY_PROTOCOL_TLS	Either the TLS 1.0, 1.1 or 1.2 protocol should be used when establishing a secure connection. The

	<p>correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers that reject any attempt to use the older SSL protocol and require that only TLS be used.</p>
SECURITY_PROTOCOL_TLS10	<p>The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.</p>
SECURITY_PROTOCOL_TLS11	<p>The TLS 1.1 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.</p>
SECURITY_PROTOCOL_TLS12	<p>The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This is the recommended version of TLS to use with secure connections.</p>

dwCipher

A numeric value which specifies the cipher that was selected when establishing the secure connection. One of the following values will be returned:

Constant	Description
SECURITY_CIPHER_RC2	The RC2 block cipher was selected. This is a variable key length cipher which supports keys between 40 and 128 bits, in 8-bit increments.
SECURITY_CIPHER_RC4	The RC4 stream cipher was selected. This is a variable key length cipher which supports keys between 40 and 128 bits, in 8-bit increments.
SECURITY_CIPHER_RC5	The RC5 block cipher was selected. This is a variable key length cipher which supports keys up to 2040 bits, in 8-bit increments.
SECURITY_CIPHER_DES	The DES (Data Encryption Standard) block cipher was selected. This is a fixed key length cipher, using 56-bit

	keys.
SECURITY_CIPHER_DES3	The Triple DES block cipher was selected. This cipher encrypts the data three times using different keys, effectively providing a 168-bit length key.
SECURITY_CIPHER_DESX	A variant of the DES block cipher which XORs an extra 64-bits of the key before and after the plaintext has been encrypted, increasing the key size to 184 bits.
SECURITY_CIPHER_AES	The Advanced Encryption Standard cipher (also known as the Rijndael cipher) is a fixed block size cipher which use a key size of 128, 192 or 256 bits. This cipher is supported on Windows XP SP3 and later versions of the operating system.
SECURITY_CIPHER_SKIPJACK	The Skipjack block cipher was selected. This is a fixed key length cipher, using 80-bit keys.
SECURITY_CIPHER_BLOWFISH	The Blowfish block cipher was selected. This is a variable key length cipher up to 448 bits, using a 64-bit block size.

dwCipherStrength

A numeric value which specifies the strength (the length of the cipher key in bits) of the cipher that was selected. Typically this value will be 128 or 256. 40-bit and 56-bit key lengths are considered weak encryption, and subject to brute force attacks. 128-bit and 256-bit key lengths are considered to be secure, and are the recommended key length for secure communications.

dwHash

A numeric value which specifies the hash algorithm which was selected. One of the following values will be returned:

Constant	Description
SECURITY_HASH_MD5	The MD5 algorithm was selected. Its use has been deprecated and is no longer considered to be cryptographically secure.
SECURITY_HASH_SHA1	The SHA-1 algorithm was selected. Its use has been deprecated and is no longer considered to be cryptographically secure.
SECURITY_HASH_SHA256	The SHA-256 algorithm was selected.
SECURITY_HASH_SHA384	The SHA-384 algorithm was selected.
SECURITY_HASH_SHA512	The SHA-512 algorithm was selected.

dwHashStrength

A numeric value which specifies the strength (the length in bits) of the message digest that was selected.

dwKeyExchange

A numeric value which specifies the key exchange algorithm which was selected. One of the following values will be returned:

--	--

Constant	Description
SECURITY_KEYEX_RSA	The RSA public key algorithm was selected.
SECURITY_KEYEX_KEA	The Key Exchange Algorithm (KEA) was selected. This is an improved version of the Diffie-Hellman public key algorithm.
SECURITY_KEYEX_DH	The Diffie-Hellman key exchange algorithm was selected.
SECURITY_KEYEX_ECDH	The Elliptic Curve Diffie-Hellman key exchange algorithm was selected. This is a variant of the Diffie-Hellman algorithm which uses elliptic curve cryptography. This key exchange algorithm is only supported on Windows XP SP3 and later versions of the operating system.

dwCertStatus

A numeric value which specifies the status of the certificate returned by the secure server. This member only has meaning for connections using the SSL or TLS protocols. One of the following values will be returned:

Constant	Description
SECURITY_CERTIFICATE_VALID	The certificate is valid.
SECURITY_CERTIFICATE_NOMATCH	The certificate is valid, but the domain name does not match the common name in the certificate.
SECURITY_CERTIFICATE_EXPIRED	The certificate is valid, but has expired.
SECURITY_CERTIFICATE_REVOKED	The certificate has been revoked and is no longer valid.
SECURITY_CERTIFICATE_UNTRUSTED	The certificate or certificate authority is not trusted on the local system.
SECURITY_CERTIFICATE_INVALID	The certificate is invalid. This typically indicates that the internal structure of the certificate has been damaged.

stCertIssued

A structure which contains the date and time that the certificate was issued by the certificate authority. If the issue date cannot be determined for the certificate, the SYSTEMTIME structure members will have zero values. This member only has meaning for connections using the SSL or TLS protocols.

stCertExpires

A structure which contains the date and time that the certificate expires. If the expiration date cannot be determined for the certificate, the SYSTEMTIME structure members will have zero values. This member only has meaning for connections using the SSL or TLS protocols.

lpszCertIssuer

A pointer to a string which contains information about the organization that issued the certificate. This string consists of one or more comma-separated tokens. Each token consists of an identifier, followed by an equal sign and a value. If the certificate issuer could not be determined, this member may be NULL. This member only has meaning for connections using the SSL or TLS protocols.

lpszCertSubject

A pointer to a string which contains information about the organization that the certificate was issued to. This string consists of one or more comma-separated tokens. Each token consists of an identifier, followed by an equal sign and a value. If the certificate subject could not be determined, this member may be NULL. This member only has meaning for connections using the SSL or TLS protocols.

lpszFingerprint

A pointer to a string which contains a sequence of hexadecimal values that uniquely identify the server. This member is only used when a connection has been established using the Secure Shell (SSH) protocol.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Unicode: Implemented as Unicode and ANSI versions.

Mail Message Library

Compose and parse standard MIME formatted email messages.

Reference

- [Functions](#)
- [Data Structures](#)
- [Error Codes](#)

Library Information

File Name	CSMSGV10.DLL
Version	10.0.1468.2518
LibID	E6D79220-7873-4170-BF39-5D7A0049655C
Import Library	CSMSGV10.LIB
Dependencies	None
Standards	RFC 822, RFC 2045, RFC 2046, RFC 2047, RFC 2048

Overview

The Mail Message library provides an interface for composing and processing email messages and newsgroup articles which are structured according to the Multipurpose Internet Mail Extensions (MIME) standard. Using this library, an application can easily create complex messages which include multiple alternative content types, such as plain text and styled HTML text, file attachments and customized headers.

It is not required that the developer understand the complex MIME standard; a single function call can be used to create multipart message, complete with a styled HTML text body and support for international character sets. The Mail Message library can be easily integrated with the other mail related protocol libraries, making it extremely easy to create and process MIME formatted messages.

The library also includes an interface for managing a local message storage file that can be used to store and retrieve multiple messages. Functions are provided to open and create storage files, add, remove and extract messages from storage, and search the stored messages for specific header field values.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). If you are using Visual C++ 6.0 it is required that you have Service Pack 6 (SP6) installed. You should install all updates for your development tools and have the current Windows SDK installed. The minimum recommended version of Visual Studio is Visual Studio 2010.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are using Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. It is recommended that you install the current service pack and all critical updates available for your version of the operating system.

This product includes both 32-bit and 64-bit libraries. Native 64-bit CPU support requires the 64-

bit version of Windows 7 or later versions of the Windows operating system.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

Mail Message Functions

Function	Description
MimeAppendMessageText	Append text to the body of the current message part
MimeAttachData	Attach the contents of a buffer to the specified message
MimeAttachFile	Attach a file to the specified message
MimeAttachImage	Attach an inline image to the specified message
MimeClearMessageText	Clear the body of the current message part
MimeCloseMessageStore	Close the specified message storage file
MimeCompareMessageText	Compare text in the body of the current message part
MimeComposeMessage	Compose a new message using the specified parameters
MimeCopyMessageStore	Duplicate the contents of the specified message store in a new file
MimeCreateMessage	Create a new empty message
MimeCreateMessageEx	Create a new message from the contents of a file or a message in memory
MimeCreateMessagePart	Create a new message part for the specified message
MimeCreateMessagePartEx	Create a new message part for the specified message
MimeDecodeText	Decode a base64 or quoted-printable encoded string
MimeDecodeTextEx	Decode a base64 or quoted-printable encoded string using a specified character set
MimeDeleteMessage	Delete the specified message
MimeDeleteMessageHeader	Delete the specified header field from the message
MimeDeleteMessagePart	Delete the specified message part
MimeDeleteStoredMessage	Remove the specified message from the message store
MimeEncodeText	Encode a string using base64 or quoted-printable encoding
MimeEncodeTextEx	Encode a string using base64 or quoted-printable encoding using a specified character set
MimeEnumAttachments	Enumerate all file attachments in the specified message
MimeEnumMessageHeaders	Enumerate all header fields in the current message part
MimeEnumMessageRecipients	Enumerate addresses of all message recipients
MimeExportMessage	Export the current message to a text file
MimeExportMessageEx	Export the current message to a file, clipboard or memory buffer
MimeExtractAllFiles	Extract all file attachments in the message and store them in the specified directory
MimeExtractFile	Extract the file attachment from the current message part
MimeExtractFileEx	Extract a file attachment from the message with additional options
MimeFindAttachment	Search for a file attachment in the specified message
MimeFindStoredMessage	Search for a message in the specified message store
MimeFormatDate	Return a standard RFC 822 formatted date string
MimeGetAllHeaders	Return the complete RFC 822 header values in a string buffer
MimeGetAllRecipients	Return a comma-separated list of recipient addresses in a string buffer
MimeGetAttachedFileName	Return the name of the file attachment for the current part
MimeGetContentDigest	Return encoded digest of message's content
MimeGetContentLength	Return the length of the current message part content

MimeGetErrorString	Return a description for the specified error code
MimeGetExportOptions	Return a bitmask that describes current message export options
MimeGetFileContentType	Return the content type for a specified file
MimeGetFirstMessageHeader	Return the first header field and value in the current message part
MimeGetLastError	Return the last error code
MimeGetMessageBoundary	Return the multipart message boundary string
MimeGetMessageDate	Return the date and time from the message header
MimeGetMessageHeader	Return the value of a specified header from the message
MimeGetMessageHeaderEx	Copy the value of specified header to a string buffer
MimeGetMessagePart	Return the current message part index
MimeGetMessagePartCount	Return the total number of message parts
MimeGetMessageSender	Return the email address of the message sender
MimeGetMessageSize	Return the size of the complete message in bytes
MimeGetMessageText	Return the text of the current message part
MimeGetMessageVersion	Return the MIME version from the message header
MimeGetNextMessageHeader	Return the next header field and value in the current message part
MimeGetStoredMessage	Retrieve a message from the specified message store
MimeGetStoredMessageCount	Return the number of messages in a message store
MimeImportMessage	Import a message from the specified text file
MimeImportMessageEx	Import a message from a file, clipboard or memory buffer
MimeInitialize	Initialize the library for use by the client
MimeLocalizeText	Localize Unicode text to ANSI using a specific character set
MimeOpenMessageStore	Open the specified message storage file
MimeParseAddress	Parse the specified email address
MimeParseBuffer	Parse the specified text and add to the current message
MimeParseDate	Parse the specified RFC 822 formatted date string
MimeParseHeader	Parse the specified text and add to message header
MimePurgeMessageStore	Purge all deleted messages from the specified message store
MimeReplaceStoredMessage	Replace the specified message in the message store
MimeResetMessage	Clear the specified message, deleting all message parts
MimeSetExportOptions	Specify a bitmask that describes current message export options
MimeSetFileContentType	Set the content type for a specific file name extension
MimeSetLastError	Set the last error code
MimeSetMessageDate	Set the current date in the header for the specified message
MimeSetMessageHeader	Create or update a header field in the specified message
MimeSetMessageHeaderEx	Create or update a header field, with additional options
MimeSetMessagePart	Set the current message part index for the specified message
MimeSetMessageText	Create or update the specified message body
MimeSetMessageVersion	Set the MIME version for the specified message
MimeStoreMessage	Store the specified message in a message store

MimeAppendMessageText Function

```
LONG WINAPI MimeAppendMessageText(  
    HMESSAGE hMessage,  
    LPCTSTR lpszText  
);
```

The **MimeAppendMessageText** function appends the specified text to the body of the current message part.

Parameters

hMessage

Handle to the message.

lpszText

A pointer to a string which specifies the text to be appended to the current message part.

Return Value

If the function succeeds, the return value is the number of bytes copied into the message. A return value of zero indicates that no text could be appended to the current message part. To get extended error information, call **MimeGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[MimeClearMessageText](#), [MimeCompareMessageText](#), [MimeGetMessageText](#),
[MimeSetMessageText](#)

MimeAttachData Function

```
BOOL WINAPI MimeAttachData(  
    HMESSAGE hMessage,  
    LPBYTE lpBuffer,  
    LONG cbBuffer,  
    LPCTSTR lpszContentName,  
    LPCTSTR lpszContentType,  
    DWORD dwOptions  
);
```

The **MimeAttachData** function attaches the contents of the buffer to the message.

Parameters

hMessage

Handle to the message.

lpBuffer

Pointer to a byte buffer which contains the data to be attached to the message. This parameter may be NULL, in which case no data is attached, but an additional empty message part will be created.

cbBuffer

An unsigned integer which specifies the number of bytes of data in the buffer pointed to by the *lpBuffer* parameter. If the *lpBuffer* parameter is NULL, this value must be zero.

lpszContentName

Pointer to a string which specifies a name for the data being attached to the message. This typically is used as a file name by the mail client to store the data in. If this parameter is NULL or an empty string then no name is defined and the data is attached as inline content. Note that if a file name is specified with a path, only the base name will be used.

lpszContentType

Pointer to a string which specifies the type of data being attached. The value must be a valid MIME content type. If this parameter is NULL or an empty string, then the buffer will be examined to determine what kind of data it contains. If there is only text characters, then the content type will be specified as "text/plain". If the buffer contains binary data, then the content type will be specified as "application/octet-stream", which is appropriate for any type of data.

dwOptions

A value which specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
MIME_ATTACH_DEFAULT	The data encoding is based on the content type. Text data is not encoded, and binary data is encoded using the standard base64 encoding algorithm.
MIME_ATTACH_BASE64	The data is always encoded using the standard base64 algorithm, even if the buffer only contains printable text characters.
MIME_ATTACH_UUCODE	The data is always encoded using the uuencode algorithm, even if the buffer only contains printable text characters.

MIME_ATTACH_QUOTED	The data is always encoded using the quoted-printable algorithm. This encoding should only be used if the data contains 8-bit text characters.
--------------------	--

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **MimeGetLastError**.

Remarks

The **MimeAttachData** function allows an application to attach data to the message as either a file attachment or as inline content. The recipient of the message will see the attached data in the same way that they would see a file attached to the message using the **MimeAttachFile** function.

If the specified message is not a multipart message, it is marked as multipart and the attached file is appended to the message. If the message is already a multipart message, an additional part is created and the attachment is added to the message.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[MimeAttachFile](#), [MimeExportMessage](#), [MimeExtractFile](#), [MimeGetAttachedFileName](#), [MimeGetFileContentType](#), [MimeImportMessage](#), [MimeSetFileContentType](#)

MimeAttachFile Function

```
BOOL WINAPI MimeAttachFile(  
    HMESSAGE hMessage,  
    LPCTSTR lpszFileName,  
    DWORD dwOptions  
);
```

The **MimeAttachFile** function attaches the specified file to the message.

Parameters

hMessage

Handle to the message.

lpszFileName

Pointer to a string which specifies the name of the file to be attached to the message.

dwOptions

A value which specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
MIME_ATTACH_DEFAULT	The file attachment encoding is based on the file content type. Text files are not encoded, and binary files are encoded using the standard base64 encoding algorithm. This is the default option for file attachments.
MIME_ATTACH_BASE64	The file attachment is always encoded using the standard base64 algorithm, even if the attached file is a plain text file.
MIME_ATTACH_UUCODE	The file attachment is always encoded using the uuencode algorithm, even if the attached file is a plain text file.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **MimeGetLastError**.

Remarks

If the specified message is not a multipart message, it is marked as multipart and the attached file is appended to the message. If the message is already a multipart message, an additional part is created and the attachment is added to the message.

To attach data that is stored in a memory buffer rather than a file, use the **MimeAttachData** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

MimeAttachImage Function

```
BOOL WINAPI MimeAttachImage(  
    HMESSAGE hMessage,  
    LPCTSTR lpszImageFile,  
    LPCTSTR lpszContentId  
);
```

The **MimeAttachImage** function attaches the specified file to the message as an inline image.

Parameters

hMessage

Handle to the message.

lpszFileName

Pointer to a string which specifies the name of the image file to be attached to the message. This parameter cannot be NULL and must specify the name of an existing file.

lpszContentId

Pointer to a string which specifies the content ID that is associated with the inline image. If this parameter is NULL, a random content ID string will be automatically generated.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **MimeGetLastError**.

Remarks

The **MimeAttachImage** function enables an application to attach an inline image to the message. Unlike a normal file attachment, this function is designed to be used with HTML formatted email messages that display images attached to the message. The *lpszContentId* parameter specifies the content ID string that is used with the HTML image tag to reference that image.

If the specified message is not a multipart message, it is marked as multipart and the attached image file is appended to the message. If the message is already a multipart message, an additional part is created and the attachment is added to the message.

To attach regular files to the message, use the **MimeAttachFile** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[MimeAttachData](#), [MimeAttachFile](#), [MimeComposeMessage](#)

MimeClearMessageText Function

```
BOOL WINAPI MimeClearMessageText(  
    HMESSAGE hMessage  
);
```

The **MimeClearMessageText** function deletes the text from the body of the current message part.

Parameters

hMessage

Handle to the message.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **MimeGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[MimeAppendMessageText](#), [MimeCompareMessageText](#), [MimeGetMessageText](#), [MimeSetMessageText](#)

MimeCloseMessageStore Function

```
BOOL WINAPI MimeCloseMessageStore(  
    HMESSAGESTORE hStorage,  
    BOOL bPurgeMessages  
);
```

The **MimeCloseMessageStore** function closes the specified message store.

Parameters

hStorage

Handle to the message store.

bPurgeMessages

An integer value which specifies if deleted messages are purged from the message store. A non-zero value specifies that all messages marked for deletion will be removed from the message store. A value of zero specifies that deleted messages will not be removed from the store.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **MimeGetLastError**.

Remarks

The **MimeCloseMessageStore** function closes the storage file that was previously opened, releasing all of the memory allocated for the message store and optionally purging all deleted messages. This function must be called when the application has finished accessing the messages in the message store. Failure to call this function will leave the storage file open and potentially locked by the process.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmsgv10.lib

See Also

[MimeCopyMessageStore](#), [MimeOpenMessageStore](#), [MimePurgeMessageStore](#)

MimeCompareMessageText Function

```
BOOL WINAPI MimeCompareMessageText(  
    HMESSAGE hMessage,  
    LONG* lpnOffset,  
    LPCTSTR lpszBuffer,  
    LONG cchBuffer,  
    BOOL bCaseSensitive  
);
```

The **MimeCompareMessageText** function compares a text string against the contents of the current message part.

Parameters

hMessage

Handle to the message.

lpnOffset

Pointer to a long integer which specifies the offset in the message at which to begin the comparison. This value will be updated when the function returns to indicate the offset position in the message where the comparison ended.

lpszBuffer

Pointer to a string buffer which contains the text that is to be compared against the body of the message.

cchBuffer

The number of characters in the buffer that should be compared against the body of the message.

bCaseSensitive

Boolean flag which specifies that the comparison should be case sensitive.

Return Value

If the text buffer matches the contents of the current message body, the function will return a non-zero value, and the *lpnOffset* argument will be set to position in the buffer where the match terminated. If the text buffer does not match, the function will return a value of zero, and the *lpnOffset* argument will be set to the position of the first non-matching character. The function will also return zero if one of the arguments is invalid. To get extended error information, call **MimeGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[MimeAppendMessageText](#), [MimeClearMessageText](#), [MimeGetMessageText](#), [MimeSetMessageText](#)

MimeComposeMessage Function

```
HMESSAGE WINAPI MimeComposeMessage(  
    LPCTSTR LpszFrom,  
    LPCTSTR LpszTo,  
    LPCTSTR LpszCc,  
    LPCTSTR LpszSubject,  
    LPCTSTR LpszMessageText,  
    LPCTSTR LpszMessageHTML,  
    UINT nCharacterSet,  
    UINT nEncodingType  
);
```

The **MimeComposeMessage** function creates a new message using the specified parameters.

Parameters

LpszFrom

A pointer to a string which specifies the sender's email address. This parameter may be NULL, in which case no sender address will be included in the message header.

LpszTo

A pointer to a string which specifies one or more recipient addresses. If multiple addresses are specified, each address must be separated by a comma. This parameter may be NULL, in which case no recipient addresses will be included in the message header.

LpszCc

A pointer to a string which specifies one or more addresses that will receive a copy of the message in addition to the listed recipients. If multiple addresses are specified, each address must be separated by a comma. This parameter may be NULL, in which case no carbon-copy addresses will be included in the message header.

LpszSubject

A pointer to a string which specifies the subject of the message. This parameter may be NULL, in which case no subject will be included in the message.

LpszMessageText

A pointer to a string which contains the body of the message as plain text. Each line of text contained in the string should be terminated with a carriage-return and linefeed (CRLF) pair, which is recognized as the end-of-line. If this parameter is NULL or points to an empty string, then the message will have an empty body unless the *LpszMessageHTML* parameter is not NULL.

LpszMessageHTML

A pointer to a string which contains the message using HTML formatting. If the *LpszMessageText* parameter is not NULL, then a multipart message will be created with both plain text and HTML text as the alternative. This allows mail clients to select which message body they wish to display. If the *LpszMessageText* argument is NULL or points to an empty string, then the message will only contain HTML. Although this is supported, it is not recommended because older mail clients may be unable to display the message correctly.

nCharacterSet

A numeric identifier which specifies the [character set](#) to use when composing the message. A value of zero specifies that the default UTF-8 character set should be used. It is recommended that you always use UTF-8 when composing a new message or creating a new message part.

nEncodingType

A numeric identifier which specifies the encoding type to use when composing the message. A value of zero specifies that default 7bit encoding should be used. The following values may also be used:

Constant	Description
MIME_ENCODING_7BIT	Each character is encoded in one or more bytes, with each byte being 8 bits long, with the most significant bit cleared. This encoding is most commonly used with plain text using the US-ASCII character set, where each character is represented by a single byte in the range of 20h to 7Eh.
MIME_ENCODING_8BIT	Each character is encoded in one or more bytes, with each byte being 8 bits long and all bits are used. 8-bit encoding is typically used with multibyte character sets and is the default encoding used with Unicode text.
MIME_ENCODING_QUOTED	Quoted-printable encoding is designed for textual messages where most of the characters are represented by the ASCII character set and is generally human-readable. Non-printable characters or 8-bit characters with the high bit set are encoded as hexadecimal values and represented as 7-bit text. Quoted-printable encoding is typically used for messages which use character sets such as ISO-8859-1, as well as those which use HTML.
MIME_ENCODING_BASE64	Base64 encoding converts binary or text data to ASCII by translating it so each base64 digit represents 6 bits of data. This encoding method is commonly used with messages that contain binary data (such as binary file attachments), or when text uses extended characters that cannot be represented by 7-bit ASCII. It is recommended that you use base64 encoding with Unicode text.

Return Value

If the function succeeds, the return value is a handle to the message. If the function fails, the return value is `INVALID_MESSAGE`. To get extended error information, call **MimeGetLastError**.

Remarks

The **MimeComposeMessage** function composes a new message and returns a handle which can be used to further modify or export the message. To create an empty message without any predefined header values, call the **MimeCreateMessage** function.

email addresses may be specified as simple addresses, or as commented addresses that include the sender's name or other information. For example, any one of these address formats are acceptable:

```
user@domain.tld
User Name <user@domain.tld>
user@domain.tld (User Name)
```

To specify multiple addresses, you should separate each address by a comma or semi-colon. Note that the *lpzFrom* parameter cannot specify multiple addresses, however it is permitted with the *lpzTo*, *lpzCc* and *lpzBcc* parameters.

To send a message that contains HTML, it is recommended that you provide both a plain text version of the message body and an HTML formatted version. While it is permitted to send a message that only contains HTML, some older mail clients may not be capable of displaying the message correctly. In some cases, anti-spam software will increase the spam score of messages that do not contain a plain text message body. This can result in your message being rejected or quarantined by the mail server.

Call the **MimeDeleteMessage** function to free the memory allocated for this message when it is no longer needed.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[MimeCreateMessage](#), [MimeCreateMessagePart](#), [MimeDeleteMessage](#), [MimeExportMessage](#), [MimeImportMessage](#), [MimeInitialize](#)

MimeCopyMessageStore Function

```
BOOL WINAPI MimeCopyMessageStore(  
    HMESSAGESTORE hStorage,  
    LPCTSTR lpszFileName  
);
```

The **MimeCopyMessageStore** function duplicates the contents of the specified message store in a new file.

Parameters

hStorage

Handle to the message store.

lpszFileName

A pointer to a string which specifies the name of the file that the messages will be copied to. This parameter cannot be NULL and must specify a valid file path and name.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **MimeGetLastError**.

Remarks

The **MimeCopyMessageStore** function is used to create a copy of the specified message store in a new file. If the file does not exist, it will be created. If the file already exists, then the contents will be overwritten with the contents of the message store.

Messages that have been marked for deletion are not copied to the new message store file.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[MimeCloseMessageStore](#), [MimeOpenMessageStore](#), [MimePurgeMessageStore](#)

MimeCreateMessage Function

```
HMESSAGE MimeCreateMessage();
```

The **MimeCreateMessage** function creates a new empty message.

Parameters

There are no parameters.

Return Value

If the function succeeds, the return value is a handle to the message. If the function fails, the return value is `INVALID_MESSAGE`. To get extended error information, call **MimeGetLastError**.

Remarks

To create a message with defined values for the sender, recipient, subject and body it is recommended that you use the **MimeComposeMessage** function.

Call the **MimeDeleteMessage** function to free the memory allocated for this message when it is no longer needed.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csmsgv10.lib`

See Also

[MimeComposeMessage](#), [MimeCreateMessageEx](#), [MimeCreateMessagePart](#), [MimeDeleteMessage](#), [MimeExportMessage](#), [MimeImportMessage](#)

MimeCreateMessageEx Function

```
HMESSAGE WINAPI MimeCreateMessageEx(  
    DWORD dwImportMode,  
    DWORD dwImportOptions,  
    LPVOID lpvMessage,  
    DWORD dwMessageSize  
);
```

The **MimeCreateMessageEx** function creates a new message and imports the contents from a file or memory.

Parameters

dwImportMode

An unsigned integer which specifies how the message contents will be imported. It may be one of the following values:

Constant	Description
MIME_IMPORT_DEFAULT	The default import mode. If the <i>lpvMessage</i> parameter is NULL, the function will return a handle to an empty message. Otherwise, the <i>lpvMessage</i> parameter is a pointer to a string which specifies the name of a file that contains the message. The <i>dwMessageSize</i> parameter is ignored.
MIME_IMPORT_FILE	The <i>lpvMessage</i> parameter is a pointer to a string which specifies the name of a file that contains the message. If the file does not exist, or is not a regular text file, an error will occur. The <i>dwMessageSize</i> parameter is ignored.
MIME_IMPORT_CLIPBOARD	The contents of the message is imported from the system clipboard. The <i>lpvMessage</i> parameter is ignored. The <i>dwMessageSize</i> parameter is ignored.
MIME_IMPORT_MEMORY	The contents of the message is imported from a local buffer. The <i>lpvMessage</i> parameter must point to a byte array which contains the message to be imported. The <i>dwMessageSize</i> parameter specifies the number of bytes to copy from the buffer. If this value is zero, it is assumed that the end of the message data in the buffer is terminated with a null character and the length is calculated automatically.
MIME_IMPORT_HGLOBAL	The contents of the message is imported from a global memory buffer. The <i>lpvMessage</i> parameter must be a global memory handle which contains the message. The <i>dwMessageSize</i> parameter specifies the number of bytes to copy from the buffer. If this value is zero, it is assumed that the end of the message data in the buffer is terminated with a null character and the length is calculated automatically.

dwImportOptions

An unsigned integer which specifies how the message will be imported:

Constant	Description
MIME_OPTION_DEFAULT	The default import options. Currently this is the only valid value for this parameter and applications should always specify this constant.

lpvMessage

A pointer to a string, a byte buffer or a global memory handle. The *dwImportMode* parameter determines how this pointer is used by the function.

dwMessageSize

An unsigned integer value which specifies the size of the message to import. This parameter is only used when importing a message from a memory buffer. The message size is determined automatically when the message is imported from a file or the system clipboard.

Return Value

If the function succeeds, the return value is a handle to the message. If the function fails, the return value is `INVALID_MESSAGE`. To get extended error information, call **MimeGetLastError**.

Remarks

The **MimeCreateMessageEx** function creates a new message from the contents of a file or memory, and returns a handle to the parsed message. When the message is no longer needed by the application, it should call **MimeDeleteMessage** to free the memory allocated for the message and release the handle.

To create a new message with predefined header values and content, use the **MimeComposeMessage** function.

