If the method succeeds, the return value is an unsigned integer value which specifies the number of milliseconds the client session has been idle. If the method fails, the return value is INFINITE. To get extended error information, call **GetLastError**.

Remarks

The **GetClientIdleTime** method will return the number of milliseconds that have elapsed since data was exchanged with the client. The elapsed time is limited to the resolution of the system timer, which is typically in the range of 10 milliseconds to 16 milliseconds.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

See Also

[GetClientHandle](#), [GetClientId](#), [GetClientMoniker](#), [GetTimeout](#)

CInternetServer::GetClientMoniker Method

```
INT GetClientMoniker(  
    SOCKET hClient,  
    LPTSTR lpszMoniker,  
    INT nMaxLength  
);
```

```
INT GetClientMoniker(  
    SOCKET hClient,  
    CString& strMoniker  
);
```

The **GetClientMoniker** method returns the moniker associated with the specified client session.

Parameters

hSocket

An optional parameter that specifies the handle to the client socket. If this parameter is omitted, the socket handle for the active client session will be used. If this method is called outside of a server event handler, the socket handle must be specified.

lpszMoniker

Pointer to a string buffer that will contain the moniker for the specified client session when the method returns. An alternate version of this method accepts a **CString** object if it is available.

nMaxLength

The maximum number of characters that may be copied into the string buffer. The buffer must be large enough to store the moniker and a terminating null character. The maximum length of a moniker is 127 characters.

Return Value

If the method succeeds, the return value is the number of characters in the moniker string. A return value of zero specifies that no moniker was assigned to the socket. If the method fails, the return value is `INET_ERROR`. To get extended error information, call **GetLastError**.

Remarks

A client moniker is a string which can be used to uniquely identify a specific client session aside from its socket handle. A moniker can be assigned to the client session using the **SetClientMoniker** method. This method will return the moniker that was previously assigned to the client, if any. To obtain the socket handle associated with a given moniker, use the **FindClient** method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cssock10.h`

Import Library: `cswskv10.lib`

See Also

[FindClient](#), [GetClientId](#), [SetClientMoniker](#)

InternetServer::GetClientPort Method

```
INT GetClientPort(  
    SOCKET hSocket  
);  
  
INT GetClientPort();
```

Returns the remote port number used by the client to establish the connection.

Parameters

hSocket

An optional parameter that specifies the handle to the client socket. If this parameter is omitted, the socket handle for the active client session will be used. If this method is called outside of a server event handler, the socket handle must be specified.

Return Value

If the method succeeds, the return value is the port number. If the method fails, the return value is INET_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetClientPort** method returns the remote port number that the client is bound to. Note that this is not the port number that the server is using to listen for connections, it is the port number that the client is bound to on the remote host. Typically this is an ephemeral port, either in the range of 1025 through 5000, or greater than 32768, depending on the client operating system.

If this method is called within the **OnAccept** event handler, providing the server socket handle as the *hSocket* parameter will return the port number of the client that is attempting to establish the connection.

It is not recommended that you use the client port number for anything other than informational and logging purposes. Do not make any assumptions about the specific port number or range of port numbers that a client is using when establishing a connection to the server. The ephemeral port number that a client is bound to can vary based on the client operating system.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

See Also

[GetClientAddress](#), [OnAccept](#), [OnConnect](#)

CIInternetServer::GetClientServer Method

```
SOCKET HttpGetClientServer(  
    UINT nClientId  
);
```

The **GetClientServer** method returns a handle to the server that created the specified client session.

Parameters

nClientId

An unsigned integer which uniquely identifies the client session.

Return Value

If the method succeeds, the return value is the handle to the server that created the client session. If the method fails, the return value is INVALID_SOCKET. To get extended error information, call the **GetLastError** method.

Remarks

The **GetClientServer** method returns the handle to the server that created the client session and is typically used within a notification message handler. If the server is in the process of shutting down, or the client session thread is terminating, this method will fail and return INVALID_SOCKET indicating that the session ID is invalid.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cswskv10.lib

See Also

[AsyncNotify](#)

InternetServer::GetClientServerById Method

```
SOCKET GetClientServerById(  
    UINT nClientId  
);
```

The **GetClientServerById** method returns a socket handle to the server for the specified client session identifier.

Parameters

nClientId

Client session identifier.

Return Value

If the method succeeds, the return value is the handle to the server that created the client session. If the method fails, the return value is INVALID_SOCKET. To get extended error information, call the **GetLastError** method.

Remarks

The **GetClientServerById** method returns the handle to the server that created the client session using the client's unique identifier. The **GetClientServer** method can be used to obtain the server handle using the client socket handle rather than the client session ID. This method is typically used in conjunction with the INET_NOTIFY_CONNECT notification message to obtain the handle to the server that generated the event using the client ID passed in the *wParam* message parameter.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cswskv10.lib

See Also

[AsyncNotify](#), [GetClientHandle](#), [GetClientId](#), [GetClientServer](#)

CInternetServer::GetClientThreadId Method

```
DWORD GetClientThreadId(  
    SOCKET hSocket  
);  
  
DWORD GetClientThreadId();
```

Returns the thread ID associated with the specified client.

Parameters

hSocket

An optional parameter that specifies the handle to the client socket. If this parameter is omitted, the socket handle for the active client session will be used. If this method is called outside of a server event handler, the socket handle must be specified.

Return Value

If the method succeeds, the return value is a thread ID. If the method fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

The **GetClientThreadId** method returns a thread ID that can be used to identify the thread that is managing the client session. The thread ID can be used with other Windows API functions such as **OpenThread**. Exercise caution when using thread-related functions, interfering with the normal operation of the thread can have unexpected results. You should never use this method to obtain a thread handle and then call the **TerminateThread** function to terminate a client session. This will prevent the thread from releasing the resources that were allocated for the session and can leave the server in an unstable state. To terminate a client session, use the **Disconnect** method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cswsock10.h

Import Library: cswskv10.lib

See Also

[EnumClients](#), [GetActiveClient](#)

CIInternetServer::GetClientThreads Method

```
INT GetClientThreads();
```

Returns the number of client session threads created by the server.

Parameters

None.

Return Value

If the method succeeds, the return value is the number of client session threads that have been created by the server. If the method fails, the return value is INET_ERROR. To get extended error information, call the **GetLastError** method.

Remarks

The **InetGetClientThreads** function returns the number of threads that are managing client sessions for the specified server. If there are no clients connected to the server, this function will return a value of zero. Because this function returns the number of session threads, the value returned will include those clients that are in the process of disconnecting from the server but their session thread has not yet terminated. This differs from the **InetEnumServerClients** function which will only enumerate active clients.

If you wish to determine when the last client has disconnected from the server, call this function within an event handler for the INET_EVENT_DISCONNECT event. If the function returns a value greater than one, then there are other client sessions that are either connected or in the process of terminating.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: csoskv10.lib

See Also

[EnumClients](#)

CInternetServer::GetErrorString Method

```
INT GetErrorString(  
    DWORD dwErrorCode,  
    LPTSTR lpszDescription,  
    INT cbDescription  
);
```

```
INT GetErrorString(  
    DWORD dwErrorCode,  
    CString& strDescription  
);
```

The **GetErrorString** method is used to return a description of a specific error code. Typically this is used in conjunction with the **GetLastError** method for use with warning dialogs or as diagnostic messages.

Parameters

dwErrorCode

The error code for which a description is returned.

lpszDescription

A pointer to the buffer that will contain a description of the specified error code. This buffer should be at least 128 characters in length. An alternate form of the method accepts a **CString** variable which will contain the error description.

cbDescription

The maximum number of characters that may be copied into the description buffer.

Return Value

If the method succeeds, the return value is the length of the description string. If the method fails, the return value is zero, meaning that no description exists for the specified error code. Typically this indicates that the error code passed to the method is invalid.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cswsock10.h`

Import Library: `cswskv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

[GetLastError](#), [SetLastError](#), [ShowError](#)

InternetServer::GetExternalAddress Method

```
INT GetExternalAddress(  
    INT nAddressFamily,  
    LPINTERNET_ADDRESS lpAddress,  
    INT nMaxLength  
);  
  
INT GetExternalAddress(  
    INT nAddressFamily,  
    LPTSTR lpszAddress,  
    INT nMaxLength  
);  
  
INT GetExternalAddress(  
    INT nAddressFamily,  
    CString& strAddress  
);
```

The **GetExternalAddress** method returns the external IP address for the local system.

Parameters

nAddressFamily

An integer which identifies the type of IP address that should be returned by this function. It may be one of the following values:

Constant	Description
INET_ADDRESS_IPV4	Specifies that the address should be in IPv4 format. The method will attempt to determine the external IP address using an IPv4 network connection.
INET_ADDRESS_IPV6	Specifies that the address should be in IPv6 format. The method will attempt to determine the external IP address using an IPv6 network connection and requires that the local host have an IPv6 network interface installed and enabled.

lpAddress

A pointer to an [INTERNET_ADDRESS](#) structure that will contain the external IP address of the local host in binary form.

lpszAddress

A pointer to a string buffer that will contain the external IP address of the local host.

nMaxLength

The maximum length of the string that will contain the IP address when the method returns.

Return Value

In the first form of the method, if it succeeds, the return value is the IP address of the local system in numeric form. If the method fails, the return value is INET_ADDRESS_NONE. In the second form, the return value is the length of the IP address string and an error is indicated by the return value INET_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetExternalAddress** method returns the IP address assigned to the router that connects the

local host to the Internet. This is typically used by an application executing on a system in a local network that uses a router which performs Network Address Translation (NAT). In that network configuration, the **GetLocalAddress** method will only return the IP address for the local system on the LAN side of the network unless a connection has already been established to a remote host. The **GetExternalAddress** function can be used to determine the IP address assigned to the router on the Internet side of the connection and can be particularly useful for servers running on a system behind a NAT router.

This method requires that you have an active connection to the Internet and calling this function on a system that uses dial-up networking may cause the operating system to automatically connect to the Internet service provider. An application should always check the return value in case there is an error; never assume that the return value is always a valid address. The function may be unable to determine the external IP address for the local host for a number of reasons, particularly if the system is behind a firewall or uses a proxy server that restricts access to external sites on the Internet. If the function is able to obtain a valid external address for the local host, that address will be cached by the library for sixty minutes. Because dial-up connections typically have different IP addresses assigned to them each time the system is connected to the Internet, it is recommended that this function only be used with broadband connections where a NAT router is being used.

Calling this function may cause the current thread to block until the external IP address can be resolved and should never be used in conjunction with asynchronous socket connections. If you need to call this function in an application which uses asynchronous sockets, it is recommended that you create a new thread and call this function from within that thread.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cswsock10.h`

Import Library: `cswskv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

[GetClientAddress](#), [GetHostAddress](#), [GetLocalAddress](#)

CInternetServer::GetHandle Method

```
SOCKET GetHandle();
```

The **GetHandle** method returns the socket handle associated with the current instance of the class.

Parameters

None.

Return Value

This method returns the socket handle associated with the current instance of the class object. If there is no active connection, the value `INVALID_SOCKET` will be returned.

Remarks

This method is used to obtain the client handle created by the class for use with the SocketWrench API.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cswsock10.h`

Import Library: `cswskv10.lib`

See Also

[AttachHandle](#), [DetachHandle](#), [IsInitialized](#)

CInternetServer::GetHostAddress Method

```
INT GetHostAddress(  
    LPCTSTR lpszHostName,  
    INT nAddressFamily,  
    LPINTERNET_ADDRESS lpAddress  
);
```

```
INT GetHostAddress(  
    LPCTSTR lpszHostName,  
    LPINTERNET_ADDRESS lpAddress  
);
```

The **InetGetHostAddress** method resolves the specified host name into an IP address in binary format.

Parameters

lpszHostName

A pointer to the name of the host to resolve; this may be a fully-qualified domain name or an IP address. This method recognizes the format for both IPv4 and IPv6 format addresses.

nAddressFamily

An integer which identifies the type of IP address to return. It may be one of the following values:

Constant	Description
INET_ADDRESS_UNKNOWN	Return the IP address for the specified host in either IPv4 or IPv6 format, depending on how the host name can be resolved. By default, a preference will be given for returning an IPv4 address. However, if the host only has an IPv6 address, that value will be returned.
INET_ADDRESS_IPV4	Specifies that the address should be returned in IPv4 format. The first four bytes of the <i>ipNumber</i> array are significant and contains the IP address. The remaining bytes are not significant and an application should not depend on them having any particular value, including zero.
INET_ADDRESS_IPV6	Specifies that the address should be returned in IPv6 format. All bytes in the <i>ipNumber</i> array are significant. Note that it is possible for an IPv6 address to actually represent an IPv4 address. This is indicated by the first 10 bytes of the address being zero.

lpAddress

A pointer to an [INTERNET_ADDRESS](#) structure that will contain the IP address of the specified host.

Return Value

If the method succeeds, the return value is zero. If the function fails, the return value is INET_ERROR. To get extended error information, call **InetGetLastError**.

Remarks

This method can also be used to convert an address in dot notation to a binary format. If the method must perform a DNS lookup to resolve the hostname, the calling thread will block. To ensure future compatibility with IPv6 networks, it is important that the application does not make any assumptions about the format of the address. If the function returns successfully, the *ipFamily* member of the **INTERNET_ADDRESS** structure should always be checked to determine the type of address.

The *nAddressFamily* parameter is used to specify a preference for the type of address returned, however it is possible that a host may not have an IPv4 or IPv6 address record, in which case this function will fail. Although IPv4 is still the most common address used at this time, an application should not assume that because a given host name does not have an IPv4 address, that the host name is invalid.

If the *nAddressFamily* parameter is specified as `INET_ADDRESS_UNKNOWN`, the application must be prepared to handle IPv6 addresses because it is possible for a host name to have an IPv6 address assigned to it and no IPv4 address. For legacy applications that only recognize IPv4 addresses, the *nAddressFamily* member should always be specified as `INET_ADDRESS_IPV4` to ensure that only IPv4 addresses are returned.

To determine if the local system has an IPv6 TCP/IP stack installed and configured on the local system, use the **IsProtocolAvailable** method. If an IPv6 stack is not installed, this method will fail if the *lpszHostName* parameter specifies a host that only has an IPv6 (AAAA) DNS record.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cswsock10.h`

Import Library: `cswskv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

See Also

[GetClientAddress](#), [GetHostName](#), [GetLocalAddress](#), [GetLocalName](#), [IsProtocolAvailable](#), [INTERNET_ADDRESS](#)

CInternetServer::GetHostName Method

```
INT GetHostName(  
    LPINTERNET_ADDRESS LpAddress,  
    LPTSTR LpszHostName,  
    INT cchHostName  
);
```

```
INT GetHostName(  
    LPINTERNET_ADDRESS LpAddress,  
    CString& strHostName  
);
```

The **GetHostName** method performs a reverse lookup, returning the host name associated with a given IP address.

Parameters

lpAddress

A pointer to an [INTERNET_ADDRESS](#) structure which specifies the IP address that should be resolved into a host name.

lpszHostName

A pointer to the buffer that will contain the host name. It is recommended that this buffer be at least 256 characters in length to accommodate the longest possible fully qualified domain name. This parameter cannot be NULL. An alternate form of the method accepts a **CString** argument which will contain the hostname.

cchHostName

The maximum number of characters that can be copied into the buffer.

Return Value

If the method succeeds, the return value is the length of the hostname. If the method fails, the return value is INET_ERROR. To get extended error information, call **InetGetLastError**.

Remarks

If the method must perform a reverse DNS lookup to resolve the IP address into a host name, the calling thread will block. This method requires that the host have a PTR record, otherwise it will fail. Because many hosts do not have a PTR record, calling this method frequently may have a negative impact on the overall performance of the application.

To determine if the local system has an IPv6 TCP/IP stack installed and configured on the local system, use the **IsProtocolAvailable** method. If an IPv6 stack is not installed, this method will fail if the *lpAddress* parameter specifies an IPv6 address, even if the address itself is valid.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

CInternetServer::GetLastError Method

```
DWORD GetLastError();  
  
DWORD GetLastError(  
    CString& strDescription  
);
```

Parameters

strDescription

A string which will contain a description of the last error code value when the method returns. If no error has been set, or the last error code has been cleared, this string will be empty.

Return Value

The return value is the last error code value for the current thread. Functions set this value by calling the **SetLastError** method. The Return Value section of each reference page notes the conditions under which the method sets the last error code.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. You should call the **GetLastError** method immediately when a method's return value indicates that an error has occurred. That is because some methods call **SetLastError(0)** when they succeed, clearing the error code set by the most recently failed method.

Most methods will set the last error code value when they fail; a few methods set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_SOCKET or INET_ERROR. Those methods which call **SetLastError** when they succeed are noted on the method reference page.