Example

The following example creates a message using an `HGLOBAL` handle that references a block of memory that contains an email message:

```
hMessage = MimeCreateMessageEx(MIME_IMPORT_HGLOBAL,  
                               MIME_OPTION_DEFAULT,  
                               (LPVOID)hgb1Message,  
                               0);  
  
if (hMessage != INVALID_MESSAGE)  
{  
    // The message has been successfully created  
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csmsgv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

See Also

MimeCreateMessagePart Function

```
INT WINAPI MimeCreateMessagePart(  
    HMESSAGE hMessage  
);
```

The **MimeCreateMessagePart** function creates a new part for the specified message. If this the first part created for a message that does not have the multipart content type specified, the message is marked as multipart and the header fields are updated.

Parameters

hMessage

Handle to the message.

Return Value

If the function succeeds, the return value is the new message part number. If the function fails, the return value is MIME_ERROR. To get extended error information, call **MimeGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmsgv10.lib

See Also

[MimeAttachFile](#), [MimeCreateMessage](#), [MimeDeleteMessagePart](#), [MimeGetMessagePart](#), [MimeGetMessagePartCount](#), [MimeSetMessagePart](#)

MimeCreateMessagePartEx Function

```
INT WINAPI MimeCreateMessagePartEx(  
    HMESSAGE hMessage,  
    UINT nCharacterSet,  
    UINT nEncodingType,  
    LPCTSTR LpszText  
);
```

The **MimeCreateMessagePartEx** function creates a new part for the specified message. If this the first part created for a message that does not have the multipart content type specified, the message is marked as multipart and the header fields are updated.

Parameters

hMessage

Handle to the message.

nCharacterSet

A numeric identifier which specifies the [character set](#) to use when composing the message. A value of zero specifies the character set should be the same character set used to initially compose the message. It is recommended that you always use UTF-8 when composing a new message or creating a new message part.

nEncodingType

A numeric identifier which specifies the encoding type to use when composing the message. A value of zero specifies that default 7bit encoding should be used. The following values may also be used:

Constant	Description
MIME_ENCODING_7BIT	Each character is encoded in one or more bytes, with each byte being 8 bits long, with the most significant bit cleared. This encoding is most commonly used with plain text using the US-ASCII character set, where each character is represented by a single byte in the range of 20h to 7Eh.
MIME_ENCODING_8BIT	Each character is encoded in one or more bytes, with each byte being 8 bits long and all bits are used. 8-bit encoding is typically used with multibyte character sets and is the default encoding used with Unicode text.
MIME_ENCODING_QUOTED	Quoted-printable encoding is designed for textual messages where most of the characters are represented by the ASCII character set and is generally human-readable. Non-printable characters or 8-bit characters with the high bit set are encoded as hexadecimal values and represented as 7-bit text. Quoted-printable encoding is typically used for messages which use Latin character sets such as ISO-8859-1, as well as those which use HTML.
MIME_ENCODING_BASE64	Base64 encoding converts binary or text data to ASCII by translating it so each base64 digit represents 6 bits of

data. This encoding method is commonly used with messages that contain binary data (such as binary file attachments), or when text uses extended characters that cannot be represented by 7-bit ASCII. It is recommended that you use base64 encoding with Unicode text.

lpzText

A pointer to a string which specifies the text to be included in the body of the new message part. If this parameter is NULL or points to an empty string, no text is added to the message part.

Return Value

If the function succeeds, the return value is the new message part number. If the function fails, the return value is MIME_ERROR. To get extended error information, call **MimeGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

MimeDecodeText Function

```
LONG WINAPI MimeDecodeText(  
    UINT nEncodingType,  
    LPCTSTR lpszInput,  
    LONG cchInput,  
    LPTSTR lpszOutput,  
    LONG cchOutput  
);
```

The **MimeDecodeText** function decodes a string which was previously encoded using base64 or quoted-printable encoding.

Parameters

nEncodingType

An integer value that specifies the encoding method used. It may be zero or one of the following values:

Constant	Description
MIME_ENCODING_QUOTED	Quoted-printable encoding is designed for textual messages where most of the characters are represented by the ASCII character set and is generally human-readable. Non-printable characters or 8-bit characters with the high bit set are encoded as hexadecimal values and represented as 7-bit text. Quoted-printable encoding is typically used for messages which use character sets such as ISO-8859-1, as well as those which use HTML.
MIME_ENCODING_BASE64	Base64 encoding converts binary or text data to ASCII by translating it so each base64 digit represents 6 bits of data. This encoding method is commonly used with messages that contain binary data (such as binary file attachments), or when text uses extended characters that cannot be represented by 7-bit ASCII. It is recommended that you use base64 encoding with Unicode text. This is the default encoding type used by this function.

lpszInput

A pointer to a null terminated string which contains the encoded text. This parameter cannot be a NULL pointer.

cchInput

An integer value which specifies the number of characters of text in the input string which should be decoded. If this value is -1, the entire length of the string up to the terminating null will be decoded.

lpszOutput

A pointer to a string buffer that will contain the decoded text. This buffer must be large enough to store all of the characters in the decoded text, including the terminating null character. This parameter cannot be NULL.

cchOutput

An integer value which specifies the maximum number of characters which can be copied into the output string buffer. The buffer must be large enough to store all of the decoded text and terminating null character. This value must be greater than zero.

Return Value

If the input buffer can be successfully decoded, the return value is the length of the decoded output string. If the function returns zero, then no text was decoded and the output string buffer will be empty. If the function fails, the return value is `MIME_ERROR`. To get extended error information, call **MimeGetLastError**.

Remarks

This function provides a means to decode text that was previously encoded using either base64 or quoted-printable encoding. In most cases, it is not necessary to use this function because the message parser will automatically decode the message text if necessary.

This function and the **MimeEncodeText** function use the UTF-8 character set. If the Unicode version of this function is called, the output text will be decoded as UTF-8, then converted to UTF-16 and returned to the caller. If the ANSI version of this function is used, the decoded output will always be returned to the caller using the UTF-8 character set.

If an unsupported encoding type is specified, this function will return `MIME_ERROR` and the output text string will be empty. In most cases, it is preferable to use `MIME_ENCODING_BASE64` as the encoding method, with quoted-printable encoding only used for legacy support.

If the original text was encoded using a different character set, use the **MimeDecodeTextEx** function, which enables you to specify an alternate character set.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csmsgv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

See Also

[MimeDecodeTextEx](#), [MimeEncodeText](#), [MimeEncodeTextEx](#), [MimeGetMessageText](#), [MimeLocalizeText](#), [MimeSetMessageText](#)

MimeDecodeTextEx Function

```
LONG WINAPI MimeDecodeTextEx(  
    UINT nCharacterSet,  
    UINT nEncodingType,  
    DWORD dwReserved,  
    LPCTSTR lpszInput,  
    LONG cchInput,  
    LPTSTR lpszOutput,  
    LONG cchOutput  
);
```

The **MimeDecodeTextEx** function decodes a string which was previously encoded using base64 or quoted-printable encoding. This extended version of the function enables the caller to specify the character set for the original text.

Parameters

nCharacterSet

A numeric identifier which specifies the [character set](#) to use when decoding the input text. A value of zero specifies the character set is undefined and no Unicode text conversion is performed when the input string is decoded. If this value does not match the character set used when the text was originally encoded, the resulting output text may be invalid.

nEncodingType

An integer value that specifies the encoding method used. It may be zero or one of the following values:

Constant	Description
MIME_ENCODING_QUOTED	Quoted-printable encoding is designed for textual messages where most of the characters are represented by the ASCII character set and is generally human-readable. Non-printable characters or 8-bit characters with the high bit set are encoded as hexadecimal values and represented as 7-bit text. Quoted-printable encoding is typically used for messages which use character sets such as ISO-8859-1, as well as those which use HTML.
MIME_ENCODING_BASE64	Base64 encoding converts binary or text data to ASCII by translating it so each base64 digit represents 6 bits of data. This encoding method is commonly used with messages that contain binary data (such as binary file attachments), or when text uses extended characters that cannot be represented by 7-bit ASCII. It is recommended that you use base64 encoding with Unicode text. This is the default encoding type used by this function.

dwReserved

An integer value reserved for internal use. This value must always be zero.

lpszInput

A pointer to a null terminated string which contains the encoded text. This parameter cannot be a NULL pointer.

cchInput

An integer value which specifies the number of characters of text in the input string which should be decoded. If this value is -1, the entire length of the string up to the terminating null will be decoded.

lpzOutput

A pointer to a string buffer that will contain the decoded text. This buffer must be large enough to store all of the characters in the decoded text, including the terminating null character. This parameter cannot be NULL.

cchOutput

An integer value which specifies the maximum number of characters which can be copied into the output string buffer. The buffer must be large enough to store all of the decoded text and terminating null character. This value must be greater than zero.

Return Value

If the input buffer can be successfully decoded, the return value is the length of the decoded output string. If the function returns zero, then no text was decoded and the output string buffer will be empty. If the function fails, the return value is `MIME_ERROR`. To get extended error information, call **MimeGetLastError**.

Remarks

This function provides a means to decode text that was previously encoded using either base64 or quoted-printable encoding. In most cases, it is not necessary to use this function because the message parser will detect which character set and encoding was used, then automatically decode the message text if necessary.

The value of the *nCharacterSet* parameter does not affect the resulting output text, it is only used when decoding the input text. If the Unicode version of this function is called, the output text will be converted to UTF-16 and returned to the caller. If the ANSI version of this function is used, the decoded output will always be returned to the caller using the UTF-8 character set.

If the *nCharacterSet* parameter is specified as `MIME_CHARSET_UTF16`, the encoding type must be `MIME_ENCODING_BASE64`. Other encoding methods are not supported for Unicode strings and will cause the function to fail. In most cases, it is preferable to use `MIME_ENCODING_BASE64` as the encoding method, with quoted-printable encoding only used for legacy support.

If an unsupported encoding type is specified, this function will return `MIME_ERROR` and the output text string will be empty. This function cannot be used to decode uuencoded text.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csmsgv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

MimeDeleteMessage Function

```
BOOL WINAPI MimeDeleteMessage(  
    HMESSAGE hMessage  
);
```

The **MimeDeleteMessage** function deletes the specified message and releases the memory allocated for the header and body.

Parameters

hMessage

Handle to the message.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **MimeGetLastError**.

Remarks

Once the message has been deleted, the handle is invalid and should not be referenced.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmsgv10.lib

See Also

[MimeCreateMessage](#), [MimeDeleteMessagePart](#), [MimeResetMessage](#)

MimeDeleteMessageHeader Function

```
BOOL WINAPI MimeDeleteMessageHeader(  
    HMESSAGE hMessage,  
    LPCTSTR lpszHeader  
);
```

The **MimeDeleteMessageHeader** function deletes the specified header field from the message.

Parameters

hMessage

Handle to the message.

lpszHeader

Pointer to a string which specifies the header field that will be deleted.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero.

To get extended error information, call **MimeGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[MimeGetMessageHeader](#), [MimeSetMessageHeader](#)

MimeDeleteMessagePart Function

```
BOOL WINAPI MimeDeleteMessagePart(  
    HMESSAGE hMessage,  
    INT nMessagePart  
);
```

The **MimeDeleteMessagePart** function deletes the specified message part from the multipart message. The memory allocated for the message part is released.

Parameters

hMessage

Handle to the message.

nMessagePart

The message part index to delete.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **MimeGetLastError**.

Remarks

This function cannot be used to delete part zero, which is the main body of the message. Instead use the **MimeResetMessage** function to clear the entire message.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[MimeCreateMessagePart](#), [MimeCreateMessagePartEx](#), [MimeGetMessagePart](#),
[MimeGetMessagePartCount](#), [MimeResetMessage](#), [MimeSetMessagePart](#)

MimeDeleteStoredMessage Function

```
BOOL WINAPI MimeDeleteStoredMessage(  
    HMESSAGESTORE hStorage,  
    LONG nMessageId  
);
```

The **MimeDeleteStoredMessage** function removes the specified message from the message store.

Parameters

hStorage

Handle to the message store.

nMessageId

An integer value which identifies the message that is to be removed from the message store. Message numbers begin at one and increment for each message in the store.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **MimeGetLastError**.

Remarks

The **MimeDeleteStoredMessage** function marks the specified message for deletion from the storage file. When the message store is closed or purged, the message is removed from the file. Once a message has been marked for deletion, it may no longer be referenced by the application. For example, you cannot access the contents of a message that has been deleted.

The message store must be opened with write access. This function will fail if you attempt to delete a message from a storage file that has been opened for read-only access. If the application needs to delete messages in the message store, it is recommended that the file be opened for exclusive access using the MIME_STORAGE_LOCK option.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmsgv10.lib

See Also

[MimeCloseMessageStore](#), [MimeFindStoredMessage](#), [MimeGetStoredMessage](#), [MimeGetStoredMessageCount](#), [MimePurgeMessageStore](#)

MimeEncodeText Function

```
LONG WINAPI MimeEncodeText(  
    UINT nEncodingType,  
    LPCTSTR lpszInput,  
    LONG cchInput,  
    LPTSTR lpszOutput,  
    LONG cchOutput  
);
```

The **MimeEncodeText** function encodes a string using base64 or quoted-printable encoding.

Parameters

nEncodingType

An integer value that specifies the encoding method used. It may be zero or one of the following values:

Constant	Description
MIME_ENCODING_QUOTED	Quoted-printable encoding is designed for textual messages where most of the characters are represented by the ASCII character set and is generally human-readable. Non-printable characters or 8-bit characters with the high bit set are encoded as hexadecimal values and represented as 7-bit text. Quoted-printable encoding is typically used for messages which use character sets such as ISO-8859-1, as well as those which use HTML.
MIME_ENCODING_BASE64	Base64 encoding converts binary or text data to ASCII by translating it so each base64 digit represents 6 bits of data. This encoding method is commonly used with messages that contain binary data (such as binary file attachments), or when text uses extended characters that cannot be represented by 7-bit ASCII. It is recommended that you use base64 encoding with Unicode text. This is the default encoding type used by this function.

lpszInput

A pointer to a null terminated string which contains the encoded text. This parameter cannot be a NULL pointer.

cchInput

An integer value which specifies the number of characters of text in the input string which should be encoded. If this value is -1, the entire length of the string up to the terminating null will be encoded.

lpszOutput

A pointer to a string buffer that will contain the encoded text. This buffer must be large enough to store all of the characters in the encoded text, including the terminating null character. This parameter cannot be NULL.

cchOutput

An integer value which specifies the maximum number of characters which can be copied into the output string buffer. The buffer must be large enough to store all of the encoded text and terminating null character. This value must be greater than zero.

Return Value

If the input buffer can be successfully encoded, the return value is the length of the encoded output string. If the function returns zero, then no text was encoded and the output string buffer will be empty. If the function fails, the return value is `MIME_ERROR`. To get extended error information, call **MimeGetLastError**.

Remarks

This function provides a means to encode text using either base64 or quoted-printable encoding. It is not necessary to use this function to encode text when using the **MimeSetMessageText** function. The library will automatically encode message text which contains non-ASCII characters using the character set specified when the message is created.

This function and the **MimeDecodeText** function use the UTF-8 character set. If the Unicode version of this function is called, the input text will be converted to UTF-8 and then encoded. If the ANSI version of this function is used, the input text is expected to be UTF-8 or ASCII text. If you are encoding text which uses non-ASCII characters, it is recommended that you use the Unicode version of this function.

If an unsupported encoding type is specified, this function will return `MIME_ERROR` and the output text string will be empty. This function cannot be used to create uuencoded text. In most cases, it is preferable to use `MIME_ENCODING_BASE64` as the encoding method, with quoted-printable encoding only used for legacy support.

If you want the text to be encoded using a different character set, you can use the **MimeEncodeTextEx** function. In most cases, your application should use the default UTF-8 character set when encoding and decoding text which contains non-ASCII characters, rather than using specific character sets.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csmsgv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

MimeEncodeTextEx Function

```
LONG WINAPI MimeEncodeTextEx(  
    UINT nCharacterSet,  
    UINT nEncodingType,  
    DWORD dwReserved,  
    LPCTSTR lpszInput,  
    LONG cchInput,  
    LPTSTR lpszOutput,  
    LONG cchOutput  
);
```

The **MimeEncodeTextEx** function encodes a string using base64 or quoted-printable encoding. This extended version of the function enables the caller to specify the character set for the input text.

Parameters

nCharacterSet

A numeric identifier which specifies the [character set](#) to use when encoding the input text. A value of zero specifies the character set is undefined and no Unicode text conversion is performed when the input string is encoded.

nEncodingType

An integer value that specifies the encoding method used. It may be one of the following values:

Constant	Description
MIME_ENCODING_QUOTED	Quoted-printable encoding is designed for textual messages where most of the characters are represented by the ASCII character set and is generally human-readable. Non-printable characters or 8-bit characters with the high bit set are encoded as hexadecimal values and represented as 7-bit text. Quoted-printable encoding is typically used for messages which use character sets such as ISO-8859-1, as well as those which use HTML.
MIME_ENCODING_BASE64	Base64 encoding converts binary or text data to ASCII by translating it so each base64 digit represents 6 bits of data. This encoding method is commonly used with messages that contain binary data (such as binary file attachments), or when text uses extended characters that cannot be represented by 7-bit ASCII. It is recommended that you use base64 encoding with Unicode text.

dwReserved

An integer value reserved for internal use. This value must always be zero.

lpszInput

A pointer to a null terminated string which contains the encoded text. This parameter cannot be a NULL pointer.

cchInput

An integer value which specifies the number of characters of text in the input string which should be encoded. If this value is -1, the entire length of the string up to the terminating null will be encoded.

lpzOutput

A pointer to a string buffer that will contain the encoded text. This buffer must be large enough to store all of the characters in the encoded text, including the terminating null character. This parameter cannot be NULL.

cchOutput

An integer value which specifies the maximum number of characters which can be copied into the output string buffer. The buffer must be large enough to store all of the encoded text and terminating null character. This value must be greater than zero.

Return Value

If the input buffer can be successfully encoded, the return value is the length of the encoded output string. If the function returns zero, then no text was encoded and the output string buffer will be empty. If the function fails, the return value is `MIME_ERROR`. To get extended error information, call **MimeGetLastError**.

Remarks

This function provides a means to encode text using either base64 or quoted-printable encoding. It is not necessary to use this function to encode text when using the **MimeSetMessageText** function. The library will automatically encode message text which contains non-ASCII characters using the character set specified when the message is created.

If the *nCharacterSet* parameter is non-zero, the function will encode the text using the specified character set. If the Unicode version of this function is called, the input text is converted to ANSI using the code page associated with the character set. If the ANSI version of this function is called, the input text is converted to Unicode using the system default code page, and then back to ANSI using the specified character set.

If the *nCharacterSet* parameter specifies the `MIME_CHARSET_UTF16` character set, you must specify `MIME_ENCODING_BASE64` as the encoding method. Other encoding methods are not supported for Unicode strings and will cause the function to fail. It is not recommended you encode text as UTF-16 unless there is a specific requirement to use that character set.

It is recommended that you use the `MIME_CHARSET_UTF8` character set whenever possible. It is capable of encoding all Unicode code points, and is a standard for virtually all modern Internet applications. In most cases, it is preferable to use `MIME_ENCODING_BASE64` as the encoding method, with quoted-printable encoding only used for legacy support.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csmsgv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

MimeEnumAttachments Function

```
INT WINAPI MimeEnumAttachments(  
    HMESSAGE hMessage,  
    LPCTSTR* lpFileNames,  
    INT nMaxFiles  
);
```

The **MimeEnumAttachments** function enumerates all of the file attachments in the specified message.

Parameters

hMessage

Handle to the message.

lpFileNames

A pointer to an array of null-terminated strings that contain the names of the files attached to the message. If this parameter is NULL, the function will only return the number of files attached to the message.

nMaxFiles

An integer value that specifies the maximum size of the array of string pointers specified by the *lpFileNames* parameter. If this value is zero, the *lpFileNames* parameter is ignored and the function will only return the number of files attached to the message.

Return Value

If the function succeeds, the return value is the number of files attached to the message. If the message does not contain any file attachments, this function will return a value of zero. If the function fails, the return value is MIME_ERROR. To get extended error information, call **MimeGetLastError**.

Remarks

This function can be used to obtain the names of the files attached to the message. If this function is used with languages other than C/C++, it is important to note that the *lpFileNames* parameter is not a pointer to a string, but rather a pointer to an array of pointers to null-terminated strings. It is not recommended that you use this function with languages that do not support C-style arrays. For example, Visual Basic represents arrays as SAFEARRAY structures and is not compatible with this function.

Example

```
LPCTSTR lpszFiles[MAXFILES];  
  
INT nFiles = MimeEnumAttachments(hMessage, lpszFiles, MAXFILES);  
if (nFiles == MIME_ERROR)  
{  
    DWORD dwError = MimeGetLastError();  
    _tprintf(_T("Unable to enumerate attachments, error 0x%08lx\n"), dwError);  
    return;  
}  
  
_tprintf(_T("There are %d files attached to the message\n"), nFiles);  
for (INT nIndex = 0; nIndex < nFiles; nIndex++)  
{  
    BOOL bResult = MimeExtractFileEx(hMessage, -1, lpszFiles[nIndex], NULL, 0);
```

```
    if (bResult)
        _tprintf(_T("%d: extracted attachment \"%s\"\n"), nIndex,
lpszFiles[nIndex]);
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

MimeEnumMessageHeaders Function

```
INT WINAPI MimeEnumMessageHeaders(  
    HMESSAGE hMessage,  
    LPCTSTR* lpHeaderList,  
    INT nMaxHeaders  
);
```

The **MimeEnumMessageHeaders** function returns a list of pointers to all header field names in the current message part. This can be used in conjunction with the **MimeGetMessageHeader** function to retrieve the values for every header in the message.

Parameters

hMessage

Handle to the message.

lpHeaderList

Pointer to an array of pointers to null terminated header field names. If this parameter is NULL, the function only returns the number of headers in the current message part.

nMaxHeaders

The maximum number of header fields which may be returned in the *lpHeaderList* parameter.

Return Value

If the function succeeds, the return value is the total number of headers that are defined in the current message part. If the function fails, the return value is MIME_ERROR. To get extended error information, call **MimeGetLastError**.

Remarks

The values returned in the header list array must not be directly modified by the application. There is no specific order in which the header fields are enumerated by this function. The header fields from an imported message may not be returned in the same order as which they appear in the message. An application should never make an assumption about the order in which one or more header fields are defined.

Example

```
// Determine the total number of headers in the current  
// message part  
  
nHeaders = MimeEnumMessageHeaders(hMessage, NULL, 0);  
if (nHeaders > 0)  
{  
  
    // Allocate memory for the list of headers  
  
    lpHeaderList = (LPCTSTR *)malloc(nHeaders * sizeof(LPCTSTR));  
    assert(lpHeaderList != NULL);  
  
    // Retrieve the list of headers in the current  
    // message part, and get their values  
  
    MimeEnumMessageHeaders(hMessage, lpHeaderList, nHeaders);  
    for (nIndex = 0; nIndex < nHeaders; nIndex++)  
    {
```

```
LPCTSTR lpszValue;  
lpszValue = MimeGetMessageHeader(hMessage, lpHeaderList[nIndex]);  
assert(lpszValue != NULL);  
  
printf("%s: %s\n", lpHeaderList[nIndex], lpszValue);  
  
    }  
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

MimeEnumMessageRecipients Function

```
INT WINAPI MimeEnumMessageRecipients(  
    HMESSAGE hMessage,  
    LPCTSTR LpszExtraAddress,  
    LPTSTR lpBuffer,  
    LPDWORD LpcchBuffer  
);
```

The **MimeEnumMessageRecipients** function returns a null-terminated list of strings which contain the email address of each recipient for the specified message.

Parameters

hMessage

Handle to the message.

lpszExtraAddress

A pointer to a string which contains one or more additional email addresses that should be included in the list, in addition to those found in the message. If more than one address is specified, each address should be separated by a comma. This parameter may be NULL if there are no extra addresses to include in the recipient list.

lpBuffer

Pointer to buffer which will contain zero or more null-terminated strings. The end of the string list is indicated by an additional terminating null. If this parameter is NULL, the function will calculate the minimum number of bytes required to store the addresses and return the value in the *lpcbBuffer* parameter.

lpcbBuffer

A pointer to an unsigned integer which should be initialized to the maximum number of characters that can be copied into the buffer specified by the *lpBuffer* parameter. When the function returns, it will be updated to contain the actual number of characters copied into the buffer. If the *lpBuffer* parameter is NULL, then this value will contain the minimum number of characters required to store all of the recipient addresses in the current message.

Return Value

If the function succeeds, the return value is the total number of recipients for the current message. If the function fails, the return value is MIME_ERROR. To get extended error information, call **MimeGetLastError**.

Remarks

The **MimeEnumMessageRecipients** function returns a list of recipient email addresses for the specified message, with each address being terminated by a null character. The end of the list is indicated by an additional null character. To determine the size of the buffer you should pass to this function, you can specify the *lpBuffer* parameter as NULL and initialize the value of the *lpcbBuffer* parameter to zero.

This function is primarily designed for use with C/C++ and languages that can easily use C-style strings and pointers to string values. In many cases, it may be preferable to use the **MimeGetAllRecipients** function which returns a comma-separated list of recipient addresses in a string buffer.

Example

```

LPTSTR lpRecipients = NULL;
DWORD cchRecipients = 0;
INT nRecipients = 0;

// Determine the number of characters that should be allocated to store
// all of the recipient addresses in the current message

nRecipients = MimeEnumMessageRecipients(hMessage,
                                         NULL,
                                         NULL,
                                         &cchRecipients);

// Allocate the memory for the string buffer that will contain all
// of the recipient addresses and call MimeEnumMessageRecipients
// again to store those addresses in the buffer

if (nRecipients > 0 && cchRecipients > 0)
{
    lpRecipients = (LPTSTR)LocalAlloc(LPTR, cchRecipients * sizeof(TCHAR));
    if (lpRecipients == NULL)
        return; // Virtual memory exhausted

    nRecipients = MimeEnumMessageRecipients(hMessage,
                                             NULL,
                                             lpRecipients,
                                             &cchRecipients);
}

// Move through the buffer, processing each recipient address
// that was returned

if (nRecipients > 0)
{
    LPTSTR lpszAddress = lpRecipients;
    INT cchAddress;

    while (lpszAddress != NULL)
    {
        if ((cchAddress = lstrlen(lpszAddress)) == 0)
            break;

        // lpszAddress specifies a recipient address
        // Advance to the next address string in the buffer
        lpszAddress += cchAddress + 1;
    }
}

if (lpRecipients)
{
    LocalFree((HLOCAL)lpRecipients);
    lpRecipients = NULL;
}

```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

MimeExportMessage Function

```
BOOL WINAPI MimeExportMessage(  
    HMESSAGE hMessage,  
    LPCTSTR LpszFileName  
);
```

The **MimeExportMessage** function writes the specified message to a file. If the file does not exist, it will be created. If it does exist, it will be overwritten with the contents of the message.

Parameters

hMessage

Handle to the message.

lpszFileName

Pointer to a string which specifies the name of the file to be created from the message. If this parameter is NULL, the contents of the message will be copied to the system clipboard.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **MimeGetLastError**.

Remarks

This function is provided for backwards compatibility with previous versions of the API. To export the contents of the message to a buffer in memory, use the **MimeExportMessageEx** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[MimeCreateMessage](#), [MimeExportMessageEx](#), [MimeImportMessage](#), [MimeImportMessageEx](#), [MimeSetExportOptions](#)

MimeExportMessageEx Function

```
BOOL WINAPI MimeExportMessageEx(  
    HMESSAGE hMessage,  
    DWORD dwExportMode,  
    DWORD dwExportOptions,  
    LPVOID lpvMessage,  
    LPDWORD lpdwMessageSize  
);
```

The **MimeExportMessageEx** function exports the message to a file, the system clipboard or global memory buffer.

Parameters

hMessage

Handle to the message.

dwExportMode

An unsigned integer which specifies how the message contents will be exported. It may be one of the following values:

Constant	Description
MIME_EXPORT_DEFAULT	The default export mode. If the <i>lpvMessage</i> parameter is NULL, then the contents of the message will be copied to the system clipboard. Otherwise, the <i>lpvMessage</i> parameter is a pointer to a string which specifies the name of a file to store the message in.
MIME_EXPORT_FILE	The <i>lpvMessage</i> parameter is a pointer to a null-terminated string which specifies the name of a file to store the message in. If the file does not exist, it will be created. Otherwise the file will be overwritten with the contents of the message.
MIME_EXPORT_CLIPBOARD	The contents of the message is copied to the system clipboard. The <i>lpvMessage</i> parameter is ignored.
MIME_EXPORT_MEMORY	The contents of the message is copied to a local buffer. The <i>lpvMessage</i> parameter must point to a byte array which will contain the message contents when the function returns. The <i>lpdwMessageSize</i> parameter must be initialized to the maximum size of the buffer and will contain the number of bytes copied to the buffer when the function returns.
MIME_EXPORT_HGLOBAL	The contents of the message is stored in a global memory buffer. The <i>lpvMessage</i> parameter must point to a global memory handle which will reference the message buffer when the function returns. The <i>lpdwMessageSize</i> parameter will contain the number of bytes allocated for the message. The client application is responsible for releasing the memory handle when the message contents are no longer needed.

dwExportOptions

An unsigned integer which specifies how the message will be exported. The following values may be combined using a bitwise Or operator:

Constant	Description
MIME_OPTION_DEFAULT	The default export options. The headers for the message are written out in a specific consistent order, with custom headers written to the end of the header block regardless of the order in which they were set or imported from another message. If the message contains Bcc, Received, Return-Path, Status or X400-Received header fields, they will not be exported.
MIME_OPTION_KEEORDER	The original order in which the message header fields were set or imported are preserved when the message is exported.
MIME_OPTION_ALLHEADERS	All headers, including the Received, Return-Path, Status and X400-Received header fields will be exported. Normally these headers are not exported because they are only used by the mail transport system. This option can be useful when exporting a message to be stored on the local system, but should not be used when exporting a message to be delivered to another user.
MIME_OPTION_NOHEADERS	When exporting a message, the main header block will not be included. This can be useful when creating a multipart message for services which expect MIME formatted data, such as HTTP POST requests. This option should never be used for email messages being submitted using SMTP.

lpvMessage

A pointer to a string, a byte buffer or a global memory handle. The *dwExportMode* parameter determines how this pointer is used by the function.

lpdwMessageSize

A pointer to an unsigned integer value which will contain the size of the message when the function exits. This parameter may be NULL if you do not require this information, except if the *dwExportMode* parameter is MIME_EXPORT_MEMORY. In this case, the parameter must point to a value initialized with the maximum size of the byte buffer that has been passed to the function.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **MimeGetLastError**.

Remarks

If the MIME_EXPORT_MEMORY mode is used to export the message to a pre-allocated buffer, the *lpdwMessageSize* parameter must be initialized to the size of the buffer before being passed to the function by reference. If this value is not properly initialized by the application, it can result in an error or a general protection exception. If the function succeeds, the message will be copied to

the buffer. If the function fails, the previous contents of the buffer will not be preserved. It is not guaranteed that the buffer will be terminated with a null byte. If the buffer is not large enough to store the entire message, the function will fail. The **MimeGetMessageSize** function can be used to determine the minimum size of the buffer required to store the message.

If the MIME_EXPORT_HGLOBAL mode is used, a global memory handle will be returned to the caller which contains the message contents. This handle must be dereferenced using the **GlobalLock** function. No changes should be made to this copy of the message. If you wish to modify the contents of the message, allocate a local buffer and copy the message contents, or use the MIME_EXPORT_MEMORY option instead. Your application is responsible for calling **GlobalUnlock** and **GlobalFree** to unlock and free the handle when it is no longer needed.

Example

The following example exports the contents of a message to a global memory buffer:

```
HGLOBAL hgb1Message = NULL;
DWORD dwMessageSize = 0;

bResult = MimeExportMessageEx(hMessage,
                              MIME_EXPORT_HGLOBAL,
                              MIME_OPTION_DEFAULT,
                              &hgb1Message,
                              &dwMessageSize);

if (bResult)
{
    LPBYTE lpMessage = (LPBYTE)GlobalLock(hgb1Message);

    if (lpMessage)
    {
        // Process the contents of the message
    }

    GlobalUnlock(hgb1Message);
    GlobalFree(hgb1Message);
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

MimeExtractAllFiles Function

```
INT WINAPI MimeExtractAllFiles(  
    HMESSAGE hMessage,  
    LPCTSTR lpszDirectory,  
    DWORD dwReserved  
);
```

The **MimeExtractAllFiles** function extracts all of the file attachments in a message and stores them in the specified directory.

Parameters

hMessage

Handle to the message.

lpszDirectory

A pointer to a string which specifies the name of the directory where the file attachments should be stored. If this parameter is NULL or points to an empty string, the attached files will be stored in the current working directory on the local system.

dwReserved

An unsigned integer value that is reserved for future use. This parameter must always have a value of zero.

Return Value

If the function succeeds, the return value is the number of file attachments which were extracted from the message. If the message does not contain any file attachments, this function will return a value of zero. If the function fails, the return value is MIME_ERROR. To get extended error information, call **MimeGetLastError**.

Remarks

This function will extract all of the files that are attached to the message and store them in the specified directory. The directory must exist and the current user must have the appropriate permissions to create files there. If a file with the same name as the attachment already exists, it will be overwritten with the contents of the attachment. If the file attachment was encoded using base64 or uuencode, this function will automatically decode the contents of the attachment.

To determine the file names for each of the attachments in a message, use the **MimeEnumAttachments** function. To store a file attachment on the local system using a name that is different than the file name of the attachment, use the **MimeExtractFile** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

MimeExtractFile Function

```
BOOL WINAPI MimeExtractFile(  
    HMESSAGE hMessage,  
    LPCTSTR lpszFileName  
);
```

The **MimeExtractFile** function extracts a file attachment from the current message part and stores it on the local system.

Parameters

hMessage

Handle to the message.

lpszFileName

A pointer to a string which specifies the name of a file on the local system.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **MimeGetLastError**.

Remarks

This function will store the contents of a file attachment in the current message part to the specified file on the local system. If a path is specified as part of the file name, it must exist and the current user must have the appropriate permissions to create the file. If a file with the same name already exists, it will be overwritten with the contents of the attachment. If the file attachment was encoded using base64 or uuencode, this function will automatically decode the contents of the attachment.

To determine if the current message part contains a file attachment, use the **MimeGetAttachedFileName** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[MimeAttachFile](#), [MimeExportMessage](#), [MimeExtractFileEx](#), [MimeGetAttachedFileName](#), [MimeImportMessage](#)

MimeExtractFileEx Function

```
BOOL WINAPI MimeExtractFileEx(  
    HMESSAGE hMessage,  
    INT nMessagePart,  
    LPCTSTR lpszAttachment,  
    LPCTSTR lpszFileName,  
    DWORD dwReserved  
);
```

The **MimeExtractFileEx** function extracts a file attachment from the message and stores it on the local system.

Parameters

hMessage

Handle to the message.

nMessagePart

An integer value that specifies the message part that contains the file attachment. This value may be -1, in which case the current message part will be used, or the function will search for an attachment with a file name that matches the value of the *lpszAttachment* parameter.

lpszAttachment

A pointer to a string that specifies the file name for the attachment in the message. If the file name of the attachment is not known, this parameter can be NULL or point to an empty string. This parameter is ignored if the *nMessagePart* parameter has a value greater than -1.

lpszFileName

A pointer to a string that specifies the name of a file on the local system. If this parameter is NULL or points to an empty string, the value of the *lpszAttachment* parameter will specify the name of the file in the current working directory. If both the *lpszAttachment* and *lpszFileName* parameters are NULL, the function will fail.

dwReserved

An unsigned integer value that is reserved for future use. This parameter must always have a value of zero.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **MimeGetLastError**.

Remarks

This function will store the contents of a file attachment in the current message part to the specified file on the local system. If a path is specified as part of the file name, it must exist and the current user must have the appropriate permissions to create the file. If a file with the same name already exists, it will be overwritten with the contents of the attachment. If the file attachment was encoded using base64 or uuencode, this function will automatically decode the contents of the attachment.

If the *nMessagePart* parameter has a value of -1 and the *lpszAttachment* parameter specifies a file name, this function will search the entire message for an attachment with the same file name. The search is not case-sensitive, however it must match the attachment file name completely. This function will not match partial file names or names that include wildcard characters. If a match is

found, the contents of that attachment will be stored in the file specified by the *lpzFileName* parameter.

If the *nMessagePart* parameter has a value of -1 and the *lpzAttachment* parameter is NULL or points to an empty string, then the attachment in the current message part will be stored in the specified file. If the current message part does not contain a file attachment, this function will fail. Calling this function in this manner is effectively the same as calling the **MimeExtractFile** function.

To extract all of the files attached to a message in a single function call, use the **MimeExtractAllFiles** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

MimeFindAttachment Function

```
INT WINAPI MimeFindAttachment(  
    HMESSAGE hMessage,  
    LPCTSTR lpszFileName  
);
```

The **MimeFindAttachment** function searches the message for an attachment with the specified file name.

Parameters

hMessage

Handle to the message.

lpszFileName

Pointer to a string that specifies the name of the file attachment to search for. This parameter should only specify a base file name; it should not include a file path and cannot be NULL.

Return Value

If the function succeeds, the return value is the message part number that contains an attachment that matches the specified file name. If the message does not contain an attachment with the specified file name, the function will return MIME_ERROR. To get extended error information, call **MimeGetLastError**.

Remarks

This function will search the message for a attachment that matches the specified file name. The search is not case-sensitive, however it must match the attachment file name completely. This function will not match partial file names or names that include wildcard characters. To obtain a list of all of the files attached to a message, use the **MimeEnumAttachments** function.

Example

```
// The name of the file attachment to search for  
LPCTSTR lpszFileName = _T("MyProject.docx");  
  
// Search for the attached file and store it on the local system  
INT nMessagePart = MimeFindAttachment(hMessage, lpszFileName);  
if (nMessagePart != MIME_ERROR)  
{  
    MimeSetMessagePart(hMessage, nMessagePart);  
  
    if (MimeExtractFile(hMessage, lpszFileName) != MIME_ERROR)  
        _tprintf(_T("Saved file attachment %s\n"), lpszFileName);  
    else  
    {  
        _tprintf(_T("Unable to save file attachment %s\n"), lpszFileName);  
        return;  
    }  
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

MimeFindStoredMessage Function

```
LONG WINAPI MimeFindStoredMessage(  
    HMESSAGESTORE hStorage,  
    LONG nMessageId,  
    LPCTSTR lpszHeaderName,  
    LPCTSTR lpszHeaderValue,  
    DWORD dwOptions  
);
```

The **MimeFindStoredMessage** function searches for a message in the specified message store.

Parameters

hStorage

Handle to the message store.

nMessageId

An integer value which specifies the message number that should be used when starting the search. The first message in the message store has a value of one.

lpszHeaderField

A pointer to the string which specifies the name of the header field that should be searched. The header field name is not case sensitive. This parameter cannot be NULL.

lpszHeaderValue

A pointer to the string which specifies the header value that should be searched for. The search options can be used to specify if the search is case-sensitive, and whether the search should return partial matches to the string. This parameter cannot be NULL.

dwOptions

A value which specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
MIME_SEARCH_DEFAULT	Perform a complete match against the specified header value. The comparison is not case-sensitive.
MIME_SEARCH_CASE_SENSITIVE	The header field value comparison will be case-sensitive. Note that this does not affect header field names. Matches for header names are always case-insensitive.
MIME_SEARCH_PARTIAL_MATCH	Perform a partial match against the specified header value. It recommended that this option be used when searching for matches to email addresses.
MIME_SEARCH_DECODE_HEADERS	Decode any encoded message headers before comparing them to the specified value. This option can increase the amount of time required to search the message store and should only be used when necessary.

Return Value

If the function succeeds, the return value is the number for the message which matches the search criteria. If the function fails, the return value is `MIME_ERROR`. To get extended error information, call `MimeGetLastError`.

Remarks

The `MimeFindStoredMessage` function is used to search the message store for a message which matches a specific header field value. For example, it can be used to find every message which is addressed to a specific recipient or has a subject which matches a particular string value.

Example

```
HMESSAGE hMessage = INVALID_MESSAGE;
LPCTSTR lpszHeader = _T("From");
LPCTSTR lpszAddress = _T("jsmith@example.com");
LONG nMessageId = 1;

// Begin searching for messages from the specified sender
while (nMessageId != MIME_ERROR)
{
    nMessageId = MimeFindStoredMessage(hStorage,
                                       nMessageId,
                                       lpszHeader,
                                       lpszAddress,
                                       MIME_SEARCH_PARTIAL_MATCH);

    if (nMessageId != MIME_ERROR)
    {
        // Get a handle to the message that was found
        hMessage = MimeGetStoredMessage(hStorage, nMessageId, 0);

        if (hMessage != INVALID_MESSAGE)
        {
            // Store the message in a file
            TCHAR szFileName[MAX_PATH];
            BOOL bExported;

            // Create a filename based on the message number
            wsprintf(szFileName, _T("msg%05ld.tmp"), nMessageId);

            // Export the message to a file
            bExported = MimeExportMessage(hMessage, szFileName);
        }

        // Increase the message ID to resume the search at the next message
        nMessageId++;
    }
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csmsgv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

MimeFormatDate Function

```
LPTSTR WINAPI MimeFormatDate(  
    LONG nSeconds,  
    LONG nTimezone,  
    LPTSTR lpszDate,  
    INT cchMaxDate  
);
```

The **MimeFormatDate** converts the specified date, expressed as the number of seconds since 1 January 1970, into a string compatible with the RFC 822 standard format for email messages.

Parameters

nSeconds

A long integer which specifies the number of seconds since 1 January 1970 00:00:00 UTC. This date is commonly called the epoch, and is the base date used by the standard C time functions. If the value of this parameter is zero, the current date and time is used.

nTimezone

A pointer to a long integer which is set to the difference in seconds between the specified date's timezone and Coordinated Universal Time. A value of zero specifies Coordinated Universal Time (UTC), while a positive value specifies a timezone west of UTC and a negative value specifies a timezone east of UTC. For example, Eastern Standard Time would be specified as 18000 and Pacific Standard Time would be 28800.

lpszDate

A pointer to a string buffer which will contain the formatted date. This parameter cannot be a NULL pointer.

cchMaxDate

The maximum number of characters, including the terminating null character, which may be copied into the date string buffer.

Return Value

If the function succeeds, a pointer to the date string buffer is returned. If the function fails, a NULL pointer is returned. To get extended error information, call **MimeGetLastError**.

Remarks

The date string is returned in a standard format as outlined in RFC 822, the document which describes the basic structure of Internet email messages. This format is as follows:

www, dd mmm yyyy hh:mm:ss [-]zzzz

Each part of the date string is defined as follows:

Format	Description
www	Weekday
dd	Day
mmm	Month
yyyy	Year
hh	Hour (24-hour clock)

mm	Minutes
ss	Seconds
zzzz	Timezone

The weekday and month are displayed using standard three-character English abbreviations. The timezone is displayed as the difference (in hours and minutes) between the specified timezone and Coordinated Universal Time. For example, if the timezone is eight hours west of Coordinated Universal Time, the *nTimezone* value would be 28800. This would be displayed as -0800 in the formatted date string.

Note that the format of the date string is defined by the RFC 822 standard, and is not affected by localization settings on the host system.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

MimeGetAllHeaders Function

```
INT WINAPI MimeGetAllHeaders(  
    HMESSAGE hMessage,  
    LPTSTR LpszHeaders,  
    INT nMaxLength  
);
```

The **MimeGetAllHeaders** function returns the complete RFC 822 header values in a string buffer.

Parameters

hMessage

Handle to the message.

lpszHeaders

Pointer to string buffer which will contain the header values for the specified message. This parameter may be NULL, in which case the function will calculate the number of characters needed to store the complete header block.

nMaxLength

An integer value which specifies the maximum number of characters that can be stored in the *lpszHeaders* string. If the *lpszHeaders* parameter is NULL, this value must be zero. If the *lpszHeaders* parameter is not NULL, this value must be large enough to store the entire list of addresses.

Return Value

If the function succeeds and the *lpszHeaders* parameter is NULL, the return value is the minimum number of characters that should be allocated to store all of the header values, including the terminating null character. If the *lpszHeaders* parameter is not NULL, then the return value is the number of characters copied into the string, not including the terminating null character. If the function fails, the return value is MIME_ERROR. To get extended error information, call **MimeGetLastError**.

Remarks

The **MimeGetAllHeaders** function will return all of the RFC 822 header values in a string buffer. This includes the message headers that are most commonly referred to, such as the To, From and Subject headers. Each header and its value are separated by a colon, and terminated with a carriage return and linefeed (CRLF) pair.

The headers and their values returned by this function will not be identical to the header block in the original message. If a header value is split across multiple lines, this function will fold the text, returning the complete header value on a single line of text and removing any extraneous whitespace. If the header value has been encoded by the mail client, this function will return the decoded value, not the original encoded value.

Example

```
LPTSTR lpszHeaders = NULL;  
INT nLength;  
  
// Determine the number of characters that should be allocated to store  
// the RFC822 headers  
  
nLength = MimeGetAllHeaders(hMessage, NULL, 0);
```

```
// Allocate the memory for the string buffer that is large enough and
// call MimeGetAllHeaders again

if (nLength > 0)
{
    lpszHeaders = (LPTSTR)LocalAlloc(LPTR, nLength * sizeof(TCHAR));
    if (lpszHeaders == NULL)
        return; // Virtual memory exhausted

    nLength = MimeGetAllHeaders(hMessage, lpszHeaders, nLength);
}

// The lpszHeaders string now contains all of the RFC822 headers for the
// message, with each header terminated by a CRLF sequence

if (lpszHeaders != NULL)
{
    LocalFree((HLOCAL)lpszHeaders);
    lpszHeaders = NULL;
}
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[MimeSetMessageHeader](#)

MimeGetAllRecipients Function

```
INT WINAPI MimeGetAllRecipients(  
    HMESSAGE hMessage,  
    LPCTSTR LpszExtraAddress,  
    LPTSTR LpszRecipients,  
    INT nMaxLength  
);
```

The **MimeGetAllRecipients** function returns a comma-separated list of recipient addresses in a string buffer.

Parameters

hMessage

Handle to the message.

lpszExtraAddress

A pointer to a string which contains one or more additional email addresses that should be included in the list, in addition to those found in the message. If more than one address is specified, each address should be separated by a comma. This parameter may be NULL if there are no extra addresses to include in the recipient list.

lpszRecipients

Pointer to string buffer which will contain a comma-separated list of email addresses when the function returns. This parameter may be NULL, in which case the function will calculate the number of characters needed to store the complete list.

nMaxLength

An integer value which specifies the maximum number of characters that can be stored in the *lpszRecipients* string. If the *lpszRecipients* parameter is NULL, this value must be zero. If the *lpszRecipients* parameter is not NULL, this value must be large enough to store the entire list of addresses.

Return Value

If the function succeeds and the *lpszRecipients* parameter is NULL, the return value is the minimum number of characters that should be allocated to store the list recipient addresses, including the terminating null character. If the *lpszRecipients* parameter is not NULL, then the return value is the number of characters copied into the buffer, not including the terminating null character. If the function returns a value of zero, then the specified message has no recipients. If the function fails, the return value is MIME_ERROR. To get extended error information, call **MimeGetLastError**.

Remarks

The **MimeGetAllRecipients** function is useful for creating a list of message recipients that can be passed to functions like **SmtplibSendMessage**. If you wish to dynamically allocate the string buffer that will contain the list of recipients, then the *lpszRecipients* parameter should be NULL and the *nMaxLength* parameter should have a value of zero. The function will then return the recommended size of the buffer that should be allocated. This value is guaranteed to be large enough to store the entire list of message recipients, including the terminating null character.

Example

```
LPTSTR lpszRecipients = NULL;
```

```

INT nLength;

// Determine the number of characters that should be allocated to store
// a list of the recipient addresses in the message

nLength = MimeGetAllRecipients(hMessage, NULL, NULL, 0);

// Allocate the memory for the string buffer that is large enough and
// call MimeGetAllRecipients again

if (nLength > 0)
{
    lpszRecipients = (LPTSTR)LocalAlloc(LPTR, nLength * sizeof(TCHAR));
    if (lpRecipients == NULL)
        return; // Virtual memory exhausted

    nLength = MimeGetAllRecipients(hMessage, NULL, lpszRecipients, nLength);
}

// The lpszRecipients string now contains a comma-separated list of
// each recipient address in the message

if (lpszRecipients != NULL)
{
    LocalFree((HLOCAL)lpszRecipients);
    lpszRecipients = NULL;
}

```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[MimeGetNextMessageHeader](#), [MimeSetMessageHeader](#)

MimeGetAttachedFileName Function

```
BOOL WINAPI MimeGetAttachedFileName(  
    HMESSAGE hMessage,  
    LPTSTR lpszFileName,  
    INT cchFileName  
);
```

The **MimeGetAttachedFileName** function returns the file name for the attachment to the current message part.

Parameters

hMessage

Handle to the message.

lpszFileName

Pointer to a buffer that will contain the current attachment file name as a string.

cchFileName

The maximum number of characters that may be copied into the buffer, including the terminating null character.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **MimeGetLastError**.

Remarks

The function will first try to get the filename from the Content-Disposition header field. If this field does not exist, it then attempts to get the name from the Content-Type header field. If neither field exists, the function will fail.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[MimeAttachFile](#), [MimeEnumAttachments](#), [MimeExtractFile](#), [MimeFindAttachment](#)

MimeGetContentDigest Function

```
INT WINAPI MimeGetContentDigest(  
    HMESSAGE hMessage,  
    LPTSTR LpszDigest,  
    INT cchDigest  
);
```

The **MimeGetContentDigest** function returns an encoded digest of the message.

Parameters

hMessage

Message handle.

lpszDigest

Pointer to a string buffer to contain the MD5 digest for the specified message.

cchDigest

Maximum length of the digest string, in bytes.

Return Value

If the function succeeds, the return value is the length of the message digest string. A value of zero specifies that there is no MD5 digest for the current message. If the function fails, the return value is `MIME_ERROR`. To get extended error information, call **MimeGetLastError**.

Remarks

This function returns the value of the Content-MD5 header field in the main body of the message. If the header exists, it contains the MD5 digest for the message as defined in RFC 1864.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csmsgv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

MimeGetContentLength Function

```
LONG WINAPI MimeGetContentLength(  
    HMESSAGE hMessage  
);
```

The **MimeGetContentLength** function returns the size of the current message part content in bytes.

Parameters

hMessage

Handle to the message.

Return Value

If the function succeeds, the return value is the content length. If the function fails, the return value is MIME_ERROR. To get extended error information, call **MimeGetLastError**.

Remarks

This function will return the size of the content in the current message part as the number of bytes and does not account for any Unicode conversion of text. Exercise caution when using this function to determine the size of the buffer that should be allocated for a function like **MimeGetMessageText**. You should always allocate enough memory to accommodate any potential text conversion and decoding which may occur.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

MimeGetErrorString Function

```
INT WINAPI MimeGetErrorString(  
    DWORD dwErrorCode,  
    LPTSTR lpszDescription,  
    INT cbDescription  
);
```

The **MimeGetErrorString** function is used to return a description of a specific error code. Typically this is used in conjunction with the **MimeGetLastError** function for use with warning dialogs or as diagnostic messages.

Parameters

dwErrorCode

The error code for which a description is returned.

lpszDescription

A pointer to the buffer that will contain a description of the specified error code. This buffer should be at least 128 characters in length.

cbDescription

The maximum number of characters that may be copied into the description buffer.

Return Value

If the function succeeds, the return value is the length of the description string. If the function fails, the return value is zero, meaning that no description exists for the specified error code. Typically this indicates that the error code passed to the function is invalid.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csmsgv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

See Also

MimeGetExportOptions Function

```
BOOL WINAPI MimeGetExportOptions(  
    HMESSAGE hMessage  
    LPDWORD LpdwOptions  
);
```

The **MimeGetExportOptions** function returns a bitmask that describes current message export options.

Parameters

hMessage

Handle to the message.

lpdwOptions

Pointer to mask of attribute options. The mask is a combination of the following values:

Constant	Description
MIME_OPTION_DEFAULT	The default export options. The headers for the message are written out in a specific consistent order, with custom headers written to the end of the header block regardless of the order in which they were set or imported from another message. If the message contains Bcc, Received, Return-Path, Status or X400-Received header fields, they will not be exported.
MIME_OPTION_KEEORDER	The original order in which the message header fields were set or imported are preserved when the message is exported.
MIME_OPTION_ALLHEADERS	All headers, including the Bcc, Received, Return-Path, Status and X400-Received header fields will be exported. Normally these headers are not exported because they are only used by the mail transport system. This option can be useful when exporting a message to be stored on the local system, but should not be used when exporting a message to be delivered to another user.
MIME_OPTION_NOHEADERS	When exporting a message, the main header block will not be included. This can be useful when creating a multipart message for services which expect MIME formatted data, such as HTTP POST requests. This option should never be used for email messages being submitted using SMTP.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is 0. To get extended error information, call **MimeGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

MimeGetFileContentType Function

```
UINT WINAPI MimeGetFileContentType(  
    HMESSAGE hMessage,  
    LPCTSTR lpszFileName,  
    LPTSTR lpszContentType,  
    INT cchContentType  
);
```

The **MimeGetFileContentType** function returns the content type for the specified file.

Parameters

hMessage

Handle to the message.

lpszFileName

Pointer to a string which specifies the name of the file for which content type information is returned.

lpszContentType

Pointer to a string buffer that will contain the MIME type for the specified file. This may be a NULL pointer, in which case this parameter is ignored. If a buffer is provided, it is recommended that it be at least 64 characters in length.

cchContentType

An integer which specifies the maximum number of characters, including the terminating null character, which may be copied into the string buffer.

Return Value

If the function succeeds, the return value is the content type of the specified file. If the function fails, the return value is `MIME_CONTENT_UNKNOWN`. To get extended error information, call **MimeGetLastError**.

The following values may be returned by this function:

Constant	Description
<code>MIME_CONTENT_UNKNOWN</code>	The file content type is unknown. This value may be returned if the message handle is invalid, or if the file extension is unknown and the file could not be opened for read access.
<code>MIME_CONTENT_APPLICATION</code>	The file content is application specific. Examples of this type of file would be a Microsoft Word document or an executable program. This is also the default type for files which have an unrecognized file name extension and contain binary data.
<code>MIME_CONTENT_AUDIO</code>	The file is an audio file in one of several standard formats. Examples of this type of file would be a Windows (.wav) file or MPEG3 (.mp3) file.
<code>MIME_CONTENT_IMAGE</code>	The file is an image file in one of several standard formats. Examples of this type of file would be a GIF or JPEG image file.
<code>MIME_CONTENT_TEXT</code>	The file is a text file. This is also the default type for files which have an unrecognized file name extension and contain only

	printable text data.
MIME_CONTENT_VIDEO	The file is a video file in one of several standard formats. Examples of this type of file would be a Windows (.avi) or Quicktime (.mov) video file.

Remarks

The content type for a given file is determined based on the file name extension, or if the extension is not recognized, the actual contents of the file. On 32-bit platforms, the system registry is used to determine the default content type values for a given extension. In all cases, file types that are explicitly set using the **MimeSetFileContentType** function will override the default system values.

The content type string which is copied to the string buffer is the standard MIME content type description, which specifies a primary type and a subtype, separated by a slash. For example, a plain text file would have a content type of text/plain, while an HTML document would have a content type of text/html. Binary files may be associated with a specific application. For example, the content type for a Microsoft Word document is application/msword. Those binary files which are not associated with a specific application, or have an unrecognized file name extension, have a content type of application/octet-stream.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[MimeAttachData](#), [MimeAttachFile](#), [MimeSetFileContentType](#)

MimeGetFirstMessageHeader Function

```
BOOL WINAPI MimeGetFirstMessageHeader(  
    HMESSAGE hMessage,  
    LPTSTR lpszHeader,  
    INT cchMaxHeader,  
    LPTSTR lpszValue,  
    INT cchMaxValue  
);
```

The **MimeGetFirstMessageHeader** function returns the header field name and value for the first header in the current message part. This function is typically used in conjunction with **MimeGetNextMessageHeader** to enumerate all of the message header fields and their values in the current message part.

Parameters

hMessage

Handle to the message.

lpszHeader

A pointer to a string buffer that will contain the name of the first header in the current message part. This parameter cannot be a NULL pointer.

cchMaxHeader

An integer which specifies the maximum number of characters which may be copied into the buffer, including the terminating null character. This parameter must have a value greater than zero.

lpszValue

A pointer to a string buffer that will contain the value of the first header in the current message part. This parameter may be a NULL pointer, in which case the value of the header field is ignored.

cchMaxValue

An integer which specifies the maximum number of characters which may be copied into the buffer, including the terminating null character. If the *lpszValue* parameter is NULL, this parameter should have a value of zero.

Return Value

If the function succeeds, the return value is non-zero. If no headers exist for the current message part, or the handle to the message is invalid, the function will return zero. To get extended error information, call **MimeGetLastError**.

Remarks

Each part in a multipart message has one or more header fields. To obtain header values for the main message, rather than the message attachments, the current part number must be set to zero using the **MimeSetMessagePart** function.

The header fields from an imported message may not be returned in the same order as which they appear in the message. An application should never make an assumption about the order in which one or more header fields are defined.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[MimeParseHeader](#), [MimeSetMessageHeader](#), [MimeSetMessagePart](#)

MimeGetLastError Function

```
DWORD WINAPI MimeGetLastError();
```

Parameters

None.

Return Value

The return value is the calling thread's last error code value. Functions set this value by calling the **MimeSetLastError** function. The Return Value section of each reference page notes the conditions under which the function sets the last-error code.

Remarks

You should call the **MimeGetLastError** function immediately when a function's return value indicates that an error has occurred. That is because some functions call **MimeSetLastError(0)** when they succeed, clearing the error code set by the most recently failed function.

Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_MESSAGE or MIME_ERROR. Those functions which call **MimeSetLastError** when they succeed are noted on the function reference page.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmsgv10.lib

See Also

[MimeGetErrorString](#), [MimeSetLastError](#)

MimeGetMessageBoundary Function

```
LPCTSTR WINAPI MimeGetMessageBoundary(  
    HMESSAGE hMessage  
);
```

The **MimeGetMessageBoundary** function returns a pointer to the boundary string used to separate the parts of a multipart message.

Parameters

hMessage

Handle to the message.

Return Value

If the function succeeds, the return value is a pointer to the boundary string. If the function fails, a NULL pointer is returned. To get extended error information, call **MimeGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[MimeCreateMessagePart](#), [MimeGetMessageHeader](#), [MimeGetMessagePart](#)

MimeGetMessageDate Function

```
LPCTSTR WINAPI MimeGetMessageDate(  
    HMESSAGE hMessage,  
    BOOL bLocalize  
);
```

The **MimeGetMessageDate** function returns a pointer to a string that contains the message date and time.

Parameters

hMessage

Handle to the message.

bLocalize

Boolean flag which specifies if the date and time should be localized for the current timezone.

Return Value

If the function succeeds, the return value is a pointer to the date and time string. If the function fails, it will return a NULL pointer. To get extended error information, call **MimeGetLastError**.

Remarks

If no date has been specified in the message, the Date header field will be set to the current date and time, and that value will be returned. The date string returned by this function should never be directly modified by the application. Each call to this function will invalidate the previous value that was returned, so if you wish to save or modify the value, you should first make a private copy of the string.

To convert this date string to a long integer value that can be used with the standard C time functions, use the **MimeParseDate** function. Refer to the **MimeFormatDate** function for information on the format of the date string.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[MimeFormatDate](#), [MimeGetMessageHeader](#), [MimeParseDate](#), [MimeSetMessageDate](#)

MimeGetMessageHeader Function

```
LPCTSTR WINAPI MimeGetMessageHeader(  
    HMESSAGE hMessage,  
    LPCTSTR lpszHeader  
);
```

The **MimeGetMessageHeader** function returns a pointer to the value associated with the specified header field in the current message part.

Parameters

hMessage

Handle to the message.

lpszHeader

A pointer to a string which specifies the message header. This parameter cannot be a NULL pointer.

Return Value

If the function succeeds, the return value is a pointer to the header value. If the header field does not exist, a NULL pointer is returned. To get extended error information, call **MimeGetLastError**.

Remarks

Each part in a multipart message has one or more header fields. To obtain header values for the main message, rather than the message attachments, the current part number must be set to zero using the **MimeSetMessagePart** function.

For languages other than C/C++, it may be preferable to use the **MimeGetMessageHeaderEx** function which copies the header value into a string buffer rather than returning a pointer to the header value itself.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[MimeEnumMessageHeaders](#), [MimeGetFirstMessageHeader](#), [MimeGetMessageHeaderEx](#), [MimeGetMessagePart](#), [MimeGetNextMessageHeader](#), [MimeParseHeader](#), [MimeSetMessageHeader](#), [MimeSetMessagePart](#)

MimeGetMessageHeaderEx Function

```
INT WINAPI MimeGetMessageHeaderEx(  
    HMESSAGE hMessage,  
    INT nMessagePart,  
    LPCTSTR lpszHeader,  
    LPTSTR lpszValue,  
    INT nMaxValue,  
    DWORD dwReserved  
);
```

The **MimeGetMessageHeaderEx** copies the value of the specified header into a string buffer.

Parameters

hMessage

Handle to the message.

nMessagePart

An integer value which specifies which part of the message to return the header value from. A value of zero returns a header value from the main message header, while a value greater than zero returns the header value from that specific part of a multipart message. A value of -1 specifies that the header value should be returned from the current message part.

lpszHeader

A pointer to a string which specifies the message header. This parameter cannot be a NULL pointer.

lpszValue

A pointer to a string buffer which will contain the value of the specified header when the function returns. If this parameter is NULL, the function will return the length of the header value without copying the data. This is useful for determining the length of a header value so that a string buffer can be allocated and passed to a subsequent call to the function.

nMaxValue

An integer value which specifies the maximum number of characters that can be copied to the string buffer, including the terminating null character. If the *lpszValue* parameter is NULL, this value should be zero.

dwReserved

A reserved parameter. This value should always be zero.

Return Value

If the function succeeds, the return value is the number of bytes copied into the string buffer, not including the terminating null byte. If the *lpszValue* parameter is NULL, the return value is the length of the header value. If the header field does not exist, a value of zero is returned. If an invalid pointer or message part is specified, a value of MIME_ERROR is returned. To get extended error information, call **MimeGetLastError**.

Example

```
LPTSTR lpszValue = NULL;  
INT cchValue = 0;  
  
// Determine the length of the To header field  
cchValue = MimeGetMessageHeaderEx(hMessage, 0, _T("To"), NULL, 0);
```

```
// If the header field exists, allocate a string buffer
// and copy the value into the buffer
if (cchValue > 0)
{
    lpszValue = (LPTSTR)LocalAlloc(LPTR, cchValue + 1);
    MimeGetMessageHeaderEx(hMessage,
                           0,
                           _T("To"),
                           lpszValue,
                           cchValue + 1);
}

// After the string buffer has been used, release the
// memory that was allocated for it
if (lpszValue)
{
    LocalFree((HLOCAL)lpszValue);
    lpszValue = NULL;
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

MimeGetMessagePart Function

```
INT WINAPI MimeGetMessagePart(  
    HMESSAGE hMessage  
);
```

The **MimeGetMessagePart** function returns the current message part index for the specified message.

Parameters

hMessage

Handle to the message.

Return Value

If the function succeeds, the return value is the message part index. If the function fails, the return value is MIME_ERROR. To get extended error information, call **MimeGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmsgv10.lib

MimeGetMessagePartCount Function

```
INT WINAPI MimeGetMessagePartCount(  
    HMESSAGE hMessage  
);
```

The **MimeGetMessagePartCount** function returns the total number of message parts for the specified message. Each message consists of at least one part.

Parameters

hMessage

Handle to the message.

Return Value

If the function succeeds, the return value is the number of message parts. If the function fails, the return value is MIME_ERROR. To get extended error information, call **MimeGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmsgv10.lib

See Also

[MimeCreateMessagePart](#), [MimeGetMessagePart](#), [MimeSetMessagePart](#)

MimeGetMessageSender Function

```
INT WINAPI MimeGetMessageSender(  
    HMESSAGE hMessage,  
    LPCTSTR LpszSender,  
    INT nMaxLength  
);
```

The **MimeGetMessageSender** function returns the email address of the message sender in the specified string buffer.

Parameters

hMessage

Handle to the message.

lpszSender

A pointer to a string buffer that will contain the email address of the message sender when the function returns.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied to the string buffer, including the terminating null character. It is recommended that the maximum length be at least 64 characters.

Return Value

If the function succeeds, the return value is the number of bytes copied to the string buffer. If an error occurs, the function will return MIME_ERROR. To get extended error information, call **MimeGetLastError**.

Remarks

This function attempts to determine the email address of the sender that originated the message. It will first check for the presence of a Sender or X-Sender header value. If these headers are not defined, it will use the value of the From header field. It will only return successfully if a valid email address can be found.

If the function succeeds, the string buffer that is provided will only contain an email address. It will not contain the display name of the user associated with the address or any extraneous comments that are included in quotes or parenthesis.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

MimeGetMessageSize Function

```
BOOL WINAPI MimeGetMessageSize(  
    HMESSAGE hMessage,  
    DWORD dwOptions,  
    LPDWORD lpdwMessageSize  
);
```

The **MimeGetMessageSize** function returns the size of the complete message in bytes.

Parameters

hMessage

Handle to the message.

dwOptions

An unsigned integer which specifies how the size of the message should be calculated, based on what header fields should be included. These are the same options used when exporting a message to a file or memory buffer. The following values may be combined using a bitwise Or operator:

Constant	Description
MIME_OPTION_DEFAULT	The default export options. The headers for the message are written out in a specific consistent order, with custom headers written to the end of the header block regardless of the order in which they were set or imported from another message. If the message contains Bcc, Received, Return-Path, Status or X400-Received header fields, they will not be exported.
MIME_OPTION_ALLHEADERS	All headers, including the Received, Return-Path, Status and X400-Received header fields will be exported. Normally these headers are not exported because they are only used by the mail transport system. This option can be useful when exporting a message to be stored on the local system, but should not be used when exporting a message to be delivered to another user.

lpdwMessageSize

A pointer to an unsigned integer value which will contain the size of the message if the function succeeds, or a value of zero if the function fails. This parameter cannot be NULL.

Return Value

If the function succeeds, the return value is non-zero. If an error occurs, the function will return zero. To get extended error information, call **MimeGetLastError**.

Remarks

This function returns the size of the complete message, including all headers, the message body and any attachments. It can be used to determine the minimum amount of memory that should be allocated to export the message to a memory buffer using the **MimeExportMessageEx** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmsgv10.lib

See Also

[MimeExportMessage](#), [MimeExportMessageEx](#), [MimeGetMessageText](#), [MimeImportMessage](#),
[MimeImportMessageEx](#)

MimeGetMessageText Function

```
LONG WINAPI MimeGetMessageText(  
    HMESSAGE hMessage,  
    LONG nOffset,  
    LPTSTR LpszBuffer,  
    LONG nMaxLength  
);
```

The **MimeGetMessageText** function copies the text of the current message part to the specified buffer.

Parameters

hMessage

Handle to the message.

nOffset

The byte offset from the beginning of the message. A value of zero specifies the first character in the body of the message part.

lpszBuffer

A pointer to the string buffer that will contain a copy of the message text when the function returns. Note that the buffer will typically contain multiple lines of text.

nMaxLength

The maximum number of bytes to copy into the buffer. The size of the buffer provided must be larger than the content length for the current message part.

Return Value

If the function succeeds, the return value is number of bytes copied into the buffer. If the function fails, the return value is `MIME_ERROR`. To get extended error information, call **MimeGetLastError**.

Remarks

If your project targets a multi-byte character set, this function will always return the message contents as UTF-8 text, regardless of the original character set specified in the message itself. This ensures that characters in the original text are preserved, regardless of the default ANSI code page on the local system. It is recommended you build your project to use Unicode whenever possible. If your application must use ANSI, you can use the **MimeLocalizeText** method to convert the Unicode text to a specific character set.

You should not determine the maximum size of the output buffer using the **MimeGetContentLength** function. That function returns the content size in bytes as it is stored in the message, and does not account for any character encoding or Unicode conversion which may be required. The content length can be used to estimate the amount of text stored in the message part, but you should always allocate a buffer which is larger than the length specified in the message.

If the *nMaxLength* parameter does not specify a buffer size large enough to store the contents of the current message part, this function will fail and the last error code will be set to `ST_ERROR_BUFFER_TOO_SMALL`. Your application must ensure the buffer is large enough to contain the complete message text and a terminating NUL character.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[MimeSetMessageText](#)

MimeGetMessageVersion Function

```
LPCTSTR WINAPI MimeGetMessageVersion(  
    HMESSAGE hMessage  
);
```

The **MimeGetMessageVersion** function returns a pointer to a string which contains the MIME version header value for the specified message.

Parameters

hMessage

Handle to the message.

Return Value

If the function succeeds, the return value is a pointer to the MIME version. If the version is not specified in the current message, the function will return NULL. To get extended error information, call **MimeGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[MimeGetMessageHeader](#), [MimeSetMessageVersion](#)

MimeGetNextMessageHeader Function

```
BOOL WINAPI MimeGetNextMessageHeader(  
    HMESSAGE hMessage,  
    LPTSTR lpszHeader,  
    INT cchMaxHeader,  
    LPTSTR lpszValue,  
    INT cchMaxValue  
);
```

The **MimeGetNextMessageHeader** function returns the header field name and value for the next header in the current message part. This function is typically used in conjunction with **MimeGetFirstMessageHeader** to enumerate all of the message header fields and their values in the current message part.

Parameters

hMessage

Handle to the message.

lpszHeader

A pointer to the string buffer that will contain the name of the next header in the current message part when the function returns. This parameter cannot be a NULL pointer.

cchMaxHeader

An integer which specifies the maximum number of characters which may be copied into the buffer, including the terminating null character. This parameter must have a value greater than zero.

lpszValue

A pointer to the string buffer that will contain the value of the next header in the current message part when the function returns. This parameter may be a NULL pointer, in which case the value of the header field is ignored.

cchMaxValue

An integer which specifies the maximum number of characters which may be copied into the buffer, including the terminating null character. If the *lpszValue* parameter is NULL, this parameter should have a value of zero.

Return Value

If the function succeeds, the return value is non-zero. If no more headers exist for the current message part, or the handle to the message is invalid, the function will return zero. To get extended error information, call **MimeGetLastError**.

Remarks

Each part in a multipart message has one or more header fields. To obtain header values for the main message, rather than the message attachments, the current part number must be set to zero using the **MimeSetMessagePart** function.

The header fields from an imported message may not be returned in the same order as which they appear in the message. An application should never make an assumption about the order in which one or more header fields are defined, with the following exception:

If an imported message has multiple Received headers, then those headers will be returned by **MimeGetNextMessageHeader** in the order in which they appeared in the original message.

Note that if **MimeGetMessageHeader** is used to retrieve the Received header, the first Received header in the message will be returned.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[MimeParseHeader](#), [MimeSetMessageHeader](#), [MimeSetMessagePart](#)

MimeGetStoredMessage Function

```
HMESSAGE WINAPI MimeGetStoredMessage(  
    HMESSAGESTORE hStorage,  
    LONG nMessageId,  
    DWORD dwOptions  
);
```

The **MimeGetStoredMessage** function retrieves a message from the specified message store.

Parameters

hStorage

Handle to the message store.

nMessageId

An integer value which specifies the message number that should be retrieved. The first message in the message store has a value of one.

dwOptions

A value which specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
0	A shared message handle returned by the function. The contents of this message will be overwritten each time this function is called.
MIME_COPY_STORED_MESSAGE	A message handle is allocated for a copy of the message that is retrieved from the message store.

Return Value

If the function succeeds, the return value is a handle to the message. If the function fails, the return value is `INVALID_MESSAGE`. To get extended error information, call **MimeGetLastError**.

Remarks

The **MimeGetStoredMessage** function returns a message handle for the specified message in the message store. If no options are specified, a temporary message handle is returned that is only valid until the next message is retrieved. The application can use message handle with any function except for the **MimeDeleteMessage** function because it does not own the message handle. If a multithreaded application changes the contents of the temporary message, it will change for all other threads that have obtained a message handle using this function.

If the application must have a unique copy of the message, the `MIME_COPY_STORED_MESSAGE` option should be specified. Instead of returning a handle to a shared message, the message is duplicated and a handle to that copy of the message is returned. If this option is used, the application must call **MimeDeleteMessage** to release the memory allocated for the message.

Example

```
HMESSAGE hMessage = INVALID_MESSAGE;  
LPCTSTR lpszHeader = _T("From");  
LPCTSTR lpszAddress = _T("jsmith@example.com");  
LONG nMessageId = 1;
```

```

// Begin searching for messages from the specified sender
while (nMessageId != MIME_ERROR)
{
    nMessageId = MimeFindStoredMessage(hStorage,
                                       nMessageId,
                                       lpszHeader,
                                       lpszAddress,
                                       MIME_SEARCH_PARTIAL_MATCH);

    if (nMessageId != MIME_ERROR)
    {
        // Get a handle to the message that was found
        hMessage = MimeGetStoredMessage(hStorage, nMessageId, 0);

        if (hMessage != INVALID_MESSAGE)
        {
            // Store the message in a file
            TCHAR szFileName[MAX_PATH];
            BOOL bExported;

            // Create a filename based on the message number
            wsprintf(szFileName, _T("msg%05ld.tmp"), nMessageId);

            // Export the message to a file
            bExported = MimeExportMessage(hMessage, szFileName);
        }

        // Increase the message ID to resume the search at the next message
        nMessageId++;
    }
}

```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmsgv10.lib

[MimeStoreMessage](#)

MimeGetStoredMessageCount Function

```
LONG WINAPI MimeGetStoredMessageCount(  
    HMESSAGESTORE hStorage,  
    LPLONG lpnMessages  
);
```

The **MimeGetStoredMessageCount** function returns the number of messages in the specified message store.