The description of the error code is the same string that is returned by the **GetErrorString** method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cswskv10.lib

See Also

[GetErrorString](#), [SetLastError](#), [ShowError](#)

InternetServer::GetLocalAddress Method

```
INT GetLocalAddress(  
    LPINTERNET_ADDRESS LpAddress,  
    UINT * LpnPort  
);
```

```
INT GetLocalAddress(  
    LPTSTR LpszAddress,  
    INT nMaxLength  
);
```

```
INT GetLocalAddress(  
    CString& strAddress  
    UINT * LpnPort  
);
```

Return the local IP address and port number for the server.

Parameters

lpAddress

A pointer to an [INTERNET_ADDRESS](#) structure that will contain the IP address of the local host. If the server is not active, this function will attempt to determine the IP address of the local host assigned by the system. If the address is not required, this parameter may be NULL.

lpszAddress

A pointer to a null terminated string that will contain the IP address of the local host. If this version of the method is used, the IP address is converted to a string format using the **FormatAddress** method. The string should be able to store at least 46 characters to ensure that both IPv4 and IPv6 formatted addresses can be returned without the possibility of a buffer overrun. An alternate form of the method accepts a **CString** argument which will contain the line of text returned by the server.

lpnPort

A pointer to an unsigned integer that will contain the local port number. If the server is active, this parameter will be set to the local port that the listening socket was bound to. If the server is not active, this parameter is ignored. If the port number is not required, this parameter may be NULL.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is `INET_ERROR`. To get extended error information, call **GetLastError**.

Remarks

To ensure future compatibility with IPv6 networks, it is important that the application does not make any assumptions about the format of the address. If the function returns successfully, the *ipFamily* member of the **INTERNET_ADDRESS** structure should always be checked to determine the type of address.

If the system is connected to the Internet through a local network and/or uses a router that performs Network Address Translation (NAT), the **GetLocalAddress** method will return the local, non-routable IP address assigned to the local system. To determine the public IP address has been assigned to the system, you should use the **GetExternalAddress** method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

CInternetServer::GetLocalName Method

```
INT GetLocalName(  
    LPTSTR lpszHostName,  
    INT cchHostName  
);  
  
INT GetLocalName(  
    CString& strHostName  
);
```

The **GetLocalName** method returns the hostname assigned to the local system.

Parameters

lpszHostName

A pointer to the buffer that will contain the hostname. This parameter cannot be NULL. An alternate form of the method accepts a **CString** argument which will contain the local hostname.

cchHostName

The maximum number of characters that can be copied into the address buffer.

Return Value

If the method succeeds, the return value is the length of the hostname. If the method fails, the return value is INET_ERROR. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

Unicode: Implemented as Unicode and ANSI versions.

[SetOptions](#), [Data Members](#)

CInternetServer::GetPriority Method

```
INT GetPriority();
```

Return the current priority assigned to the specified server.

Parameters

None.

Return Value

If the method succeeds, the return value is the priority for the specified server. If the method fails, the return value is INET_PRIORITY_INVALID. To get extended error information, call the **GetLastError** method.

Remarks

The **GetPriority** method can be used to determine the current priority assigned to the server. It will return one of the following values:

Constant	Description
INET_PRIORITY_BACKGROUND (0)	This priority significantly reduces the memory, processor and network resource utilization for the server. It is typically used with lightweight services running in the background that are designed for few client connections. The server thread will be assigned a lower scheduling priority and will be frequently forced to yield execution to other threads.
INET_PRIORITY_LOW (1)	This priority lowers the overall resource utilization for the server and meters the processor utilization for the server thread. The server thread will be assigned a lower scheduling priority and will occasionally be forced to yield execution to other threads.
INET_PRIORITY_NORMAL (2)	The default priority which balances resource and processor utilization. This is the priority that is initially assigned to the server when it is started, and it is recommended that most applications use this priority.
INET_PRIORITY_HIGH (3)	This priority increases the overall resource utilization for the server and the thread will be given higher scheduling priority. It is not recommended that this priority be used on a system with a single processor.
INET_PRIORITY_CRITICAL (4)	This priority can significantly increase processor, memory and network utilization. The server thread will be given higher scheduling priority and will be more responsive to client connection requests. It is not recommended that this priority be used on a system with a single processor.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

CInternetServer::GetStackSize Method

```
DWORD GetStackSize();
```

Return the initial size of the stack allocated for threads created by the server.

Parameters

None.

Return Value

If the method succeeds, the return value is the amount of memory that will be allocated for the stack in bytes. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **GetStackSize** method returns the initial amount of memory that is committed to the stack for each thread created by the server. By default, the stack size for each thread is set to 256K for 32-bit processes and 512K for 64-bit processes.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: csuskv10.lib

[SetStackSize](#), [Start](#)

CInternetServer::GetStatus Method

INT GetStatus();

Return the current status of the server.

Parameters

None.

Return Value

An integer value that specifies the server status.

Remarks

The return value is one of the following values:

Constant	Description
INET_SERVER_INACTIVE	The server is currently inactive.
INET_SERVER_STARTED	The server has initialized and is preparing to listen for client connections.
INET_SERVER_LISTENING	The server is actively listening for incoming client connections.
INET_SERVER_SUSPENDED	The server has been suspended and is no longer accepting client connections.
INET_SERVER_SHUTDOWN	The server has been stopped and is in the process of terminating all active client connections.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cswsock10.h

Import Library: csWSKV10.lib

See Also

[IsInitialized](#), [IsListening](#), [IsLocked](#)

CInternetServer::GetStreamInfo Method

```
BOOL GetStreamInfo(  
    SOCKET hSocket  
    LPINETSTREAMINFO lpStreamInfo  
);  
  
BOOL GetStreamInfo(  
    LPINETSTREAMINFO lpStreamInfo  
);
```

The **GetStreamInfo** function fills a structure with information about the current stream I/O operation.

Parameters

hSocket

An optional parameter that specifies the handle to the client socket. If this parameter is omitted, the socket handle for the active client session will be used. If this method is called outside of a server event handler, the socket handle must be specified.

lpSecurityInfo

A pointer to an **INETSTREAMINFO** structure which contains information about the status of the current operation.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **GetStreamInfo** method returns information about the current streaming socket operation, including the average number of bytes transferred per second and the estimated amount of time until the operation completes. If there is no operation currently in progress, this method will return the status of the last successful streaming read or write performed by the client.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

See Also

[ReadStream](#), [StoreStream](#), [WriteStream](#), [INETSTREAMINFO](#)

CInternetServer::GetThreadClient Method

```
SOCKET WINAPI InetGetThreadClient(  
    DWORD dwThreadId  
);
```

The **GetThreadClient** method returns the socket handle for the client session that is being managed by the specified thread.

Parameters

dwThreadId

An unsigned integer value which identifies the thread managing the client session. If this parameter has a value of zero, then the client handle for the current thread is returned.

Return Value

If the method succeeds, the return value is the socket handle for the specified client session. If the method fails, the return value is INVALID_SOCKET. To get extended error information, call **InetGetLastError**.

Remarks

The **GetThreadClient** is used to obtain the socket handle for the client session that is being managed by the specified thread. If the specified thread ID is zero, then the method will return the client socket for the current thread, otherwise it will search the internal table of all active client sessions and return the handle to the session that is being managed by that thread.

This method will fail if the thread ID does not specify an active client session thread.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

See Also

[GetActiveClient](#), [GetClientHandle](#), [GetClientId](#), [GetClientThreadId](#)

CInternetServer::GetTimeout Method

```
INT GetTimeout();
```

Return the timeout interval for blocking network operations in seconds.

Parameters

None.

Return Value

The return value is the timeout period in seconds. If there is no active server, this will return the timeout period that will be used when the server is started. A value of zero specifies that a reasonable default timeout period will be automatically selected.

Remarks

The **GetTimeout** method returns the number of seconds the server will wait for a blocking network operation to complete, such as sending or receiving data. This value also determines the amount of time that the server will wait for the client to send data before invoking the **OnTimeout** event handler for that session.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cssock10.h`

Import Library: `cssock10.lib`

See Also

CInternetServer::IsActive Method

```
BOOL IsActive();
```

Determine if the server has been started.

Return Value

This method returns a non-zero value if the server has been started. If the server is stopped this method will return zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cswsock10.h

Import Library: cswskv10.lib

See Also

[CInternetServer](#), [IsListening](#), [Start](#), [Stop](#)

CIInternetServer::IsAddressNull Method

```
BOOL IsAddressNull(  
    LPCTSTR lpszAddress  
);  
  
BOOL IsAddressNull(  
    LPINTERNET_ADDRESS lpAddress  
);
```

The **IsAddressNull** method determines if the IP address is null.

Parameters

lpszAddress

A string that specifies the IP address.

lpAddress

A pointer to an INTERNET_ADDRESS structure that specifies the IP address.

Return Value

If the method succeeds and the IP address is null, or the parameter is a NULL pointer, the return value is non-zero. If the method fails or the address is not null, the return value is zero. If the address family is not supported, the last error code will be updated. If the address is valid but not null, the last error code will be set to NO_ERROR.

Remarks

A null IP address is one where all bits for the address (32 bits for IPv4 or 128 bits for IPv6) are zero. This is a special address that is typically used when creating a passive socket that should listen for connections on all available network interfaces.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

See Also

[GetAddress](#), [IsAddressRoutable](#), [INTERNET_ADDRESS](#)

InternetServer::IsAddressRoutable Method

```
BOOL IsAddressRoutable(  
    LPCTSTR lpszAddress  
);  
  
BOOL IsAddressRoutable(  
    LPINTERNET_ADDRESS lpAddress  
);
```

The **IsAddressRoutable** method determines if the IP address is routable over the Internet.

Parameters

lpszAddress

A string that specifies the IP address.

lpAddress

A pointer to an INTERNET_ADDRESS structure that specifies the IP address.

Return Value

If the method succeeds and the IP address is routable over the Internet, the return value is non-zero. If the method fails or the address is not routable, the return value is zero. If the parameter is NULL, or the address family is not supported, the last error code will be updated. If the address is valid but not routable, the last error code will be set to NO_ERROR.

Remarks

A routable IP address is one that can be reached by anyone over the public Internet. These are also commonly referred to as "public addresses" which are typically assigned to networks and individual hosts by an Internet service provider. There are also certain addresses that are not routable over the Internet, and used to address systems over a local network or private intranet. This function can be used to determine if a given IP address is public (routable) or private.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

See Also

[GetAddress](#), [GetExternalAddress](#), [IsAddressNull](#), [INTERNET_ADDRESS](#)

CInternetServer::IsInitialized Method

```
BOOL IsInitialized();
```

The **IsInitialized** method returns whether or not the class object has been successfully initialized.

Parameters

None.

Return Value

This method returns a non-zero value if the class object has been successfully initialized. A return value of zero indicates that the runtime license key could not be validated or the networking library could not be loaded by the current process.

Remarks

When an instance of the class is created, the class constructor will attempt to initialize the component with the runtime license key that was created when SocketTools was installed. If the constructor is unable to validate the license key or load the networking libraries, this initialization will fail.

If SocketTools was installed with an evaluation license, the application cannot be redistributed to another system. The class object will fail to initialize if the application is executed on another system, or if the evaluation period has expired. To redistribute your application, you must purchase a development license which will include the runtime key that is needed to redistribute your software to other systems. Refer to the Developer's Guide for more information.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cswskv10.lib

[CInternetServer](#), [IsListening](#), [IsLocked](#)

CInternetServer::IsListening Method

```
BOOL IsListening();
```

Determine if the server is listening for client connections.

Parameters

None.

Return Value

If the server has started and is listening for client connections, the method returns a non-zero value. If the server is not listening for connections, the return value is zero.

Remarks

The **IsListening** method determines if the server has been started and is actively listening for incoming connection requests from client applications. This method will return zero if the server is not active, if it has been suspended using the **Suspend** method or if the **Stop** method has been called to shutdown the server.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

See Also

[IsActive](#), [Start](#), [Stop](#), [Suspend](#)

CInternetServer::IsLocked Method

BOOL IsLocked();

Determine if the server is currently in a locked state.

Parameters

None.

Return Value

If the server is locked, the method returns a non-zero value. If the server is not locked, the return value is zero.

Remarks

The **IsLocked** method determines if a server has been locked using the **Lock** method. Only the thread that has locked the server may interact with it and all other threads will block when they attempt to perform a network operation. After the server is unlocked, the blocked threads will resume normal execution. If the application has created multiple instances of the **CInternetServer** class, this method will return a non-zero value if any of those servers have been locked, not only the current instance.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

See Also

[Lock](#), [Unlock](#)

CInternetServer::IsProtocolAvailable Method

```
BOOL IsProtocolAvailable(  
    INT nAddressFamily,  
    INT nProtocol  
);
```

The **IsProtocolAvailable** method determines if the operating system supports creating a socket for the specified address family and protocol.

Parameters

nAddressFamily

An integer which identifies the address family that should be checked. It should be one of the following values:

Constant	Description
INET_ADDRESS_IPV4	Specifies that the function should determine if it can create an Internet Protocol version 4 (IPv4) socket. This requires that the system have an IPv4 TCP/IP stack bound to at least one network adapter on the local system. All Windows systems include support for IPv4 by default.
INET_ADDRESS_IPV6	Specifies that the function should determine if it can create an Internet Protocol version 6 (IPv6) socket. This requires that the system have an IPv6 TCP/IP stack bound to at least one network adapter on the local system. Windows XP and Windows Server 2003 includes support for IPv6, however it is not installed by default. Windows Vista and later versions include support for IPv6 and enable it by default.

nProtocol

An integer which identifies the protocol that should be checked. It should be one of the following values:

Constant	Description
INET_PROTOCOL_TCP	Specifies the Transmission Control Protocol. This protocol provides a reliable, bi-directional byte stream. This requires that the system be capable of creating a stream socket using the specified address family.
INET_PROTOCOL_UDP	Specifies the User Datagram Protocol. This protocol is message oriented, sending data in discrete packets. This requires that the system be capable of creating a datagram socket using the specified address family.

Return Value

If the the system is capable of creating a socket using the specified address family and protocol, this method will return a non-zero value. If the combination of address family and protocol is not supported, this method will return a value of zero.

Remarks

The **IsProtocolAvailable** method is used to determine if the operating system supports creating a particular type of socket. Typically it is used by an application to determine if the system has an IPv6 TCP/IP stack installed and configured. By default, all Windows systems will have an IPv4 stack installed if the system has a network adapter. However, not all systems may have an IPv6 stack installed, particularly older Windows XP and Windows Server 2003 systems. Note that if an IPv6 stack is not installed, the library will not recognize IPv6 addresses and cannot resolve host names that only have an IPv6 (AAAA) record, even if the address or host name is valid.

Example

```
if (!pSocket->IsProtocolAvailable(INET_ADDRESS_IPV6, INET_PROTOCOL_TCP))
{
    AfxMessageBox(_T("This system does not support IPv6"), MB_ICONEXCLAMATION);
    return;
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

See Also

[GetAddress](#), [GetHostAddress](#), [GetHostName](#)

CInternetServer::IsReadable Method

```
BOOL IsReadable();  
  
BOOL IsReadable(  
    SOCKET hSocket  
);  
  
BOOL IsReadable(  
    SOCKET hSocket,  
    INT nTimeout,  
    LPDWORD lpdwAvail  
);
```

The **IsReadable** method is used to determine if data is available to be read from the client.

Parameters

hSocket

An optional parameter that specifies the handle to the client socket. If this parameter is omitted, the socket handle for the active client session will be used. If this method is called outside of a server event handler, the socket handle must be specified.

nTimeout

Timeout for remote host response, in seconds. A value of zero specifies that the connection should be polled without blocking the current thread.

lpdwAvail

A pointer to an unsigned integer which will contain the number of bytes available to read. This parameter may be NULL if this information is not required.

Return Value

If the server can read data from the client within the specified timeout period, the method returns a non-zero value. If there is no data available to be read, the method returns zero.

Remarks

On some platforms, this value will not exceed the size of the receive buffer (typically 64K bytes). Because of differences between TCP/IP stack implementations, it is not recommended that your application exclusively depend on this value to determine the exact number of bytes available. Instead, it should be used as a general indicator that there is data available to be read.

If the connection is secure, the value returned in *lpdwAvail* will reflect the number of bytes available in the encrypted data stream. The actual amount of data available to the application after it has been decrypted will vary.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cswsock10.h`

Import Library: `cswskv10.lib`

See Also

[IsWritable](#), [Peek](#), [Read](#), [ReadLine](#), [ReadStream](#)

CIInternetServer::IsWritable Method

```
BOOL IsWritable(  
    INT nTimeout  
);
```

The **IsWritable** method is used to determine if data can be written to the remote host.

Parameters

nTimeout

Timeout for remote host response, in seconds. A value of zero specifies that the connection should be polled without blocking the current thread.

Return Value

If data can be sent to the client within the specified timeout period, the method returns a non-zero value. The method will return zero if the socket send buffer is full.

Remarks

The **IsWritable** method cannot be used to determine the amount of data that can be sent to the client without blocking the current thread. A non-zero return value only indicates that the send buffer is not full and can accept some data. In most cases, it is recommended that larger blocks of data be broken into smaller logical blocks rather than attempting to send it all of the data at once. For very large streams of data, it is recommended that you use the **WriteStream** method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: csuskv10.lib

See Also

[IsReadable](#), [Write](#), [WriteLine](#), [WriteStream](#)

InternetServer::Lock Method

```
BOOL Lock();
```

Lock the server, causing other client threads to block until it is unlocked.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

The **Lock** method causes the specified server to enter a locked state where only the current thread may interact with the server and the clients that are connected to it. While a server is locked, all other threads will block when they attempt to perform a network operation. When the server is unlocked, the blocked threads will resume normal execution.

This method should be used carefully, and a server should never be left in a locked state for an extended period of time. It is meant to be used when the server process updates a global data structure and it must prevent any other threads from performing a network operation during the update. Only one server can be locked at any one time, and once a server has been locked, it can only be unlocked by the same thread.

The program should always check the return value from this method, and should never assume that the lock has been established. If more than one thread attempts to lock a server at the same time, there is no guarantee as to which thread will actually establish the lock. If a potential deadlock situation is detected, this method will fail and return a value of zero.

Every time the **Lock** method is called, an internal lock counter is incremented, and the lock will not be released until the lock count drops to zero. This means that each call to the **Lock** method must be matched by an equal number of calls to the **Unlock** method. Failure to do so will result in the server becoming non-responsive as it remains in a locked state.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cswskv10.lib

See Also

[IsLocked](#), [Unlock](#)

InternetServer::MatchHostName Method

```
BOOL MatchHostName(  
    LPCTSTR lpszHostName,  
    LPCTSTR lpszHostMask  
    BOOL bResolve  
);
```

The **MatchHostName** method matches a host name against one or more strings that may contain wildcards.

Parameters

lpszHostName

A pointer to a string which specifies the host name or IP address to match.

lpszHostMask

A pointer to a string which specifies one or more values to match against the host name. The asterisk character can be used to match any number of characters in the host name, and the question mark can be used to match any single character. Multiple values may be specified by separating them with a semicolon.

bResolve

A boolean value which specifies if the host name or IP address should be resolved when matching the host against the mask string. If this parameter is non-zero, two checks against the host mask string will be performed; once for the host name specified and once for its IP address. If this parameter is zero, then the match is made only against the host name string provided.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **MatchHostName** method provides a convenient way for an application to determine if a given host name matches one or more mask strings which may contain wildcard characters. For example, the host name could be "www.microsoft.com" and the host mask string could be "*.microsoft.com". In this example, the method would return a non-zero value indicating the host name matched the mask. However, if the mask string was "*.net" then the method would return zero, indicating that there was no match. Multiple mask values can be combined by separating them with a semicolon; for example, the mask "*.com;*.org" would match any host name in either the .com or .org top-level domains.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[GetAddress](#), [GetHostAddress](#), [GetHostName](#)

InternetServer::Peek Method

```
INT Peek(  
    SOCKET hSocket,  
    LPBYTE lpBuffer,  
    INT cbBuffer  
);  
  
INT Peek(  
    LPBYTE lpBuffer,  
    INT cbBuffer  
);
```

Read data from the client without removing it from the socket buffer.

Parameters

hSocket

An optional parameter that specifies the handle to the client socket. If this parameter is omitted, the socket handle for the active client session will be used. If this method is called outside of a server event handler, the socket handle must be specified.

lpBuffer

Pointer to the buffer in which the data will be stored. This argument may be NULL, in which case no data is copied from the socket buffers, however the function will return the number of bytes available to read.

cbBuffer

The maximum number of bytes to read and copy into the specified buffer. If the *lpBuffer* parameter is not NULL, this value must be greater than zero.

Return Value

If the function succeeds, the return value is the number of bytes available to read from the socket. A return value of zero indicates that there is no data available to read at that time. If the function fails, the return value is INET_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **Peek** method returns data that is available to read from the socket, up to the number of bytes specified. The data returned by this method is not removed from the socket buffers. It must be consumed by a subsequent call to the **Read** method. The return value indicates the number of bytes that can be read in a single operation, up to the specified buffer size. However, it is important to note that it may not indicate the total amount of data available to be read from the socket at that time.

If no data is available to be read, the method will return a value of zero. To determine if there is data available to be read, use the **IsReadable** method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cswsock10.h

Import Library: cswskv10.lib

See Also

[IsReadable](#), [IsWritable](#), [Read](#), [ReadLine](#), [Write](#), [WriteLine](#)

CIInternetServer::PreProcessEvent Method

```
virtual LONG PreProcessEvent(  
    SOCKET hServer,  
    UINT nClientId,  
    UINT nEventId,  
    DWORD dwError,  
    BOOL& bHandled  
);
```

A virtual method that is invoked for each event generated by the server.

Parameters

hServer

The server handle. The application should treat this as an opaque value that is only valid as long as the server is active. This value should not be stored by the application and the handle value will change if the server is restarted.

nClientId

An unsigned integer which uniquely identifies the client that has issued a request to the server. This value is guaranteed to be unique to the client session throughout the life of the server and is never reused. The application should never make assumptions about the order in which IDs are allocated to the client sessions.

nEventId

An unsigned integer which specifies which event occurred. For a list of events, see [Server Event Constants](#).

dwError

An unsigned integer which specifies any error that occurred. If no error occurred, then this parameter will be zero.

bHandled

An integer which specifies if the event has been handled by the application. If this parameter is set to a non-zero value, the default event handler will not be invoked for the event.

Return Value

The method should return a value of zero to indicate that the default event handler should be invoked for the event. If the method returns a non-zero value, this value is passed back to the event dispatcher and the default handler will not be invoked.

Remarks

The **PreProcessEvent** method is invoked for each event that is generated, prior to the default handler for that event. To implement an event handler, the application should create a class derived from the **CIInternetServer** class, and then override this method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cswsock10.h

Import Library: cswskv10.lib

CInternetServer::Read Method

```
INT Read(  
    SOCKET hSocket,  
    LPBYTE lpBuffer,  
    INT cbBuffer  
);  
  
INT Read(  
    LPBYTE lpBuffer,  
    INT cbBuffer  
);
```

Read data from the client.

Parameters

hSocket

An optional parameter that specifies the handle to the client socket. If this parameter is omitted, the socket handle for the active client session will be used. If this method is called outside of a server event handler, the socket handle must be specified.

lpBuffer

Pointer to the buffer in which the data will be stored. This parameter cannot be NULL.

cbBuffer

The maximum number of bytes to read and copy into the specified buffer. This value must be greater than zero.

Return Value

If the method succeeds, the return value is the number of bytes read. A return value of zero indicates that the client has closed the connection and there is no more data available to be read. If the method fails, the return value is `INET_ERROR`. To get extended error information, call the **GetLastError** method.

Remarks

The **Read** method will read up to the specified number of bytes and store the data in the buffer provided by the caller. If there is no data available to be read at the time this method is invoked, the session thread will block until at least one byte of data becomes available, the timeout period elapses or an error occurs. This method will return if any amount of data is sent by the client, and will not block until the entire buffer has been filled.

The application should never make an assumption about the amount of data that will be available to read. TCP considers all data to be an arbitrary stream of bytes and does not impose any structure on the data itself. For example, if the client is sending data to the server in fixed 512 byte blocks of data, it is possible that a single call to the **Read** method will return only a partial block of data, or it may return multiple blocks combined together. It is the responsibility of the application to buffer and process this data appropriately.

For applications that are built using the Unicode character set, it is important to note that the buffer is an array of bytes, not characters. If the client is sending string data to the server, it must be read as a stream of bytes and converted using the **MultiByteToWideChar** function. If the client is sending lines of text terminated with a linefeed or carriage return and linefeed pair, the **ReadLine** method will return a line of text at a time and perform this conversion for you.

To determine if there is data available to be read without causing the session thread to block, call the **IsReadable** method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cswsock10.h`

Import Library: `cswskv10.lib`

See Also

[IsReadable](#), [IsWritable](#), [Peek](#), [ReadLine](#), [Write](#), [WriteLine](#)

CInternetServer::ReadLine Method

```
BOOL ReadLine(  
    SOCKET hSocket,  
    LPTSTR lpszBuffer,  
    LPINT lpnLength  
);  
  
BOOL ReadLine(  
    LPTSTR lpszBuffer,  
    LPINT lpnLength  
);  
  
BOOL ReadLine(  
    SOCKET hSocket,  
    CString& strBuffer,  
    INT nMaxLength  
);  
  
BOOL ReadLine(  
    CString& strBuffer,  
    INT nMaxLength  
);
```

Read up to a line of data from the socket and return it in a string buffer.

Parameters

hSocket

An optional parameter that specifies the handle to the client socket. If this parameter is omitted, the socket handle for the active client session will be used. If this method is called outside of a server event handler, the socket handle must be specified.

lpszBuffer

Pointer to the string buffer that will contain the data when the method returns. The string will be terminated with a null character, and will not contain the end-of-line characters. An alternate form of the method accepts a **CString** argument which will contain the line of text returned by the server.

lpnLength

A pointer to an integer value which specifies the length of the buffer. The value should be initialized to the maximum number of characters that can be copied into the string buffer, including the terminating null character. When the method returns, its value will updated with the actual length of the string.

nMaxLength

An integer value which specifies the maximum length of the buffer.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **ReadLine** method reads data from the socket and copies into a specified string buffer. Unlike the **Read** method which reads arbitrary bytes of data, this method is specifically designed to return a single line of text data in a string. When an end-of-line character sequence is

encountered, the method will stop and return the data up to that point. The string buffer is guaranteed to be null-terminated and will not contain the end-of-line characters. This method will force the thread to block until an end-of-line character sequence is processed, the read operation times out or the remote host closes its end of the socket connection.

There are some limitations when using **ReadLine**. The method should only be used to read text, never binary data. In particular, the method will discard nulls, linefeed and carriage return control characters. The Unicode version of this method will return a Unicode string, however it does not support reading raw Unicode data from the socket. Any data read from the socket is internally buffered as octets (eight-bit bytes) and converted to Unicode using the **MultiByteToWideChar** function.

The **Read** and **ReadLine** method calls can be intermixed, however be aware that **Read** will consume any data that has already been buffered by the **ReadLine** method and this may have unexpected results.

Unlike the **Read** method, it is possible for data to be returned in the string buffer even if the return value is zero. Applications should check the length of the string to determine if any data was copied into the buffer. For example, if a timeout occurs while the method is waiting for more data to arrive on the socket, it will return zero; however, data may have already been copied into the string buffer prior to the error condition. It is the responsibility of the application to process that data, regardless of the return value.

Example

```
CString strBuffer;
BOOL bResult;

do
{
    bResult = pServer->ReadLine(strBuffer);

    if (strBuffer.GetLength() > 0)
    {
        // Process the line of data returned in the string
        // buffer; the string is always null-terminated
    }
} while (bResult);

DWORD dwError = pServer->GetLastError();

if (dwError == ST_ERROR_CONNECTION_CLOSED)
{
    // The remote host has closed its side of the connection and
    // there is no more data available to be read
}
else if (dwError != 0)
{
    // An error has occurred while reading a line of data
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cswskv10.lib

Unicode: Implemented as Unicode and ANSI versions.

CIInternetServer::ReadStream Method

```
BOOL ReadStream(  
    SOCKET hSocket,  
    LPVOID lpvBuffer,  
    LPDWORD lpdwLength,  
    DWORD dwOptions,  
    LPBYTE lpMarker,  
    DWORD cbMarker  
);
```

```
BOOL ReadStream(  
    LPVOID lpvBuffer,  
    LPDWORD lpdwLength,  
    DWORD dwOptions,  
    LPBYTE lpMarker,  
    DWORD cbMarker  
);
```

Read a stream of data from the client and store it in the specified buffer.

Parameters

hSocket

An optional parameter that specifies the handle to the client socket. If this parameter is omitted, the socket handle for the active client session will be used. If this method is called outside of a server event handler, the socket handle must be specified.

lpvBuffer

Pointer to the buffer that will contain or reference the data when the method returns. The actual argument depends on the value of the *dwOptions* parameter which specifies how the data stream will be stored.

lpdwLength

A pointer to an unsigned integer value which specifies the maximum length of the buffer and contains the number of bytes read when the method returns. This argument should always point to an initialized value. If the *lpvBuffer* argument specifies a memory buffer, then this argument cannot point to an initialized value of zero; if any other type of stream buffer is used and the initialized value is zero, that indicates that all available data from the socket should be returned until the end-of-stream marker is encountered or the remote host disconnects.

dwOptions

An unsigned integer value which specifies both the stream buffer type and any options to be used when reading the data stream. One of the following stream types may be specified:

Constant	Description
INET_STREAM_DEFAULT	The default stream buffer type is determined by the value passed as the <i>lpvBuffer</i> parameter. If the argument specifies a pointer to a global memory handle initialized to NULL, then the method will return a handle which references the data; otherwise, the method will consider the parameter a pointer to a block of pre-allocated memory which will contain the stream data when the

	method returns. In most cases, it is recommended that an application explicitly specify the stream buffer type rather than using the default value.
INET_STREAM_MEMORY	The <i>lpvBuffer</i> argument specifies a pointer to a pre-allocated block of memory which will contain the data read from the socket when the method returns. If this stream buffer type is used, the <i>lpdwLength</i> argument must point to an unsigned integer which has been initialized with the maximum length of the buffer.
INET_STREAM_HGLOBAL	The <i>lpvBuffer</i> argument specifies a pointer to a global memory handle. When the method returns, the handle will reference a block of memory that contains the stream data. The application should take care to make sure that the handle passed to the method does not currently reference a valid block of memory; it is recommended that the handle be initialized to NULL prior to calling this method.
INET_STREAM_HANDLE	The <i>lpvBuffer</i> argument specifies a Windows handle to an open file, console or pipe. This should be the same handle value returned by the CreateFile function in the Windows API. The data read from the socket will be written to this handle using the WriteFile function.
INET_STREAM_SOCKET	The <i>lpvBuffer</i> argument specifies a socket handle. The data read from the socket specified by the <i>hSocket</i> argument will be written to this socket. The socket handle passed to this method must have been created by this library; if it is a socket created by an third-party library or directly by the Windows Sockets API, you should either create another instance of the class and attach the socket using the AttachHandle method or use the INET_STREAM_HANDLE stream buffer type instead.

In addition to the stream buffer types listed above, the *dwOptions* parameter may also have one or more of the following bit flags set. Programs should use a bitwise operator to combine values.

Constant	Description
INET_STREAM_CONVERT	The data stream is considered to be textual and will be modified so that end-of-line character sequences are converted to follow standard Windows conventions. This will ensure that all lines of text are terminated with a carriage-return and linefeed sequence. Because this option modifies the data stream, it should never be used with binary data. Using this option may result in the

	amount of data returned in the buffer to be larger than the source data. For example, if the source data only terminates a line of text with a single linefeed, this option will have the effect of inserting a carriage-return character before each linefeed.
INET_STREAM_UNICODE	The data stream should be converted to Unicode. This option should only be used with text data, and will result in the stream data being returned as 16-bit wide characters rather than 8-bit bytes. The amount of data returned will be twice the amount read from the source data stream; if the application is using a pre-allocated memory buffer, this must be considered before calling this method.

lpMarker

A pointer to an array of bytes which marks the end of the data stream. When this byte sequence is encountered by the method, it will stop reading and return to the caller. The buffer will contain all of the data read from the socket up to and including the end-of-stream marker. If this argument is NULL, then the method will continue to read from the socket until the maximum buffer size is reached, the remote host closes its socket or an error is encountered.

cbMarker

An unsigned integer value which specifies the length of the end-of-stream marker in bytes. If the *lpMarker* parameter is NULL, then this value must be zero.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **ReadStream** method enables an application to read an arbitrarily large stream of data and store it in memory, write it to a file or even another socket. Unlike the **Read** method, which will return immediately when any amount of data has been read, **ReadStream** will only return when the buffer is full as specified by the *lpdwLength* parameter, the logical end-of-stream marker has been read, the socket closed by the remote host or when an error occurs. This method will force the session thread to block until the operation completes.

It is possible for data to be returned in the buffer even if the method returns a value of zero. Applications should also check the value of the *lpdwLength* argument to determine if any data was copied into the buffer. For example, if a timeout occurs while the method is waiting for more data to arrive on the socket, it will return zero; however, data may have already been copied into the buffer prior to the error condition. It is the responsibility of the application to process that data, regardless of the method return value.