Parameters

hStorage

Handle to the message store.

lpnLastMessage

A pointer to an integer which will contain the message number for the last message in the storage file. If this information is not required, a NULL pointer may be specified.

Return Value

If the function succeeds, the return value is the number of messages in the message store. If the function fails, the return value is MIME_ERROR. To get extended error information, call

MimeGetLastError.

Remarks

The **MimeGetStoredMessageCount** function returns the number of messages in the message store. It is important to note that does not count those messages which have been marked for deletion. This means that the value returned by this function will decrease as messages are deleted.

The message number returned in the *lpnLastMessage* parameter will specify the total number of messages in the message store, including deleted messages.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

MimeImportMessage Function

```
BOOL WINAPI MimeImportMessage(  
    HMESSAGE hMessage,  
    LPCTSTR lpszFileName  
);
```

The **MimeImportMessage** function reads the specified file and replaces the current message with its contents.

Parameters

hMessage

Handle to the message.

lpszFileName

Pointer to a string which specifies the name of the text file to import.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **MimeGetLastError**.

Remarks

This function will delete the contents of the current message before importing the new message from the specified file.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[MimeAttachFile](#), [MimeExportMessage](#), [MimeExportMessageEx](#), [MimeExtractFile](#), [MimeImportMessageEx](#), [MimeInitialize](#), [MimeParseBuffer](#)

MimeImportMessageEx Function

```
BOOL WINAPI MimeImportMessageEx(  
    HMESSAGE hMessage,  
    DWORD dwImportMode,  
    DWORD dwImportOptions,  
    LPVOID lpvMessage,  
    DWORD dwMessageSize  
);
```

The **MimeImportMessageEx** function imports the contents of a message from a file, string or memory handle.

Parameters

hMessage

Handle to the message.

dwImportMode

An unsigned integer which specifies how the message contents will be imported. It may be one of the following values:

Constant	Description
MIME_IMPORT_DEFAULT	The default import mode. If the <i>lpvMessage</i> parameter is NULL, then the contents of the message will be imported from the system clipboard. Otherwise, the <i>lpvMessage</i> parameter is a pointer to a string which specifies the name of a file that contains the message. The <i>dwMessageSize</i> parameter is ignored.
MIME_IMPORT_FILE	The <i>lpvMessage</i> parameter is a pointer to a string which specifies the name of the file that contains the message. If the file does not exist, or is not a regular text file, an error will occur. The <i>dwMessageSize</i> parameter is ignored.
MIME_IMPORT_CLIPBOARD	The contents of the message is imported from the system clipboard. The <i>lpvMessage</i> parameter is ignored. The <i>dwMessageSize</i> parameter is ignored.
MIME_IMPORT_MEMORY	The contents of the message is imported from a local buffer. The <i>lpvMessage</i> parameter must point to a byte array which contains the message to be imported. The <i>dwMessageSize</i> parameter specifies the number of bytes to copy from the buffer. If this value is zero, it is assumed that the end of the message data in the buffer is terminated with a null character and the length is calculated automatically.
MIME_IMPORT_HGLOBAL	The contents of the message is imported from a global memory buffer. The <i>lpvMessage</i> parameter must be a global memory handle which contains the message. The <i>dwMessageSize</i> parameter specifies the number of bytes to copy from the buffer. If this value is zero, it is assumed

that the end of the message data in the buffer is terminated with a null character and the length is calculated automatically.

dwImportOptions

An unsigned integer which specifies how the message will be imported:

Constant	Description
MIME_OPTION_DEFAULT	The default import options. Currently this is the only valid value for this parameter and applications should always specify this constant.

lpvMessage

A pointer to a string, a byte buffer or a global memory handle. The *dwImportMode* parameter determines how this pointer is used by the function.

dwMessageSize

An unsigned integer value which specifies the size of the message to import. This parameter is only used when importing a message from a memory buffer. The message size is determined automatically when the message is imported from a file or the system clipboard.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **MimeGetLastError**.

Example

The following example imports a message using an HGLOBAL handle that references a block of memory that contains an email message:

```
bResult = MimeImportMessageEx(hMessage,  
                             MIME_IMPORT_HGLOBAL,  
                             MIME_OPTION_DEFAULT,  
                             (LPVOID)hgb1Message,  
                             0);  
  
if (bResult)  
{  
    // The message has been successfully imported  
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

MimeInitialize Function

```
BOOL WINAPI MimeInitialize(  
    LPCTSTR lpszLicenseKey,  
    LPINITDATA lpData  
);
```

The **MimeInitialize** function initializes the library and validates the specified license key at runtime.

Parameters

lpszLicenseKey

Pointer to a string that specifies the runtime license key to be validated. If this parameter is NULL, the library will validate the development license installed on the local system.

lpData

Pointer to an INITDATA data structure. This parameter may be NULL if the initialization data for the library is not required.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **MimeGetLastError**. All other client functions will fail until a license key has been successfully validated.

Remarks

This must be the first function that an application calls before using any of the other functions in the library. When a NULL license key is specified, the library will only function on the development system. Before redistributing the application to an end-user, you must insure that this function is called with a valid license key.

If the *lpData* argument is specified, it must point to an INITDATA structure which has been initialized by setting the *dwSize* member to the size of the structure. All other structure members should be set to zero. If the function is successful, then the INITDATA structure will be filled with identifying information about the library.

Although it is only required that **MimeInitialize** be called once for the current process, it may be called multiple times; however, each call must be matched by a corresponding call to **MimeUninitialize**.

This function dynamically loads other system libraries and allocates thread local storage. If you are calling the functions in this library from within another DLL, it is important that you do not call the **MimeInitialize** or **MimeUninitialize** functions from the **DllMain** function because it can result in deadlocks or access violation errors. If the DLL is linked with the C runtime library (CRT), it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

MimeLocalizeText Function

```
LONG WINAPI MimeLocalizeText(  
    UINT nCharacterSet,  
    LPCTSTR lpszInput,  
    LONG cchInput,  
    LPBYTE lpOutput,  
    LONG cbOutput  
);
```

The **MimeLocalizeText** function converts a Unicode string to its ANSI equivalent using the specified character set.

Parameters

nCharacterSet

A numeric identifier which specifies the [character set](#) to use when localizing the text. A value of zero specifies the locale for the current thread should be used when localizing the text.

lpszInput

A pointer to a null terminated string which contains the Unicode text which should be localized. If the ANSI version of this function is called, the input text must be in UTF-8 format or the function will fail. This parameter cannot be a NULL pointer.

cchInput

An integer value which specifies the number of characters of text in the input string which should be localized. If this value is -1, the entire length of the string up to the terminating null will be decoded.

lpOutput

A pointer to a byte buffer which will contain the localized ANSI version of the input text. This parameter cannot be a NULL pointer.

cbOutput

An integer value which specifies the maximum number of bytes which can be copied into the output buffer. The buffer must be large enough to store all of the localized text. This value must be greater than zero.

Return Value

If the input text can be successfully localized, the return value is the number of bytes copied into the output buffer. If the function returns zero, then no text was localized. If the function fails, the return value is MIME_ERROR. To get extended error information, call **MimeGetLastError**.

Remarks

The **MimeLocalizeText** function enables the application to localize a Unicode string, returning the ANSI version of that text using the specified character set. Because library handles all text as Unicode internally, the ANSI functions in this library will always return UTF-8 encoded text. This function allows you to easily convert that UTF-8 text to another supported character set.

If the ANSI version of this function is called, the input text must use UTF-8 character encoding or the function will fail with the last error set to ST_ERROR_INVALID_CHARACTER_SET.

If the *nCharacterSet* parameter is MIME_CHARSET_DEFAULT or MIME_CHARSET_UNKNOWN the input text will be converted to the default ANSI code page for the current thread locale. If there are characters in the Unicode input text which cannot be converted to an ANSI equivalent using

the specified character set, those characters will be replaced by the default character for your locale, typically a question mark symbol. You cannot specify `MIME_CHARSET_UTF16` as the character set.

This function will always attempt to ensure that the output buffer is terminated with an extra null byte so it is easier to work with as a standard C-style null terminated string. However, if the output buffer is not large enough to accommodate the extra null byte, it will not be copied. It is always recommended that your output buffer be somewhat larger than the length of the original input text to account for multi-byte character sequences. If the output buffer is not large enough to contain the entire localized text, no bytes will be copied to the output buffer and the function will fail with the last error set to `ST_ERROR_BUFFER_TOO_SMALL`.

This function is only required if your application needs to localize the UTF-8 text returned by another function and convert it to a specific 8-bit ANSI character set. For example, if you have an application which calls the ANSI version of **MimeGetMessageText**, it will return the message contents as UTF-8 text. If you need to display that text as localized ANSI, you can call this function to convert the UTF-8 text to your current locale or a specific character set.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csmsgv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

MimeOpenMessageStore Function

```
HMESSAGESTORE WINAPI MimeOpenMessageStore(  
    LPCTSTR lpszFileName,  
    DWORD dwOpenMode  
);
```

The **MimeOpenMessageStore** function opens the specified message storage file.

Parameters

lpszFileName

A pointer to a string which specifies the name of the storage file.

dwOpenMode

A value which specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
MIME_STORAGE_READ	The message store will be opened for read access. The contents of the message store can be accessed, but cannot be modified by the process unless it has also been opened for writing.
MIME_STORAGE_WRITE	The message store will be opened for writing. This mode also implies read access and must be specified if the application needs to modify the contents of the message store.
MIME_STORAGE_CREATE	The message store will be created if the storage file does not exist. If the file exists, it will be truncated. This mode implies read and write access.
MIME_STORAGE_LOCK	The message store will be opened so that it may only be accessed and modified by the current process.
MIME_STORAGE_COMPRESS	The contents of the message store are compressed. This option is automatically enabled if a compressed message store is opened for reading or writing.
MIME_STORAGE_MAILBOX	The message store should use the UNIX mbox format when reading and storing messages. This option is provided for backwards compatibility and is not recommended for general use.

Return Value

If the function succeeds, the return value is a handle to the message store. If the function fails, the return value is `INVALID_MESSAGESTORE`. To get extended error information, call **MimeGetLastError**.

Remarks

The **MimeOpenMessageStore** function opens a message storage file which contains one or more messages. If the storage file is opened for read access, the application can search the message store and extract messages but it cannot add or delete messages. To add new messages

or delete existing messages from the store, it must be opened with write access.

The message store is designed to be a simple, effective way to store multiple messages together in a single file. When the message store is opened, the contents are indexed in memory. Although there is no specific limit to the number of messages that can be stored, there must be sufficient memory available to build an index of each message and its headers. If the application must store and manage a very large number of messages, it is recommended that you use a database rather than a flat-file message store.

Message Store Format

Each message is prefixed by a control sequence of five ASCII 01 characters followed by an ASCII 10 and ASCII 13 character. The messages themselves are stored unmodified in their original text format. The length of each message is calculated based on the location of the control sequence that delimits each message, and explicit message lengths are not stored in the file. This means that it is safe to manually change the message contents, as long as the message delimiters are preserved.

If the message store is compressed, the contents of the storage file are expanded when the file is opened and then re-compressed when the storage file is closed. Using the `MIME_STORAGE_COMPRESS` option reduces the size of the storage file and prevents the contents of the message store from being read using a text file editor. However, enabling compression will increase the amount of memory allocated by the library and can increase the amount of time that it takes to open and close the storage file.

The library also has a backwards compatibility mode where it will recognize storage files that use the UNIX mbox format. While this format is supported for accessing existing files, it is not recommended that you use it when creating new message stores or adding messages to an existing store. There are a number of different variants on the mbox format that have been used by different Mail Transfer Agents (MTAs) on the UNIX platform. For example, the `mboxrd` variant looks identical to the `mboxcl2` variant, and they are programmatically indistinguishable from one another, but they are not compatible. For this reason, the use of the mbox format is strongly discouraged.

Example

```
HMESSAGE hMessage;

// Compose a new message
hMessage = MimeComposeMessage(lpszSender,
                              lpszRecipient,
                              NULL,
                              lpszSubject,
                              lpszMessage,
                              NULL,
                              MIME_CHARSET_DEFAULT,
                              MIME_ENCODING_DEFAULT);

if (hMessage != INVALID_MESSAGE)
{
    HMESSAGESTORE hStorage;

    // Open the message storage file
    hStorage = MimeOpenMessageStore(lpszFileName, MIME_STORAGE_WRITE);

    if (hStorage == INVALID_MESSAGESTORE)
    {
        // Delete the message and return if we are unable to
```

```
        // open the storage file
        MimeDeleteMessage(hMessage);
        return;
    }

    // Store a copy of the message in the message store
    nMessageId = MimeStoreMessage(hStorage, hMessage, 0);

    if (nMessageId == MIME_ERROR)
    {
        // We were unable to store the message
    }

    // Close the message store
    MimeCloseMessageStore(hStorage);

    // Destroy the message that was created
    MimeDeleteMessage(hMessage);
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

MimeParseAddress Function

```
INT WINAPI MimeParseAddress(  
    LPCTSTR lpszString,  
    LPCTSTR lpszDomain,  
    LPTSTR lpszAddress,  
    INT nMaxLength  
);
```

The **MimeParseAddress** function parses a string for an email address, copying the address to the specified buffer.

Parameters

lpszString

A pointer to a string which contains the email address to parse.

lpszDomain

A pointer to a string which specifies a default domain for the address. This parameter may be NULL or point to an empty string if no default domain is required.

lpszAddress

A pointer to a string buffer which will contain the parsed email address when the function returns. It is recommended that this buffer be at least 128 characters in length.

nMaxLength

The maximum number of characters which can be copied into the string buffer, including the terminating null character.

Return Value

If the function succeeds, the return value is the length of the address. If the function fails, the return value is MIME_ERROR. To get extended error information, call **MimeGetLastError**.

Remarks

The **MimeParseAddress** function is useful for parsing the email addresses that may be specified in various header fields in the message. In many cases, the addresses have additional comment characters which are not part of the address itself. For example, one common format used is as follows:

```
"User Name" <user@domain.com>
```

In this case, the email address is enclosed in angle brackets and the name outside of the brackets is considered to be a comment which is not part of the address itself. Another common format is:

```
user@domain.com (User Name)
```

In this case, there is the address followed by a comment which is enclosed in parenthesis. The **MimeParseAddress** function recognizes both formats, and when passed either string, would return the following address:

```
user@domain.com
```

If there was no domain specified in the address, that is just a user name was specified, then the value the *lpszDomain* parameter is added to the address.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

MimeParseBuffer Function

```
BOOL WINAPI MimeParseBuffer(  
    HMESSAGE hMessage,  
    LPCTSTR lpszBuffer,  
    INT cbBuffer  
);
```

The **MimeParseBuffer** function parses the contents of the specified buffer and adds the contents to the message.

Parameters

hMessage

Handle to the message.

lpszBuffer

Pointer to a buffer that contains the text to be added to the message contents.

cbBuffer

The length of the specified buffer.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **MimeGetLastError**.

Remarks

This function is useful when the application needs to parse an arbitrary block of text and add it to the specified message. If the buffer contains header fields, the values will be added to the message header. Once the end of the header block is detected, all subsequent text is added to the body of the message.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[MimeImportMessage](#), [MimeImportMessageEx](#), [MimeParseHeader](#)

MimeParseDate Function

```
BOOL WINAPI MimeParseDate(  
    LPCTSTR lpszDate,  
    BOOL bLocalize,  
    LPLONG lpnSeconds,  
    LPLONG lpnTimezone  
);
```

The **MimeParseDate** function parses a message date string, returning the number of seconds since 1 January 1970 and the difference in seconds between the specified timezone and Coordinated Universal Time.

Parameters

lpszDate

A pointer to a string which specifies the date to be parsed. The date string must be in the standard format defined by RFC 822.

bLocalize

A boolean flag which determines if the date should be localized to the current timezone, regardless of the timezone specified in the date string. A non-zero value specifies the timezone for the local system will be used, adjusted for daylight savings time if applicable.

lpnSeconds

A pointer to a long integer which is set to the number of seconds since 1 January 1970 00:00:00 UTC. This date is commonly called the epoch, and is the base date used by the standard C time functions. This pointer may be NULL, in which case the parameter is ignored.

lpnTimezone

A pointer to a long integer which is set to the difference in seconds between the specified date's timezone and coordinated universal time (also known as Greenwich Mean Time). This pointer may be NULL, in which case the parameter is ignored.

Return Value

If the date could be successfully parsed, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **MimeGetLastError**.

Remarks

This is not a general purpose date parsing function, and it may not be capable of parsing dates for a specific locale. The date and time should be in a standard format as outlined in RFC 822, which describes the basic structure of Internet email messages. For a description of the date string format, refer to the **MimeFormatDate** function.

If the date and time does not include any timezone information, Coordinated Universal Time (UTC) will be used by default. This is an important consideration if you use this function to parse input from a user, because in most cases they will not provide a timezone and will assume the date and time they enter is for their current timezone.

The value of the *bLocalize* parameter will only change the number of seconds offset by the current timezone and does not affect the value returned in the *lpnSeconds* parameter. If the date and time is localized, the timezone offset will be adjusted for daylight savings if it was in effect at the time.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

MimeParseHeader Function

```
BOOL WINAPI MimeParseHeader(  
    HMESSAGE hMessage,  
    LPCTSTR LpszBuffer  
);
```

The **MimeParseHeader** function parses a line of text and adds the header and value to the current message.

Parameters

hMessage

Handle to the message.

lpszBuffer

Pointer to a string which contains the header and value to be added to the message.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **MimeGetLastError**.

Remarks

This function is used to parse a line of text that is part of a message header. The string must consist of a header name, followed by a colon, followed by the header value. The header name may only consist of printable characters, and may not contain whitespace (space, tab, carriage return or linefeed characters).

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[MimeImportMessage](#), [MimeParseBuffer](#)

MimePurgeMessageStore Function

```
BOOL WINAPI MimePurgeMessageStore(  
    HMESSAGESTORE hStorage  
);
```

The **MimePurgeMessageStore** function purges all deleted messages from the specified message store.

Parameters

hStorage

Handle to the message store.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **MimeGetLastError**.

Remarks

The **MimePurgeMessageStore** function purges all deleted messages from the message store. If the storage file has been opened in read-only mode or there are no messages marked for deletion, this function will take no action.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmsgv10.lib

See Also

[MimeDeleteStoredMessage](#)

MimeReplaceStoredMessage Function

```
BOOL WINAPI MimeReplaceStoredMessage(  
    HMESSAGESTORE hStorage,  
    LONG nMessageId,  
    HMESSAGE hMessage,  
    DWORD dwReserved  
);
```

The **MimeReplaceStoredMessage** function replaces the specified message in a message store.

Parameters

hStorage

Handle to the message store.

nMessageId

An integer value which specifies the message number that should be replaced.

hMessage

Handle to the message that will be stored.

dwReserved

A reserved parameter. This value must always be zero.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **MimeGetLastError**.

Remarks

The **MimeReplaceStoredMessage** function replaces the specified message with a new message. The message number may be a message that has been previously marked for deletion. It is important to note that the change will not be reflected in the physical storage file until it has been closed. If the application needs to replace messages in the message store, it is recommended that the file be opened for exclusive access using the MIME_STORAGE_LOCK option.

Example

```
HMESSAGE hMessage;  
  
// Compose a new message  
hMessage = MimeComposeMessage(lpszSender,  
                               lpszRecipient,  
                               NULL,  
                               lpszSubject,  
                               lpszMessage,  
                               NULL,  
                               MIME_CHARSET_DEFAULT,  
                               MIME_ENCODING_DEFAULT);  
  
if (hMessage != INVALID_MESSAGE)  
{  
    HMESSAGESTORE hStorage;  
    LONG nLastMessage;  
    BOOL bResult;  
  
    // Open the message storage file
```

```

hStorage = MimeOpenMessageStore(lpszFileName, MIME_STORAGE_WRITE);

if (hStorage == INVALID_MESSAGESTORE)
{
    // Delete the message and return if we are unable to
    // open the storage file
    MimeDeleteMessage(hMessage);
    return;
}

if (MimeGetStoredMessageCount(hStorage, &nLastMessage) < 1)
{
    // No messages are stored in the file
    MimeCloseMessageStore(hStorage);
    MimeDeleteMessage(hMessage);
    return;
}

// Replace the last message in the message store
bResult = MimeReplaceStoredMessage(hStorage, nLastMessage, hMessage, 0);

if (bResult == FALSE)
{
    // We were unable to replace the message
}

// Close the message store
MimeCloseMessageStore(hStorage);

// Destroy the message that was created
MimeDeleteMessage(hMessage);
}

```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmsgv10.lib

MimeResetMessage Function

```
BOOL WINAPI MimeResetMessage(  
    HMESSAGE hMessage  
);
```

The **MimeResetMessage** function clears the header and body of the specified message, and deletes all message parts.

Parameters

hMessage

Handle to the message.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **MimeGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmsgv10.lib

See Also

[MimeCreateMessage](#), [MimeDeleteMessage](#)

MimeSetExportOptions Function

```
BOOL WINAPI MimeSetExportOptions(  
    HMESSAGE hMessage,  
    DWORD dwOptions  
);
```

The **MimeSetExportOptions** function specifies a bitmask that describes current message export options.

Parameters

hMessage

Handle to the message.

dwOptions

Mask of attribute options. The mask is a combination of the following values:

Constant	Description
MIME_OPTION_DEFAULT	The default export options. The headers for the message are written out in a specific consistent order, with custom headers written to the end of the header block regardless of the order in which they were set or imported from another message. If the message contains Bcc, Received, Return-Path, Status or X400-Received header fields, they will not be exported.
MIME_OPTION_KEEPOORDER	The original order in which the message header fields were set or imported are preserved when the message is exported.
MIME_OPTION_ALLHEADERS	All headers, including the Bcc, Received, Return-Path, Status and X400-Received header fields will be exported. Normally these headers are not exported because they are only used by the mail transport system. This option can be useful when exporting a message to be stored on the local system, but should not be used when exporting a message to be delivered to another user.
MIME_OPTION_NOHEADERS	When exporting a message, the main header block will not be included. This can be useful when creating a multipart message for services which expect MIME formatted data, such as HTTP POST requests. This option should never be used for email messages being submitted using SMTP.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **MimeGetLastError**.

Remarks

By default, the Received and Return-Path headers are not exported. In addition, the order of the

headers in an exported message is undefined. This is reasonable behavior for most mail clients, but may not be appropriate for applications which need access to all of the header fields.

Example

```
MimeSetExportOptions(hMessage, MIME_EXPORT_OPTIONS_ALL |
                    MIME_EXPORT_OPTIONS_KEEP_ORDER);

if (MimeImportMessage(hMessage, lpszFileName))
{
    // Process the message and make any modifications
    // then write the message back out, preserving all
    // of the headers in their original order
    bResult = MimeExportMessage(hMessage, lpszFileName);
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

MimeSetFileContentType Function

```
BOOL WINAPI MimeSetFileContentType(  
    HMESSAGE hMessage,  
    UINT nContentType,  
    LPCTSTR LpszSubtype,  
    LPCTSTR LpszExtension  
);
```

The **MimeSetFileContentType** function associates a per-message content type with a given file name extension. This association is specific to the message, and is not shared by other messages that may be opened by the process.

Parameters

hMessage

Handle to the message.

nContentType

An identifier which specifies the primary content type. It may be one of the following values:

Constant	Description
MIME_CONTENT_UNKNOWN	The default content type for the specified extension should be used. This value should only be used to delete a previously defined content type.
MIME_CONTENT_APPLICATION	The file content is application specific. Examples of this type of file would be a Microsoft Word document or an executable program. This is also the default type for files which have an unrecognized file name extension and contain binary data.
MIME_CONTENT_AUDIO	The file is an audio file in one of several standard formats. Examples of this type of file would be a Windows (.wav) file or MPEG3 (.mp3) file.
MIME_CONTENT_IMAGE	The file is an image file in one of several standard formats. Examples of this type of file would be a GIF or JPEG image file.
MIME_CONTENT_TEXT	The file is a text file. This is also the default type for files which have an unrecognized file name extension and contain only printable text data.
MIME_CONTENT_VIDEO	The file is a video file in one of several standard formats. Examples of this type of file would be a Windows (.avi) or Quicktime (.mov) video file.

lpszSubtype

A pointer to a string which specifies the MIME subtype. This parameter may be NULL if the content type association is being deleted.

lpszExtension

A pointer to a string which specifies the file name extension that will be associated with the MIME content type.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **MimeGetLastError**.

Remarks

The **MimeSetFileContentType** function allows an application to specify a content type for a given file extension, and is typically used to define custom content types for file attachments. The content type will override any default content types associated with the extension, as well as allow new content types to be defined for application-specific files.

Example

In the following example, the file extension ".dat" is associated with a custom content type, a file is attached to the message and then the custom content type is deleted. Note that because the primary content type designates the file as an application specific (non-text) file, it will be automatically encoded when attached to a message:

```
if (MimeSetFileContentType(hMessage, MIME_CONTENT_APPLICATION, "octet-stream",
"dat"))
{
    bResult = MimeAttachFile(hMessage, lpszFileName, MIME_ATTACH_DEFAULT);
    MimeSetFileContentType(hMessage, MIME_CONTENT_UNKNOWN, NULL, "dat");
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[MimeAttachData](#), [MimeAttachFile](#), [MimeGetFileContentType](#)

MimeSetLastError Function

```
VOID WINAPI MimeSetLastError(  
    DWORD dwErrorCode  
);
```

The **MimeSetLastError** function sets the last error code for the current thread.

Parameters

dwErrorCode

Specifies the last error code for the caller. A value of zero clears the last error code.

Return Value

None.

Remarks

Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value error code such as FALSE, NULL, INVALID_MESSAGE or MIME_ERROR. Those functions which call **MimeSetLastError** when they succeed are noted on the function reference page.

Applications can retrieve the value saved by this function by using the **MimeGetLastError** function. The use of **MimeGetLastError** is optional. An application can call it to find out the specific reason for a function failure.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmsgv10.lib

See Also

MimeSetMessageDate Function

```
BOOL WINAPI MimeSetMessageDate(  
    HMESSAGE hMessage,  
    LPCTSTR lpszDate,  
    BOOL bLocalize  
);
```

The **MimeSetMessageDate** function sets the date and time in the header for the specified message.

Parameters

hMessage

Handle to the message.

lpszDate

Pointer to a string which specifies the date and time. If this parameter specifies a zero-length string or a NULL pointer, the current date and time will be used.

bLocalize

Boolean flag that specifies the date and time should be localized for the current timezone.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **MimeGetLastError**.

Remarks

The date string should be in a standard format as outlined in RFC 822, the document which describes the basic structure of Internet email messages. For a description of the date string format, refer to the **MimeFormatDate** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

MimeSetMessageHeader Function

```
BOOL WINAPI MimeSetMessageHeader(  
    HMESSAGE hMessage,  
    LPCTSTR LpszHeader,  
    LPCTSTR LpszValue  
);
```

The **MimeSetMessageHeader** function adds or updates a header field in the specified message.

Parameters

hMessage

Handle to the message.

lpszHeader

Pointer to a string which specifies the header field that will be added or updated.

lpszValue

Pointer to a string which specifies the value for the header field. This pointer may be NULL, which causes the header field to be removed from the message.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero.

To get extended error information, call **MimeGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

MimeSetMessageHeaderEx Function

```
BOOL WINAPI MimeSetMessageHeaderEx(  
    HMESSAGE hMessage,  
    INT nMessagePart,  
    LPCTSTR lpszHeader,  
    LPCTSTR lpszValue,  
    DWORD dwReserved  
);
```

The **MimeSetMessageHeaderEx** function adds or updates a header field in the specified message.

Parameters

hMessage

Handle to the message.

nMessagePart

An integer value which specifies which part of the message the header should be set or modified in. A value of zero sets a header value in the main message header block, while a value greater than zero sets the header value in that specific part of a multipart message. A value of -1 specifies that the header value should be set in the current message part.

lpszHeader

Pointer to a string which specifies the header field that will be added or updated.

lpszValue

Pointer to a string which specifies the value for the header field. This pointer may be NULL, which causes the header field to be removed from the message.

dwReserved

A reserved parameter. This value should always be zero.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **MimeGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

MimeSetMessagePart Function

```
INT WINAPI MimeSetMessagePart(  
    HMESSAGE hMessage,  
    INT nNewPart  
);
```

The **MimeSetMessagePart** function sets the current message part index for the specified message.

Parameters

hMessage

Handle to the message.

nNewPart

The new message part index. A value of zero specifies the main message part.

Return Value

If the function succeeds, the return value is the previous message part index. If the function fails, the return value is MIME_ERROR. To get extended error information, call **MimeGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

MimeSetMessageText Function

```
LONG WINAPI MimeSetMessageText(  
    HMESSAGE hMessage,  
    LONG nOffset,  
    LPCTSTR lpszText  
);
```

The **MimeSetMessageText** function copies the specified text into the body of the current message part.

Parameters

hMessage

Handle to the message.

nOffset

The offset into the body of the message part. A value of -1 specifies that the text will be appended to the message body.

lpszText

A pointer to a string which specifies the text to be copied to the current message part at the given offset.

Return Value

If the function succeeds, the return value is the number of bytes copied into the message. A return value of zero indicates that no text could be copied into the current message part. To get extended error information, call **MimeGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

MimeSetMessageVersion Function

```
BOOL WINAPI MimeSetMessageVersion(  
    HMESSAGE hMessage,  
    LPCTSTR LpszVersion  
);
```

Parameters

hMessage

Handle to the message.

lpszVersion

Pointer to a string which specifies the MIME version. A value of NULL sets the version to the default value of 1.0.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **MimeGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

MimeStoreMessage Function

```
LONG WINAPI MimeStoreMessage(  
    HMESSAGESTORE hStorage,  
    HMESSAGE hMessage,  
    DWORD dwReserved  
);
```

The **MimeStoreMessage** function stores the specified message in a message store.

Parameters

hStorage

Handle to the message store.

hMessage

Handle to the message that will be stored.

dwReserved

A reserved parameter. This value must always be zero.

Return Value

If the function succeeds, the return value is the message number for the message that was just stored. If the function fails, the return value is `MIME_ERROR`. To get extended error information, call **MimeGetLastError**.

Remarks

The **MimeStoreMessage** function will always append the specified message to the storage file. If you want to replace a message in the message store, you should use the **MimeReplaceStoredMessage** function.

Example

```
HMESSAGE hMessage;  
  
// Compose a new message  
hMessage = MimeComposeMessage(lpszSender,  
                               lpszRecipient,  
                               NULL,  
                               lpszSubject,  
                               lpszMessage,  
                               NULL,  
                               MIME_CHARSET_DEFAULT,  
                               MIME_ENCODING_DEFAULT);  
  
if (hMessage != INVALID_MESSAGE)  
{  
    HMESSAGESTORE hStorage;  
  
    // Open the message storage file  
    hStorage = MimeOpenMessageStore(lpszFileName, MIME_STORAGE_WRITE);  
  
    if (hStorage == INVALID_MESSAGESTORE)  
    {  
        // Delete the message and return if we are unable to  
        // open the storage file  
        MimeDeleteMessage(hMessage);  
    }  
}
```

```
        return;
    }

    // Store a copy of the message in the message store
    nMessageId = MimeStoreMessage(hStorage, hMessage, 0);

    if (nMessageId == MIME_ERROR)
    {
        // We were unable to store the message
    }

    // Close the message store
    MimeCloseMessageStore(hStorage);

    // Destroy the message that was created
    MimeDeleteMessage(hMessage);
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmsgv10.lib

See Also

MimeUninitialize Function

```
VOID WINAPI MimeUninitialize();
```

The **MimeUninitialize** function terminates the use of the library.

Parameters

There are no parameters.

Return Value

None.

Remarks

An application is required to perform a successful **MimeInitialize** call before it can call any of the other the library functions. When it has completed the use of library, the application must call **MimeUninitialize** to allow the library to free any resources allocated on behalf of the process. Any pending blocking or asynchronous calls in this process are canceled without posting any notification messages, and all sockets that were opened by the process are closed.

There must be a call to **MimeUninitialize** for every successful call to **MimeInitialize** made by a process. In a multithreaded environment, operations for all threads in the client are terminated.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmsgv10.lib

Mail Message Data Structures

- INITDATA

INITDATA Structure

This structure contains information about the SocketTools library when the initialization function returns.

```
typedef struct _INITDATA
{
    DWORD      dwSize;
    DWORD      dwVersionMajor;
    DWORD      dwVersionMinor;
    DWORD      dwVersionBuild;
    DWORD      dwOptions;
    DWORD_PTR  dwReserved1;
    DWORD_PTR  dwReserved2;
    TCHAR      szDescription[128];
} INITDATA, *LPINITDATA;
```

Members

dwSize

Size of this structure. This structure member must be set to the size of the structure prior to calling the initialization function. Failure to do so will cause the function to fail.

dwVersionMajor

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the major version number for the library.

dwVersionMinor

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the minor version number for the library.

dwVersionBuild

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the build number for the library.

dwOptions

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

dwReserved1

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

dwReserved2

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

szDescription

A null terminated string which describes the library.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Unicode: Implemented as Unicode and ANSI versions.

Message Character Sets

Constant	Value	Name	Code Page	Description
MIME_CHARSET_USASCII	1	us-ascii	20127	A character set which defines 7-bit printable characters with values ranging from 20h to 7Eh. An application that uses this character set has the broadest compatibility with most mail servers (MTAs) because it does not require the server to handle 8-bit characters correctly when the message is delivered.
MIME_CHARSET_ISO8859_1	2	iso-8859-1	28591	A character set for most western European languages such as English, French, Spanish and German. This character set is also commonly referred to as Latin-1. This character set is similar to Windows code page 1252 (Windows-1252), however there are differences such as the Euro symbol.
MIME_CHARSET_ISO8859_2	3	iso-8859-2	28592	A character set for most central and eastern European languages such as Czech, Hungarian, Polish and Romanian. This character set is also commonly referred to as Latin-2. This character set is similar to Windows code page 1250, however the characters are arranged differently.
MIME_CHARSET_ISO8859_3	12	iso-8859-3	28593	A character set for southern European languages such as Maltese and Esperanto. This character set was also used with the Turkish language, but it was superseded by ISO 8859-9 which is the preferred character set for Turkish. This character set is not widely used in mail messages and it is recommended that you use UTF-8 instead.
MIME_CHARSET_ISO8859_4	13	iso-8859-4	28594	A character set for northern European languages such as

				Latvian, Lithuanian and Greenlandic. This character set is not widely used in mail messages and it is recommended that you use UTF-8 instead.
MIME_CHARSET_ISO8859_5	4	iso-8859-5	28595	A character set for Cyrillic languages such as Russian, Bulgarian and Serbian. This character set was never widely adopted and most mail messages use either KOI8 or UTF-8 encoding.
MIME_CHARSET_ISO8859_6	5	iso-8859-6	28596	A character set for Arabic languages. Note that the application is responsible for displaying text that uses this character set. In particular, any display engine needs to be able to handle the reverse writing direction and analyze the context of the message to correctly combine the glyphs.
MIME_CHARSET_ISO8859_7	6	iso-8859-7	28597	A character set for the Greek language. This character set is also commonly referred to as Latin/Greek. This character set is no longer widely used and has largely been replaced with UTF-8 which provides more complete coverage of the Greek alphabet.
MIME_CHARSET_ISO8859_8	7	iso-8859-8	28598	A character set for the Hebrew language. Note that similar to Arabic, Hebrew uses a reverse writing direction. An application which displays this character should be capable of processing bi-directional text where a single message may include both right-to-left and left-to-right languages, such as Hebrew and English. In most cases it is recommended that you use UTF-8 instead of this character set.
MIME_CHARSET_ISO8859_9	8	iso-8859-9	28599	A character set for the Turkish language. This character set is

				also commonly referred to as Latin-5. This character set is nearly identical to ISO 8859-1, except that it replaces certain Icelandic characters with Turkish characters.
MIME_CHARSET_ISO8859_10	14	iso-8859-10	28600	A character set for the Danish, Icelandic, Norwegian and Swedish languages. This character set is also commonly referred to as Latin-6 and is similar to ISO 8859-4.
MIME_CHARSET_ISO8859_13	15	iso-8859-13	28603	A character set for Baltic languages. This character set is also commonly referred to as Latin-7. This character set is similar to ISO 8859-4, except it adds certain Polish characters and does not support Nordic languages.
MIME_CHARSET_ISO8859_14	16	iso-8859-14	28604	A character set for Gaelic languages such as Irish, Manx and Scottish Gaelic. This character set is also commonly referred to as Latin-8. This character set replaced ISO 8859-12 which was never fully implemented.
MIME_CHARSET_ISO8859_15	17	iso-8859-15	28605	A character set for western European languages. This character set is also commonly referred to as Latin-9 and is nearly identical to ISO8859-1 except that it replaces lesser-used symbols with the Euro sign and some letters.
MIME_CHARSET_ISO2022_JP	18	iso-2022-jp	50222	A multi-byte character encoding for Japanese that is widely used with mail messages. This is a 7-bit encoding where all characters start with ASCII and uses escape sequences to switch to the double-byte character sets.
MIME_CHARSET_ISO2022_KR	19	iso-2022-kr	50225	A multi-byte character encoding for Korean which encodes both ASCII and Korean

				double-byte characters. This is a 7-bit encoding which uses the shift in and shift out control characters to switch to the double-byte character set.
MIME_CHARSET_ISO2022_CN	20	x-cp50227	50227	A multi-byte character encoding for Simplified Chinese which encodes both ASCII and Chinese double-byte characters. This is a 7-bit encoding which uses the shift in and shift out control characters to switch to the double-byte character set.
MIME_CHARSET_KOI8R	21	koi8-r	20866	A character set for Russian using the Cyrillic alphabet. This character set also covers the Bulgarian language. Most mail messages in the Russian language use this character set or UTF-8 instead of ISO 8859-5, which was never widely adopted.
MIME_CHARSET_KOI8U	22	koi8-u	21866	A character set for Ukrainian using the Cyrillic alphabet. This character set is similar to the KOI8-R character set, but replaces certain symbols with Ukrainian letters. Most mail messages in the Ukrainian language use this character set or UTF-8 instead of ISO 8859-5, which was never widely adopted.
MIME_CHARSET_GB2312	23	x-cp20936	20936	A multi-byte character encoding which can represent ASCII and simplified Chinese characters. It has been superseded by GB18030, however it remains widely used in China.
MIME_CHARSET_GB18030	24	gb18030	54936	A Unicode transformation format which can represent all Unicode code points and supports both simplified and traditional Chinese characters. It is backwards compatible with GB2312 and supersedes that

				character set.
MIME_CHARSET_BIG5	25	big5	950	A multi-byte character set that supports both ASCII characters and traditional Chinese characters. It is widely used in Taiwan, Hong Kong and Macau. It is no longer commonly used in China, which has developed GB18030 as a standard encoding. Microsoft's implementation of Big5 on Windows does not support all of the extensions and is missing certain code points.
MIME_CHARSET_UTF7	9	utf-7	65000	A Unicode transformation format that uses variable-length character encoding to represent Unicode text as a stream of ASCII characters that are safe to transport between mail servers that only support 7-bit printable characters. It is primarily used as an alternative to UTF-8 when quoted-printable or base64 encoding is not desired.
MIME_CHARSET_UTF8	10	utf-8	65001	A Unicode transformation format that uses multi-byte character sequences to represent Unicode text. It is backwards compatible with the ASCII character set, however because it uses 8-bit text, it is recommended that you use either quoted-printable or base64 encoding to ensure compatibility with mail servers that do not support 8-bit characters.
MIME_CHARSET_UTF16	11	utf-16le	N/A	A 16-bit Unicode format that represents each character as a 16-bit value in little endian byte order. This character set is not widely used in mail messages and it is recommended that you use UTF-8 instead. UTF-16 characters in big endian byte order are not supported.

Remarks

When composing a new message, it is recommended that you always use UTF-8 as the character set encoding which ensures broad compatibility with most applications. The other character sets are primarily used when parsing messages generated by other applications. Internally, all message headers and text are processed as UTF-8. If you use the ANSI version of the these functions, header values and message text will always be returned to your application as UTF-8 encoded Unicode, regardless of the original character set used in the message.

In addition to the character sets listed above, the library will recognize additional character sets which correspond to specific Windows code pages, as well several variants. These additional character sets are included for compatibility with other applications; they are not defined because they should not be used when composing new messages.

It is important to note that while certain Windows character sets are similar to standard ISO character sets, they are not identical. For example, although the Windows-1252 character set is nearly identical to ISO 8859-1, they are not interchangeable. Some legacy applications make the error of representing Windows ANSI character sets as 8-bit ISO character sets, which can result in errors when converting them to Unicode. This is something to be aware of when encoding and decoding text generated by older applications. Before the widespread adoption of UTF-8, it was particularly common for legacy Windows mail clients to default to using Windows-1252 for text and label it as using ISO 8859-1.

Although the library supports UTF-16, it is recommended you use UTF-8 instead. Text which uses UTF-16 will always be base64 encoded, and some mail clients may not recognize it as a valid character set. If the message does not specify if big endian or little endian byte order is used, the library will default to little endian. When UTF-16 is used when composing a new message, it will always use little endian byte order.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Network News Transfer Protocol Library

Download and submit articles to a news server.

Reference

- [Functions](#)
- [Data Structures](#)
- [Error Codes](#)

Library Information

File Name	CSNWSV10.DLL
Version	10.0.1468.2518
LibID	F37CEE4C-BAFE-43B9-B224-80975DF553B2
Import Library	CSNWSV10.LIB
Dependencies	None
Standards	RFC 977, RFC 2980

Overview

The Network News Transfer Protocol (NNTP) is used with servers that provide news services. This is similar in functionality to bulletin boards or message boards, where topics are organized hierarchically into groups, called newsgroups. Users can browse and search for messages, called news articles, which have been posted by other users. On many servers, they can also post their own articles which can be read by others. The largest collection of public newsgroups available is called USENET, a world-wide distributed discussion system. In addition, there are a large number of smaller news servers. For example, Catalyst Development operates a news server which functions as a forum for technical questions and announcements.

The SocketTools library provides a comprehensive interface for accessing newsgroups, retrieving articles and posting new articles. In combination with the Mail Message library to process the news articles, SocketTools can be used to integrate newsgroup access with an existing email application, or you can implement your own full-featured newsgroup client.

This library supports secure connections using the standard SSL and TLS protocols.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). If you are using Visual C++ 6.0 it is required that you have Service Pack 6 (SP6) installed. You should install all updates for your development tools and have the current Windows SDK installed. The minimum recommended version of Visual Studio is Visual Studio 2010.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are using Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. It is recommended that you install the current service pack and all critical updates available for your version of the operating system.

This product includes both 32-bit and 64-bit libraries. Native 64-bit CPU support requires the 64-bit version of Windows 7 or later versions of the Windows operating system.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

Network News Transfer Protocol Functions

Function	Description
NntpAsyncConnect	Establish an asynchronous connection to the specified server
NntpAttachThread	Attach the specified client handle to another thread
NntpAuthenticate	Authenticate the specified user on the news server
NntpCancel	Cancel the current blocking operation
NntpCloseArticle	Close the article being posted to the current newsgroup
NntpCommand	Send a command to the server
NntpConnect	Connect to the specified server
NntpCreateArticle	Create a new article in the current newsgroup
NntpCreateSecurityCredentials	Create a new security credentials structure
NntpDeleteSecurityCredentials	Delete a previously created security credentials structure
NntpDisableEvents	Disable asynchronous event notification
NntpDisableTrace	Disable logging of socket function calls to the trace log
NntpDisconnect	Disconnect from the current server
NntpEnableEvents	Enable asynchronous event notification
NntpEnableTrace	Enable logging of socket function calls to a file
NntpEventProc	Callback function that processes events generated by the client
NntpFreezeEvents	Suspend asynchronous event processing
NntpGetArticle	Retrieve an article from the server and store the contents in a local buffer
NntpGetArticleEx	Retrieve an article from the server with support for large article IDs
NntpGetArticleByMessageId	Retrieve an article from the server using a message ID and store the contents in a local buffer
NntpGetArticleHeaders	Return the contents of the specified article header
NntpGetArticleHeadersEx	Return the contents of the specified article header with support for large article IDs
NntpGetArticleMessageId	Return the message identifier for the specified article
NntpGetArticleMessageIdEx	Return the message identifier for the specified article with support for large article IDs
NntpGetArticleRange	Return the first and last article number for the current group
NntpGetArticleRangeEx	Return the first and last article number for the current group with support for large article IDs
NntpGetArticleSize	Return the size of the specified news article in bytes
NntpGetArticleSizeEx	Return the size of the specified article with support for large article IDs
NntpGetCurrentArticle	Return the current article number for the selected group
NntpGetCurrentArticleEx	Return the current article number for the selected group with support for large article IDs
NntpGetCurrentDate	Return the current date and time
NntpGetErrorString	Return a description for the specified error code
NntpGetFirstArticle	Return the first available article in the currently selected newsgroup
NntpGetFirstArticleEx	Return the first available article in the currently selected newsgroup with support for large article IDs
NntpGetFirstGroup	Return the first available newsgroup from the server
NntpGetFirstGroupEx	Return the first available newsgroup from the server with support for large article IDs
NntpGetGroupName	Return the name of the currently selected newsgroup
NntpGetGroupTitle	Return a description of the currently selected newsgroup
NntpGetLastError	Return the last error code
NntpGetMessageIdArticle	Return the article number for the specified message identifier

NntpGetMessageIdArticleEx	Return the article number for the specified message with support for large article IDs
NntpGetMultiLine	Return the client multi-line output flag
NntpGetNextArticle	Return the next available article from the current newsgroup
NntpGetNextArticleEx	Return the next available article from the current newsgroup with support for large article IDs
NntpGetNextGroup	Return the next available newsgroup from the server
NntpGetNextGroupEx	Return the next available newsgroup from the server with support for large article IDs
NntpGetResultCode	Return the result code from the previous command
NntpGetResultString	Return the result string from the previous command
NntpGetSecurityInformation	Return security information about the current client connection
NntpGetStatus	Return the current client status
NntpGetTimeout	Return the number of seconds until an operation times out
NntpGetTransferStatus	Return data transfer statistics
NntpGetTransferStatusEx	Return data transfer statistics with support for large article IDs
NntpInitialize	Initialize the library and validate the specified license key at runtime
NntpIsBlocking	Determine if the client is blocked, waiting for information
NntpIsConnected	Determine if the client is connected to the server
NntpIsReadable	Determine if data can be read from the server
NntpIsWritable	Determine if data can be written to the server
NntpListArticles	Return a list of articles in the currently selected newsgroup
NntpListArticlesEx	Return a list of articles in the currently selected newsgroup with support for large article IDs
NntpListGroup	Return a list of newsgroups maintained by the server
NntpListNewGroups	Return a list of newsgroups created since a specified date
NntpOpenArticle	Open the specified article in the current newsgroup
NntpOpenArticleEx	Open the specified article in the current newsgroup with support for large article IDs
NntpOpenArticleByMessageId	Open the specified article by message ID in the current newsgroup
NntpOpenNextArticle	Open the next available article
NntpOpenPreviousArticle	Open the previous article
NntpPostArticle	Post a new article to the news server
NntpRead	Read data returned by the news server
NntpRegisterEvent	Register an event callback function
NntpReset	Reset the client
NntpSelectGroup	Select the specified newsgroup to retrieve articles from
NntpSetLastError	Set the last error code
NntpSetMultiLine	Set the client multi-line output flag
NntpSetTimeout	Set the number of seconds until an operation times out
NntpStoreArticle	Retrieve an article and store the contents in a local file
NntpStoreArticleEx	Retrieve an article and store the contents in a local file with support for large article IDs
NntpUninitialize	Terminate use of the library by the application
NntpWrite	Write data to the news server

NntpAsyncConnect Function

```
HCLIENT WINAPI NntpAsyncConnect(  
    LPCTSTR lpszRemoteHost,  
    UINT nRemotePort,  
    UINT nTimeout,  
    DWORD dwOptions,  
    LPSECURITYCREDENTIALS LpCredentials,  
    HWND hEventWnd,  
    UINT uEventMsg  
);
```

The **NntpAsyncConnect** function is used to establish a connection with the server.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

The application should create a background worker thread and establish a connection by calling **NntpConnect** within that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each client session.

Parameters

lpszRemoteHost

A pointer to the name of the server to connect to; this may be a fully-qualified domain name or an IP address.

nRemotePort

The port number the server is listening on; a value of zero specifies that the default port number should be used.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
NNTP_OPTION_NONE	No connection options specified. A standard connection to the server will be established using the specified host name and port number.
NNTP_OPTION_TUNNEL	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established.
NNTP_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The

	server certificate will not be validated and the connection will always be permitted. This option only affects connections using either the SSL or TLS protocols.
NNTP_OPTION_SECURE	This option specifies the client should attempt to establish a secure connection with the server. Note that the server must support secure connections using either the SSL or TLS protocol.
NNTP_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
NNTP_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
NNTP_OPTION_FREETHREAD	This option specifies the handle returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the handle is synchronized across multiple threads.

lpCredentials

Pointer to credentials structure [SECURITYCREDENTIALS](#). This parameter is only used if the `NNTP_OPTION_SECURE` option is specified for the connection. This parameter may be `NULL`, in which case no client credentials will be provided to the server. If client credentials are required, the fields *dwSize*, *lpszCertStore*, and *lpszCertName* must be defined, while other fields may be left undefined. Set *dwSize* to the size of the **SECURITYCREDENTIALS** structure.

hEventWnd

The handle to the event notification window. This window receives messages which notify the client of various asynchronous socket events that occur.

uEventMsg

The message identifier that is used when an asynchronous socket event occurs. This value should be greater than `WM_USER` as defined in the Windows header files.

Return Value

If the function succeeds, the return value is a handle to a client session. If the function fails, the return value is `INVALID_CLIENT`. To get extended error information, call **NntpGetLastError**.

Remarks

The *dwOptions* argument can be used to specify the threading model that is used by the library when a connection is established. By default, the handle is initially attached to the thread that created it. From that point on, until the it is released, only the owner may call functions using that handle. The ownership of the handle may be transferred from one thread to another using the **NntpAttachThread** function.

Specifying the NNTP_OPTION_FREETHREAD option enables any thread to call any function using the handle, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the handle is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same handle.

When a message is posted to the notification window, the low word of the *lParam* parameter contains the event identifier. The high word of *lParam* contains the low word of the error code, if an error has occurred. The *wParam* parameter contains the client handle. One or more of the following event identifiers may be sent:

Constant	Description
NNTP_EVENT_CONNECT	The connection to the server has completed. The high word of the <i>lParam</i> parameter should be checked, since this notification message will be posted if an error has occurred.
NNTP_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
NNTP_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
NNTP_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
NNTP_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
NNTP_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.
NNTP_EVENT_COMMAND	A command has been issued by the client and the server response has been received and processed. This event can be used to log the result codes and messages returned by the server in response to actions taken by the client.
NNTP_EVENT_LISTARTICLE	The client is retrieving a list of articles from the server and information about another article has been processed. The client

	should use this event to retrieve the next available article from the server.
NNTP_EVENT_LASTARTICLE	The client is retrieving a list of articles from the server and all of the available articles have been processed. This event is generated when there are no further articles.
NNTP_EVENT_LISTGROUP	The client is retrieving a list of newsgroups from the server and information about another group has been processed. The client should use this event to retrieve the next available newsgroup from the server.
NNTP_EVENT_LASTGROUP	The client is retrieving a list of newsgroups from the server and all of the available groups have been processed. This event is generated when there are no further newsgroups.
NNTP_EVENT_PROGRESS	The client is in the process of sending or receiving data from the server. This event is called periodically during a transfer so that the client can update any user interface components such as a status control or progress bar.

To cancel asynchronous notification and return the client to a blocking mode, use the **NntpDisableEvents** function.

It is recommended that you only establish an asynchronous connection if you understand the implications of doing so. In most cases, it is preferable to create a synchronous connection and create threads for each additional session if more than one active client session is required.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnwsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

NntpAttachThread Function

```
DWORD WINAPI NntpAttachThread(  
    HCLIENT hClient  
    DWORD dwThreadId  
);
```

The **NntpAttachThread** function attaches the specified client handle to another thread.

Parameters

hClient

Handle to the client session.

dwThreadId

The ID of the thread that will become the new owner of the handle. A value of zero specifies that the current thread should become the owner of the client handle.

Return Value

If the function succeeds, the return value is the thread ID of the previous owner. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Remarks

When a client handle is created, it is associated with the current thread that created it. Normally, if another thread attempts to perform an operation using that handle, an error is returned since it does not own the handle. This is used to ensure that other threads cannot interfere with an operation being performed by the owner thread. In some cases, it may be desirable for one thread in a client application to create the client handle, and then pass that handle to another worker thread. The **NntpAttachThread** function can be used to change the ownership of the handle to the new worker thread. By preserving the return value from the function, the original owner of the handle can be restored before the worker thread terminates.

This function should be called by the new thread immediately after it has been created, and if the new thread does not release the handle itself, the ownership of the handle should be restored to the parent thread before it terminates. Under no circumstances should **NntpAttachThread** be used to forcibly release a handle allocated by another thread while a blocking operation is in progress. To cancel an operation, use the **NntpCancel** function and then release the handle after the blocking function exits and control is returned to the current thread.

Note that the *dwThreadId* parameter is presumed to be a valid thread ID and no checks are performed to ensure that the thread actually exists. Specifying an invalid thread ID will orphan the handle until the **NntpUninitialize** function is called.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csnwsv10.lib

See Also

[NntpCancel](#), [NntpAsyncConnect](#), [NntpConnect](#), [NntpDisconnect](#), [NntpUninitialize](#)

NntpAuthenticate Function

```
INT WINAPI NntpAuthenticate(  
    HCLIENT hClient,  
    LPCTSTR lpszUserName,  
    LPCTSTR lpszPassword  
);
```

The **NntpAuthenticate** function is used to authenticate access to the news server. Not all news servers require authentication by the client.

Parameters

hClient

Handle to the client session.

lpszUserName

Pointer to a string which specifies the user name required for authentication on the news server.

lpszPassword

Pointer to a string which specifies the password required for authentication on the news server.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Remarks

This function should only be called if the server requires authentication. Two authentication methods, "original" and "simple" authentication, are recognized by the library.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnwsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

NntpCancel Function

```
INT WINAPI NntpCancel(  
    HCLIENT hClient  
);
```

The **NntpCancel** function cancels any outstanding blocking operation in the client, causing the blocking function to fail. The application may then retry the operation or terminate the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Remarks

When the **NntpCancel** function is called, the blocking function will not immediately fail. An internal flag is set which causes the blocking operation to exit with an error. This means that the application cannot cancel an operation and immediately perform some other operation. Instead it must allow the calling stack to unwind, returning back to the blocking operation before making any further function calls.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnwsv10.lib

See Also

[NntpIsBlocking](#), [NntpRead](#), [NntpReset](#), [NntpWrite](#)

NntpCloseArticle Function

```
INT WINAPI NntpCloseArticle(  
    HCLIENT hClient  
);
```

The **NntpCloseArticle** function closes the current article that has been opened or created.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Remarks

If an article is being created, this function actually submits the article to the server. Note that the client application is responsible for generating the message headers as well as the body of the message. News articles conform to the same general characteristics of an email message.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnwsv10.lib

See Also

NntpCommand Function

```
INT WINAPI NntpCommand(  
    HCLIENT hClient,  
    LPCTSTR lpszCommand,  
    LPCTSTR lpszParameter  
);
```

The **NntpCommand** function sends a command to the server and returns the result code back to the caller. This function is typically used for site-specific commands not directly supported by the API.

Parameters

hClient

Handle to the client session.

lpszCommand

The command which will be executed by the server.

lpszParameter

An optional command parameter. If the command requires more than one parameter, then they should be combined into a single string, with a space separating each parameter. If the command does not accept any parameters, this value may be NULL.

Return Value

If the function succeeds, the return value is the result code returned by the server. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Remarks

A list of valid commands can be found in the technical specification for the protocol. Many servers will list supported commands when the HELP command is used.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csnwsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

NntpConnect Function

```
HCLIENT WINAPI NntpConnect(  
    LPCTSTR lpszRemoteHost,  
    UINT nRemotePort,  
    UINT nTimeout,  
    DWORD dwOptions,  
    LPSECURITYCREDENTIALS LpCredentials  
);
```

The **NntpConnect** function is used to establish a connection with the server.

Parameters

lpszRemoteHost

A pointer to the name of the server to connect to; this may be a fully-qualified domain name or an IP address.

nRemotePort

The port number the server is listening on; a value of zero specifies that the default port number should be used.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
NNTP_OPTION_NONE	No connection options specified. A standard connection to the server will be established using the specified host name and port number.
NNTP_OPTION_TUNNEL	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established.
NNTP_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using either the SSL or TLS protocols.
NNTP_OPTION_SECURE	This option specifies the client should attempt to establish a secure connection with the server. Note that the server must support secure connections using either the SSL or TLS protocol.
NNTP_OPTION_SECURE_FALLBACK	This option specifies the client should permit the

	use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
NNTP_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
NNTP_OPTION_FREETHREAD	This option specifies the handle returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the handle is synchronized across multiple threads.

lpCredentials

Pointer to credentials structure [SECURITYCREDENTIALS](#). This parameter is only used if the `NNTP_OPTION_SECURE` option is specified for the connection. This parameter may be `NULL`, in which case no client credentials will be provided to the server. If client credentials are required, the fields *dwSize*, *lpzCertStore*, and *lpzCertName* must be defined, while other fields may be left undefined. Set *dwSize* to the size of the `SECURITYCREDENTIALS` structure.

Return Value

If the function succeeds, the return value is a handle to a client session. If the function fails, the return value is `INVALID_CLIENT`. To get extended error information, call **NntpGetLastError**.

Remarks

To prevent this function from blocking the main user interface thread, the application should create a background worker thread and establish a connection by calling **NntpConnect** in that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each client session.

The *dwOptions* argument can be used to specify the threading model that is used by the library when a connection is established. By default, the handle is initially attached to the thread that created it. From that point on, until the it is released, only the owner may call functions using that handle. The ownership of the handle may be transferred from one thread to another using the **NntpAttachThread** function.

Specifying the `NNTP_OPTION_FREETHREAD` option enables any thread to call any function using the handle, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the handle is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same handle.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnwsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

NntpCreateArticle Function

```
INT WINAPI NntpCreateArticle(  
    HCLIENT hClient  
);
```

The **NntpCreateArticle** function creates a new article in the current newsgroup.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Remarks

This function sends the POST command to the news server. Not all servers permit clients to post articles. The client application is responsible for generating the message headers as well as the body of the message. News articles conform to the same general characteristics of an email message.

The **NntpCloseArticle** function must be called once the contents of the article has been written to the server.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csnwsv10.lib

See Also

[NntpOpenArticleByMessageId](#), [NntpOpenNextArticle](#), [NntpOpenPreviousArticle](#), [NntpWrite](#)

NntpCreateSecurityCredentials Function

```
BOOL WINAPI NntpCreateSecurityCredentials(  
    DWORD dwProtocol,  
    DWORD dwOptions,  
    LPCTSTR lpszUserName,  
    LPCTSTR lpszPassword,  
    LPCTSTR lpszCertStore,  
    LPCTSTR lpszCertName,  
    LPVOID lpvReserved,  
    LPSECURITYCREDENTIALS* lppCredentials  
);
```

The **NntpCreateSecurityCredentials** function creates a **SECURITYCREDENTIALS** structure.

Parameters

dwProtocol

A bitmask of supported security protocols. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_SSL	Either SSL 2.0 or SSL 3.0 should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, TLS will be excluded from the list of supported protocols. Both SSL 2.0 and 3.0 have been deprecated and will never be used unless explicitly specified. It is not recommended that you enable either of these protocols for secure connections because it will cause most servers to reject your connection request, even if a version of TLS is also specified.
SECURITY_PROTOCOL_TLS	Either the TLS 1.0, 1.1 or 1.2 protocol should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers that reject any attempt to use the older SSL protocol and require that only TLS be used.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol should be used when establishing a secure connection. This version is

	supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This is the recommended version of TLS to use with secure connections.

dwOptions

A value which specifies one or options. This member is constructed by using a bitwise operator with any of the following values:

Constant	Description
CREDENTIAL_STORE_CURRENT_USER	The library will attempt to open a store for the current user using the certificate store name provided in this structure. If no options are specified, then this is the default behavior.
CREDENTIAL_STORE_LOCAL_MACHINE	The library will attempt to open a local machine store using the certificate store name provided in this structure. If this option is specified, the library will always search for a local machine store before searching for the store by that name for the current user.
CREDENTIAL_STORE_FILENAME	The certificate store name is a file that contains the certificate and private key that will be used.

lpszUserName

A pointer to a string which specifies the certificate owner's username. A value of NULL specifies that no username is required. Currently this parameter is not used and any value specified will be ignored.

lpszPassword

A pointer to a string which specifies the certificate owner's password. A value of NULL specifies

that no password is required. This parameter is only used if a PKCS12 (PFX) certificate file is specified and that certificate has been secured with a password. This value will be ignored the current user or local machine certificate store is specified.

lpszCertStore

A pointer to a string which specifies the name of the certificate store to open. A certificate store is a collection of certificates and their private keys, typically organized by how they are used. If this value is NULL or points to an empty string, the default certificate store "MY" will be used.

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as VeriSign and Thawte act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. This corresponds to the "Personal" store that is displayed by the certificate manager utility and is the default store used by the library.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as VeriSign and Thawte are installed as part of the operating system and periodically updated by Microsoft.

lpszCertName

A pointer to a null terminated string which specifies the name of the certificate to use. The function will first search the certificate store for a certificate with a matching "friendly name"; this is a name for the certificate that is assigned by the user. Note that the name must match completely, but the comparison is not case sensitive. If no matching certificate is found, the function will then attempt to find a certificate that has a matching common name (also called the certificate subject). This comparison is less stringent, and the first partial match will be returned. If this second search fails, the function will return an error indicating that the certificate could not be found.

lpvReserved

Pointer reserved for future use. Set it to NULL when using this function.

lppCredentials

Pointer to an [LPSECURITYCREDENTIALS](#) pointer. The memory for the credentials structure will be allocated by this function and must be released by calling the **NntpDeleteSecurityCredentials** function when it is no longer needed. The pointer value must be set to NULL before the function is called. It is important to note that this is a pointer to a pointer variable, not a pointer to the SECURITYCREDENTIALS structure itself.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **NntpGetLastError**.

Remarks

The structure that is created by this function may be used as client credentials when establishing a secure connection. This is particularly useful for programming languages other than C/C++ which may not support C structures or pointers. The pointer to the SECURITYCREDENTIALS structure can

be declared as an unsigned integer variable which is passed by reference to this function, and then passed by value to the **NntpAsyncConnect** or **NntpConnect** functions.

Example

```
LPSECURITYCREDENTIALS lpSecCred = NULL;
NntpCreateSecurityCredentials(SEcurity_PROTOCOL_DEFAULT,
                             0,
                             NULL,
                             NULL,
                             lpzCertStore,
                             lpzCertName,
                             NULL,
                             &lpSecCred);

hClient = NntpConnect(lpzHostName,
                     NNTP_PORT_SECURE,
                     NNTP_TIMEOUT,
                     NNTP_OPTION_SECURE,
                     lpSecCred);
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csnwsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

NntpDeleteSecurityCredentials Function

```
VOID WINAPI NntpDeleteSecurityCredentials(  
    LPSECURITYCREDENTIALS* LppCredentials  
);
```

The **NntpDeleteSecurityCredentials** function deletes an existing **SECURITYCREDENTIALS** structure.

Parameters

lppCredentials

Pointer to an **LPSECURITYCREDENTIALS** pointer. On exit from the function, the pointer will be NULL.

Return Value

None.

Example

```
if (lpSecCred)  
    NntpDeleteSecurityCredentials(&lpSecCred);  
  
NntpUninitialize();
```

Remarks

This function can be used to release the memory allocated to the client or server credentials after a secure connection has been terminated.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csnwsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

NntpDisableEvents Function

```
INT WINAPI NntpDisableEvents(  
    HCLIENT hClient  
);
```

The **NntpDisableEvents** function disables the event notification mechanism, preventing subsequent event notification messages from being posted to the application's message queue.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Remarks

This function affects both event notification and event callbacks. Any outstanding events in the message queue should be ignored by the client application.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csnwsv10.lib

See Also

NntpDisableTrace Function

```
BOOL WINAPI NntpDisableTrace();
```

The **NntpDisableTrace** function disables the logging of socket function calls to the trace log.

Parameters

None.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csntsv10.lib

See Also

[NntpEnableTrace](#)

NntpDisconnect Function

```
INT WINAPI NntpDisconnect(  
    HCLIENT hClient  
);
```

The **NntpDisconnect** function terminates the connection with the server, closing the socket and releasing the memory allocated for the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csnwsv10.lib

See Also

[NntpAsyncConnect](#), [NntpConnect](#), [NntpUninitialize](#)

NntpEnableEvents Function

```
INT WINAPI NntpEnableEvents(  
    HCLIENT hClient,  
    HWND hEventWnd,  
    UINT uEventMsg  
);
```

The **NntpEnableEvents** function enables event notifications using Windows messages.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Applications should use the **NntpRegisterEvent** function to register an event handler which is invoked when an event occurs.

Parameters

hClient

Handle to the client session.

hEventWnd

Handle to the event notification window. This window receives a user-defined message which specifies the event that has occurred. If this value is NULL, event notification is disabled.

uEventMsg

An unsigned integer which specifies the user-defined message that is sent when an event occurs. This parameter's value must be greater than the value of WM_USER. If the *hEventWnd* parameter is NULL, this value must be specified as WM_NULL.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Remarks

When a message is posted to the notification window, the low word of the *lParam* parameter contains the event identifier. The high word of *lParam* contains the low word of the error code, if an error has occurred. The *wParam* parameter contains the client handle. One or more of the following event identifiers may be sent:

Constant	Description
NNTP_EVENT_CONNECT	The connection to the server has completed. The high word of the <i>lParam</i> parameter should be checked, since this notification message will be posted if an error has occurred.
NNTP_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
NNTP_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.

NNTP_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
NNTP_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
NNTP_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.
NNTP_EVENT_COMMAND	A command has been issued by the client and the server response has been received and processed. This event can be used to log the result codes and messages returned by the server in response to actions taken by the client.
NNTP_EVENT_LISTARTICLE	The client is retrieving a list of articles from the server and information about another article has been processed. The client should use this event to retrieve the next available article from the server.
NNTP_EVENT_LASTARTICLE	The client is retrieving a list of articles from the server and all of the available articles have been processed. This event is generated when there are no further articles.
NNTP_EVENT_LISTGROUP	The client is retrieving a list of newsgroups from the server and information about another group has been processed. The client should use this event to retrieve the next available newsgroup from the server.
NNTP_EVENT_LASTGROUP	The client is retrieving a list of newsgroups from the server and all of the available groups have been processed. This event is generated when there are no further newsgroups.
NNTP_EVENT_PROGRESS	The client is in the process of sending or receiving data from the server. This event is called periodically during a transfer so that the client can update any user interface components such as a status control or progress bar.

As noted, some events are only generated when the client is asynchronous mode. These events depend on the Windows Sockets asynchronous notification mechanism.

If event notification is disabled by specifying a NULL window handle, there may still be outstanding events in the message queue that must be processed. Since event handling has been disabled, these events should be ignored by the client application.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

NntpEnableTrace Function

```
BOOL WINAPI NntpEnableTrace(  
    LPCTSTR lpszTraceFile,  
    DWORD dwTraceFlags  
);
```

The **NntpEnableTrace** function enables the logging of Windows Sockets function calls to a file.

Parameters

lpszTraceFile

A pointer to a string which specifies the name of the trace log file. If this parameter is NULL or an empty string, the default file name **cstrace.log** is used. The file is stored in the directory specified by the TEMP environment variable, if it is defined; otherwise, the current working directory is used.

dwTraceFlags

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
TRACE_INFO	All function calls are written to the trace file. This is the default value.
TRACE_ERROR	Only those function calls which fail are recorded in the trace file.
TRACE_WARNING	Only those function calls which fail or return values which indicate a warning are recorded in the trace file.
TRACE_HEXDUMP	All functions calls are written to the trace file, plus all the data that is sent or received is displayed, in both ASCII and hexadecimal format.
TRACE_PROCESS	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for multithreaded applications that are using worker threads.

Return Value

If the function succeeds, the return value is non-zero. A return value of zero indicates an error. Failure typically indicates that the tracing library **cstrcv10.dll** cannot be loaded on the local system.

Remarks

When trace logging is enabled, the file is opened, appended to and closed for each socket function call. This makes it possible for an application to append its own logging information, however care should be taken to ensure that the file is closed before the next network operation is performed. To limit the size of the log files, enable and disable logging only around those sections of code that you wish to trace.