Example

```
HGLOBAL hgb1Buffer = NULL; // Return data in a global memory buffer
DWORD cbBuffer = 102400; // Read up to 100K bytes
BOOL bResult;
```

```
bResult = pServer->ReadStream(&hgblBuffer, &cbBuffer,  
                              INET_STREAM_HGLOBAL | INET_STREAM_CONVERT);  
  
if (bResult && cbBuffer > 0)  
{  
    LPBYTE lpBuffer = (LPBYTE)GlobalLock(hgblBuffer);  
  
    // Use data in the stream buffer  
  
    GlobalUnlock(hgblBuffer);  
    GlobalFree(hgblBuffer);  
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

See Also

CIInternetServer::Reject Method

BOOL Reject();

Reject a pending client connection.

Parameters

None.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **Reject** method rejects a pending client connection and the remote host will see this as the connection being aborted. If there are no pending client connections at the time, this method will immediately return with an error indicating that the operation would cause the server thread to block. This method should only be invoked from within an **OnAccept** event handler if the application wishes to reject the incoming connection before a client session is created.

To determine the IP address of a client that is attempting to connect to the server from within the **OnAccept** event, use the **GetClientAddress** method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

See Also

[GetClientAddress](#), [OnAccept](#)

CIInternetServer::Restart Method

```
BOOL Restart();
```

Restart the server, terminating all active client sessions.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **Restart** method will restart the specified server, terminating all active client sessions. If the method is unable to restart the server for any reason, the server thread is terminated. The server retains all of the options specified for the previous instance.

If an application calls this method from within an event handler, the active client session (the client for which the event handler was invoked) may not get a disconnect notification. It is recommended that this method only be called by the same thread that created the server using the **Start** method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cssock10.h

Import Library: csoskv10.lib

See Also

[Start](#), [Stop](#)

CInternetServer::Resume Method

BOOL Resume();

Resume accepting client connections.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **Resume** method instructs the server to resume accepting new client connections after the **Suspend** method has been called.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cswsock10.h

Import Library: csWSKV10.lib

See Also

[Restart](#), [Start](#), [Stop](#), [Suspend](#), [Throttle](#)

CIInternetServer::SetBacklog Method

```
BOOL SetBacklog(  
    UINT nBackLog  
);
```

Set the size of the backlog connection queue for the server.

Parameters

nBacklog

An integer value that specifies the size of the connection backlog queue.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero.

Remarks

The **SetBacklog** method specifies the size of the queue allocated for pending client connections. A value of zero specifies that the queue should be set to a reasonable default value. On Windows server platforms, the maximum value is large enough to queue several hundred pending connections. This method should only be called prior to invoking the **Start** method, it does not have any effect on an active server. To get the current size of the backlog queue, use the **GetBacklog** method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

InternetServer::SetCertificate Method

```
BOOL SetCertificate(  
    DWORD dwProtocol,  
    LPCTSTR lpszCertStore,  
    LPCTSTR lpszCertName,  
    LPCTSTR lpszPassword  
);
```

```
BOOL SetCertificate(  
    LPCTSTR lpszCertStore,  
    LPCTSTR lpszCertName,  
    LPCTSTR lpszPassword  
);
```

```
BOOL SetCertificate(  
    LPCTSTR lpszCertName,  
    LPCTSTR lpszPassword  
);
```

Specify the server certificate that should be used with secure connections.

Parameters

dwProtocol

An optional bitmask of supported security protocols. If this parameter is not specified, then a default set of security protocols will be automatically selected. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
SECURITY_PROTOCOL_DEFAULT	The default selection of security protocols will be used when establishing a connection. The TLS 1.2, TLS 1.1 and TLS 1.0 protocols will be negotiated with the client, in that order of preference. This option will always request the latest version of the preferred security protocols and is the recommended value.
SECURITY_PROTOCOL_SSL	Either SSL 2.0 or SSL 3.0 should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the client. If this is the only protocol specified, TLS will be excluded from the list of supported protocols. Note that SSL 2.0 has been deprecated and will never be used by default.
SECURITY_PROTOCOL_TLS	The TLS 1.0, 1.1 or 1.2 protocol should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the client. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some clients that reject any

attempt to use the older SSL protocol and require that only TLS be used.
--

lpzCertStore

An optional string value that specifies the name of the certificate store that contains the server certificate. If the certificate is stored in the registry, this parameter must specify a valid local certificate store name. If the certificate is stored in a file, this parameter should specify the full path to the file that contains the certificate. If this parameter is omitted, the personal certificate store for the current process will be used.

lpzCertName

A string value that specifies the name of the certificate. This parameter is required and cannot be NULL. Either the common name or the name assigned to the certificate may be specified. In most cases, this will be the fully qualified domain name of the host that the server is running on.

lpzPassword

An optional string value that specifies a password associated with the server certificate. This parameter is usually only required when the *lpzCertStore* parameter specifies a certificate stored in a file. If the server certificate does not have a password associated with it, this parameter is omitted.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cssock10.h`

Import Library: `csksk10.lib`

Unicode: Implemented as Unicode and ANSI versions.

InternetServer::SetClientData Method

```
BOOL SetClientData(  
    SOCKET hClient,  
    VOID LpvData  
);
```

```
BOOL SetClientData(  
    VOID LpvData  
);
```

Associate application defined data with the specified client session.

Parameters

hSocket

An optional parameter that specifies the handle to the client socket. If this parameter is omitted, the socket handle for the active client session will be used. If this method is called outside of a server event handler, the socket handle must be specified.

lppvData

Pointer to the application defined data associated with the specified client session.

Return Value

If the method succeeds, the return value is non-zero. A return value of zero indicates that application defined data for the client session could not be modified. To get extended error information, call the **GetLastError** method.

Remarks

The **SetClientData** method is used to associate application defined data with a specific client session. This is typically used to associate a pointer to a data structure or a class instance with the client socket. A pointer to the data can be retrieved using the **GetClientData** method.

You should never specify a pointer to a local variable or data structure that will go out of scope when the calling method exits. If you do this, the pointer will no longer be valid after the method exits and attempting to dereference that pointer at some later time can cause an exception to be thrown and terminate the program. You should always allocate a block of memory for the data using a method such as **HeapAlloc** or **LocalAlloc**. If you specify the address of a static or global data structure, you must use thread synchronization methods when dereferencing and modifying that structure.

Example

```
UINT *pnValue1 = new UINT;  
UINT *pnValue2 = NULL;  
  
*pnValue1 = 1234;  
  
if (!pServer->SetClientData(hClient, pnValue1))  
{  
    // Unable to associate the data with this session  
    return;  
}  
  
if (!pServer->GetClientData(hClient, (LPVOID *)&pnValue2))  
{
```

```
    // Unable to retrieve the data associated with this session
    return;
}

// pnValue2 == pnValue1
printf("The value of the user defined data is %u\n", *pnValue2);
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

See Also

[GetClientData](#)

CIInternetServer::SetClientMoniker Method

```
INT SetClientMoniker(  
    SOCKET hSocket,  
    LPCTSTR LpszMoniker  
);  
  
INT SetClientMoniker(  
    LPCTSTR LpszMoniker  
);
```

Associate a unique string alias with the specified client session.

Parameters

hSocket

An optional parameter that specifies the handle to the client socket. If this parameter is omitted, the socket handle for the active client session will be used. If this method is called outside of a server event handler, the socket handle must be specified.

lpszMoniker

Pointer to a string which specifies the moniker for the specified client socket. If this parameter is NULL or specifies an empty string, a moniker will no longer be associated with the client session.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is INET_ERROR. To get extended error information, call the **GetLastError** method.

Remarks

A client moniker is a string which can be used to uniquely identify a specific client session aside from its socket handle. The **GetClientMoniker** method will return the moniker that was previously assigned to the client, if any. To obtain the socket handle associated with a given moniker, use the **FindClient** method.

Monikers are not case-sensitive, and they must be unique so that no client socket for a particular server can have the same moniker. The maximum length for a moniker is 127 characters.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cswsock10.h

Import Library: cswskv10.lib

See Also

[FindClient](#), [GetClientHandle](#), [GetClientId](#), [GetClientMoniker](#)

CInternetServer::SetLastError Method

```
VOID SetLastError(  
    DWORD dwErrorCode  
);
```

The **SetLastError** method sets the last error code for the current thread. This method is typically used to clear the last error by specifying a value of zero as the parameter.

Parameters

dwErrorCode

Specifies the last error code for the current thread.

Return Value

None.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. Most methods will set the last error code value when they fail; a few methods set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_SOCKET or INET_ERROR. Those methods which call **SetLastError** when they succeed are noted on the method reference page.

Applications can retrieve the value saved by this method by using the **GetLastError** method. The use of **GetLastError** is optional; an application can call the method to determine the specific reason for a method failure.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cswsock10.h

Import Library: cswskv10.lib

See Also

[GetErrorString](#), [GetLastError](#), [ShowError](#)

CIInternetServer::SetOptions Method

```
BOOL SetOptions(  
    DWORD dwOptions  
);
```

Set one or more server options.

Parameters

dwOptions

An unsigned integer that specifies one or more option bitflags.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero.

Remarks

The **SetOptions** method sets the server options for the class instance. For a list of the available options, see [Server Option Constants](#). This method should only be called prior to invoking the **Start** method, it does not have any effect on an active server. The **GetOptions** method returns the options that are currently specified for the server.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

See Also

[GetOptions](#), [Data Members](#)

InternetServer::SetPriority Method

```
INT SetPriority(  
    INT nPriority  
);
```

Set the priority assigned to the specified server.

Parameters

nPriority

An integer that specifies the server priority. It may be one of the following values:

Constant	Description
INET_PRIORITY_BACKGROUND (0)	This priority significantly reduces the memory, processor and network resource utilization for the server. It is typically used with lightweight services running in the background that are designed for few client connections. The server thread will be assigned a lower scheduling priority and will be frequently forced to yield execution to other threads.
INET_PRIORITY_LOW (1)	This priority lowers the overall resource utilization for the server and meters the processor utilization for the server thread. The server thread will be assigned a lower scheduling priority and will occasionally be forced to yield execution to other threads.
INET_PRIORITY_NORMAL (2)	The default priority which balances resource and processor utilization. This is the priority that is initially assigned to the server when it is started, and it is recommended that most applications use this priority.
INET_PRIORITY_HIGH (3)	This priority increases the overall resource utilization for the server and the thread will be given higher scheduling priority. It is not recommended that this priority be used on a system with a single processor.
INET_PRIORITY_CRITICAL (4)	This priority can significantly increase processor, memory and network utilization. The server thread will be given higher scheduling priority and will be more responsive to client connection requests. It is not recommended that this priority be used on a system with a single processor.

Return Value

If the method succeeds, the return value is the previous priority assigned to the server. If the method fails, the return value is INET_ERROR.

Remarks

The **SetPriority** method changes the current priority assigned to the specified server. Client connections that are accepted after this method is called will inherit the new priority as their default priority. Previously existing client connections will not be affected by this function.

Higher priority values increase the thread priority and processor utilization for each client session. You should only change the server priority if you understand the impact it will have on the system and have thoroughly tested your application. Configuring the server to run with a higher priority can have a negative effect on the performance of other programs running on the system.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: csoskv10.lib

See Also

[GetPriority](#)

CInternetServer::SetStackSize Method

```
BOOL SetStackSize(  
    DWORD dwStackSize  
);
```

Change the initial size of the stack allocated for threads created by the server.

Parameters

dwStackSize

The amount of memory that will be committed to the stack for each thread created by the server. If this value is zero, a default stack size will be used.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **SetStackSize** method changes the initial amount of memory that is committed to the stack for each thread created by the server. By default, the stack size for each thread is set to 256K for 32-bit processes and 512K for 64-bit processes. Increasing or decreasing the stack size will only affect new threads that are created by the server, it will not affect those threads that have already been created to manage active client sessions. It is recommended that most applications use the default stack size.

You should not change this value unless you understand the impact that it will have on your system and have thoroughly tested your application. Increasing the initial commit size of the stack will remove pages from the total system commit limit, and every page of memory that is reserved for stack cannot be used for any other purpose.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

See Also

[GetStackSize](#), [Start](#)

CInternetServer::SetTimeout Method

```
INT SetTimeout(  
    UINT nTimeout  
);
```

Set the timeout interval used when waiting for a blocking operation to complete.

Parameters

nTimeout

The number of seconds to wait for a blocking operation to complete.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is INET_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **SetTimeout** method sets the amount of time that the server will wait for data to become available to read, and the default timeout for blocking network operations for each client session. If this method is invoked before the server has started, it will change the default timeout period for the entire server. If this method is invoked within a server event handler, it will change the timeout period for the active client session.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

See Also

CInternetServer::ShowError Method

```
INT ShowError(  
    LPCTSTR lpszAppTitle,  
    UINT uType,  
    DWORD dwErrorCode  
);
```

Display a message box which describes the specified error.

Parameters

lpszAppTitle

A pointer to a string which specifies the title of the message box that is displayed. If this argument is NULL or omitted, then the default title of "Error" will be displayed.

uType

An unsigned integer which specifies the type of message box that will be displayed. This is the same value that is used by the **MessageBox** method in the Windows API. If a value of zero is specified, then a message box with a single OK button will be displayed. Refer to that method for a complete list of options.

dwErrorCode

Specifies the error code that will be used when displaying the message box. If this argument is zero, then the last error that occurred in the current thread will be displayed.

Return Value

If the method is successful, the return value will be the return value from the **MessageBox** function. If the method fails, it will return a value of zero.

Remarks

The **ShowError** method will display a modal message box with an error message that corresponds to the specified error code. All top-level windows belonging to the current thread will be disabled until the user responds to the message box. An application should only invoke this method from within the main UI thread, never from within a server event handler such as **OnConnect**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cswsock10.h`

Import Library: `cswskv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

[GetErrorString](#), [GetLastError](#), [SetLastError](#)

CInternetServer::Start Method

```
BOOL Start(  
    LPCTSTR lpszLocalHost,  
    UINT nLocalPort,  
    UINT nMaxClients,  
    DWORD dwOptions  
);
```

```
BOOL Start(  
    LPCTSTR lpszLocalHost,  
    UINT nLocalPort,  
    DWORD dwOptions  
);
```

```
BOOL Start(  
    UINT nLocalPort,  
    DWORD dwOptions  
);
```

```
BOOL Start(  
    UINT nLocalPort  
);
```

The **Start** method begins listening for client connections on the specified local address and port number. The server is started in its own thread and manages the client sessions independently of the calling thread. All interaction with the server and its client sessions takes place inside the class event handlers.

Parameters

lpszLocalHost

A pointer to a string which specifies the local hostname or IP address address that the server should be bound to. If this parameter is omitted or specifies a NULL pointer an appropriate address will automatically be used. If a specific address is used, the server will only accept client connections on the network interface that is bound to that address.

nLocalPort

The port number the server should use to listen for client connections. The port number used by the application must be unique and multiple instances of a server cannot use the same port number. It is recommended that a port number greater than 5000 be used for private, application-specific implementations.

nMaxClients

The maximum number of client connections that can be established with the server. A value of zero specifies that there should not be any fixed limit on the number of active client connections. This value can be adjusted after the server has been created by calling the **Throttle** method.

dwOptions

An unsigned integer value that specifies one or more options to be used when creating an instance of the server. For a list of the available options, see [Server Option Constants](#). If this parameter is omitted, the default options for the server instance will be used.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero.

To get extended error information, call **GetLastError**.

Remarks

In most cases, the *lpszLocalHost* parameter should be omitted or a NULL pointer. On a multihomed system, this will enable the server to accept connections on any appropriately configured network adapter. Specifying a hostname or IP address will limit client connections to that particular address. Note that the hostname or address must be one that is assigned to the local system, otherwise an error will occur.

If an IPv6 address is specified as the local address, the system must have an IPv6 stack installed and configured, otherwise the method will fail.

To listen for connections on any suitable IPv4 interface, specify the special dotted-quad address "0.0.0.0". You can accept connections from clients using either IPv4 or IPv6 on the same socket by specifying the special IPv6 address "::0", however this is only supported on Windows 7 and Windows Server 2008 R2 or later platforms. If no local address is specified, then the server will only listen for connections from clients using IPv4. This behavior is by design for backwards compatibility with systems that do not have an IPv6 TCP/IP stack installed.

The server instance is managed in another thread, and all interaction with the server and active client connections are performed inside the event handlers. To disconnect all active connections, close the listening socket and terminate the server thread, call the **Stop** method.

Example

```
// EchoServer implementation
class CEchoServer : public CInternetServer
{
    void OnRead(SOCKET hSocket)
    {
        // Read data sent by the client to the server
        BYTE ioBuffer[1024];
        INT nBytesRead = Read(hSocket, ioBuffer, sizeof(ioBuffer));

        // Send a copy of the data back to the client
        if (nBytesRead > 0)
            Write(hSocket, ioBuffer, nBytesRead);
    }
};

int _tmain(int argc, _TCHAR* argv[])
{
    CEchoServer myServer;

    // Start the server listening for connections on port 7000
    if (myServer.Start(7000))
    {
        TCHAR szCommand[128], *pszCommand;

        // Process commands entered by the user at the console
        while (TRUE)
        {
            if ((pszCommand = _fgetts(szCommand, 128, stdin)) == NULL)
                break;

            if (_tcsicmp(pszCommand, _T("quit")) == 0)
                break;
        }
    }
}
```

```
        // Stop the server and terminate all clients
        myServer.Stop();
    }

    return 0;
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cswsock10.h

Import Library: cswskv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[EnumClients](#), [Restart](#), [Stop](#)

CInternetServer::Stop Method

BOOL Stop();

Stop the server, terminating all active client sessions and releasing the resources that were allocated for the server.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, it will return a value of zero.

Remarks

The **Stop** method instructs the server to stop accepting client connections, disconnects all active client connections and terminates the thread that is managing the server session. The handle is no longer valid after the server has been stopped and should no longer be used. Note that it is possible that the actual handle value may be re-used at a later point when a new server is started. An application should always consider the server handle to be opaque and never depend on it being a specific value.

If an application calls this method from within an event handler, the active client session (the client for which the event handler was invoked) may not get a disconnect notification. It is recommended that this method only be called by the same thread that created the server using the **Start** method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cssock10.h

Import Library: cswskv10.lib

See Also

[Restart](#), [Start](#)

InternetServer::StoreStream Method

```
BOOL StoreStream(  
    LPCTSTR lpszFileName,  
    DWORD dwLength,  
    LPDWORD lpdwCopied  
    DWORD dwOffset,  
    DWORD dwOptions  
);
```

The **StoreStream** method reads the socket data stream and stores the contents in the specified file.

Parameters

lpszFileName

Pointer to a string which specifies the name of the file to create or overwrite.

dwLength

An unsigned integer which specifies the maximum number of bytes to read from the socket and write to the file. If this value is zero, then the method will continue to read data from the socket until the remote host disconnects or an error occurs.

lpdwCopied

A pointer to an unsigned integer value which will contain the number of bytes written to the file when the method returns.

dwOffset

An unsigned integer which specifies the byte offset into the file where the method will start storing data read from the socket. Note that all data after this offset will be truncated. A value of zero specifies that the file should be completely overwritten if it already exists.

dwOptions

An unsigned integer value which specifies one or more options. Programs can use a bitwise operator to combine any of the following values:

Constant	Description
INET_STREAM_CONVERT	The data stream is considered to be textual and will be modified so that end-of-line character sequences are converted to follow standard Windows conventions. This will ensure that all lines of text are terminated with a carriage-return and linefeed sequence. Because this option modifies the data stream, it should never be used with binary data. Using this option may result in the amount of data written to the file to be larger than the source data. For example, if the source data only terminates a line of text with a single linefeed, this option will have the effect of inserting a carriage-return character before each linefeed.
INET_STREAM_UNICODE	The data stream should be converted to Unicode. This option should only be used with text data, and will result in the stream data being written as 16-bit

wide characters rather than 8-bit bytes. The amount of data returned will be twice the amount read from the source data stream. If the *dwOffset* parameter has a value of zero, the Unicode byte order mark (BOM) will be written to the beginning of the file.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **StoreStream** method enables an application to read an arbitrarily large stream of data and store it in a file. This method is essentially a simplified version of the **ReadStream** method, designed specifically to be used with files rather than memory buffers or handles.

Example

```
// Store all data sent by the client in a file
DWORD dwCopied = 0;
BOOL bResult = pServer->StoreStream(lpszFileName, 0, &dwCopied, 0,
INET_STREAM_CONVERT);

// Close the client connection to the server
pServer->Disconnect();

if (bResult && dwCopied > 0)
{
    // Process the data has been written to the file
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: csuskv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[Read](#), [ReadLine](#), [ReadStream](#), [Write](#), [WriteLine](#), [WriteStream](#)

CInternetServer::Suspend Method

```
BOOL Suspend();
```

Suspend the server and reject new client connections.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **Suspend** method instructs the server to suspend accepting new client connections. Any incoming client connections will be rejected with an error message indicating that the server is currently unavailable. To resume accepting client connections, call the **Resume** method. Suspending the server will have no effect on clients that have already established a connection with the server.

It is recommended that you only suspend a server if absolutely necessary, and only for brief periods of time. If you want to limit the number of active client connections or control the connection rate for clients, use the **Throttle** method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cswsock10.h

Import Library: cswskv10.lib

See Also

[Restart](#), [Resume](#), [Start](#), [Stop](#), [Throttle](#)

CIInternetServer::Throttle Method

```
BOOL Throttle(  
    UINT nMaxClients,  
    UINT nMaxClientsPerAddress,  
    DWORD dwConnectionRate  
);
```

The **Throttle** method limits the number of active client connections, connections per address and connection rate.

Parameters

nMaxClients

A value which specifies the maximum number of clients that may connect to the server. A value of zero specifies that there is no fixed limit to the number of client connections. A value of -1 specifies that the maximum number of clients should not be changed.

nMaxClientsPerAddress

A value which specifies the maximum number of clients that may connect to the server from the same IP address. A value of zero specifies that there is no fixed limit to the number of client connections per address. By default, there is a limit of four client connections per address. A value of -1 specifies that the maximum number of clients should not be changed.

dwConnectionRate

A value which specifies a restriction on the rate of client connections, limiting the number of connections that will be accepted within that period of time. A value of zero specifies that there is no restriction on the rate of client connections. The higher this value, the fewer the number of connections that will be accepted within a specific period of time. By default, there is no limit on the client connection rate. A value of -1 specifies that the connection rate should not be changed.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **Throttle** method is used to limit the number of connections and the connection rate to minimize the potential impact of a large number of client connections over a short period of time. This can be used to protect the server from a client application that is malfunctioning or a deliberate denial-of-service attack in which the attacker attempts to flood the server with connection attempts.

If the maximum number of client connections or maximum number of connections per address is exceeded, the server will reject subsequent connection attempts until the number of active client sessions drops below the specified threshold. Note that adjusting these values lower than the current connection limits will not affect clients that have already connected to the server. For example, if the **Start** method is called with the maximum number of clients set to 100, and then **Throttle** is called lowering that value to 75, no existing client connections will be affected by the change. However, the server will not accept any new connections until the number of active clients drops below 75.

Increasing the connection rate value will force the server to slow down the rate at which it will accept incoming client connection requests. For example, setting this parameter to a value of 1000

would limit the server to accepting one client connection every second, while a value of 250 would allow the server to accept four client connections per second. Note that significantly increasing the amount of time the server must wait to accept client connections can exceed the connection backlog queue, resulting in client connections being rejected.

It is recommended that you always specify conservative connection limits for your server application based on expected usage. Allowing an unlimited number of client connections can potentially expose the system to denial-of-service attacks and should never be done for servers that are accessible over the Internet.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cswsock10.h

Import Library: cswskv10.lib

See Also

[Restart](#), [Resume](#), [Start](#), [Suspend](#)

CIInternetServer::Unlock Method

```
BOOL Unlock();
```

Unlock the server, allowing other client threads to resume execution.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

The **Unlock** method releases the lock on the specified server and allows any blocked threads to resume execution. Only one server may be locked at any one time, and only the thread which established the lock can unlock the server.

Every time the **Lock** method is called, an internal lock counter is incremented, and the lock will not be released until the lock count drops to zero. This means that each call to the **Lock** method must be matched by an equal number of calls to the **Unlock** method. Failure to do so will result in the server becoming non-responsive as it remains in a locked state.

The program should always check the return value from this method, and should never assume that the lock has been released. If a potential deadlock situation is detected, this method will fail and return a value of zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cswskv10.lib

CInternetServer::Write Method

```
INT Write(  
    SOCKET hSocket,  
    LPBYTE lpBuffer,  
    INT cbBuffer  
);  
  
INT Write(  
    LPBYTE lpBuffer,  
    INT cbBuffer  
);
```

Send the contents of the specified buffer to to the client.

Parameters

hSocket

An optional parameter that specifies the handle to the client socket. If this parameter is omitted, the socket handle for the active client session will be used. If this method is called outside of a server event handler, the socket handle must be specified.

lpBuffer

The pointer to the buffer which contains the data that is to be sent to the client.

cbBuffer

The number of bytes to send from the specified buffer. This value must be greater than zero.

Return Value

If the method succeeds, the return value is the number of bytes actually written. If the method fails, the return value is `INET_ERROR`. To get extended error information, call the **GetLastError** method.

Remarks

The return value may be less than the number of bytes specified by the *cbBuffer* parameter. In this case, the data has been partially written and it is the responsibility of the client application to send the remaining data at some later point.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cswsock10.h`

Import Library: `cswskv10.lib`

See Also

[IsReadable](#), [IsWritable](#), [Read](#), [ReadLine](#), [WriteLine](#)

CInternetServer::WriteLine Method

```
BOOL WriteLine(  
    SOCKET hSocket,  
    LPCTSTR lpszBuffer,  
    LPINT lpnLength  
);
```

```
BOOL WriteLine(  
    LPCTSTR lpszBuffer,  
    LPINT lpnLength  
);
```

Write a line of data to the client, terminated with a carriage-return and linefeed.

Parameters

hSocket

An optional parameter that specifies the handle to the client socket. If this parameter is omitted, the socket handle for the active client session will be used. If this method is called outside of a server event handler, the socket handle must be specified.

lpszBuffer

The pointer to a string buffer which contains the data that will be sent to the remote host. All characters up to, but not including, the terminating null character will be written to the socket. The data will always be terminated with a carriage-return and linefeed control character sequence. If this parameter points to an empty string or NULL pointer, then only a carriage-return and linefeed are written to the socket.

lpnLength

A pointer to an integer value which will contain the number of characters written to the socket, including the carriage-return and linefeed sequence. If this information is not required, a NULL pointer may be specified.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **WriteLine** method writes a line of text to the remote host and terminates the line with a carriage-return and linefeed control character sequence. Unlike the **Write** method which writes arbitrary bytes of data to the socket, the **WriteLine** method is specifically designed to write a single line of text data from a null-terminated string. This method will force the session thread to block until the complete line of text has been written, the write operation times out or the remote host aborts the connection.

There are some limitations when using **WriteLine**. This method should only be used to send text, never binary data. In particular, it will discard nulls and append linefeed and carriage return control characters to the data stream. The Unicode version of this method will accept a Unicode string, however it does not support writing raw Unicode data to the socket. Unicode strings will be automatically converted to UTF-8 encoding using the **WideCharToMultiByte** function and then written to the socket as a stream of bytes.

The **Write** and **WriteLine** methods can be safely intermixed.

Unlike the **Write** method, it is possible for data to have been written to the socket if the return value is zero. For example, if a timeout occurs while the method is waiting to send more data to the remote host, it will return zero; however, some data may have already been written prior to the error condition. If this is the case, the *lpnLength* argument will specify the number of characters actually written up to that point.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cssock10.h`

Import Library: `cswskv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

See Also

[IsWritable](#), [Read](#), [ReadLine](#), [ReadStream](#), [Write](#), [WriteStream](#)

CInternetServer::WriteStream Method

```
BOOL WriteStream(  
    SOCKET hSocket,  
    LPVOID lpvBuffer,  
    LPDWORD lpdwLength,  
    DWORD dwOptions  
);
```

```
BOOL WriteStream(  
    LPVOID lpvBuffer,  
    LPDWORD lpdwLength,  
    DWORD dwOptions  
);
```

Write a stream of data to the client.

Parameters

hSocket

An optional parameter that specifies the handle to the client socket. If this parameter is omitted, the socket handle for the active client session will be used. If this method is called outside of a server event handler, the socket handle must be specified.

lpvBuffer

Pointer to the buffer that contains or references the data to be written to the socket. The actual argument depends on the value of the *dwOptions* parameter which specifies how the data stream will be accessed.

lpdwLength

A pointer to an unsigned integer value which specifies the size of the buffer and contains the number of bytes written when the method returns. This argument should always point to an initialized value. If the *lpvBuffer* argument specifies a memory buffer or global memory handle, then this argument cannot point to an initialized value of zero.

dwOptions

An unsigned integer value which specifies the stream buffer type to be used when writing the data stream to the socket. One of the following stream types may be specified:

Constant	Description
INET_STREAM_DEFAULT	The default stream buffer type is determined by the value passed as the <i>lpvBuffer</i> parameter. If the argument specifies a global memory handle, then the method will write the data referenced by that handle; otherwise, the method will consider the parameter a pointer to a block of memory which contains data to be written. In most cases, it is recommended that an application explicitly specify the stream buffer type rather than using the default value.
INET_STREAM_MEMORY	The <i>lpvBuffer</i> argument specifies a pointer to a block of memory which contains the data to be written to the socket. If this stream buffer type is

	used, the <i>lpdwLength</i> argument must point to an unsigned integer which has been initialized with the size of the buffer.
INET_STREAM_HGLOBAL	The <i>lpvBuffer</i> argument specifies a global memory handle that references the data to be written to the socket. The handle must have been created by a call to the GlobalAlloc or GlobalReAlloc function. If this stream buffer type is used, the <i>lpdwLength</i> argument must point to an unsigned integer which has been initialized with the size of the buffer.
INET_STREAM_HANDLE	The <i>lpvBuffer</i> argument specifies a Windows handle to an open file, console or pipe. This should be the same handle value returned by the CreateFile function in the Windows API. The data read using the ReadFile function with this handle will be written to the socket.
INET_STREAM_SOCKET	The <i>lpvBuffer</i> argument specifies a socket handle. The data read from the socket specified by this handle will be written to the socket specified by the <i>hSocket</i> parameter. The socket handle passed to this method must have been created by this library; if it is a socket created by an third-party library or directly by the Windows Sockets API, you should either create another instance of the class and attach the socket using the AttachHandle method or use the INET_STREAM_HANDLE stream buffer type instead.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **InetGetLastError**.

Remarks

The **WriteStream** method enables an application to write an arbitrarily large stream of data from memory or a file to the specified socket. Unlike the **Write** method, which may not write all of the data in a single method call, **WriteStream** will only return when all of the data has been written or an error occurs. This method will force the thread to block until the operation completes.

It is possible for some data to have been written even if the method returns a value of zero. Applications should also check the value of the *lpdwLength* argument to determine if any data was sent. For example, if a timeout occurs while the method is waiting to write more data, it will return zero; however, some data may have already been written to the socket prior to the error condition.

Example

```
CFile *pFile = new CFile();
DWORD dwLength = 0;

if (!pFile->Open(strFileName, CFile::modeRead | CFile::shareDenyWrite))
```

```
        return;

    dwLength = pFile->GetLength();

    if (dwLength > 0)
    {
        BOOL bResult = pServer->WriteStream(
            pFile->m_hFile,
            &dwLength,
            INET_STREAM_HANDLE);
    }

    delete pFile;
```

Requirements

CInternetServer Event Handlers

Method	Description
OnAccept	The client is attempting to establish a connection to the server
OnConnect	The client has established a connection to the server
OnDisconnect	The client has disconnected from the server
OnError	The event handler encountered an error when processing a client event
OnRead	The client has sent data to the server
OnTimeout	The client has not sent data within the specified timeout period
OnWrite	The client is ready to receive data from the server

CInternetServer::OnAccept Method

```
virtual void OnAccept(  
    SOCKET hSocket  
);
```

A virtual method that is invoked when a client attempts to connect to the server.

Parameters

hSocket

A handle to the server socket.

Return Value

None.

Remarks

The **OnAccept** event handler is invoked when a client attempts to connect to the server, but prior to the connection being accepted. To implement an event handler, the application should create a class derived from the **CInternetServer** class, and then override this method.

This event only occurs before the server has checked the active client limits. This event is typically used to reject a connection based on some criteria established by the server, such as the IP address of the client attempting to make the connection. To obtain the IP address of the client that is attempting to connect to the server, use the **GetClientAddress** method using the server handle.

If this event handler is not implemented, the server will permit the client connection to complete. To reject the connection attempt, call the **Reject** method using the handle to the server socket. Rejecting the client connection within the **OnAccept** event handler may cause unexpected behavior by the client application because the connection process will not complete normally. Instead of rejecting the client connection within the **OnAccept** handler, it is recommended that most server applications implement an **OnConnect** event handler, perform any required checks and then gracefully disconnect the client using the **Disconnect** method if needed.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cssock10.h

Import Library: csuskv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[Disconnect](#), [OnConnect](#), [OnDisconnect](#)

CInternetServer::OnConnect Method

```
virtual void OnConnect(  
    SOCKET hSocket,  
    UINT nClientId,  
    LPCTSTR lpszAddress,  
    UINT nPort  
);
```

A virtual method that is invoked after the client has connected to the server.