Note that the TRACE_HEXDUMP trace level generates very large log files since it includes all of the data exchanged between your application and the server.

Trace function logging is managed on a per-thread basis, not for each client handle. This means that all SocketTools libraries and components share the same settings in the current thread. If you

are using multiple SocketTools libraries or components in your application, you only need to enable logging once.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnwsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

NntpEventProc Function

```
VOID CALLBACK NntpEventProc(  
    HCLIENT hClient,  
    UINT nEvent,  
    DWORD dwError,  
    DWORD_PTR dwParam  
);
```

The **NntpEventProc** function is an application-defined callback function that processes events generated by the client.

Parameters

hClient

Handle to the client session.

nEvent

An unsigned integer which specifies which event occurred. For a complete list of events, refer to the **NntpRegisterEvent** function.

dwError

An unsigned integer which specifies any error that occurred. If no error occurred, then this parameter will be zero.

dwParam

A user-defined integer value which was specified when the event callback was registered.

Return Value

None.

Remarks

An application must register this callback function by passing its address to the **NntpRegisterEvent** function. The **NntpEventProc** function is a placeholder for the application-defined function name.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csnwsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[NntpDisableEvents](#), [NntpEnableEvents](#), [NntpFreezeEvents](#), [NntpRegisterEvent](#)

NntpFreezeEvents Function

```
INT WINAPI NntpFreezeEvents(  
    HCLIENT hClient,  
    BOOL bFreeze  
);
```

The **NntpFreezeEvents** function is used to suspend and resume event handling by the client.

Parameters

hClient

Handle to the client session.

bFreeze

A non-zero value specifies that event handling should be suspended by the client. A zero value specifies that event handling should be resumed.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Remarks

This function should be used when the application does not want to process events, such as when a modal dialog is being displayed. When events are suspended, all client events are queued. If events are re-enabled at a later point, those queued events will be sent to the application for processing. Note that only one of each event will be generated. For example, if the client has suspended event handling, and four read events occur, once event handling is resumed only one of those read events will be posted to the client. This prevents the application from being flooded by a potentially large number of queued events.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnwsv10.lib

NntpGetArticle Function

```
INT WINAPI NntpGetArticle(  
    HCLIENT hClient,  
    LONG nArticleId,  
    LPVOID lpvBuffer,  
    LPDWORD lpdwLength,  
    DWORD dwReserved  
);
```

The **NntpGetArticle** function retrieves the specified article and copies the contents to a local buffer.

Parameters

hClient

Handle to the client session.

nArticleId

Number of article to retrieve from the server. This value must be greater than zero.

lpvBuffer

A pointer to a byte buffer which will contain the data transferred from the server, or a pointer to a global memory handle which will reference the data when the function returns.

lpdwLength

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the *lpvBuffer* parameter. If the *lpvBuffer* parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the actual length of the file that was downloaded.

dwReserved

A reserved parameter. This value should always be zero.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Remarks

The **NntpGetArticle** function is used to retrieve an article from the server and copy it into a local buffer. The function may be used in one of two ways, depending on the needs of the application. The first method is to pre-allocate a buffer large enough to store the contents of the article. In this case, the *lpvBuffer* parameter will point to the buffer that was allocated, the value that the *lpdwLength* parameter points to should be initialized to the size of that buffer.

The second method that can be used is have the *lpvBuffer* parameter point to a global memory handle which will contain the article data when the function returns. In this case, the value that the *lpdwLength* parameter points to must be initialized to zero. It is important to note that the memory handle returned by the function must be freed by the application, otherwise a memory leak will occur. See the example code below.

This function will cause the current thread to block until the complete article has been retrieved, a timeout occurs or the operation is canceled. During the transfer, the NNTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls.

Event notification must be enabled, either by calling **NntpEnableEvents**, or by registering a callback function using the **NntpRegisterEvent** function.

To determine the current status of a transfer while it is in progress, use the **NntpGetTransferStatus** function. If you need to retrieve an article based on its message ID rather than the article number, use the **NntpGetArticleByMessageId** function.

Your application should use the **NntpGetArticleEx** function if the server uses 64-bit article IDs.

Example

```
HGLOBAL hgblBuffer = (HGLOBAL)NULL;
LPBYTE lpBuffer = (LPBYTE)NULL;
DWORD cbBuffer = 0;

// Return the article into block of global memory allocated by
// the GlobalAlloc function; the handle to this memory will be
// returned in the hgblBuffer parameter
nResult = NntpGetArticle(hClient,
                        nArticleId,
                        &hgblBuffer,
                        &cbBuffer,
                        0);

if (nResult != NNTP_ERROR)
{
    // Lock the global memory handle, returning a pointer to the
    // article text
    lpBuffer = (LPBYTE)GlobalLock(hgblBuffer);

    // After the data has been used, the handle must be unlocked
    // and freed, otherwise a memory leak will occur
    GlobalUnlock(hgblBuffer);
    GlobalFree(hgblBuffer);
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnwsv10.lib

See Also

[NntpCreateArticle](#), [NntpEnableEvents](#), [NntpGetArticleEx](#), [NntpGetArticleByMessageId](#), [NntpGetArticleHeaders](#), [NntpGetTransferStatus](#), [NntpRegisterEvent](#)

NntpGetArticleByMessageId Function

```
INT WINAPI NntpGetArticleByMessageId(  
    HCLIENT hClient,  
    LPCTSTR lpszMessageId,  
    LPVOID lpvBuffer,  
    LPDWORD lpdwLength,  
    DWORD dwReserved  
);
```

The **NntpGetArticleByMessageId** function retrieves an article using the specified message ID and copies the contents to a local buffer.

Parameters

hClient

Handle to the client session.

lpszMessageId

A pointer to a string which specifies the message ID of the article that you want to retrieve. If this parameter is a NULL pointer or specifies a zero-length string, an error will be returned.

lpvBuffer

A pointer to a byte buffer which will contain the data transferred from the server, or a pointer to a global memory handle which will reference the data when the function returns.

lpdwLength

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the *lpvBuffer* parameter. If the *lpvBuffer* parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the actual length of the file that was downloaded.

dwReserved

A reserved parameter. This value should always be zero.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Remarks

The **NntpGetArticleByMessageId** function is used to retrieve an article from the server and copy it into a local buffer. This function is identical to the **NntpGetArticle** function except that a message ID string is used to identify the article, rather than an article number. The function may be used in one of two ways, depending on the needs of the application. The first method is to pre-allocate a buffer large enough to store the contents of the article. In this case, the *lpvBuffer* parameter will point to the buffer that was allocated, the value that the *lpdwLength* parameter points to should be initialized to the size of that buffer.

The second method that can be used is have the *lpvBuffer* parameter point to a global memory handle which will contain the article data when the function returns. In this case, the value that the *lpdwLength* parameter points to must be initialized to zero. It is important to note that the memory handle returned by the function must be freed by the application, otherwise a memory leak will occur. See the example code below.

This function will cause the current thread to block until the complete article has been retrieved, a timeout occurs or the operation is canceled. During the transfer, the NNTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **NntpEnableEvents**, or by registering a callback function using the **NntpRegisterEvent** function.

To determine the current status of a transfer while it is in progress, use the **NntpGetTransferStatus** function.

Example

```
HGLOBAL hgblBuffer = (HGLOBAL)NULL;
LPBYTE lpBuffer = (LPBYTE)NULL;
DWORD cbBuffer = 0;

// Return the article into block of global memory allocated by
// the GlobalAlloc function; the handle to this memory will be
// returned in the hgblBuffer parameter
nResult = NntpGetArticleById(hClient,
                             lpzMessageId,
                             &hgblBuffer,
                             &cbBuffer,
                             0);

if (nResult != NNTP_ERROR)
{
    // Lock the global memory handle, returning a pointer to the
    // article text
    lpBuffer = (LPBYTE)GlobalLock(hgblBuffer);

    // After the data has been used, the handle must be unlocked
    // and freed, otherwise a memory leak will occur
    GlobalUnlock(hgblBuffer);
    GlobalFree(hgblBuffer);
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csnwsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

NntpGetArticleHeaders Function

```
INT WINAPI NntpGetArticleHeaders(  
    HCLIENT hClient,  
    LONG nArticleId,  
    LPVOID lpvHeaders,  
    LPDWORD lpdwLength  
);
```

The **NntpGetArticleHeaders** function retrieves the headers for the specified article from the server.

Parameters

hClient

Handle to the client session.

nArticleId

Number of article to retrieve from the server. This value must be greater than zero.

lpvHeaders

A pointer to a byte buffer which will contain the data transferred from the server, or a pointer to a global memory handle which will reference the data when the function returns.

lpdwLength

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the *lpvHeaders* parameter. If the *lpvHeaders* parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the actual length of the message that was downloaded.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Remarks

The **NntpGetArticleHeaders** function is used to retrieve an article header block from the server and copy it into a local buffer. The function may be used in one of two ways, depending on the needs of the application. The first method is to pre-allocate a buffer large enough to store the contents of the file. In this case, the *lpvHeaders* parameter will point to the buffer that was allocated, the value that the *lpdwLength* parameter points to should be initialized to the size of that buffer.

The second method that can be used is have the *lpvHeaders* parameter point to a global memory handle which will contain the message headers when the function returns. In this case, the value that the *lpdwLength* parameter points to must be initialized to zero. It is important to note that the memory handle returned by the function must be freed by the application, otherwise a memory leak will occur.

This function will cause the current thread to block until the transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the NNTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **NntpEnableEvents**, or by registering a callback function using the **NntpRegisterEvent** function.

Your application should use the **NntpGetArticleHeadersEx** function if the server uses 64-bit article IDs.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnwsv10.lib

[NntpGetArticle](#), [NntpGetArticleHeadersEx](#), [NntpGetArticleRange](#), [NntpListArticles](#), [NntpPostArticle](#)

NntpGetArticleHeadersEx Function

```
INT WINAPI NntpGetArticleHeadersEx(  
    HCLIENT hClient,  
    ULONGLONG nArticleId,  
    LPVOID lpvHeaders,  
    LPDWORD lpdwLength  
);
```

The **NntpGetArticleHeadersEx** function retrieves the headers for the specified article from the server.

Parameters

hClient

Handle to the client session.

nArticleId

Number of article to retrieve from the server.

lpvHeaders

A pointer to a byte buffer which will contain the data transferred from the server, or a pointer to a global memory handle which will reference the data when the function returns.

lpdwLength

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the *lpvHeaders* parameter. If the *lpvHeaders* parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the actual length of the message that was downloaded.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Remarks

The **NntpGetArticleHeadersEx** function is used to retrieve an article header block from the server and copy it into a local buffer. This function provides support for servers which use 64-bit article IDs. The function may be used in one of two ways, depending on the needs of the application. The first method is to pre-allocate a buffer large enough to store the contents of the file. In this case, the *lpvHeaders* parameter will point to the buffer that was allocated, the value that the *lpdwLength* parameter points to should be initialized to the size of that buffer.

The second method that can be used is have the *lpvHeaders* parameter point to a global memory handle which will contain the message headers when the function returns. In this case, the value that the *lpdwLength* parameter points to must be initialized to zero. It is important to note that the memory handle returned by the function must be freed by the application, otherwise a memory leak will occur.

This function will cause the current thread to block until the transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the NNTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **NntpEnableEvents**, or by registering a callback function using the **NntpRegisterEvent** function.

NntpGetArticleMessageId Function

```
INT WINAPI NntpGetArticleMessageId(  
    HCLIENT hClient,  
    LONG nArticleId,  
    LPTSTR lpszMessageId,  
    INT cbMessageId  
);
```

The **NntpGetArticleMessageId** function returns the message identifier for the specified article in the current newsgroup.

Parameters

hClient

Handle to the client session.

nArticleId

Article number to retrieve the message identifier for. The value may be zero, in which case the current article number is used.

lpszMessageId

Pointer to a string buffer which will contain the message identifier for the specified article.

cbMessageId

Maximum number of characters that may be copied into the buffer, including the terminating null character.

Return Value

If the function succeeds, the return value is the length of the message identifier string. If the function fails, the return value is NNTP_ERROR. To get extended error information, call

NntpGetLastError.

Remarks

The message identifier is a string which can uniquely identify the message on the news server. This value may be used to retrieve the contents of the article. Your application should use the

NntpGetArticleMessageIdEx function if the server uses 64-bit article IDs.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csnews10.lib

Unicode: Implemented as Unicode and ANSI versions.

NntpGetArticleMessageIdEx Function

```
INT WINAPI NntpGetArticleMessageIdEx(  
    HCLIENT hClient,  
    ULONGLONG nArticleId,  
    LPTSTR lpszMessageId,  
    INT cbMessageId  
);
```

The **NntpGetArticleMessageIdEx** function returns the message identifier for the specified article in the current newsgroup.

Parameters

hClient

Handle to the client session.

nArticleId

Article number to retrieve the message identifier for. The value may be zero, in which case the current article number is used.

lpszMessageId

Pointer to a string buffer which will contain the message identifier for the specified article.

cbMessageId

Maximum number of characters that may be copied into the buffer, including the terminating null character.

Return Value

If the function succeeds, the return value is the length of the message identifier string. If the function fails, the return value is NNTP_ERROR. To get extended error information, call

NntpGetLastError.

Remarks

The message identifier is a string which can uniquely identify the message on the news server. This value may be used to retrieve the contents of the article. This function provides support for servers which use 64-bit article IDs.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csnews10.lib

Unicode: Implemented as Unicode and ANSI versions.

NntpGetArticleRange Function

```
LONG WINAPI NntpGetArticleRange(  
    HCLIENT hClient,  
    LPLONG lpnFirstArticle,  
    LPLONG lpnLastArticle  
);
```

The **NntpGetArticleRange** function returns the first and last article numbers for the currently selected newsgroup.

Parameters

hClient

Handle to the client session.

lpnFirstArticle

Pointer to a long integer that will contain the first article number in the currently selected newsgroup. If this parameter is NULL, it will be ignored.

lpnLastArticle

Pointer to a long integer that will contain the last article number in the currently selected newsgroup. If this parameter is NULL, it will be ignored.

Return Value

If the function succeeds, the return value is number of articles in the selected newsgroup. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Remarks

It is possible that there will be gaps in the articles within the range of the first and last articles in the newsgroup. This may be due to a message being canceled or expired. If the server uses 64-bit article IDs, your application should use the **NntpGetArticleRangeEx** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csnewsv10.lib

See Also

[NntpGetArticleRangeEx](#), [NntpOpenArticle](#), [NntpOpenArticleByMessageId](#), [NntpListArticles](#)

NntpGetArticleRangeEx Function

```
BOOL WINAPI NntpGetArticleRangeEx(  
    HCLIENT hClient,  
    ULONGLONG * LpnFirstArticle,  
    ULONGLONG * LpnLastArticle,  
    ULONGLONG * LpnArticleCount  
);
```

The **NntpGetArticleRangeEx** function returns the first and last article numbers for the currently selected newsgroup.

Parameters

hClient

Handle to the client session.

lpnFirstArticle

Pointer to an unsigned 64-bit integer that will contain the first article number in the currently selected newsgroup. If this parameter is NULL, it will be ignored.

lpnLastArticle

Pointer to an unsigned 64-bit integer that will contain the last article number in the currently selected newsgroup. If this parameter is NULL, it will be ignored.

lpnArticleCount

Pointer to an unsigned 64-bit integer that will contain the total number of articles in the selected newsgroup. If this parameter is NULL, it will be ignored.

Return Value

If the function succeeds, the return value will be non-zero. If the function fails, the return value is zero. To get extended error information, call **NntpGetLastError**.

Remarks

It is possible that there will be gaps in the articles within the range of the first and last articles in the newsgroup. This may be due to a message being canceled or expired. This function provides support for servers which use 64-bit article IDs.

The **NntpGetArticleRangeEx** function returns a BOOL (a signed 32-bit integer) to indicate success or failure, and the article count is returned in a variable that is passed by reference to the function. If you are updating your code to use this function, make sure you also change how you check the return value.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

NntpGetArticleSize Function

```
DWORD WINAPI NntpGetArticleSize(  
    HCLIENT hClient,  
    LONG nArticleId  
);
```

The **NntpGetArticleSize** function returns the size of the specified article.

Parameters

hClient

Handle to the client session.

nArticleId

An integer value that identifies the article. The value may be zero, in which case the current article number is used.

Return Value

If the function succeeds, the return value is the size of the article in bytes. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Remarks

The **NntpGetArticleSize** function sends the XOVER command to the server to request the size of the specified article. If the server uses 64-bit article IDs, your application should use the **NntpGetArticleSizeEx** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

    HCLIENT hClient,  
    ULONGLONG * lpnArticleId  
);
```

The **NntpGetCurrentArticle** function returns the current article number for the currently selected newsgroup.

Parameters

hClient

Handle to the client session.

lpnArticleId

Pointer to an unsigned 64-bit integer that will contain the current article number in the selected newsgroup. This parameter cannot be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **NntpGetLastError**.

Remarks

The **NntpGetCurrentArticleEx** function returns a BOOL (a signed 32-bit integer) to indicate success or failure, and the article ID is returned in a variable that is passed by reference to the function. This function provides support for servers which use 64-bit article IDs. If you are updating your code to use this function, make sure you also change how you check the return value.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

NntpGetCurrentDate Function

```
INT WINAPI NntpGetCurrentDate(  
    LPTSTR lpszDate,  
    INT nMaxLength  
);
```

The **NntpGetCurrentDate** function copies the current date and time to the specified buffer in a format that is commonly used in news articles. This date format should be used in all date-related fields in the message header.

Parameters

lpszDate

Pointer to a string buffer that will contain the current date and time when the function returns.

nMaxLength

The maximum number of characters that can be copied into the string buffer.

Return Values

If the function succeeds, the return value is the number of characters copied into the buffer, not including the null-terminator. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Remarks

The date value that is returned is adjusted for the local timezone.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csntv10.lib

Unicode: Implemented as Unicode and ANSI versions.

NntpGetErrorString Function

```
INT WINAPI NntpGetErrorString(  
    DWORD dwErrorCode,  
    LPTSTR lpszDescription,  
    INT cbDescription  
);
```

The **NntpGetErrorString** function is used to return a description of a specific error code. Typically this is used in conjunction with the **NntpGetLastError** function for use with warning dialogs or as diagnostic messages.

Parameters

dwErrorCode

The error code for which a description is returned.

lpszDescription

A pointer to the buffer that will contain a description of the specified error code. This buffer should be at least 128 characters in length.

cbDescription

The maximum number of characters that may be copied into the description buffer.

Return Value

If the function succeeds, the return value is the length of the description string. If the function fails, the return value is zero, meaning that no description exists for the specified error code. Typically this indicates that the error code passed to the function is invalid.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csnwsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[NntpGetLastError](#), [NntpSetLastError](#)

NntpGetFirstArticle Function

```
BOOL WINAPI NntpGetFirstArticle(  
    HCLIENT hClient,  
    LPNEWSARTICLE lpArticle  
);
```

The **NntpGetFirstArticle** function returns information about the first article in the currently selected newsgroup.

Parameters

hClient

Handle to the client session.

lpArticle

A pointer to a [NEWSARTICLE](#) structure which will contain information about the first article in the currently selected directory.

Return Value

If the function succeeds, the return value is non-zero. If there are no articles in the current newsgroup, or the function fails, the return value is zero. To get extended error information, call **NntpGetLastError**.

Remarks

The **NntpGetFirstArticle** function returns information about the first article in the currently selected newsgroup. This function is used in conjunction with the **NntpGetNextArticle** function to enumerate all of the articles in the newsgroup. Typically this is used to provide the user with a list of articles to access.

While the articles in the newsgroup are being listed, the client cannot retrieve the contents of a specific article. For example, the **NntpGetArticle** function cannot be called while inside a loop calling **NntpGetNextArticle**. The client should store those articles which it wants to retrieve in an array, and then once all of the articles have been listed, it can begin calling **NntpGetArticle** for each article number to retrieve the article text.

The date and time that the article was posted is returned in the *stPosted* member of the [NEWSARTICLE](#) structure. This value is returned in Universal Coordinated Time (UTC) and can be converted to local time using the **SystemTimeToTzSpecificLocalTime** function.

If the server uses 64-bit article IDs, your application should use the **NntpGetFirstArticleEx** and **NntpGetNextArticleEx** functions.

Example

```
NEWSARTICLE newsArticle;  
BOOL bResult;  
INT nResult;  
  
// List all articles in the current group  
nResult = NntpListArticles(hClient, -1L, -1L);  
  
if (nResult == NNTP_ERROR)  
{  
    TCHAR szError[ASTRING];  
    DWORD dwError = NntpGetLastError();
```

```
NntpGetErrorString(dwError, szError, ASTRING);
_ftprintf(stderr, _T("Error %08x: %s\n"), dwError, szError);
return;
}

// Get each article in the current newsgroup, printing the article
// number and the subject of the article
bResult = NntpGetFirstArticle(hClient, &newsArticle);

while (bResult)
{
    _tprintf(_T("%ld %s\n"), newsArticle.nArticleId, newsArticle.szSubject);
    bResult = NntpGetNextArticle(hClient, &newsArticle);
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnwsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

NntpGetFirstArticleEx Function

```
BOOL WINAPI NntpGetFirstArticleEx(  
    HCLIENT hClient,  
    LPNEWSARTICLEEX lpArticleEx  
);
```

The **NntpGetFirstArticleEx** function returns information about the first article in the currently selected newsgroup.

Parameters

hClient

Handle to the client session.

lpArticleEx

A pointer to a [NEWSARTICLEEX](#) structure which will contain information about the first article in the currently selected directory.

Return Value

If the function succeeds, the return value is non-zero. If there are no articles in the current newsgroup, or the function fails, the return value is zero. To get extended error information, call **NntpGetLastError**.

Remarks

The **NntpGetFirstArticleEx** function returns information about the first article in the currently selected newsgroup. This function is used in conjunction with the **NntpGetNextArticleEx** function to enumerate all of the articles in the newsgroup. Typically this is used to provide the user with a list of articles to access. This function provides support for servers which use 64-bit article IDs.

While the articles in the newsgroup are being listed, the client cannot retrieve the contents of a specific article. For example, the **NntpGetArticleEx** function cannot be called while inside a loop calling **NntpGetNextArticleEx**. The client should store those articles which it wants to retrieve in an array, and then once all of the articles have been listed, it can begin calling **NntpGetArticleEx** for each article number to retrieve the article text.

The date and time that the article was posted is returned in the *stPosted* member of the NEWSARTICLE structure. This value is returned in Universal Coordinated Time (UTC) and can be converted to local time using the **SystemTimeToTzSpecificLocalTime** function.

Example

```
NEWSARTICLEEX newsArticle;  
BOOL bResult;  
INT nResult;  
  
// List all articles in the current group  
nResult = NntpListArticlesEx(hClient, (ULONGLONG)-1, (ULONGLONG)-1);  
  
if (nResult == NNTP_ERROR)  
{  
    TCHAR szError[ASTRING];  
    DWORD dwError = NntpGetLastError();  
  
    NntpGetErrorString(dwError, szError, ASTRING);  
    _ftprintf(stderr, _T("Error %08x: %s\n"), dwError, szError);  
}
```

```
    return;
}

// Get each article in the current newsgroup, printing the article
// number and the subject of the article
bResult = NntpGetFirstArticleEx(hClient, &newsArticle);

while (bResult)
{
    _tprintf(_T("%I64u %s\n"), newsArticle.nArticleId, newsArticle.szSubject);
    bResult = NntpGetNextArticleEx(hClient, &newsArticle);
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnwsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[NEWSGROUPEX](#)

NntpGetFirstGroup Function

```
BOOL WINAPI NntpGetFirstGroup(  
    HCLIENT hClient,  
    LPNEWSGROUP lpGroup  
);
```

The **NntpGetFirstGroup** function returns information about the first available newsgroup.

Parameters

hClient

Handle to the client session.

lpGroup

A pointer to a [NEWSGROUP](#) structure which will contain information about the first available newsgroup.

Return Value

If the function succeeds, the return value is non-zero. If there are no newsgroups available, or the function fails, the return value is zero. To get extended error information, call **NntpGetLastError**.

Remarks

The **NntpGetFirstGroup** function returns information about the first newsgroup on the server. This function is used in conjunction with the **NntpGetNextGroup** function to enumerate all of the available newsgroups. Typically this is used to provide the user with a list of newsgroups to select.

While the the newsgroups are being listed, the client cannot select a newsgroup or retrieve the contents of a specific article. The client should store those newsgroups which it wants to retrieve articles from, and then once all of the newsgroups have been listed, it can then select each newsgroup and retrieve the available articles from that group.

Note that if no newsgroups are returned by the server, it may indicate that it requires the client to authenticate itself prior to requesting a list of groups or articles.

If the server uses 64-bit article IDs, your application should use the **NntpGetFirstGroupEx** and **NntpGetNextGroupEx** functions.

Example

```
NEWSGROUP newsGroup;  
BOOL bResult;  
INT nResult;  
  
// List all available newsgroups  
nResult = NntpListGroup(hClient);  
  
if (nResult == NNTP_ERROR)  
{  
    TCHAR szError[ASTRING];  
    DWORD dwError = NntpGetLastError();  
  
    NntpGetErrorString(dwError, szError, ASTRING);  
    _ftprintf(stderr, _T("Error %08x: %s\n"), dwError, szError);  
    return;  
}
```

```
// Get each newsgroup, printing the article range and
// the name of the group
bResult = NntpGetFirstGroup(hClient, &newsGroup);

while (bResult)
{
    _tprintf(_T("%ld %ld %s\n"), newsGroup.nFirstArticle,
            newsGroup.nLastArticle,
            newsGroup.szName);

    bResult = NntpGetNextGroup(hClient, &newsGroup);
}
```

Requirements

NntpGetFirstGroupEx Function

```
BOOL WINAPI NntpGetFirstGroupEx(  
    HCLIENT hClient,  
    LPNEWSGROUPEX lpGroupEx  
);
```

The **NntpGetFirstGroupEx** function returns information about the first available newsgroup.

Parameters

hClient

Handle to the client session.

lpGroupEx

A pointer to a [NEWSGROUPEX](#) structure which will contain information about the first available newsgroup.

Return Value

If the function succeeds, the return value is non-zero. If there are no newsgroups available, or the function fails, the return value is zero. To get extended error information, call **NntpGetLastError**.

Remarks

The **NntpGetFirstGroupEx** function returns information about the first newsgroup on the server. This function is used in conjunction with the **NntpGetNextGroupEx** function to enumerate all of the available newsgroups. Typically this is used to provide the user with a list of newsgroups to select. This function provides support for servers which use 64-bit article IDs.

While the the newsgroups are being listed, the client cannot select a newsgroup or retrieve the contents of a specific article. The client should store those newsgroups which it wants to retrieve articles from, and then once all of the newsgroups have been listed, it can then select each newsgroup and retrieve the available articles from that group.

Note that if no newsgroups are returned by the server, it may indicate that it requires the client to authenticate itself prior to requesting a list of groups or articles.

Example

```
NEWSGROUPEX newsGroup;  
BOOL bResult;  
INT nResult;  
  
// List all available newsgroups  
nResult = NntpListGroupEx(hClient);  
  
if (nResult == NNTP_ERROR)  
{  
    TCHAR szError[ASTRING];  
    DWORD dwError = NntpGetLastError();  
    NntpGetErrorString(dwError, szError, ASTRING);  
    fprintf(stderr, "Error %08x: %s\n", dwError, szError);  
    return;  
}  
  
// Get each newsgroup, printing the article range and  
// the name of the group  
bResult = NntpGetFirstGroupEx(hClient, &newsGroup);
```

```
while (bResult)
{
    printf("%I64u %I64u %s\n", newsGroup.nFirstArticle,
        newsGroup.nLastArticle,
        newsGroup.szName);

    bResult = NntpGetNextGroupEx(hClient, &newsGroup);
}
```

Requirements

NntpGetGroupName Function

```
INT WINAPI NntpGetGroupName(  
    HCLIENT hClient,  
    LPTSTR lpszGroupName,  
    INT nMaxLength  
);
```

The **NntpGetGroupName** function returns the name of the currently selected newsgroup.

Parameters

hClient

Handle to the client session.

lpszGroupName

Pointer to a string buffer that will contain the name of the currently selected newsgroup.

nMaxLength

The maximum number of characters that may be copied into the buffer, including the terminating null character.

Return Value

If the function succeeds, the return value is the length of the newsgroup name. If no newsgroup has been selected, the function will return a value of zero. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csnwsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

NntpGetGroupTitle Function

```
INT WINAPI NntpGetGroupTitle(  
    HCLIENT hClient,  
    LPTSTR lpszGroupTitle,  
    INT nMaxLength  
);
```

The **NntpGetGroupTitle** function returns a description of the currently selected newsgroup.

Parameters

hClient

Handle to the client session.

lpszGroupTitle

Pointer to a string buffer that will contain a description of the currently selected newsgroup.

nMaxLength

The maximum number of characters that may be copied into the buffer, including the terminating null character.

Return Value

If the function succeeds, the return value is the length of the description. If no newsgroup has been selected, the function will return a value of zero. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Remarks

The news server must support the XGTITLE command so that the group description can be obtained when the newsgroup is selected. If this command is not recognized, then no description will be returned.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csnewsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[NntpGetGroupName](#), [NntpListGroup](#), [NntpListNewGroups](#), [NntpSelectGroup](#)

NntpGetLastError Function

```
DWORD WINAPI NntpGetLastError();
```

Parameters

None.

Return Value

The return value is the last error code value for the current thread. Functions set this value by calling the **NntpSetLastError** function. The Return Value section of each reference page notes the conditions under which the function sets the last error code.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. You should call the **NntpGetLastError** function immediately when a function's return value indicates that an error has occurred. That is because some functions call **NntpSetLastError(0)** when they succeed, clearing the error code set by the most recently failed function.

Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or NNTP_ERROR. Those functions which call **NntpSetLastError** when they succeed are noted on the function reference page.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

NntpGetMessageIdArticle Function

```
LONG WINAPI NntpGetMessageIdArticle(  
    HCLIENT hClient,  
    LPCTSTR lpszMessageId  
);
```

The **NntpGetMessageIdArticle** function returns the article number associated with a message identifier in the current newsgroup.

Parameters

hClient

Handle to the client session.

lpszMessageId

A pointer to a message identifier string.

Return Value

If the function succeeds, the return value is the article number. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Remarks

If the server uses 64-bit article IDs, your application should use the **NntpGetMessageIdArticleEx** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csnews10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[NntpGetMessageIdArticleEx](#), [NntpGetArticleMessageId](#), [NntpListArticles](#)

NntpGetMessageIdArticleEx Function

```
BOOL WINAPI NntpGetMessageIdArticleEx(  
    HCLIENT hClient,  
    LPCTSTR LpszMessageId  
    ULONGLONG * LpnArticleId  
);
```

The **NntpGetMessageIdArticleEx** function returns the article number associated with a message identifier in the current newsgroup.

Parameters

hClient

Handle to the client session.

lpszMessageId

A pointer to a message identifier string.

lpnArticleId

A pointer to an unsigned 64-bit integer which will contain the article ID. This parameter cannot be NULL.

Return Value

If the function succeeds, the return value non-zero. If the function fails, the return value is zero. To get extended error information, call **NntpGetLastError**.

Remarks

The **NntpGetMessageIdArticleEx** function returns a BOOL (a signed 32-bit integer) to indicate success or failure, and the article count is returned in a variable that is passed by reference to the function. If you are updating your code to use this function, make sure you also change how you check the return value.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csnwsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[NntpGetArticleMessageIdEx](#), [NntpListArticlesEx](#)

NntpGetMultiLine Function

```
INT WINAPI NntpGetMultiLine(  
    HCLIENT hClient,  
    LPBOOL lpbMultiLine  
);
```

The **NntpGetMultiLine** function returns the value of the client multi-line flag in the specified boolean parameter.

Parameters

hClient

Handle to the client session.

lpbMultiLine

A pointer to a boolean variable. This variable will be set to the current value of the client's internal multi-line flag.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Remarks

The multi-line flag is used by the library to determine if multiple lines of data will be returned by the server as the result of a command. Unlike a single line response, which consists of a result code and result string, a multi-line response consists of one or more lines of text, terminated by a special end-of-data marker.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnwsv10.lib

NntpGetNextArticle Function

```
BOOL WINAPI NntpGetNextArticle(  
    HCLIENT hClient,  
    LPNEWSARTICLE lpArticle  
);
```

The **NntpGetNextArticle** function returns information about the next article in the currently selected newsgroup.

Parameters

hClient

Handle to the client session.

lpArticle

A pointer to a [NEWSARTICLE](#) structure which will contain information about the next available article in the currently selected directory.

Return Value

If the function succeeds, the return value is non-zero. If there are no more articles in the current newsgroup, or the function fails, the return value is zero. To get extended error information, call **NntpGetLastError**.

Remarks

The **NntpGetNextArticle** function returns information about the next available article in the currently selected newsgroup. This function is used in conjunction with the **NntpGetFirstArticle** function to enumerate all of the articles in the newsgroup. Typically this is used to provide the user with a list of articles to access.

While the articles in the newsgroup are being listed, the client cannot retrieve the contents of a specific article. For example, the **NntpGetArticle** function cannot be called while inside a loop calling **NntpGetNextArticle**. The client should store those articles which it wants to retrieve in an array, and then once all of the articles have been listed, it can begin calling **NntpGetArticle** for each article number to retrieve the article text.

If the server uses 64-bit article IDs, your application should use the **NntpGetFirstArticleEx** and **NntpGetNextArticleEx** functions.

Example

```
NEWSARTICLE newsArticle;  
BOOL bResult;  
INT nResult;  
  
// List all articles in the current group  
nResult = NntpListArticles(hClient, -1L, -1L);  
  
if (nResult == NNTP_ERROR)  
{  
    TCHAR szError[ASTRING];  
    DWORD dwError = NntpGetLastError();  
  
    NntpGetErrorString(dwError, szError, ASTRING);  
    _ftprintf(stderr, _T("Error %08x: %s\n"), dwError, szError);  
    return;  
}
```

```
// Get each article in the current newsgroup, printing the article
// number and the subject of the article
bResult = NntpGetNextArticle(hClient, &newsArticle);

while (bResult)
{
    _tprintf(_T("%ld %s\n"), newsArticle.nArticleId, newsArticle.szSubject);
    bResult = NntpGetNextArticle(hClient, &newsArticle);
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnwsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

NntpGetNextArticleEx Function

```
BOOL WINAPI NntpGetNextArticleEx(  
    HCLIENT hClient,  
    LPNEWSARTICLEEX lpArticleEx  
);
```

The **NntpGetNextArticleEx** function returns information about the next article in the currently selected newsgroup.