Parameters

hSocket

A handle to the client socket.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszAddress

A string that specifies the IP address of the client. This address may either be in IPv4 or IPv6 format, depending on how the server was configured and the address the client used to establish the connection.

nPort

An integer that specifies the port number that the client socket is bound to.

Return Value

None.

Remarks

The **OnConnect** event handler is invoked after the client has connected to the server. To implement an event handler, the application should create a class derived from the **CInternetServer** class, and then override this method.

This event only occurs after the server has checked the active client limits and the TLS handshake has been performed, if security has been enabled. If the server has been suspended, or the limit on the maximum number of client sessions has been exceeded, the server will reject the connection prior to this event handler being invoked.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cssock10.h

Import Library: cswskv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[Disconnect](#), [OnAccept](#), [OnDisconnect](#)

CInternetServer::OnDisconnect Method

```
virtual void OnDisconnect(  
    SOCKET hSocket  
);
```

A virtual method that is invoked when a client disconnects from the server.

Parameters

hSocket

A handle to the client socket.

Return Value

None.

Remarks

The **OnDisconnect** event handler is invoked when a client disconnects from the server, immediately before the client session is terminated. To implement an event handler, the application should create a class derived from the **CInternetServer** class, and then override this method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cswsock10.h

Import Library: cswskv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[Disconnect](#), [OnConnect](#)

CInternetServer::OnError Method

```
virtual void OnConnect(  
    SOCKET hSocket,  
    UINT nEventId,  
    DWORD dwError  
);
```

A virtual method that is invoked when the server encounters an error while handling a client request.

Parameters

hSocket

An unsigned integer which uniquely identifies the client session.

nEventId

An unsigned integer which identifies the client event that was being processed when the error occurred. For a list of event identifiers, see [Server Event Constants](#).

dwError

An unsigned integer value that specifies the error code.

Return Value

None.

Remarks

The **OnError** event handler is invoked whenever an error occurs while an event is being processed by the server. To implement an event handler, the application should create a class derived from the **CInternetServer** class, and then override this method.

It is important to note that this event is not raised for every error that occurs. The event only occurs when another event is being processed and an unhandled error occurs that must be reported back to the server application. The following are some common situations in which this event handler may be invoked:

- A network error occurs when the client connection is being accepted by the server. This could be the result of an aborted connection or some other lower-level failure reported by the networking subsystem on the server.
- The server is configured to use implicit SSL but cannot obtain the security credentials required to create the security context for the session. Usually this indicates that the server certificate cannot be found, or the certificate does not have a private key associated with it. It could also indicate a general problem with the cryptographic subsystem where the client and server could not successfully negotiate a cipher suite.
- Network errors that may occur when attempting to buffer data sent by the client. This usually indicates that the connection to the client has been aborted, either because the client is not acknowledging the data that has been exchanged with the server, or the client has terminated abnormally. This event will not occur if the client terminates the connection normally.

In most situations where this event handler is invoked, the error is not recoverable and the only action that can be taken is to terminate the client session.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cssock10.h

Import Library: cswskv10.lib

See Also

[OnConnect](#), [OnDisconnect](#), [OnTimeout](#)

CInternetServer::OnRead Method

```
virtual void OnRead(  
    SOCKET hSocket  
);
```

A virtual method that is invoked when a client sends data to the server.

Parameters

hSocket

A handle to the client socket.

Return Value

None.

Remarks

The **OnRead** event handler is invoked when a client sends data to the server. To implement an event handler, the application should create a class derived from the **CInternetServer** class, and then override this method. All server applications must implement an **OnRead** event handler to process the data sent by the client.

This event occurs whenever there is data available to be read from the client. The server application reads the data using the **Read** or **ReadLine** method, and can then send data back to the client using the **Write** or **WriteLine** method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cswsock10.h

Import Library: cswskv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[Read](#), [ReadLine](#), [Write](#), [WriteLine](#), [OnWrite](#)

CInternetServer::OnTimeout Method

```
virtual void OnTimeout(  
    SOCKET hSocket  
);
```

A virtual method that is invoked when the client has not sent any data to the server within the timeout period.

Parameters

hSocket

A handle to the client socket.

Return Value

None.

Remarks

The **OnTimeout** event handler is invoked when a client has not sent any data to the server within the timeout period specified when the server was started. To implement an event handler, the application should create a class derived from the **CInternetServer** class, and then override this method.

This event handler is typically used to monitor the amount of time that a client is idle. The default timeout period for the server is 20 seconds, which would cause this event handler to be invoked whenever a client has not sent any data to the server in the last 20 seconds. The server may take no action, or it may disconnect the client after it has been idle for an extended period of time. To get the total amount of time that the client has been idle, call the **GetClientIdleTime** method. Note that while the server timeout period is specified in seconds, the **GetClientIdleTime** method returns the client idle time in milliseconds.

The default implementation for this event handler is to take no action. It is recommended that most server applications disconnect clients that are inactive. For typical client-server implementations that use transitory connections (where the client sends a single request to the server, the server responds and the connection is terminated) the amount of time that a client should be permitted to remain idle should be relatively low, usually 60 seconds or less. For persistent connections where there are multiple requests issued by the client over the lifetime of the session, a longer idle timeout period may be preferable.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cswsock10.h

Import Library: csWSKV10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[GetClientIdleTime](#)

CInternetServer::OnWrite Method

```
virtual void OnWrite(  
    SOCKET hSocket  
);
```

A virtual method that is invoked when the client is ready to receive data.

Parameters

hSocket

A handle to the client socket.

Return Value

None.

Remarks

The **OnWrite** event handler is invoked when a client is ready to receive data. To implement an event handler, the application should create a class derived from the **CInternetServer** class, and then override this method. All server applications must implement an **OnRead** event handler to process the data sent by the client.

This event occurs immediately after the **OnConnect** event and if security is enabled, after the TLS handshake has completed. It is used to notify the server application that the client is ready to receive data, and may be used to send an initial message to the client, typically identifying the server that it has connected to. In most cases, the **OnWrite** event handler will only be invoked once over the lifetime of the client session.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cswsock10.h

Import Library: cswskv10.lib

Unicode: Implemented as Unicode and ANSI versions.

Internet Server Data Structures

- INETSTREAMINFO
- INTERNET_ADDRESS

Copyright © 2023 Catalyst Development Corporation. All rights reserved.

INETSTREAMINFO Structure

This structure contains information about the data stream being currently read or written.

```
typedef struct _INETSTREAMINFO
{
    DWORD    dwStreamThread;
    DWORD    dwStreamSize;
    DWORD    dwStreamCopied;
    DWORD    dwStreamMode;
    DWORD    dwStreamError;
    DWORD    dwBytesPerSecond;
    DWORD    dwTimeElapsed;
    DWORD    dwTimeEstimated;
} INETSTREAMINFO, *LPINETSTREAMINFO;
```

Members

dwStreamThread

Specifies the numeric ID for the thread that created the socket.

dwStreamSize

The maximum number of bytes that will be read or written. This is the same value as the buffer length specified by the caller, and may be zero which indicates that no maximum size was specified. Note that if this value is zero, the application will be unable to calculate a completion percentage or estimate the amount of time for the operation to complete.

dwStreamCopied

The total number of bytes that have been copied to or from the stream buffer.

dwStreamMode

A numeric value which specifies the stream operation that is current being performed. It may be one of the following values:

Constant	Description
INET_STREAM_READ	Data is being read from the socket and stored in the specified stream buffer.
INET_STREAM_WRITE	Data is being written from the specified stream buffer to the socket.

dwStreamError

The last error that occurred when reading or writing the data stream. If no error has occurred, this value will be zero.

dwBytesPerSecond

The average number of bytes that have been copied per second.

dwTimeElapsed

The number of seconds that have elapsed since the file transfer started.

dwTimeEstimated

The estimated number of seconds until the operation is completed. This is based on the average number of bytes transferred per second and requires that a maximum stream buffer size be specified by the caller.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

See Also

[ReadStream](#), [StoreStream](#), [WriteStream](#)

INTERNET_ADDRESS Structure

This structure represents a numeric IPv4 or IPv6 address in network byte order.

```
typedef struct _INTERNET_ADDRESS
{
    INT    ipFamily;
    BYTE   ipNumber[16];
} INTERNET_ADDRESS, *LPINTERNET_ADDRESS;
```

Members

ipFamily

An integer which identifies the type of IP address. It will be one of the following values:

Constant	Description
INET_ADDRESS_UNKNOWN	The address has not been specified or the bytes in the <i>ipNumber</i> array does not represent a valid address. Functions which populate this structure will use this value to indicate that the address cannot be determined.
INET_ADDRESS_IPV4	Specifies that the address is in IPv4 format. The first four bytes of the <i>ipNumber</i> array are significant and contains the IP address. The remaining bytes are not significant and an application should not depend on them having any particular value, including zero.
INET_ADDRESS_IPV6	Specifies that the address is in IPv6 format. All bytes in the <i>ipNumber</i> array are significant. Note that it is possible for an IPv6 address to actually represent an IPv4 address. This is indicated by the first 10 bytes of the address being zero.

ipNumber

A byte array which contains the numeric form of the IP address. This array is large enough to store both IPv4 (32 bit) and IPv6 (128 bit) addresses. The values are stored in network byte order.

Remarks

The **INTERNET_ADDRESS** structure is used by some functions to represent an Internet address in a binary format that is compatible with both IPv4 and IPv6 addresses. Applications that use this structure should consider it to be opaque, and should not modify the contents of the structure directly.

For compatibility with legacy applications that expect an IP address to be 32 bits and stored in an unsigned integer, you can copy the first four bytes of the *ipNumber* array using the **CopyMemory** function or equivalent. Note that if this is done, your application should always check the *ipFamily* member first to make sure that it is actually an IPv4 address.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Mail Message Class Library

Compose and parse standard MIME formatted email messages.

Reference

- [Class Methods](#)
- [Error Codes](#)

Library Information

Class Name	CMailMessage
File Name	CSMSGV10.DLL
Version	10.0.1468.2518
LibID	E6D79220-7873-4170-BF39-5D7A0049655C
Import Library	CSMSGV10.LIB
Dependencies	None
Standards	RFC 822, RFC 2045, RFC 2046, RFC 2047, RFC 2048

Overview

The Mail Message class provides an interface for composing and processing email messages and newsgroup articles which are structured according to the Multipurpose Internet Mail Extensions (MIME) standard. Using this class, an application can easily create complex messages which include multiple alternative content types, such as plain text and styled HTML text, file attachments and customized headers.

It is not required that the developer understand the complex MIME standard; a single method call can be used to create multipart message, complete with a styled HTML text body and support for international character sets. The Mail Message class can be easily integrated with the other mail related protocol libraries, making it extremely easy to create and process MIME formatted messages.

SocketTools also includes a class for managing a local message storage file that can be used to store and retrieve multiple messages. Methods are provided to open and create storage files, add, remove and extract messages from storage, and search the stored messages for specific header field values. For more information, refer to the [CMessageStore](#) class.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). If you are using Visual C++ 6.0 it is required that you have Service Pack 6 (SP6) installed. You should install all updates for your development tools and have the current Windows SDK installed. The minimum recommended version of Visual Studio is Visual Studio 2010.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are using Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. It is recommended that you install the current service pack and all critical updates available for your version of the operating system.

This product includes both 32-bit and 64-bit libraries. Native 64-bit CPU support requires the 64-

bit version of Windows 7 or later versions of the Windows operating system.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

Mail Message Class Methods

Class	Description
CMailMessage	Constructor which initializes the current instance of the class
~CMailMessage	Destructor which releases resources allocated by the class
Method	Description
AppendText	Append text to the body of the current message part
AttachData	Attach the contents of a buffer to the specified message
AttachFile	Attach a file to the specified message
AttachHandle	Attach the specified message handle to this instance of the class
ClearMessage	Clear the specified message, deleting all message parts
ClearText	Clear the body of the current message part
CompareText	Compare text in the body of the current message part
ComposeMessage	Compose a new message using the specified parameters
CopyMessage	Copy the contents of another message into the current message
CreatePart	Create a new message part for the specified message
DecodeText	Decode a base64 or quoted-printable encoded string
DeleteHeader	Delete the specified header field from the message
DeletePart	Delete the specified message part
DetachHandle	Detach the handle for the current instance of this class
EncodeText	Encode a string using base64 or quoted-printable encoding
EnumAttachments	Enumerate all file attachments in the current message
EnumHeaders	Enumerate all header fields in the current message part
EnumRecipients	Enumerate addresses of all message recipients
ExportMessage	Export the current message to a string buffer or text file
ExtractAllFiles	Extract all file attachments in the message and store them in the specified directory
ExtractFile	Extract the file attachment from the current message part
FindAttachment	Search for a file attachment in the specified message
FormatDate	Return a standard RFC 822 formatted date string
GetAllHeaders	Return the complete RFC 822 header values in a string buffer
GetAllRecipients	Return a comma-separated list of recipient addresses in a string buffer
GetAttachedFileName	Return the name of the file attachment for the current part
GetBoundary	Return the multipart message boundary string
GetContentDigest	Return encoded digest of message's content

GetContentLength	Return the length of the current message part content
GetDate	Return the date and time from the message header
GetErrorString	Return a description for the specified error code
GetExportOptions	Return a bitmask that describes current message export options
GetFileContentType	Return the content type for a specified file
GetFirstHeader	Return the first header field and value in the current message part
GetHandle	Return the message handle used by this instance of the class
GetHeader	Return the value of a specified header from the message
GetLastError	Return the last error code
GetMessageSize	Return the size of the complete message in bytes
GetNextHeader	Return the next header field and value in the current message part
GetPart	Return the current message part index
GetPartCount	Return the total number of message parts
GetSender	Return the email address of the message sender
GetText	Return the text of the current message part
ImportMessage	Import a message from the specified text file, clipboard or buffer
IsInitialized	Determine if the class has been successfully initialized
LocalizeText	Localize Unicode text to ANSI using a specific character set
ParseAddress	Parse the specified email address
ParseBuffer	Parse the specified text and add to the current message
ParseDate	Parse the specified RFC 822 formatted date string
ParseHeader	Parse the specified text and add to message header
SetExportOptions	Specify a bitmask that describes current message export options
SetFileContentType	Set the content type for a specific file name extension
SetLastError	Set the last error code
SetDate	Set the current date in the header for the specified message
SetHeader	Create or update a header field in the specified message
SetPart	Set the current message part index for the specified message
SetText	Create or update the specified message body
ShowError	Display a message box with a description of the specified error

CMailMessage::CMailMessage Method

`CMailMessage();`

The **CMailMessage** constructor initializes the class library and validates the license key at runtime.

Remarks

If the constructor fails to validate the runtime license, subsequent methods in this class will fail. If the product is installed with an evaluation license, then the application will only function on the development system and cannot be redistributed.

The constructor calls the **MimeInitialize** function to initialize the library, which dynamically loads other system libraries and allocates thread local storage. If you are using this class within another DLL, it is important that you do not create or destroy an instance of the class from within the **DllMain** function because it can result in deadlocks or access violation errors. You should not declare static or global instances of this class within another DLL if it is linked with the C runtime library (CRT) because it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csmsgv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

See Also

[~CMailMessage](#), [IsInitialized](#)

CMailMessage::~CMailMessage

`~CMailMessage();`

The **CMailMessage** destructor releases resources allocated by the current instance of the **CMailMessage** object. It also uninitialized the library if there are no other concurrent uses of the class.

Remarks

When a **CMailMessage** object goes out of scope, the destructor is automatically called to allow the library to free any resources allocated on behalf of the process. All handles that were created for the session are destroyed.

The destructor is not called explicitly by the application.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csmsgv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

See Also

[CMailMessage](#)

CMailMessage::AppendText Method

```
LONG AppendText(  
    LPCTSTR lpszText  
);
```

The **AppendText** method appends the specified text to the body of the current message part.

Parameters

lpszText

A pointer to a string which specifies the text to be appended to the current message part.

Return Value

If the method succeeds, the return value is the number of bytes copied into the message. A return value of zero indicates that no text could be appended to the current message part. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[ClearText](#), [CompareText](#), [GetText](#), [SetText](#)

CMailMessage::AttachData Method

```
BOOL AttachData(  
    LPBYTE lpBuffer,  
    LONG cbBuffer,  
    LPCTSTR lpszContentName,  
    LPCTSTR lpszContentType,  
    DWORD dwOptions  
);
```

```
BOOL AttachData(  
    CString& strBuffer,  
    LPCTSTR lpszContentName,  
    LPCTSTR lpszContentType,  
    DWORD dwOptions  
);
```

The **AttachData** method attaches the contents of the buffer to the message.

Parameters

lpBuffer

Pointer to a byte buffer which contains the data to be attached to the message. This parameter may be NULL, in which case no data is attached, but an additional empty message part will be created. An alternate form of this method accepts a **CString** object which contains the text to be attached to the message.

cbBuffer

An unsigned integer which specifies the number of bytes of data in the buffer pointed to by the *lpBuffer* parameter. If the *lpBuffer* parameter is NULL, this value must be zero.

lpszContentName

Pointer to a string which specifies a name for the data being attached to the message. This typically is used as a file name by the mail client to store the data in. If this parameter is NULL or an empty string then no name is defined and the data is attached as inline content. Note that if a file name is specified with a path, only the base name will be used.

lpszContentType

Pointer to a string which specifies the type of data being attached. The value must be a valid MIME content type. If this parameter is NULL or an empty string, then the buffer will be examined to determine what kind of data it contains. If there is only text characters, then the content type will be specified as "text/plain". If the buffer contains binary data, then the content type will be specified as "application/octet-stream", which is appropriate for any type of data.

dwOptions

A value which specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
MIME_ATTACH_DEFAULT	The data encoding is based on the content type. Text data is not encoded, and binary data is encoded using the standard base64 encoding algorithm.
MIME_ATTACH_BASE64	The data is always encoded using the standard base64 algorithm, even if the buffer only contains printable text

	characters.
MIME_ATTACH_UUCODE	The data is always encoded using the uuencode algorithm, even if the buffer only contains printable text characters.
MIME_ATTACH_QUOTED	The data is always encoded using the quoted-printable algorithm. This encoding should only be used if the data contains 8-bit text characters.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **AttachData** method allows an application to attach data to the message as either a file attachment or as inline content. The recipient of the message will see the attached data in the same way that they would see a file attached to the message using the **AttachFile** method.

If the specified message is not a multipart message, it is marked as multipart and the attached file is appended to the message. If the message is already a multipart message, an additional part is created and the attachment is added to the message.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[AttachFile](#), [ExportMessage](#), [ExtractFile](#), [GetAttachedFileName](#), [GetFileContentType](#), [ImportMessage](#), [SetFileContentType](#)

CMailMessage::AttachFile Method

```
BOOL AttachFile(  
    LPCTSTR lpszFileName,  
    DWORD dwOptions  
);
```

The **AttachFile** method attaches the specified file to the message.

Parameters

lpszFileName

Pointer to a string which specifies the name of the file to be attached to the message.

dwOptions

A value which specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
MIME_ATTACH_DEFAULT	The file attachment encoding is based on the file content type. Text files are not encoded, and binary files are encoded using the standard base64 encoding algorithm. This is the default option for file attachments.
MIME_ATTACH_BASE64	The file attachment is always encoded using the standard base64 algorithm, even if the attached file is a plain text file.
MIME_ATTACH_UUCODE	The file attachment is always encoded using the uuencode algorithm, even if the attached file is a plain text file.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

If the specified message is not a multipart message, it is marked as multipart and the attached file is appended to the message. If the message is already a multipart message, an additional part is created and the attachment is added to the message.

To attach data that is stored in a memory buffer rather than a file, use the **AttachData** method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[AttachData](#), [ExportMessage](#), [ExtractFile](#), [GetAttachedFileName](#), [GetFileContentType](#), [ImportMessage](#), [SetFileContentType](#)

CNetMessage::AttachHandle Method

```
VOID AttachHandle(  
    HMESSAGE hMessage  
);
```

The **AttachHandle** method attaches the specified message handle to the current instance of the class.

Parameters

hMessage

The handle to the message that will be attached to the current instance of the class object.

Return Value

None.

Remarks

This method is used to attach a message handle created outside of the class using the SocketTools API. Once the handle is attached to the class, the other class member functions may be used with that message.

If a message handle already has been created for the class, that handle will be released when the new handle is attached to the class object. If you want to prevent the previous message from being destroyed, you must call the **DetachHandle** method. Failure to release the detached handle may result in a resource leak in your application.

Note that the *hMessage* parameter is presumed to be a valid message handle and no checks are performed to ensure that the handle is valid. Specifying an invalid message handle will cause subsequent method calls to fail.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmsgv10.lib

See Also

[DetachHandle](#), [GetHandle](#)

CMailMessage::ClearMessage Method

```
BOOL ClearMessage();
```

The **ClearMessage** method clears the header and body of the specified message, and deletes all message parts.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmsgv10.lib

See Also

[ImportMessage](#), [ParseBuffer](#)

CMailMessage::ClearText Method

```
BOOL ClearText();
```

The **ClearText** method deletes the text from the body of the current message part.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[AppendText](#), [CompareText](#), [GetText](#), [SetText](#)

CMailMessage::CompareText Method

```
BOOL CompareText(  
    LONG*lpnOffset,  
    LPCTSTR lpszBuffer,  
    LONG cchBuffer,  
    BOOL bCaseSensitive  
);
```

The **CompareText** method compares a text string against the contents of the current message part.

Parameters

lpnOffset

Pointer to a long integer which specifies the offset in the message at which to begin the comparison. This value will be updated when the method returns to indicate the offset position in the message where the comparison ended.

lpszBuffer

Pointer to a string buffer which contains the text that is to be compared against the body of the message.

cchBuffer

The number of characters in the buffer that should be compared against the body of the message.

bCaseSensitive

Boolean flag which specifies that the comparison should be case sensitive.

Return Value

If the text buffer matches the contents of the current message body, the method will return a non-zero value, and the *lpnOffset* argument will be set to position in the buffer where the match terminated. If the text buffer does not match, the method will return a value of zero, and the *lpnOffset* argument will be set to the position of the first non-matching character. The method will also return zero if one of the arguments is invalid. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csmsgv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

See Also

[AppendText](#), [ClearText](#), [GetText](#), [SetText](#)

CMailMessage::ComposeMessage Method

```
BOOL ComposeMessage(  
    LPCTSTR lpszFrom,  
    LPCTSTR lpszTo,  
    LPCTSTR lpszCc,  
    LPCTSTR lpszSubject,  
    LPCTSTR lpszMessageText,  
    LPCTSTR lpszMessageHTML,  
    UINT nCharacterSet,  
    UINT nEncodingType  
);
```

The **ComposeMessage** method creates a new message using the specified parameters.

Parameters

lpszFrom

A pointer to a string which specifies the sender's email address. This parameter may be NULL, in which case no sender address will be included in the message header.

lpszTo

A pointer to a string which specifies one or more recipient addresses. If multiple addresses are specified, each address must be separated by a comma. This parameter may be NULL, in which case no recipient addresses will be included in the message header.

lpszCc

A pointer to a string which specifies one or more addresses that will receive a copy of the message in addition to the listed recipients. If multiple addresses are specified, each address must be separated by a comma. This parameter may be NULL, in which case no carbon-copy addresses will be included in the message header.

lpszSubject

A pointer to a string which specifies the subject of the message. This parameter may be NULL, in which case no subject will be included in the message.

lpszMessageText

A pointer to a string which contains the body of the message as plain text. Each line of text contained in the string should be terminated with a carriage-return and linefeed (CRLF) pair, which is recognized as the end-of-line. If this parameter is NULL or points to an empty string, then the message will have an empty body unless the *lpszMessageHTML* parameter is not NULL.

lpszMessageHTML

A pointer to a string which contains the message using HTML formatting. If the *lpszMessageText* parameter is not NULL, then a multipart message will be created with both plain text and HTML text as the alternative. This allows mail clients to select which message body they wish to display. If the *lpszMessageText* argument is NULL or points to an empty string, then the message will only contain HTML. Although this is supported, it is not recommended because older mail clients may be unable to display the message correctly.

nCharacterSet

A numeric identifier which specifies the [character set](#) to use when composing the message. A value of zero specifies that the default UTF-8 character set should be used. It is recommended that you always use UTF-8 when composing a new message or creating a new message part.

nEncodingType

A numeric identifier which specifies the encoding type to use when composing the message. A value of zero specifies that default 7bit encoding should be used. The following values may also be used:

Constant	Description
MIME_ENCODING_7BIT	Each character is encoded in one or more bytes, with each byte being 8 bits long, with the most significant bit cleared. This encoding is most commonly used with plain text using the US-ASCII character set, where each character is represented by a single byte in the range of 20h to 7Eh.
MIME_ENCODING_8BIT	Each character is encoded in one or more bytes, with each byte being 8 bits long and all bits are used. 8-bit encoding is typically used with multibyte character sets and is the default encoding used with Unicode text.
MIME_ENCODING_QUOTED	Quoted-printable encoding is designed for textual messages where most of the characters are represented by the ASCII character set and is generally human-readable. Non-printable characters or 8-bit characters with the high bit set are encoded as hexadecimal values and represented as 7-bit text. Quoted-printable encoding is typically used for messages which use character sets such as ISO-8859-1, as well as those which use HTML.
MIME_ENCODING_BASE64	Base64 encoding converts binary or text data to ASCII by translating it so each base64 digit represents 6 bits of data. This encoding method is commonly used with messages that contain binary data (such as binary file attachments), or when text uses extended characters that cannot be represented by 7-bit ASCII. It is recommended that you use base64 encoding with Unicode text.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

email addresses may be specified as simple addresses, or as commented addresses that include the sender's name or other information. For example, any one of these address formats are acceptable:

```
user@domain.tld
User Name <user@domain.tld>
user@domain.tld (User Name)
```

To specify multiple addresses, you should separate each address by a comma or semi-colon. Note that the *lpszFrom* parameter cannot specify multiple addresses, however it is permitted with the *lpszTo*, *lpszCc* and *lpszBcc* parameters.

To send a message that contains HTML, it is recommended that you provide both a plain text version of the message body and an HTML formatted version. While it is permitted to send a message that only contains HTML, some older mail clients may not be capable of displaying the message correctly. In some cases, anti-spam software will increase the spam score of messages that do not contain a plain text message body. This can result in your message being rejected or quarantined by the mail server.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

CMailMessage::CopyMessage Method

```
BOOL CopyMessage(  
    CMailMessage* pMessage  
);
```

The **CopyMessage** method copies the contents of the specified message.

Parameters

pMessage

A pointer to a CMailMessage object which contains the message to be copied. If this argument is NULL, the current message contents will be cleared.

Return Value

If the message was successfully copied, the method will return a non-zero value. If the method fails, it will return value of zero. To get extended error information, call **GetLastError**.

Remarks

This method is used to create a copy of the specified message, replacing the current message contents. Note that this method creates a duplicate of the message referenced by the *pMessage* object, and any subsequent changes to the contents of the original message will not be reflected in the copy of that message.

Example

```
CMailMessage *pMessage1 = new CMailMessage();  
CMailMessage *pMessage2 = new CMailMessage();  
  
// Compose a test message  
pMessage1->ComposeMessage(_T("Bob Jones <bob@example.com>"),  
                          _T("Tom Smith <tom@example.com>"),  
                          NULL,  
                          _T("This is a test message"),  
                          _T("This is a test, this is only a test."));  
  
// Create a copy of the message and change the subject  
// The original subject in pMessage1 remains unchanged  
if (pMessage2->CopyMessage(pMessage1))  
{  
    CString &strSubject;  
    if (pMessage2->GetHeader(0, _T("Subject"), strSubject))  
    {  
        strSubject = _T("Re: ") + strSubject;  
        pMessage2->SetHeader(0, _T("Subject"), strSubject);  
    }  
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

CMailMessage::CreatePart Method

```
INT CreatePart();  
  
INT CreatePart(  
    LPCTSTR lpszText,  
    UINT nCharacterSet,  
    UINT nEncodingType  
);
```

The **CreatePart** method creates a new part for the specified message. If this the first part created for a message that does not have the multipart content type specified, the message is marked as multipart and the header fields are updated.

Parameters

lpszText

A pointer to a string which specifies the text to be included in the body of the new message part. If this parameter is NULL or points to an empty string, no text is added to the message part.

nCharacterSet

A numeric identifier which specifies the [character set](#) to use when composing the message. A value of zero specifies the character set should be the same character set used to initially compose the message. It is recommended that you always use UTF-8 when composing a new message or creating a new message part.

nEncodingType

A numeric identifier which specifies the encoding type to use when composing the message. A value of zero specifies that default 7bit encoding should be used. The following values may also be used:

Constant	Description
MIME_ENCODING_7BIT	Each character is encoded in one or more bytes, with each byte being 8 bits long, with the most significant bit cleared. This encoding is most commonly used with plain text using the US-ASCII character set, where each character is represented by a single byte in the range of 20h to 7Eh.
MIME_ENCODING_8BIT	Each character is encoded in one or more bytes, with each byte being 8 bits long and all bits are used. 8-bit encoding is typically used with multibyte character sets and is the default encoding used with Unicode text.
MIME_ENCODING_QUOTED	Quoted-printable encoding is designed for textual messages where most of the characters are represented by the ASCII character set and is generally human-readable. Non-printable characters or 8-bit characters with the high bit set are encoded as hexadecimal values and represented as 7-bit text. Quoted-printable encoding is typically used for messages which use character sets such as ISO-8859-1, as well as those which use HTML.

MIME_ENCODING_BASE64	Base64 encoding converts binary or text data to ASCII by translating it so each base64 digit represents 6 bits of data. This encoding method is commonly used with messages that contain binary data (such as binary file attachments), or when text uses extended characters that cannot be represented by 7-bit ASCII. It is recommended that you use base64 encoding with Unicode text.
----------------------	--

Return Value

If the method succeeds, the return value is the new message part number. If the method fails, the return value is `MIME_ERROR`. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csmsgv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

CMailMessage::DecodeText Method

```
LONG DecodeText(  
    LPCTSTR lpszInput,  
    LONG cchInput,  
    LPTSTR lpszOutput,  
    LONG cchOutput,  
    UINT nCharacterSet,  
    UINT nEncodingType  
);
```

```
LONG DecodeText(  
    LPCTSTR lpszInput,  
    LONG cchInput,  
    CString& strOutput,  
    UINT nCharacterSet,  
    UINT nEncodingType  
);
```

The **DecodeText** method decodes a string that was previously encoded using base64 or quoted-printable encoding.

Parameters

lpszInput

A pointer to a null terminated string which contains the encoded text. This parameter cannot be a NULL pointer.

cchInput

An integer value which specifies the number of characters of text in the input string which should be decoded. If this parameter is omitted or the value is -1, the entire length of the string up to the terminating null will be decoded.

lpszOutput

A pointer to a string buffer that will contain the decoded text. This buffer must be large enough to store all of the characters in the decoded text, including the terminating null character. This parameter cannot be NULL. An alternate version of this method accepts a **CString** object instead of a fixed-length string buffer.

cchOutput

An integer value which specifies the maximum number of characters which can be copied into the output string buffer. The buffer must be large enough to store all of the decoded text and terminating null character. This value must be greater than zero. This parameter is not used if output buffer is specified as a **CString** object.

nCharacterSet

A numeric identifier which specifies the [character set](#) to use when decoding the input text. A value of zero specifies the character set is undefined and no Unicode text conversion is performed when the input string is decoded. If this value does not match the character set used when the text was originally encoded, the resulting output text may be invalid. This parameter may be omitted, in which case the method will default to using the UTF-8 character set.

nEncodingType

An integer value that specifies the encoding method used. This parameter may be omitted, or it may be one of the following values:

Constant	Description
MIME_ENCODING_QUOTED	Quoted-printable encoding is designed for textual messages where most of the characters are represented by the ASCII character set and is generally human-readable. Non-printable characters or 8-bit characters with the high bit set are encoded as hexadecimal values and represented as 7-bit text. Quoted-printable encoding is typically used for messages which use character sets such as ISO-8859-1, as well as those which use HTML.
MIME_ENCODING_BASE64	Base64 encoding converts binary or text data to ASCII by translating it so each base64 digit represents 6 bits of data. This encoding method is commonly used with messages that contain binary data (such as binary file attachments), or when text uses extended characters that cannot be represented by 7-bit ASCII. It is recommended that you use base64 encoding with Unicode text. This is the default encoding type used by this method.

Return Value

If the input buffer can be successfully decoded, the return value is the length of the decoded output string. If the method returns zero, then no text was decoded and the output string buffer will be empty. If the method fails, the return value is `MIME_ERROR`. To get extended error information, call **GetLastError**.

Remarks

This method provides a means to decode text that was previously encoded using either base64 or quoted-printable encoding. In most cases, it is not necessary to use this method because the message parser will detect which character set and encoding was used, then automatically decode the message text if necessary.

The value of the *nCharacterSet* parameter does not affect the resulting output text, it is only used when decoding the input text. If the Unicode version of this method is called, the output text will be converted to UTF-16 and returned to the caller. If the ANSI version of this method is used, the decoded output will always be returned to the caller using the UTF-8 character set.

If the *nCharacterSet* parameter is specified as `MIME_CHARSET_UTF16`, the encoding type must be `MIME_ENCODING_BASE64`. Other encoding methods are not supported for Unicode strings and will cause the method to fail. In most cases, it is preferable to use `MIME_ENCODING_BASE64` as the encoding method, with quoted-printable encoding only used for legacy support.

If an unsupported encoding type is specified, this method will return `MIME_ERROR` and the output text string will be empty. This method cannot be used to decode uuencoded text.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

CMailMessage::DeleteHeader Method