Parameters

hClient

Handle to the client session.

lpArticle

A pointer to a [NEWSARTICLEEX](#) structure which will contain information about the next available article in the currently selected directory.

Return Value

If the function succeeds, the return value is non-zero. If there are no more articles in the current newsgroup, or the function fails, the return value is zero. To get extended error information, call **NntpGetLastError**.

Remarks

The **NntpGetNextArticleEx** function returns information about the next available article in the currently selected newsgroup. This function is used in conjunction with the **NntpGetFirstArticleEx** function to enumerate all of the articles in the newsgroup. Typically this is used to provide the user with a list of articles to access. This function provides support for servers which use 64-bit article IDs.

While the articles in the newsgroup are being listed, the client cannot retrieve the contents of a specific article. For example, the **NntpGetArticleEx** function cannot be called while inside a loop calling **NntpGetNextArticleEx**. The client should store those articles which it wants to retrieve in an array, and then once all of the articles have been listed, it can begin calling **NntpGetArticleEx** for each article number to retrieve the article text.

Example

```
NEWSARTICLEEX newsArticle;  
BOOL bResult;  
INT nResult;  
  
// List all articles in the current group  
nResult = NntpListArticlesEx(hClient, (ULONGLONG)-1, (ULONGLONG)-1);  
  
if (nResult == NNTP_ERROR)  
{  
    TCHAR szError[ASTRING];  
    DWORD dwError = NntpGetLastError();  
  
    NntpGetErrorString(dwError, szError, ASTRING);  
    _ftprintf(stderr, _T("Error %08x: %s\n"), dwError, szError);  
    return;  
}
```

```
// Get each article in the current newsgroup, printing the article
// number and the subject of the article
bResult = NntpGetNextArticleEx(hClient, &newsArticle);

while (bResult)
{
    _tprintf(_T("%I64u %s\n"), newsArticle.nArticleId, newsArticle.szSubject);
    bResult = NntpGetNextArticleEx(hClient, &newsArticle);
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnwsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[NEWSGROUPEX](#)

NntpGetNextGroup Function

```
BOOL WINAPI NntpGetNextGroup(  
    HCLIENT hClient,  
    LPNEWSGROUP lpGroup  
);
```

The **NntpGetNextGroup** function returns information about the next available newsgroup.

Parameters

hClient

Handle to the client session.

lpGroup

A pointer to a [NEWSGROUP](#) structure which will contain information about the next available newsgroup.

Return Value

If the function succeeds, the return value is non-zero. If there are no more newsgroups available, or the function fails, the return value is zero. To get extended error information, call

NntpGetLastError.

Remarks

The **NntpGetNextGroup** function returns information about the next newsgroup on the server. This function is used in conjunction with the **NntpGetFirstGroup** function to enumerate all of the available newsgroups. Typically this is used to provide the user with a list of newsgroups to select.

While the the newsgroups are being listed, the client cannot select a newsgroup or retrieve the contents of a specific article. The client should store those newsgroups which it wants to retrieve articles from, and then once all of the newsgroups have been listed, it can then select each newsgroup and retrieve the available articles from that group.

If the server uses 64-bit article IDs, your application should use the **NntpGetFirstGroupEx** and **NntpGetNextGroupEx** functions.

Example

```
NEWSGROUP newsGroup;  
BOOL bResult;  
INT nResult;  
  
// List all available newsgroups  
nResult = NntpListGroup(hClient);  
  
if (nResult == NNTP_ERROR)  
{  
    TCHAR szError[ASTRING];  
    DWORD dwError = NntpGetLastError();  
  
    NntpGetErrorString(dwError, szError, ASTRING);  
    _ftprintf(stderr, _T("Error %08x: %s\n"), dwError, szError);  
    return;  
}  
  
// Get each newsgroup, printing the article range and  
// the name of the group
```

```
bResult = NntpGetFirstGroup(hClient, &newsGroup);

while (bResult)
{
    _tprintf(_T("%ld %ld %s\n"), newsGroup.nFirstArticle,
            newsGroup.nLastArticle,
            newsGroup.szName);

    bResult = NntpGetNextGroup(hClient, &newsGroup);
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnwsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

NntpGetNextGroupEx Function

```
BOOL WINAPI NntpGetNextGroupEx(  
    HCLIENT hClient,  
    LPNEWSGROUPEX lpGroupEx  
);
```

The **NntpGetNextGroupEx** function returns information about the next available newsgroup.

Parameters

hClient

Handle to the client session.

lpGroup

A pointer to a [NEWSGROUPEX](#) structure which will contain information about the next available newsgroup.

Return Value

If the function succeeds, the return value is non-zero. If there are no more newsgroups available, or the function fails, the return value is zero. To get extended error information, call

NntpGetLastError.

Remarks

The **NntpGetNextGroupEx** function returns information about the next newsgroup on the server. This function is used in conjunction with the **NntpGetFirstGroupEx** function to enumerate all of the available newsgroups. Typically this is used to provide the user with a list of newsgroups to select. This function provides support for servers which use 64-bit article IDs.

While the the newsgroups are being listed, the client cannot select a newsgroup or retrieve the contents of a specific article. The client should store those newsgroups which it wants to retrieve articles from, and then once all of the newsgroups have been listed, it can then select each newsgroup and retrieve the available articles from that group.

Example

```
NEWSGROUPEX newsGroup;  
BOOL bResult;  
INT nResult;  
  
// List all available newsgroups  
nResult = NntpListGroupEx(hClient);  
  
if (nResult == NNTP_ERROR)  
{  
    TCHAR szError[ASTRING];  
    DWORD dwError = NntpGetLastError();  
  
    NntpGetErrorString(dwError, szError, ASTRING);  
    _ftprintf(stderr, _T("Error %08x: %s\n"), dwError, szError);  
    return;  
}  
  
// Get each newsgroup, printing the article range and  
// the name of the group  
bResult = NntpGetFirstGroupEx(hClient, &newsGroup);
```

```
while (bResult)
{
    _tprintf(_T("%I64u %I64u %s\n"), newsGroup.nFirstArticle,
            newsGroup.nLastArticle,
            newsGroup.szName);

    bResult = NntpGetNextGroup(hClient, &newsGroup);
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnwsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

NntpGetResultCode Function

```
INT WINAPI NntpGetResultCode(  
    HCLIENT hClient  
);
```

The **NntpGetResultCode** function reads the result code returned by the server in response to a command. The result code is a three-digit numeric code, and indicates if the operation succeeded, failed or requires additional action by the client.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the result code. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Remarks

Result codes are three-digit numeric values returned by the server. They may be broken down into the following ranges:

Value	Description
100-199	Positive preliminary result. This indicates that the requested action is being initiated, and the client should expect another reply from the server before proceeding.
200-299	Positive completion result. This indicates that the server has successfully completed the requested action.
300-399	Positive intermediate result. This indicates that the requested action cannot complete until additional information is provided to the server.
400-499	Transient negative completion result. This indicates that the requested action did not take place, but the error condition is temporary and may be attempted again.
500-599	Permanent negative completion result. This indicates that the requested action did not take place.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csnwsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[NntpCommand](#), [NntpGetMultiLine](#), [NntpGetResultString](#), [NntpSetMultiLine](#)

NntpGetResultString Function

```
INT WINAPI NntpGetResultString(  
    HCLIENT hClient,  
    LPTSTR lpszResult,  
    INT nMaxLength  
);
```

The **NntpGetResultString** function returns the last message sent by the server along with the result code.

Parameters

hClient

Handle to the client session.

lpszResult

A pointer to the buffer that will contain the result string returned by the server.

nMaxLength

The maximum number of characters that may be copied into the result string buffer, including the terminating null character.

Return Value

If the function succeeds, the return value is the length of the result string. If a value of zero is returned, this means that no result string was sent by the server. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Remarks

The **NntpGetResultString** function is most useful when an error occurs because the server will typically include a brief description of the cause of the error. This can then be parsed by the application or displayed to the user. The result string is updated each time the client sends a command to the server and then calls **NntpGetResultCode** to obtain the result code for the operation.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csntv10.lib

Unicode: Implemented as Unicode and ANSI versions.

NntpGetSecurityInformation Function

```
BOOL WINAPI NntpGetSecurityInformation(  
    HCLIENT hClient,  
    LPSECURITYINFO lpSecurityInfo  
);
```

The **NntpGetSecurityInformation** function returns security protocol, encryption and certificate information about the current client connection.

Parameters

hClient

Handle to the client session.

lpSecurityInfo

A pointer to a [SECURITYINFO](#) structure which contains information about the current client connection. The *dwSize* member of this structure must be initialized to the size of the structure before passing the address of the structure to this function.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **NntpGetLastError**.

Remarks

This function is used to obtain security related information about the current client connection to the server. It can be used to determine if a secure connection has been established, what security protocol was selected, and information about the server certificate. Note that a secure connection has not been established, the *dwProtocol* structure member will contain the value `SECURITY_PROTOCOL_NONE`.

Example

The following example notifies the user if the connection is secure or not:

```
SECURITYINFO securityInfo;  
  
securityInfo.dwSize = sizeof(SECURITYINFO);  
if (NntpGetSecurityInformation(hClient, &securityInfo))  
{  
    if (securityInfo.dwProtocol == SECURITY_PROTOCOL_NONE)  
    {  
        MessageBox(NULL, _T("The connection is not secure"),  
                    _T("Connection"), MB_OK);  
    }  
    else  
    {  
        if (securityInfo.dwCertStatus == SECURITY_CERTIFICATE_VALID)  
        {  
            MessageBox(NULL, _T("The connection is secure"),  
                        _T("Connection"), MB_OK);  
        }  
        else  
        {  
            MessageBox(NULL, _T("The server certificate not valid"),  
                        _T("Connection"), MB_OK);  
        }  
    }  
}
```

```
}  
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnwsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

NntpGetStatus Function

```
INT WINAPI NntpGetStatus(  
    HCLIENT hClient  
);
```

The **NntpGetStatus** function returns the current status of the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the client status code. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Remarks

The **NntpGetStatus** function returns a numeric code which identifies the current state of the client session. The following values may be returned:

Value	Constant	Description
1	NNTP_STATUS_IDLE	The client is current idle and not sending or receiving data.
2	NNTP_STATUS_CONNECT	The client is establishing a connection with the server.
3	NNTP_STATUS_READ	The client is reading data from the server.
4	NNTP_STATUS_WRITE	The client is writing data to the server.
5	NNTP_STATUS_DISCONNECT	The client is disconnecting from the server.

In a multithreaded application, any thread in the current process may call this function to obtain status information for the specified client session.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csntv10.lib

NntpGetTimeout Function

```
INT WINAPI NntpGetTimeout(  
    HCLIENT hClient  
);
```

The **NntpGetTimeout** function returns the number of seconds the client will wait for a response from the server. Once the specified number of seconds has elapsed, the function will fail and return to the caller.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the timeout period in seconds. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Remarks

The timeout value is only used with blocking client connections. A value of zero indicates that the default timeout period of 20 seconds should be used.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csnwsv10.lib

[NntpSetTimeout](#)

NntpGetTransferStatus Function

```
INT WINAPI NntpGetTransferStatus(  
    HCLIENT hClient,  
    LPNNTPTRANSFERSTATUS lpStatus  
);
```

The **NntpGetTransferStatus** function returns information about the current news article transfer in progress.

Parameters

hClient

Handle to the client session.

lpStatus

A pointer to an [NNTPTRANSFERSTATUS](#) structure which contains information about the status of the current article transfer.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is `NNTP_ERROR`. To get extended error information, call **NntpGetLastError**.

Remarks

The **NntpGetTransferStatus** function returns information about the current data transfer, including the average number of bytes transferred per second and the estimated amount of time until the transfer completes. If no article is currently being retrieved or submitted to the server, this function will return the status of the last successful data transfer made by the client.

In a multithreaded application, any thread in the current process may call this function to obtain status information for the specified client session.

If the server uses 64-bit article IDs, your application should use the **NntpGetTransferStatusEx** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csnwsv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

See Also

NntpGetTransferStatusEx Function

```
INT WINAPI NntpGetTransferStatusEx(  
    HCLIENT hClient,  
    LPNNTPTTRANSFERSTATUSEX lpStatusEx  
);
```

The **NntpGetTransferStatusEx** function returns information about the current news article transfer in progress.

Parameters

hClient

Handle to the client session.

lpStatus

A pointer to an [NNTPTTRANSFERSTATUSEX](#) structure which contains information about the status of the current article transfer.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is `NNTP_ERROR`. To get extended error information, call **NntpGetLastError**.

Remarks

The **NntpGetTransferStatusEx** function returns information about the current data transfer, including the average number of bytes transferred per second and the estimated amount of time until the transfer completes. This function provides support for servers which use 64-bit article IDs. If no article is currently being retrieved or submitted to the server, this function will return the status of the last successful data transfer made by the client.

In a multithreaded application, any thread in the current process may call this function to obtain status information for the specified client session.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csnwsv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

[NntpEnableEvents](#), [NntpRegisterEvent](#), [NNTPTTRANSFERSTATUSEX](#)

NntpInitialize Function

```
BOOL WINAPI NntpInitialize(  
    LPCTSTR lpszLicenseKey,  
    LPINITDATA lpData  
);
```

The **NntpInitialize** function initializes the library and validates the specified license key at runtime.

Parameters

lpszLicenseKey

Pointer to a string that specifies the runtime license key to be validated. If this parameter is NULL, the library will validate the development license installed on the local system.

lpData

Pointer to an INITDATA data structure. This parameter may be NULL if the initialization data for the library is not required.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **NntpGetLastError**. All other client functions will fail until a license key has been successfully validated.

Remarks

This must be the first function that an application calls before using any of the other functions in the library. When a NULL license key is specified, the library will only function on the development system. Before redistributing the application to an end-user, you must insure that this function is called with a valid license key.

If the *lpData* argument is specified, it must point to an INITDATA structure which has been initialized by setting the *dwSize* member to the size of the structure. All other structure members should be set to zero. If the function is successful, then the INITDATA structure will be filled with identifying information about the library.

Although it is only required that **NntpInitialize** be called once for the current process, it may be called multiple times; however, each call must be matched by a corresponding call to **NntpUninitialize**.

This function dynamically loads other system libraries and allocates thread local storage. If you are calling the functions in this library from within another DLL, it is important that you do not call the **NntpInitialize** or **NntpUninitialize** functions from the **DllMain** function because it can result in deadlocks or access violation errors. If the DLL is linked with the C runtime library (CRT), it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnwsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

NntpIsBlocking Function

```
BOOL WINAPI NntpIsBlocking(  
    HCLIENT hClient  
);
```

The **NntpIsBlocking** function is used to determine if the client is currently performing a blocking operation.

Parameters

hClient

Handle to the client session.

Return Value

If the client is performing a blocking operation, the function returns a non-zero value. If the client is not performing a blocking operation, or the client handle is invalid, the function returns zero.

Remarks

Because a blocking operation can allow the application to be re-entered (for example, by pressing a button while the operation is being performed), it is possible that another blocking function may be called while it is in progress. Since only one thread of execution may perform a blocking operation at any one time, an error would occur. The **NntpIsBlocking** function can be used to determine if the client is already blocked, and if so, take some other action (such as warning the user that they must wait for the operation to complete).

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnwsv10.lib

See Also

[NntpCancel](#), [NntpCommand](#), [NntpIsConnected](#), [NntpIsReadable](#), [NntpIsWritable](#)

NntpIsConnected Function

```
BOOL WINAPI NntpIsConnected(  
    HCLIENT hClient  
);
```

The **NntpIsConnected** function is used to determine if the client is currently connected to a server.

Parameters

hClient

Handle to the client session.

Return Value

If the client is connected to a server, the function returns a non-zero value. If the client is not connected, or the client handle is invalid, the function returns zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csnwsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[NntpIsBlocking](#), [NntpIsReadable](#), [NntpIsWritable](#)

NntpIsReadable Function

```
BOOL WINAPI NntpIsReadable(  
    HCLIENT hClient,  
    INT nTimeout,  
    LPDWORD lpdwAvail  
);
```

The **NntpIsReadable** function is used to determine if data is available to be read from the server.

Parameters

hClient

Handle to the client session.

nTimeout

Timeout for server response, in seconds. A value of zero specifies that the connection should be polled without blocking the current thread.

lpdwAvail

A pointer to an unsigned integer which will contain the number of bytes available to read. This parameter may be NULL if this information is not required.

Return Value

If the client can read data from the server within the specified timeout period, the function returns a non-zero value. If the client cannot read any data, the function returns zero.

Remarks

On some platforms, this value will not exceed the size of the receive buffer (typically 64K bytes). Because of differences between TCP/IP stack implementations, it is not recommended that your application exclusively depend on this value to determine the exact number of bytes available. Instead, it should be used as a general indicator that there is data available to be read.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csnwsv10.lib

See Also

[NntpGetStatus](#), [NntpIsBlocking](#), [NntpIsConnected](#), [NntpIsWritable](#), [NntpRead](#)

NntpIsWritable Function

```
BOOL WINAPI NntpIsWritable(  
    HCLIENT hClient,  
    INT nTimeout  
);
```

The **NntpIsWritable** function is used to determine if data can be written to the server.

Parameters

hClient

Handle to the client session.

nTimeout

Timeout for server response, in seconds. A value of zero specifies that the connection should be polled without blocking the current thread.

Return Value

If the client can write data to the server within the specified timeout period, the function returns a non-zero value. If the client cannot write any data, the function returns zero.

Remarks

Although this function can be used to determine if some amount of data can be sent to the remote process it does not indicate the amount of data that can be written without blocking the client. In most cases, it is recommended that large amounts of data be broken into smaller logical blocks, typically some multiple of 512 bytes in length.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csnews10.lib

NntpListArticles Function

```
INT WINAPI NntpListArticles(  
    HCLIENT hClient,  
    LONG nFirstArticle,  
    LONG nLastArticle  
);
```

The **NntpListArticles** function returns a list of articles in the currently selected newsgroup, within the specified article range.

Parameters

hClient

Handle to the client session.

nFirstArticle

The first newsgroup article to be returned in the list. If this value is -1, the list will begin with the first available article in the newsgroup.

nLastArticle

The last newsgroup article to be returned in the list. If the value is -1, the list will end with the last available article in the newsgroup.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Remarks

It is possible that there will be gaps in the articles within the range of the first and last articles in the newsgroup. This may be due to a message being canceled or expired. Use the **NntpGetFirstArticle** and **NntpGetNextArticle** functions to read the list of articles returned by the server.

If the server uses 64-bit article IDs, your application should use the **NntpListArticlesEx** function.

Example

```
NEWSARTICLE newsArticle;  
BOOL bResult;  
INT nResult;  
  
// List all articles in the current group  
nResult = NntpListArticles(hClient, -1L, -1L);  
  
if (nResult == NNTP_ERROR)  
{  
    TCHAR szError[ASTRING];  
    DWORD dwError = NntpGetLastError();  
  
    NntpGetErrorString(dwError, szError, ASTRING);  
    _ftprintf(stderr, _T("Error %08x: %s\n"), dwError, szError);  
    return;  
}  
  
// Get each article in the current newsgroup, printing the article  
// number and the subject of the article
```

```
bResult = NntpGetNextArticle(hClient, &newsArticle);
while (bResult)
{
    _tprintf(_T("%ld %s\n"), newsArticle.nArticleId, newsArticle.szSubject);
    bResult = NntpGetNextArticle(hClient, &newsArticle);
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnwsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[NntpGetArticleRange](#), [NntpGetCurrentArticle](#), [NntpGetFirstArticle](#), [NntpGetNextArticle](#),
[NntpListGroup](#)s, [NntpListArticlesEx](#), [NntpListNewGroups](#)

NntpListGroup Function

```
INT WINAPI NntpListGroup(  
    HCLIENT hClient  
);
```

The **NntpListGroup** function instructs the server to begin sending a list of newsgroups back to the client.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Remarks

The **NntpListGroup** function is used in conjunction with the **NntpGetFirstGroup** and **NntpGetNextGroup** functions to enumerate all of the available newsgroups. Typically this is used to provide the user with a list of newsgroups to select. To list only those newsgroups which have been added since a certain date, use the **NntpListNewGroups** function.

While the newsgroups are being listed, the client cannot select a newsgroup or retrieve the contents of a specific article. The client should store those newsgroups which it wants to retrieve articles from, and then once all of the newsgroups have been listed, it can then select each newsgroup and retrieve the available articles from that group.

Example

```
NEWSGROUP newsGroup;  
BOOL bResult;  
INT nResult;  
  
// List all available newsgroups  
nResult = NntpListGroup(hClient);  
  
if (nResult == NNTP_ERROR)  
{  
    TCHAR szError[ASTRING];  
    DWORD dwError = NntpGetLastError();  
    NntpGetErrorString(dwError, szError, ASTRING);  
    fprintf(stderr, "Error %08x: %s\n", dwError, szError);  
    return;  
}  
  
// Get each newsgroup, printing the article range and  
// the name of the group  
bResult = NntpGetFirstGroup(hClient, &newsGroup);  
while (bResult)  
{  
    printf("%ld %ld %s\n", newsGroup.nFirstArticle,  
        newsGroup.nLastArticle,  
        newsGroup.szName);  
    bResult = NntpGetNextGroup(hClient, &newsGroup);  
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnwsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[NntpSelectGroup](#)

NntpListNewGroups Function

```
INT WINAPI NntpListNewGroups(  
    HCLIENT hClient,  
    LPCTSTR lpszLastUpdated,  
    BOOL bLocalTime  
);
```

The **NntpListNewGroups** function instructs the server to begin sending a list of newsgroups that were created since the specified date.

Parameters

hClient

Handle to the client session.

lpszLastUpdated

Pointer to a string which specifies the date and time that the list of newsgroups were last retrieved from the server. This parameter may be NULL or an empty string, in which case all available newsgroups will be listed by the server.

bLocalTime

A boolean value which indicates if the time specified in the *lpszLastUpdated* parameter is for the current timezone. If the value is non-zero, the time is assumed to be in the local timezone. If the value is zero, the time is assumed to be in Coordinated Universal Time (UTC).

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Remarks

The **NntpListNewGroups** function is used in conjunction with the **NntpGetFirstGroup** and **NntpGetNextGroup** functions to enumerate all of the newsgroups that were added to the server since a specific date and time. Typically this is used to provide the user with a list of updated newsgroups to select. To list all of the newsgroups available on the server, use the **NntpListGroup** function.

While the newsgroups are being listed, the client cannot select a newsgroup or retrieve the contents of a specific article. The client should store those newsgroups which it wants to retrieve articles from, and then once all of the newsgroups have been listed, it can then select each newsgroup and retrieve the available articles from that group.

Example

```
NEWSGROUP newsGroup;  
LPCTSTR lpszUpdated = _T("1/1/2004 12:00 AM");  
BOOL bResult;  
INT nResult;  
  
// List all newsgroups that were added after a  
// specific date  
nResult = NntpListNewGroups(hClient, lpszUpdated, TRUE);  
  
if (nResult == NNTP_ERROR)  
{  
    TCHAR szError[ASTRING];
```

```
    DWORD dwError = NntpGetLastError();
    NntpGetErrorString(dwError, szError, ASTRING);
    fprintf(stderr, "Error %08x: %s\n", dwError, szError);
    return;
}

// Get each newsgroup, printing the article range and
// the name of the group
bResult = NntpGetFirstGroup(hClient, &newsGroup);
while (bResult)
{
    printf("%ld %ld %s\n", newsGroup.nFirstArticle,
           newsGroup.nLastArticle,
           newsGroup.szName);
    bResult = NntpGetNextGroup(hClient, &newsGroup);
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnwsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[NntpGetArticleRange](#), [NntpGetFirstGroup](#), [NntpGetNextGroup](#), [NntpListGroup](#), [NntpSelectGroup](#)

NntpOpenArticle Function

```
INT WINAPI NntpOpenArticle(  
    HCLIENT hClient,  
    LONG nArticleId  
);
```

The **NntpOpenArticle** function opens the specified article in the currently selected newsgroup.

Parameters

hClient

Handle to the client session.

nArticleId

An integer value that specifies which article in the current newsgroup to retrieve. This value may be zero, which specifies that the current article should be opened.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Remarks

The **NntpOpenArticle** function sends a request to begin returning the contents of the specified article. The **NntpRead** function is used to read the article contents after it has been opened. When the complete article has been read, the **NntpCloseArticle** function must be called to close the article and complete the request.

It is recommended most applications use the **NntpGetArticle** function, which will retrieve the complete article in a single function call. This function is typically only used if the application needs to modify the contents of the article as it is being read. If you wish to download an article and store it in a file on the local system, use the **NntpStoreArticle** function.

If the server uses 64-bit article IDs, your application should use the **NntpOpenArticleEx** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnwsv10.lib

See Also

NntpOpenArticleEx Function

```
INT WINAPI NntpOpenArticleEx(  
    HCLIENT hClient,  
    ULONGLONG nArticleId  
);
```

The **NntpOpenArticle** function opens the specified article in the currently selected newsgroup.

Parameters

hClient

Handle to the client session.

nArticleId

An unsigned 64-bit integer that specifies which article in the current newsgroup to retrieve. This value may be zero, which specifies that the current article should be opened.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Remarks

The **NntpOpenArticleEx** function sends a request to begin returning the contents of the specified article. This function provides support for servers which use 64-bit article IDs. The **NntpRead** function is used to read the article contents after it has been opened. When the complete article has been read, the **NntpCloseArticle** function must be called to close the article and complete the request.

It is recommended most applications use the **NntpGetArticleEx** function, which will retrieve the complete article in a single function call. This function is typically only used if the application needs to modify the contents of the article as it is being read. If you wish to download an article and store it in a file on the local system, use the **NntpStoreArticleEx** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csntsv10.lib

See Also

NntpOpenArticleByMessageId Function

```
INT WINAPI NntpOpenArticleByMessageId(  
    HCLIENT hClient,  
    LPCTSTR lpszMessageId  
);
```

The **NntpOpenArticleByMessageId** function opens the article specified by the message identifier string.

Parameters

hClient

Handle to the client session.

lpszMessageId

Pointer to a string which contains the message identifier for the article in the current newsgroup.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csnews10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

NntpOpenNextArticle Function

```
INT WINAPI NntpOpenNextArticle(  
    HCLIENT hClient  
);
```

The **NntpOpenNextArticle** function opens the next available article in the current newsgroup.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnwsv10.lib

See Also

[NntpCloseArticle](#), [NntpGetArticle](#), [NntpGetArticleRange](#), [NntpGetCurrentArticle](#), [NntpListArticles](#), [NntpOpenArticleByMessageId](#), [NntpOpenPreviousArticle](#), [NntpRead](#)

NntpOpenPreviousArticle Function

```
INT WINAPI NntpOpenPreviousArticle(  
    HCLIENT hClient  
);
```

The **NntpOpenPreviousArticle** function opens the previous article in the current newsgroup.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnwsv10.lib

See Also

[NntpCloseArticle](#), [NntpGetArticle](#), [NntpGetArticleRange](#), [NntpGetCurrentArticle](#), [NntpListArticles](#), [NntpOpenArticleByMessageId](#), [NntpOpenNextArticle](#), [NntpRead](#)

NntpPostArticle Function

```
INT WINAPI NntpPostArticle(  
    HCLIENT hClient,  
    LPCTSTR lpBuffer,  
    DWORD dwLength,  
    DWORD dwReserved  
);
```

The **NntpPostArticle** function post the contents of the specified buffer to the server as a new article in the current newsgroup.

Parameters

hClient

Handle to the client session.

lpBuffer

A pointer to a character buffer which contains the article to be posted to the currently selected newsgroup.

dwLength

Specifies the length of the string which contains the article. If this parameter is -1, the actual length of the string is calculated by searching the buffer for a terminating null byte.

dwReserved

Reserved parameter. This value should always be zero.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Remarks

The **NntpPostArticle** function is used to post the contents of the specified buffer to the server as a new article in the current newsgroup. Not all newsgroups permit new articles to be posted, and some newsgroups may require that you email the article to a moderator for approval instead of posting directly to the group. It may be required that the client authenticate itself using the **NntpAuthenticate** function prior to posting the article.

A news article is similar to an email message in that it contains one or more header fields, followed by an empty line, followed by the body of the article. Each line of text should be terminated by a carriage return/linefeed sequence of characters. The Mail Message library can be used to compose a message if needed. Note that the article header must contain a header field named "Newsgroups" with a value that specifies the newsgroup or newsgroups the article is being posted to. If this header field is missing, the news server will reject the article.

This function will cause the current thread to block until the transfer has completed, a timeout occurs or the transfer is canceled. During the transfer, the HTTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **NntpEnableEvents**, or by registering a callback function using the **NntpRegisterEvent** function.

To determine the current status of a transfer while it is in progress, use the **NntpGetTransferStatus** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnwsv10.lib

See Also

[NntpGetTransferStatus](#), [NntpIsBlocking](#), [NntpIsWritable](#), [NntpRead](#), [NntpReset](#), [NntpWrite](#)

NntpRead Function

```
INT WINAPI NntpRead(  
    HCLIENT hClient,  
    LPBYTE lpBuffer,  
    INT cbBuffer  
);
```

The **NntpRead** function reads the specified number of bytes from the client socket and copies them into the buffer. The data may be of any type, and is not terminated with a null character.

Parameters

hClient

Handle to the client session.

lpBuffer

Pointer to the buffer in which the data will be copied.

cbBuffer

The maximum number of bytes to read and copy into the specified buffer. This value must be greater than zero.

Return Value

If the function succeeds, the return value is the number of bytes actually read. A return value of zero indicates that the server has closed the connection and there is no more data available to be read. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Remarks

When **NntpRead** is called and the client is in non-blocking mode, it is possible that the function will fail because there is no available data to read at that time. This should not be considered a fatal error. Instead, the application should simply wait to receive the next asynchronous notification that data is available.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csnwsv10.lib

See Also

[NntpCloseArticle](#), [NntpIsBlocking](#), [NntpIsConnected](#), [NntpIsReadable](#), [NntpOpenArticle](#), [NntpWrite](#)

NntpRegisterEvent Function

```
INT WINAPI NntpRegisterEvent(  
    HCLIENT hClient,  
    UINT nEvent,  
    NNTPEVENTPROC LpEventProc,  
    DWORD_PTR dwParam  
);
```

The **NntpRegisterEvent** function registers an event handler for the specified event.

Parameters

hClient

Handle to the client session.

nEvent

An unsigned integer which specifies which event should be registered with the specified callback function. One of the following values may be used:

Constant	Description
NNTP_EVENT_CONNECT	The connection to the server has completed.
NNTP_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
NNTP_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
NNTP_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
NNTP_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
NNTP_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.
NNTP_EVENT_COMMAND	A command has been issued by the client and the server response has been received and processed. This event can be used to log the result codes and messages returned by the server in response to actions taken by the client.
NNTP_EVENT_LISTARTICLE	The client is retrieving a list of articles from the server and information about another article has been

	processed. The client should use this event to retrieve the next available article from the server.
NNTP_EVENT_LASTARTICLE	The client is retrieving a list of articles from the server and all of the available articles have been processed. This event is generated when there are no further articles.
NNTP_EVENT_LISTGROUP	The client is retrieving a list of newsgroups from the server and information about another group has been processed. The client should use this event to retrieve the next available newsgroup from the server.
NNTP_EVENT_LASTGROUP	The client is retrieving a list of newsgroups from the server and all of the available groups have been processed. This event is generated when there are no further newsgroups.
NNTP_EVENT_PROGRESS	The client is in the process of sending or receiving data from the server. This event is called periodically during a transfer so that the client can update any user interface components such as a status control or progress bar.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **NntpEventProc** callback function. If this parameter is NULL, the callback for the specified event is disabled.

dwParam

A user-defined integer value that is passed to the callback function. If the application targets the x86 (32-bit) platform, this parameter must be a 32-bit unsigned integer. If the application targets the x64 (64-bit) platform, this parameter must be a 64-bit unsigned integer.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Remarks

The **NntpRegisterEvent** function associates a callback function with a specific event. The event handler is an **NntpEventProc** function that is invoked when the event occurs. Arguments are passed to the function to identify the client session, the event type and the user-defined value specified when the event handler is registered. If the event occurs because of an error condition, the error code will be provided to the handler.

This function is typically used to register an event handler that is invoked while a news article is being uploaded or downloaded. The NNTP_EVENT_PROGRESS event will only be generated periodically during the transfer to ensure the application is not flooded with event notifications. It is guaranteed that at least one NNTP_EVENT_PROGRESS notification will occur at the beginning of the transfer, and one at the end of the transfer when it has completed.

The callback function specified by the *lpEventProc* parameter must be declared using the **__stdcall** calling convention. This ensures the arguments passed to the event handler are pushed on to the stack in the correct order. Failure to use the correct calling convention will corrupt the stack and cause the application to terminate abnormally.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnwsv10.lib

NntpReset Function

```
INT WINAPI NntpReset(  
    HCLIENT hClient  
);
```

The **NntpReset** function resets the client state and resynchronizes with the server. This function is typically called after an unexpected error has occurred, or an operation has been canceled.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Remarks

The client cannot be reset while it is in a blocked state.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csnwsv10.lib

[NntpCancel](#), [NntpIsBlocking](#)

NntpSelectGroup Function

```
INT WINAPI NntpSelectGroup(  
    HCLIENT hClient,  
    LPCTSTR lpszGroupName  
);
```

The **NntpSelectGroup** function selects the specified newsgroup from which articles will be retrieved.

Parameters

hClient

Handle to the client session.

lpszGroupName

Pointer to a string which specifies the newsgroup to be selected. This value may be NULL, in which case the current newsgroup is unchanged, but the article count is updated.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Remarks

This function selects the newsgroup and obtains a description and the first and last article numbers for that group.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csnwsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[NntpGetGroupName](#), [NntpGetGroupTitle](#), [NntpListGroup](#), [NntpListNewGroups](#)

NntpSetLastError Function

```
VOID WINAPI NntpSetLastError(  
    DWORD dwErrorCode  
);
```

The **NntpSetLastError** function sets the last error code for the current thread. This function is typically used to clear the last error by specifying a value of zero as the parameter.

Parameters

dwErrorCode

Specifies the last error code for the current thread.

Return Value

None.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or NNTP_ERROR. Those functions which call **NntpSetLastError** when they succeed are noted on the function reference page.

Applications can retrieve the value saved by this function by using the **NntpGetLastError** function. The use of **NntpGetLastError** is optional; an application can call the function to determine the specific reason for a function failure.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csntools10.lib

See Also

[NntpGetErrorString](#), [NntpGetLastError](#)

NntpSetMultiLine Function

```
INT WINAPI NntpSetMultiLine(  
    HCLIENT hClient,  
    BOOL bMultiLine  
);
```

The **NntpSetMultiLine** function sets the client multi-line flag into the specified value.

Parameters

hClient

Handle to the client session.

bMultiLine

A boolean flag which determines if the client is processing multiple lines of data as the result of a command.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Remarks

The multi-line flag is used by the library to determine if multiple lines of data will be returned by the server as the result of a command. Unlike a single line response, which consists of a result code and result string, a multi-line response consists of one or more lines of text, terminated by a special end-of-data marker.

The **NntpSetMultiLine** function should only be used in conjunction with the **NntpCommand** function. If a command is issued which would result in multiple lines of output, the multi-line flag must be set TRUE. The multi-line flag must be set after each command, since it is reset to FALSE with each command that is sent to the server.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csnwsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[NntpCommand](#), [NntpGetMultiLine](#), [NntpGetResultCode](#), [NntpGetResultString](#)

NntpSetTimeout Function

```
INT WINAPI NntpSetTimeout(  
    HCLIENT hClient,  
    INT nTimeout  
);
```

The **NntpSetTimeout** function sets the number of seconds the client will wait for a response from the server. Once the specified number of seconds has elapsed, the function will fail and return to the caller.

Parameters

hClient

Handle to the client session.

nTimeout

The number of seconds to wait for a blocking operation to complete.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csntools10.lib

See Also

[NntpConnect](#), [NntpGetTimeout](#)

NntpStoreArticle Function

```
INT WINAPI NntpStoreArticle(  
    HCLIENT hClient,  
    LONG nArticleId,  
    LPCTSTR lpszFileName  
);
```

The **NntpStoreMessage** function retrieves an article from the current newsgroup and stores it in a local file.

Parameters

hClient

Handle to the client session.

nArticleId

An integer value that specifies the article to be downloaded.

lpszFileName

Pointer to a string which specifies the file that the article will be stored in. If the file does not exist, it will be created. If the file does exist, it will be overwritten with the contents of the article.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Remarks

The **NntpStoreArticle** function provides a method of retrieving and storing an article on the local system. The contents of the article is stored as a text file, using the specified file name. This function always causes the caller to block until the entire message has been retrieved, even if the client has been put in asynchronous mode. If you wish to download the article to memory rather than a file, use the **NntpGetArticle** function.

If event handling is enabled, the NNTP_EVENT_PROGRESS event will fire periodically during the transfer of the article to the local system. An application can determine how much of the article has been retrieved by calling the **NntpGetTransferStatus** function.

If the server uses 64-bit article IDs, your application should use the **NntpStoreArticleEx** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csnwsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

NntpStoreArticleEx Function

```
INT WINAPI NntpStoreArticleEx(  
    HCLIENT hClient,  
    ULONGLONG nArticleId,  
    LPCTSTR lpszFileName,  
    DWORD dwReserved  
);
```

The **NntpStoreMessageEx** function retrieves an article from the current newsgroup and stores it in a local file.

Parameters

hClient

Handle to the client session.

nArticleId

An unsigned 64-integer value which specifies the article to be downloaded.

lpszFileName

Pointer to a string which specifies the file that the article will be stored in. If the file does not exist, it will be created. If the file does exist, it will be overwritten with the contents of the article.

dwReserved

Number of the article to retrieve. This value must be greater than zero.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Remarks

The **NntpStoreArticleEx** function provides a method of retrieving and storing an article on the local system. This function provides support for servers which use 64-bit article IDs.

The contents of the article is stored as a text file, using the specified file name. This function always causes the caller to block until the entire message has been retrieved, even if the client has been put in asynchronous mode. If you wish to download the article to memory rather than a file, use the **NntpGetArticle** function.

If event handling is enabled, the NNTP_EVENT_PROGRESS event will fire periodically during the transfer of the article to the local system. An application can determine how much of the article has been retrieved by calling the **NntpGetTransferStatusEx** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csnwsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[NntpGetArticleEx](#), [NntpGetArticleHeadersEx](#), [NntpGetTransferStatusEx](#)

NntpUninitialize Function

```
VOID WINAPI NntpUninitialize();
```

The **NntpUninitialize** function terminates the use of the library.

Parameters

There are no parameters.

Return Value

None.

Remarks

An application is required to perform a successful **NntpInitialize** call before it can call any of the other library functions. When it has completed the use of library, the application must call **NntpUninitialize** to allow the library to free any resources allocated on behalf of the process. Any pending blocking or asynchronous calls in this process are canceled without posting any notification messages, and all sockets that were opened by the process are closed.

There must be a call to **NntpUninitialize** for every successful call to **NntpInitialize** made by a process. In a multithreaded environment, operations for all threads in the client are terminated.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnwsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[NntpDisconnect](#), [NntpInitialize](#)

NntpWrite Function

```
INT WINAPI NntpWrite(  
    HCLIENT hClient,  
    LPBYTE lpBuffer,  
    INT cbBuffer  
);
```

The **NntpWrite** function sends the specified number of bytes to the server.

Parameters

hClient

Handle to the client session.

lpBuffer

The pointer to the buffer which contains the data that is to be sent to the server.

cbBuffer

The number of bytes to send from the specified buffer.

Return Value

If the function succeeds, the return value is the number of bytes actually written. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Remarks

The return value may be less than the number of bytes specified by the *cbBuffer* parameter. In this case, the data has been partially written and it is the responsibility of the client application to send the remaining data at some later point. For non-blocking clients, the client must wait for the NNTP_EVENT_WRITE asynchronous notification message before it resumes sending data.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csnwsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

Network News Transfer Protocol Data Structures

- INITDATA
- NEWSARTICLE
- NEWSARTICLEX
- NEWSGROUP
- NEWSGROUPEX
- NNTPTRANSFERSTATUS
- NNTPTRANSFERSTATUSEX
- SECURITYCREDENTIALS
- SECURITYINFO
- SYSTEMTIME

INITDATA Structure

This structure contains information about the SocketTools library when the initialization function returns.

```
typedef struct _INITDATA
{
    DWORD      dwSize;
    DWORD      dwVersionMajor;
    DWORD      dwVersionMinor;
    DWORD      dwVersionBuild;
    DWORD      dwOptions;
    DWORD_PTR  dwReserved1;
    DWORD_PTR  dwReserved2;
    TCHAR      szDescription[128];
} INITDATA, *LPINITDATA;
```

Members

dwSize

Size of this structure. This structure member must be set to the size of the structure prior to calling the initialization function. Failure to do so will cause the function to fail.

dwVersionMajor

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the major version number for the library.

dwVersionMinor

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the minor version number for the library.

dwVersionBuild

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the build number for the library.

dwOptions

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

dwReserved1

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

dwReserved2

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

szDescription

A null terminated string which describes the library.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Unicode: Implemented as Unicode and ANSI versions.

NEWSARTICLE Structure

This structure is used by the **NntpGetFirstArticle** and **NntpGetNextArticle** functions to return information about articles in the currently selected directory. If the server uses 64-bit article IDs your application should use the [NEWSARTICLEEX](#) structure and related functions.

```
typedef struct _NEWSARTICLE
{
    LONG        nArticleId;
    LONG        nBytes;
    LONG        nLines;
    TCHAR       szSubject[NNTP_MAXSUBJLEN];
    TCHAR       szAuthor[NNTP_MAXAUTHLEN];
    TCHAR       szMessageId[NNTP_MAXMSGIDLEN];
    TCHAR       szReferences[NNTP_MAXREFLEN];
    SYSTEMTIME  stPosted;
} NEWSARTICLE, *LPNEWSARTICLE;
```

Members

nArticleId

A long integer which specifies the article number.

nBytes

The length of the news article in bytes.

nLines

The length of the news article specified as the number of lines of text.

szSubject

A pointer to a string which specifies the subject of the article.

szAuthor

A pointer to a string which specifies the email address of the user who posted the article.

szMessageId

A pointer to a string which specifies the message ID for the article.

szReferences

A pointer to a string which specifies references to the article.

stPosted

A SYSTEMTIME structure which specifies when the article was posted in Universal Coordinated Time (UTC).

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnwsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

NEWSARTICLEEX Structure

This structure is used by the **NntpGetFirstArticleEx** and **NntpGetNextArticleEx** functions to return information about articles in the currently selected directory. This structure is intended for use with servers that return 64-bit article IDs.

```
typedef struct _NEWSARTICLEEX
{
    ULONGLONG    nArticleId;
    ULONG        nBytes;
    ULONG        nLines;
    TCHAR        szSubject[NNTP_MAXSUBJLEN];
    TCHAR        szAuthor[NNTP_MAXAUTHLEN];
    TCHAR        szMessageId[NNTP_MAXMSGIDLEN];
    TCHAR        szReferences[NNTP_MAXREFLEN];
    SYSTEMTIME   stPosted;
} NEWSARTICLEEX, *LPNEWSARTICLEEX;
```

Members

nArticleId

An unsigned 64-bit integer which specifies the article number.

nBytes

The length of the news article in bytes.

nLines

The length of the news article specified as the number of lines of text.

szSubject

A pointer to a string which specifies the subject of the article.

szAuthor

A pointer to a string which specifies the email address of the user who posted the article.

szMessageId

A pointer to a string which specifies the message ID for the article.

szReferences

A pointer to a string which specifies references to the article.

stPosted

A SYSTEMTIME structure which specifies when the article was posted in Universal Coordinated Time (UTC).

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnwsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

NEWSGROUP Structure

This structure is used by the **NntpGetFirstGroup** and **NntpGetNextGroup** functions to return information about available newsgroups. If the server uses 64-bit article IDs your application should use the [NEWSGROUPEX](#) structure and related functions.

```
typedef struct _NEWSGROUP
{
    LONG        nFirstArticle;
    LONG        nLastArticle;
    DWORD       dwAccess;
    TCHAR       szName[NNTP_MAXGRPNAMLEN];
} NEWSGROUP, *LPNEWSGROUP;
```

Members

nFirstArticle

A long integer which specifies the article number of the first available article in the newsgroup.

nLastArticle

A long integer which specifies the article number of the last available article in the newsgroup. Note that posted articles may not be contiguous in the range between the first and last article numbers. Some servers may assign numbers in a different order than the articles were posted, or there may be gaps where articles have been removed.

dwAccess

An unsigned integer which specifies the access mode for the group. It may be one of the following values:

Constant	Description
NNTP_GROUP_READONLY	The group is read-only and cannot be modified. Attempts to post articles to the newsgroup will result in an error.
NNTP_GROUP_READWRITE	Articles can be posted to the newsgroup. Even though a newsgroup is read-write, it may require that the client authenticate before being given permission to post articles to the server.
NNTP_GROUP_MODERATED	The newsgroup is moderated and articles can only be posted by the group moderator. To request that an article be posted to the newsgroup, you must email the message to the moderator.

szName

A pointer to a string which specifies the name of the newsgroup.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csnews10.lib

Unicode: Implemented as Unicode and ANSI versions.

NEWSGROUPEX Structure

This structure is used by the **NntpGetFirstGroupEx** and **NntpGetNextGroupEx** functions to return information about available newsgroups. This structure is intended for use with servers that return 64-bit article IDs.

```
typedef struct _NEWSGROUPEX
{
    ULONGLONG    nFirstArticle;
    ULONGLONG    nLastArticle;
    DWORD        dwAccess;
    TCHAR        szName[NNTP_MAXGRPNAMELEN];
} NEWSGROUP, *LPNEWSGROUP;
```

Members

nFirstArticle

An unsigned 64-bit integer which specifies the article number of the first available article in the newsgroup.

nLastArticle

An unsigned 64-bit integer which specifies the article number of the last available article in the newsgroup. Note that posted articles may not be contiguous in the range between the first and last article numbers. Some servers may assign numbers in a different order than the articles were posted, or there may be gaps where articles have been removed.

dwAccess

An unsigned integer which specifies the access mode for the group. It may be one of the following values:

Constant	Description
NNTP_GROUP_READONLY	The group is read-only and cannot be modified. Attempts to post articles to the newsgroup will result in an error.
NNTP_GROUP_READWRITE	Articles can be posted to the newsgroup. Even though a newsgroup is read-write, it may require that the client authenticate before being given permission to post articles to the server.
NNTP_GROUP_MODERATED	The newsgroup is moderated and articles can only be posted by the group moderator. To request that an article be posted to the newsgroup, you must email the message to the moderator.

szName

A pointer to a string which specifies the name of the newsgroup.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csnwsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

NNTPTRANSFERSTATUS Structure

This structure is used by the **NntpGetTransferStatus** function to return information about an article transfer in progress. If the server uses 64-bit article IDs your application should use the [NNTPTRANSFERSTATUSEX](#) structure and related functions.

```
typedef struct _NNTPTRANSFERSTATUS
{
    LONG    nArticleId;
    DWORD   dwBytesTotal;
    DWORD   dwBytesCopied;
    DWORD   dwBytesPerSecond;
    DWORD   dwTimeElapsed;
    DWORD   dwTimeEstimated;
} NNTPTRANSFERSTATUS, *LPNNTPTRANSFERSTATUS;
```

Members

nArticleId

A signed integer that specifies the article ID of the current article that is being transferred. If an article is being posted, this value will be zero.

dwBytesTotal

An unsigned integer that specifies the total number of bytes that will be transferred. If the article is being copied from the server to the local host, this is the size of the article on the server. If the article is being posted to the server, it is the size of article on the local system. If the article size cannot be determined, this value will be zero.

dwBytesCopied

An unsigned integer that specifies the total number of bytes that have been copied.

dwBytesPerSecond

An unsigned integer that specifies the average number of bytes that have been copied per second.

dwTimeElapsed

An unsigned integer that specifies the number of seconds that have elapsed since the transfer started.

dwTimeEstimated

An unsigned integer that specifies the estimated number of seconds until the transfer is completed. This is based on the average number of bytes transferred per second.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

NNTPTRANSFERSTATUSEX Structure

This structure is used by the **NntpGetTransferStatusEx** function to return information about an article transfer in progress. This structure is intended for use with servers that return 64-bit article IDs.

```
typedef struct _NNTPTRANSFERSTATUSEX
{
    ULONGLONG nArticleId;
    DWORD     dwBytesTotal;
    DWORD     dwBytesCopied;
    DWORD     dwBytesPerSecond;
    DWORD     dwTimeElapsed;
    DWORD     dwTimeEstimated;
} NNTPTRANSFERSTATUSEX, *LPNNTPTRANSFERSTATUSEX;
```

Members

nArticleId

An unsigned 64-bit integer that specifies the article ID of the current article that is being transferred. If an article is being posted, this value will be zero.

dwBytesTotal

An unsigned integer that specifies the total number of bytes that will be transferred. If the article is being copied from the server to the local host, this is the size of the article on the server. If the article is being posted to the server, it is the size of article on the local system. If the article size cannot be determined, this value will be zero.

dwBytesCopied

An unsigned integer that specifies the total number of bytes that have been copied.

dwBytesPerSecond

An unsigned integer that specifies the average number of bytes that have been copied per second.

dwTimeElapsed

An unsigned integer that specifies the number of seconds that have elapsed since the transfer started.

dwTimeEstimated

An unsigned integer that specifies the estimated number of seconds until the transfer is completed. This is based on the average number of bytes transferred per second.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

SECURITYCREDENTIALS Structure

The **SECURITYCREDENTIALS** structure specifies the information needed by the library to specify additional security credentials, such as a client certificate or private key, when establishing a secure connection.

```
typedef struct _SECURITYCREDENTIALS
{
    DWORD    dwSize;
    DWORD    dwProtocol;
    DWORD    dwOptions;
    DWORD    dwReserved;
    LPCTSTR  lpszHostName;
    LPCTSTR  lpszUserName;
    LPCTSTR  lpszPassword;
    LPCTSTR  lpszCertStore;
    LPCTSTR  lpszCertName;
    LPCTSTR  lpszKeyFile;
} SECURITYCREDENTIALS, *LPSECURITYCREDENTIALS;
```

Members

dwSize

Size of this structure. If the structure is being allocated dynamically, this member must be set to the size of the structure and all other unused structure members must be initialized to a value of zero or NULL.

dwProtocol

A bitmask of supported security protocols. The value of this structure member is constructed by using a bitwise operator with any of the following values:

Constant	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_SSL	Either SSL 2.0 or SSL 3.0 should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, TLS will be excluded from the list of supported protocols. Both SSL 2.0 and 3.0 have been deprecated and will never be used unless explicitly specified. It is not recommended that you enable either of these protocols for secure connections because it will cause most servers to reject your connection request, even if a version of TLS is also specified.
SECURITY_PROTOCOL_TLS	Either the TLS 1.0, 1.1 or 1.2 protocol should be used when establishing a secure connection. The correct protocol is automatically selected, based on

	what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers that reject any attempt to use the older SSL protocol and require that only TLS be used.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This is the recommended version of TLS to use with secure connections.

dwOptions

A value which specifies one or options. This member is constructed by using a bitwise operator with any of the following values:

Constant	Description
CREDENTIAL_STORE_CURRENT_USER	The library will attempt to open a store for the current user using the certificate store name provided in this structure. If no options are specified, then this is the default behavior.
CREDENTIAL_STORE_LOCAL_MACHINE	The library will attempt to open a local machine store using the certificate store name provided in this structure. If this option is specified, the library will always search for a local machine store before searching for the store by that name for the current user.
CREDENTIAL_STORE_FILENAME	The certificate store name is a file that contains the certificate and private key that

will be used.

dwReserved

This structure member is reserved for future use and should always be initialized to zero.

lpszHostName

A pointer to a null terminated string which specifies the hostname that will be used when validating the server certificate. If this member is NULL, then the server certificate will be validated against the hostname used to establish the connection.

lpszUserName

A pointer to a null terminated string which identifies the owner of client certificate. Currently this member is not used by the library and should always be initialized as a NULL pointer.

lpszPassword

A pointer to a null terminated string which specifies the password needed to access the certificate. Currently this member is only used if the CREDENTIAL_STORE_FILENAME option has been specified. If there is no password associated with the certificate, then this member should be initialized as a NULL pointer.

lpszCertStore

A pointer to a null terminated string which specifies the name of the certificate store to open. A certificate store is a collection of certificates and their private keys, typically organized by how they are used. If this value is NULL or points to an empty string, the default certificate store "MY" will be used.

Store Name	Description
------------	-------------

CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as VeriSign and Thawte act as certification authorities.
----	---

MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. This corresponds to the "Personal" store that is displayed by the certificate manager utility and is the default store used by the library.
----	--

ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as VeriSign and Thawte are installed as part of the operating system and periodically updated by Microsoft.
------	--

lpszCertName

A pointer to a null terminated string which specifies the name of the certificate to use. The library will first search the certificate store for a certificate with a matching "friendly name"; this is a name for the certificate that is assigned by the user. Note that the name must match completely, but the comparison is not case sensitive. If no matching certificate is found, the library will then attempt to find a certificate that has a matching common name (also called the certificate subject). This comparison is less stringent, and the first partial match will be returned. If this second search fails, the library will return an error indicating that the certificate could not be found. If the SECURITY_PROTOCOL_SSH protocol has been specified, this member should be NULL.

lpszKeyFile

A pointer to a null terminated string which specifies the name of the file which contains the private key required to establish the connection. This member is only used for SSH connections

and should always be NULL when establishing a secure connection using SSL or TLS.

Remarks

A client application only needs to create this structure if the server requires that the client provide a certificate as part of the process of negotiating the secure session. If a certificate is required, note that it must have a private key associated with it. Attempting to use a certificate that does not have a private key will result in an error during the connection process indicating that the client credentials could not be established.

If you are using a local certificate store, with the certificate and private key stored in the registry, you can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU:" for the current user, or "HKLM:" for the local machine. For example, a certificate store name of "HKLM:MY" would specify the personal certificate store for the local machine, rather than the current user. If neither prefix is specified, then it will default to the certificate store for the current user. You can manage these certificates using the CertMgr.msc Microsoft Management Console (MMC) snap-in.

It is possible to load the certificate from a file rather than from current user's certificate store. The *dwOptions* member should be set to CREDENTIAL_STORE_FILENAME and the *lpzCertStore* member should specify the name of the file that contains the certificate and its private key. The file must be in Private Information Exchange (PFX) format, also known as PKCS#12. These certificate files typically have an extension of .pfx or .p12. Note that if a password was specified when the certificate file was created, it must be provided in the *lpzPassword* member or the library will be unable to access the certificate.

Note that the *lpzUserName* and *lpzPassword* members are values which are used to access the certificate store or private key file. They are not the credentials which are used when establishing the connection with the remote host or authenticating the client session.

The TLS 1.1 and TLS 1.2 protocols are only supported on Windows 7, Windows Server 2008 R2 and later versions of the platform. If these options are specified and the application is running on Windows XP or Windows Vista, the protocol version will be downgraded to TLS 1.0 for backwards compatibility with those platforms.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cstools10.h

Unicode: Implemented as Unicode and ANSI versions.

SECURITYINFO Structure

This structure contains information about a secure connection that has been established.

```
typedef struct _SECURITYINFO
{
    DWORD        dwSize;
    DWORD        dwProtocol;
    DWORD        dwCipher;
    DWORD        dwCipherStrength;
    DWORD        dwHash;
    DWORD        dwHashStrength;
    DWORD        dwKeyExchange;
    DWORD        dwCertStatus;
    SYSTEMTIME   stCertIssued;
    SYSTEMTIME   stCertExpires;
    LPCTSTR      lpszCertIssuer;
    LPCTSTR      lpszCertSubject;
    LPCTSTR      lpszFingerprint;
} SECURITYINFO, *LPSECURITYINFO;
```

Members

dwSize

Specifies the size of the data structure. This member must always be initialized to **sizeof(SECURITYINFO)** prior to passing the address of this structure to the function. Note that if this member is not initialized, an error will be returned indicating that an invalid parameter has been passed to the function.

dwProtocol

A numeric value which specifies the protocol that was selected to establish the secure connection. One of the following values will be returned:

Constant	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_SSL	Either SSL 2.0 or SSL 3.0 should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, TLS will be excluded from the list of supported protocols. Both SSL 2.0 and 3.0 have been deprecated and will never be used unless explicitly specified. It is not recommended that you enable either of these protocols for secure connections because it will cause most servers to reject your connection request, even if a version of TLS is also specified.
SECURITY_PROTOCOL_TLS	Either the TLS 1.0, 1.1 or 1.2 protocol should be used when establishing a secure connection. The

	<p>correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers that reject any attempt to use the older SSL protocol and require that only TLS be used.</p>
SECURITY_PROTOCOL_TLS10	<p>The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.</p>
SECURITY_PROTOCOL_TLS11	<p>The TLS 1.1 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.</p>
SECURITY_PROTOCOL_TLS12	<p>The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This is the recommended version of TLS to use with secure connections.</p>

dwCipher

A numeric value which specifies the cipher that was selected when establishing the secure connection. One of the following values will be returned:

Constant	Description
SECURITY_CIPHER_RC2	The RC2 block cipher was selected. This is a variable key length cipher which supports keys between 40 and 128 bits, in 8-bit increments.
SECURITY_CIPHER_RC4	The RC4 stream cipher was selected. This is a variable key length cipher which supports keys between 40 and 128 bits, in 8-bit increments.
SECURITY_CIPHER_RC5	The RC5 block cipher was selected. This is a variable key length cipher which supports keys up to 2040 bits, in 8-bit increments.
SECURITY_CIPHER_DES	The DES (Data Encryption Standard) block cipher was selected. This is a fixed key length cipher, using 56-bit

	keys.
SECURITY_CIPHER_DES3	The Triple DES block cipher was selected. This cipher encrypts the data three times using different keys, effectively providing a 168-bit length key.
SECURITY_CIPHER_DESX	A variant of the DES block cipher which XORs an extra 64-bits of the key before and after the plaintext has been encrypted, increasing the key size to 184 bits.
SECURITY_CIPHER_AES	The Advanced Encryption Standard cipher (also known as the Rijndael cipher) is a fixed block size cipher which use a key size of 128, 192 or 256 bits. This cipher is supported on Windows XP SP3 and later versions of the operating system.
SECURITY_CIPHER_SKIPJACK	The Skipjack block cipher was selected. This is a fixed key length cipher, using 80-bit keys.
SECURITY_CIPHER_BLOWFISH	The Blowfish block cipher was selected. This is a variable key length cipher up to 448 bits, using a 64-bit block size.

dwCipherStrength

A numeric value which specifies the strength (the length of the cipher key in bits) of the cipher that was selected. Typically this value will be 128 or 256. 40-bit and 56-bit key lengths are considered weak encryption, and subject to brute force attacks. 128-bit and 256-bit key lengths are considered to be secure, and are the recommended key length for secure communications.

dwHash

A numeric value which specifies the hash algorithm which was selected. One of the following values will be returned:

Constant	Description
SECURITY_HASH_MD5	The MD5 algorithm was selected. Its use has been deprecated and is no longer considered to be cryptographically secure.
SECURITY_HASH_SHA1	The SHA-1 algorithm was selected. Its use has been deprecated and is no longer considered to be cryptographically secure.
SECURITY_HASH_SHA256	The SHA-256 algorithm was selected.
SECURITY_HASH_SHA384	The SHA-384 algorithm was selected.
SECURITY_HASH_SHA512	The SHA-512 algorithm was selected.

dwHashStrength

A numeric value which specifies the strength (the length in bits) of the message digest that was selected.

dwKeyExchange

A numeric value which specifies the key exchange algorithm which was selected. One of the following values will be returned:

--	--

Constant	Description
SECURITY_KEYEX_RSA	The RSA public key algorithm was selected.
SECURITY_KEYEX_KEA	The Key Exchange Algorithm (KEA) was selected. This is an improved version of the Diffie-Hellman public key algorithm.
SECURITY_KEYEX_DH	The Diffie-Hellman key exchange algorithm was selected.
SECURITY_KEYEX_ECDH	The Elliptic Curve Diffie-Hellman key exchange algorithm was selected. This is a variant of the Diffie-Hellman algorithm which uses elliptic curve cryptography. This key exchange algorithm is only supported on Windows XP SP3 and later versions of the operating system.

dwCertStatus

A numeric value which specifies the status of the certificate returned by the secure server. This member only has meaning for connections using the SSL or TLS protocols. One of the following values will be returned:

Constant	Description
SECURITY_CERTIFICATE_VALID	The certificate is valid.
SECURITY_CERTIFICATE_NOMATCH	The certificate is valid, but the domain name does not match the common name in the certificate.
SECURITY_CERTIFICATE_EXPIRED	The certificate is valid, but has expired.
SECURITY_CERTIFICATE_REVOKED	The certificate has been revoked and is no longer valid.
SECURITY_CERTIFICATE_UNTRUSTED	The certificate or certificate authority is not trusted on the local system.
SECURITY_CERTIFICATE_INVALID	The certificate is invalid. This typically indicates that the internal structure of the certificate has been damaged.

stCertIssued

A structure which contains the date and time that the certificate was issued by the certificate authority. If the issue date cannot be determined for the certificate, the SYSTEMTIME structure members will have zero values. This member only has meaning for connections using the SSL or TLS protocols.

stCertExpires

A structure which contains the date and time that the certificate expires. If the expiration date cannot be determined for the certificate, the SYSTEMTIME structure members will have zero values. This member only has meaning for connections using the SSL or TLS protocols.

lpszCertIssuer

A pointer to a string which contains information about the organization that issued the certificate. This string consists of one or more comma-separated tokens. Each token consists of an identifier, followed by an equal sign and a value. If the certificate issuer could not be determined, this member may be NULL. This member only has meaning for connections using the SSL or TLS protocols.

lpszCertSubject

A pointer to a string which contains information about the organization that the certificate was issued to. This string consists of one or more comma-separated tokens. Each token consists of an identifier, followed by an equal sign and a value. If the certificate subject could not be determined, this member may be NULL. This member only has meaning for connections using the SSL or TLS protocols.

lpszFingerprint

A pointer to a string which contains a sequence of hexadecimal values that uniquely identify the server. This member is only used when a connection has been established using the Secure Shell (SSH) protocol.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Unicode: Implemented as Unicode and ANSI versions.

SYSTEMTIME Structure

The **SYSTEMTIME** structure represents a date and time using individual members for the month, day, year, weekday, hour, minute, second, and millisecond.

```
typedef struct _SYSTEMTIME
{
    WORD wYear;
    WORD wMonth;
    WORD wDayOfWeek;
    WORD wDay;
    WORD wHour;
    WORD wMinute;
    WORD wSecond;
    WORD wMilliseconds;
} SYSTEMTIME, *LPSYSTEMTIME;
```

Members

wYear

Specifies the current year. The year value must be greater than 1601.

wMonth

Specifies the current month. January is 1, February is 2 and so on.

wDayOfWeek

Specifies the current day of the week. Sunday is 0, Monday is 1 and so on.

wDay

Specifies the current day of the month

wHour

Specifies the current hour.

wMinute

Specifies the current minute

wSecond

Specifies the current second.

wMilliseconds

Specifies the current millisecond.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include windows.h.

News Feed Library

Retrieve and process the contents of a syndicated news feed.

Reference

- [Functions](#)
- [Data Structures](#)
- [Error Codes](#)

Library Information

File Name	CSRSSV10.DLL
Version	10.0.1468.2518
LibID	1F65A283-7BC8-4F5B-B739-D211EAF1CA35
Import Library	CSRSSV10.LIB
Dependencies	None

Overview

Really Simple Syndication (RSS) is a collection of standardized formats that are used to publish information about content that is frequently changed. A news feed is published in XML format, which contains one or more items that includes summary text, hyperlinks to source content and additional metadata that is used to describe the item. News feeds can be used for a variety of purposes, including providing updates for weblogs, news headlines, video and audio content. RSS can also be used for other purposes, such as a software updates, where new updates are listed as items in the feed.

News feeds can be accessed remotely from a web server, or locally as an XML formatted text file. The source of the feed is determined by the URI scheme that is specified. If the http or https scheme is specified, then the feed is retrieved from a web server. If the file scheme is used, the feed is considered to be local and is accessed from the disk or local network. The News Feed library provides an API that enables you to open a feed by URL and iterate through each of the items in the feed or search for a specific feed item. The API also provides a function that can be used to parse a string that contains XML data in RSS format, where the feed may have been retrieved from other sources such as a database.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). If you are using Visual C++ 6.0 it is required that you have Service Pack 6 (SP6) installed. You should install all updates for your development tools and have the current Windows SDK installed. The minimum recommended version of Visual Studio is Visual Studio 2010.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are using Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. It is recommended that you install the current service pack and all critical updates available for your version of the operating system.

This product includes both 32-bit and 64-bit libraries. Native 64-bit CPU support requires the 64-bit version of Windows 7 or later versions of the Windows operating system.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

News Feed Functions

Function	Description
RssCloseFeed	Close the specified news feed and release memory allocated for the channel
RssDisableTrace	Disable logging of network function calls
RssEnableTrace	Enable logging of network function calls to a text file
RssFindItem	Find a specific news feed item using its unique identifier (GUID) property
RssGetErrorString	Return a description for the specified error code
RssGetFirstItem	Return information about the first item in the news feed channel
RssGetItem	Return information about the specified news feed item
RssGetItemCount	Return the number of news feed items in the channel
RssGetItemProperty	Return the value of the specified news feed item property or attribute
RssGetItemText	Return the text description of the specified news feed item
RssGetLastError	Return the last error code
RssGetNextItem	Return information about the next item in the news feed channel
RssInitialize	Initialize the library and validate the specified license key at runtime
RssOpenFeed	Open the specified news feed and return information about the channel
RssParseFeed	Parse the contents of a string and return information about the channel
RssRefreshFeed	Refresh the specified news feed, updating the items in the channel
RssSetLastError	Set the last error code
RssStoreFeed	Store the contents of the specified news feed in an XML formatted text file
RssUninitialize	Terminate use of the library by the application
RssValidateFeed	Validate the contents of the specified news feed, returning the number of items in the feed

RssCloseFeed Function

```
INT WINAPI RssCloseFeed(  
    HCHANNEL hChannel  
);
```

The **RssCloseFeed** function closes the specified news feed and releases memory allocated for the channel.

Parameters

hChannel

Handle to the news feed channel.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is `RSS_ERROR`. To get extended error information, call **RssGetLastError**.

Remarks

The **RssCloseFeed** function must be called whenever the application has completed processing the news feed. It is important to note that the memory allocated for the channel will be released when this function is called, which means that any data referenced in the `RSSCHANNEL` and `RSSCHANNELITEM` structures will no longer be valid and must not be used by the application after the feed has been closed.

This function can fail if the feed is currently being updated, such as when the **RssRefreshFeed** function is called. In this case, the channel handle will not be released and the application must attempt to close the feed at a later time.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csrsv10.lib`

See Also

[RssOpenFeed](#) [RssParseFeed](#) [RssStoreFeed](#)

RssDisableTrace Function

```
BOOL WINAPI RssDisableTrace();
```

The **RssDisableTrace** function disables the logging of network function calls.

Parameters

None.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csrssv10.lib

See Also

[RssEnableTrace](#)

RssEnableTrace Function

```
BOOL WINAPI RssEnableTrace(  
    LPCTSTR lpszTraceFile,  
    DWORD dwTraceFlags  
);
```

The **RssEnableTrace** function enables the logging of network function calls to a text file.

Parameters

lpszTraceFile

A pointer to a string which specifies the name of the trace log file. If this parameter is NULL or an empty string, the default file name **cstrace.log** is used. The file is stored in the directory specified by the TEMP environment variable, if it is defined; otherwise, the current working directory is used.

dwTraceFlags

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
TRACE_INFO	All function calls are written to the trace file. This is the default value.
TRACE_ERROR	Only those function calls which fail are recorded in the trace file.
TRACE_WARNING	Only those function calls which fail or return values which indicate a warning are recorded in the trace file.
TRACE_HEXDUMP	All functions calls are written to the trace file, plus all the data that is sent or received is displayed, in both ASCII and hexadecimal format.
TRACE_PROCESS	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for multithreaded applications that are using worker threads.

Return Value

If the function succeeds, the return value is non-zero. A return value of zero indicates an error. Failure typically indicates that the tracing library **cstrcv10.dll** cannot be loaded on the local system.

Remarks

When trace logging is enabled, the file is opened, appended to and closed for each socket function call. This makes it possible for an application to append its own logging information, however care should be taken to ensure that the file is closed before the next network operation is performed. To limit the size of the log files, enable and disable logging only around those sections of code that you wish to trace.

Note that the TRACE_HEXDUMP trace level generates very large log files since it includes all of the data exchanged between your application and the server.

Trace function logging is managed on a per-thread basis, not for each client handle. This means that all SocketTools libraries and components share the same settings in the current thread. If you