```
BOOL DeleteHeader(  
    LPCTSTR lpszHeader  
);
```

The **DeleteHeader** method deletes the specified header field from the message.

Parameters

lpszHeader

Pointer to a string which specifies the header field that will be deleted.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero.

To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

CMailMessage::DeletePart Method

```
BOOL DeletePart(  
    INT nMessagePart  
);
```

The **DeletePart** method deletes the specified message part from the multipart message. The memory allocated for the message part is released.

Parameters

nMessagePart

The message part index to delete.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

This method cannot be used to delete part zero, which is the main body of the message. Instead use the **Clear** method to clear the entire message.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

CNetMessage::DetachHandle Method

```
HMESSAGE DetachHandle();
```

The **DetachHandle** method detaches the client handle associated with the current instance of the class.

Parameters

None.

Return Value

This method returns the message handle associated with the current instance of the class object. If there is no active client session, the value `INVALID_MESSAGE` will be returned.

Remarks

This method is used to detach a message handle created by the class for use with the SocketTools API. Once the message handle is detached from the class, no other class member functions may be called. Note that the handle must be explicitly released at some later point by the process or a resource leak will occur.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csmsgv10.lib`

CMailMessage::EncodeText Method

```
LONG EncodeText(  
    LPCTSTR lpszInput,  
    LONG cchInput,  
    LPTSTR lpszOutput,  
    LONG cchOutput,  
    UINT nCharacterSet,  
    UINT nEncodingType  
);
```

```
LONG EncodeText(  
    LPCTSTR lpszInput,  
    LONG cchInput,  
    CString& strOutput,  
    UINT nCharacterSet,  
    UINT nEncodingType  
);
```

The **EncodeText** method encodes a string using base64 or quoted-printable encoding.

Parameters

lpszInput

A pointer to a null terminated string which contains the encoded text. This parameter cannot be a NULL pointer.

cchInput

An integer value which specifies the number of characters of text in the input string which should be encoded. If this parameter is omitted or the value is -1, the entire length of the string up to the terminating null will be encoded.

lpszOutput

A pointer to a string buffer that will contain the encoded text. This buffer must be large enough to store all of the characters in the encoded text, including the terminating null character. This parameter cannot be NULL. An alternate version of this method accepts a **CString** object instead of a fixed-length string buffer.

cchOutput

An integer value which specifies the maximum number of characters which can be copied into the output string buffer. The buffer must be large enough to store all of the encoded text and terminating null character. This value must be greater than zero.

nCharacterSet

A numeric identifier which specifies the [character set](#) to use when encoding the input text. A value of zero specifies the character set is undefined and no Unicode text conversion is performed when the input string is encoded.

nEncodingType

An integer value that specifies the encoding method used. It may be one of the following values:

Constant	Description
MIME_ENCODING_QUOTED	Quoted-printable encoding is designed for textual messages where most of the characters are represented

	by the ASCII character set and is generally human-readable. Non-printable characters or 8-bit characters with the high bit set are encoded as hexadecimal values and represented as 7-bit text. Quoted-printable encoding is typically used for messages which use character sets such as ISO-8859-1, as well as those which use HTML.
MIME_ENCODING_BASE64	Base64 encoding converts binary or text data to ASCII by translating it so each base64 digit represents 6 bits of data. This encoding method is commonly used with messages that contain binary data (such as binary file attachments), or when text uses extended characters that cannot be represented by 7-bit ASCII. It is recommended that you use base64 encoding with Unicode text.

Return Value

If the input buffer can be successfully encoded, the return value is the length of the encoded output string. If the method returns zero, then no text was encoded and the output string buffer will be empty. If the method fails, the return value is `MIME_ERROR`. To get extended error information, call **GetLastError**.

Remarks

This method provides a means to encode text using either base64 or quoted-printable encoding. It is not necessary to use this method to encode text when using the **SetText** method. The class will automatically encode message text which contains non-ASCII characters using the character set specified when the message is created.

If the *nCharacterSet* parameter is non-zero, the method will encode the text using the specified character set. If the Unicode version of this method is called, the input text is converted to ANSI using the code page associated with the character set. If the ANSI version of this method is called, the input text is converted to Unicode using the system default code page, and then back to ANSI using the specified character set.

If the *nCharacterSet* parameter specifies the `MIME_CHARSET_UTF16` character set, you must specify `MIME_ENCODING_BASE64` as the encoding method. Other encoding methods are not supported for Unicode strings and will cause the method to fail. It is not recommended you encode text as UTF-16 unless there is a specific requirement to use that character set.

It is recommended that you use the `MIME_CHARSET_UTF8` character set whenever possible. It is capable of encoding all Unicode code points, and is a standard for virtually all modern Internet applications. In most cases, it is preferable to use `MIME_ENCODING_BASE64` as the encoding method, with quoted-printable encoding only used for legacy support.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csmsgv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

See Also

CMailMessage::EnumAttachments Method

```
INT EnumAttachments(  
    LPCTSTR* lpFileNames,  
    INT nMaxFiles  
);
```

The **EnumAttachments** method enumerates all of the file attachments in the current message.

Parameters

lpFileNames

A pointer to an array of null-terminated strings that contain the names of the files attached to the message. If this parameter is NULL, the method will only return the number of files attached to the message.

nMaxFiles

An integer value that specifies the maximum size of the array of string pointers specified by the *lpFileNames* parameter. If this value is zero, the *lpFileNames* parameter is ignored and the method will only return the number of files attached to the message.

Return Value

If the method succeeds, the return value is the number of files attached to the message. If the message does not contain any file attachments, this method will return a value of zero. If the method fails, the return value is MIME_ERROR. To get extended error information, call **GetLastError**.

Example

```
LPCTSTR lpszFiles[MAXFILES];  
  
INT nFiles = pMessage->EnumAttachments(lpszFiles, MAXFILES);  
if (nFiles == MIME_ERROR)  
{  
    DWORD dwError = pMessage->GetLastError();  
    _tprintf(_T("Unable to enumerate attachments, error 0x%08lx\n"), dwError);  
    return;  
}  
  
_tprintf(_T("There are %d files attached to the message\n"), nFiles);
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

CMailMessage::EnumHeaders Method

```
INT EnumHeaders();

INT EnumHeaders(
    LPCTSTR* lpHeaderList,
    INT nMaxHeaders
);
```

The **EnumHeaders** method returns a list of pointers to all header field names in the current message part. This can be used in conjunction with the **GetHeader** method to retrieve the values for every header in the message.

Parameters

lpHeaderList

Pointer to an array of pointers to null terminated header field names. If this parameter is NULL, the method only returns the number of headers in the current message part.

nMaxHeaders

The maximum number of header fields which may be returned in the *lpHeaderList* parameter.

Return Value

If the method succeeds, the return value is the total number of headers that are defined in the current message part. If the method fails, the return value is MIME_ERROR. To get extended error information, call **GetLastError**.

Remarks

The values returned in the header list array must not be directly modified by the application. There is no specific order in which the header fields are enumerated by this method. The header fields from an imported message may not be returned in the same order as which they appear in the message. An application should never make an assumption about the order in which one or more header fields are defined.

If this method is called without any arguments, it returns the number of headers in the current message part but does not return any data. This is useful for determining how much memory must be allocated for the *lpHeaderList* argument.

Example

```
// Determine the total number of headers in the current
// message part

nHeaders = pMessage->EnumHeaders();
if (nHeaders > 0)
{

    // Allocate memory for the list of headers

    lpHeaderList = (LPCTSTR *)malloc(nHeaders * sizeof(LPCTSTR));
    assert(lpHeaderList != NULL);

    // Retrieve the list of headers in the current
    // message part, and get their values

    pMessage->EnumHeaders(lpHeaderList, nHeaders);
    for (nIndex = 0; nIndex < nHeaders; nIndex++)
```

```
{  
  
    LPCTSTR lpszValue;  
    lpszValue = pMessage->GetHeader(lpHeaderList[nIndex]);  
    assert(lpszValue != NULL);  
  
    printf("%s: %s\n", lpHeaderList[nIndex], lpszValue);  
  
}  
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

CMailMessage::EnumRecipients Method

```
INT EnumRecipients(  
    LPCTSTR lpszExtraAddress,  
    LPTSTR lpBuffer,  
    LPDWORD lpcchBuffer  
);  
  
INT EnumRecipients(  
    LPTSTR lpBuffer,  
    LPDWORD lpcchBuffer  
);  
  
INT EnumRecipients(  
    CStringArray& arrayRecipients,  
    LPCTSTR lpszExtraAddress  
);
```

The **EnumRecipients** method returns a null-terminated list of strings which contain the email address of each recipient for the specified message.

Parameters

lpszExtraAddress

A pointer to a string which contains one or more additional email addresses that should be included in the list, in addition to those found in the message. If more than one address is specified, each address should be separated by a comma. This parameter may be NULL if there are no extra addresses to include in the recipient list.

lpBuffer

Pointer to buffer which will contain zero or more null-terminated strings. The end of the string list is indicated by an additional terminating null. If this parameter is NULL, the method will calculate the minimum number of characters required to store the addresses and return the value in the *lpcchBuffer* parameter.

lpcchBuffer

A pointer to an unsigned integer which should be initialized to the maximum number of characters that can be copied into the buffer specified by the *lpBuffer* parameter. When the method returns, it will be updated to contain the actual number of characters copied into the buffer. If the *lpBuffer* parameter is NULL, then this value will contain the minimum number of characters required to store all of the recipient addresses in the current message.

arrayRecipients

A reference to a **CStringArray** object that will contain each of the recipient addresses specified in the message. This version of the method is only available if the program is compiled using Microsoft Foundation Classes (MFC).

Return Value

If the method succeeds, the return value is the total number of recipients for the current message. If the method fails, the return value is MIME_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **EnumRecipients** method returns a list of recipient email addresses for the specified message, with each address being terminated by a null character. The end of the list is indicated by an

additional null character. To determine the size of the buffer you should pass to this function, you can specify the *lpBuffer* parameter as NULL and initialize the value of the *lpcchBuffer* parameter to zero.

An alternative to the **EnumRecipients** method is the **GetAllRecipients** method that returns a comma-separated list of recipient addresses in a string buffer.

Example

```
LPTSTR lpRecipients = NULL;
DWORD cchRecipients = 0;
INT nRecipients = 0;

// Determine the number of characters that should be allocated to store
// all of the recipient addresses in the current message

nRecipients = pMessage->EnumRecipients(NULL, &cchRecipients);

// Allocate the memory for the string buffer that will contain all
// of the recipient addresses and call EnumRecipients
// again to store those addresses in the buffer

if (nRecipients > 0 && cchRecipients > 0)
{
    lpRecipients = (LPTSTR)::LocalAlloc(LPTR, (cchRecipients * sizeof(TCHAR)));
    if (lpRecipients == NULL)
        return; // Virtual memory exhausted

    nRecipients = pMessage->EnumRecipients(lpRecipients,
                                           &cchRecipients);
}

// Move through the buffer, processing each recipient address
// that was returned

if (nRecipients > 0)
{
    LPTSTR lpszAddress = lpRecipients;
    INT cchAddress;

    while (lpszAddress != NULL)
    {
        if ((cchAddress = lstrlen(lpszAddress)) == 0)
            break;

        // lpszAddress specifies a recipient address
        // Advance to the next address string in the buffer
        lpszAddress += cchAddress + 1;
    }
}

if (lpRecipients != NULL)
{
    LocalFree((HLOCAL)lpRecipients);
    lpRecipients = NULL;
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmsgv10.lib

CMailMessage::ExportMessage Method

```
BOOL ExportMessage(  
    LPCTSTR lpszFileName,  
    DWORD dwExportOptions  
);  
  
BOOL ExportMessage(  
    HGLOBAL* LphBuffer,  
    LPDWORD LpdwBufferSize,  
    DWORD dwExportOptions  
);  
  
BOOL ExportMessage(  
    LPTSTR lpszMessage,  
    DWORD dwMessageSize,  
    DWORD dwExportOptions  
);  
  
BOOL ExportMessage(  
    CString& strMessage,  
    DWORD dwExportOptions  
);
```

The **ExportMessage** method exports the message to a file, the system clipboard or global memory buffer.

Parameters

lpszFileName

A pointer to a string which specifies the file name that will contain the message. If the file already exists, it will be overwritten with the message contents.

lpszMessage

A pointer to a string which will contain the message. An alternate form of this method accepts a pointer to a global memory handle which will contain the message data when the method returns.

dwMessageSize

An unsigned integer value which specifies the maximum size of the *lpszMessage* buffer.

dwExportOptions

An unsigned integer which specifies how the message will be exported. The following values may be combined using a bitwise Or operator:

Constant	Description
MIME_OPTION_DEFAULT	The default export options. The headers for the message are written out in a specific consistent order, with custom headers written to the end of the header block regardless of the order in which they were set or imported from another message. If the message contains Bcc, Received, Return-Path, Status or X400-Received header fields, they will not be exported.
MIME_OPTION_KEEPPORDER	The original order in which the message header fields were set or imported are preserved when the message

	is exported.
MIME_OPTION_ALLHEADERS	All headers, including the Received, Return-Path, Status and X400-Received header fields will be exported. Normally these headers are not exported because they are only used by the mail transport system. This option can be useful when exporting a message to be stored on the local system, but should not be used when exporting a message to be delivered to another user.
MIME_OPTION_NOHEADERS	When exporting a message, the main header block will not be included. This can be useful when creating a multipart message for services which expect MIME formatted data, such as HTTP POST requests. This option should never be used for email messages being submitted using SMTP.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

If the version of this method is used which exports the message to a pre-allocated string buffer, the *dwMessageSize* parameter must specify the maximum size of the buffer. If the method succeeds, the message will be copied to the buffer. If the method fails, the previous contents of the buffer will not be preserved. If the buffer provided is not large enough to store the entire message, the message contents will be truncated. The **GetMessageSize** method can be used to determine the minimum size of the buffer required to store the complete message.

If the version of this method is used which returns an HGLOBAL memory handle to the caller, the handle must be dereferenced using the **GlobalLock** function. No changes should be made to this copy of the message. If you wish to modify the contents of the message, allocate a local buffer and make a copy of the message contents, or use the method which exports the message to a pre-allocated string buffer. Your application is responsible for calling **GlobalUnlock** and **GlobalFree** to unlock and free the handle when it is no longer needed.

Example

The following example exports the contents of a message to a global memory buffer:

```
HGLOBAL hgb1Message = NULL;
DWORD dwMessageSize = 0;

if (pMessage->Export(&hgb1Message, &dwMessageSize))
{
    LPBYTE lpMessage = (LPBYTE)GlobalLock(hgb1Message);

    if (lpMessage)
    {
        // Process the contents of the message
    }

    GlobalUnlock(hgb1Message);
    GlobalFree(hgb1Message);
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[ImportMessage](#), [GetMessageSize](#), [SetExportOptions](#)

CMailMessage::ExtractAllFiles Method

```
INT ExtractAllFiles(  
    LPCTSTR lpszDirectory  
);
```

The **ExtractAllFiles** method extracts all of the file attachments in a message and stores them in the specified directory.

Parameters

lpszDirectory

A pointer to a string which specifies the name of the directory where the file attachments should be stored. If this parameter is NULL or points to an empty string, the attached files will be stored in the current working directory on the local system.

Return Value

If the method succeeds, the return value is the number of file attachments which were extracted from the message. If the message does not contain any file attachments, this method will return a value of zero. If the method fails, the return value is MIME_ERROR. To get extended error information, call **GetLastError**.

Remarks

This method will extract all of the files that are attached to the message and store them in the specified directory. The directory must exist and the current user must have the appropriate permissions to create files there. If a file with the same name as the attachment already exists, it will be overwritten with the contents of the attachment. If the file attachment was encoded using base64 or uuencode, this function will automatically decode the contents of the attachment.

To determine the file names for each of the attachments in a message, use the **EnumAttachments** method. To store a file attachment on the local system using a name that is different than the file name of the attachment, use the **ExtractFile** method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[MimeAttachFile](#), [EnumAttachments](#), [ExportMessage](#), [ExtractFile](#), [GetAttachedFileName](#), [ImportMessage](#)

CMailMessage::ExtractFile Method

```
BOOL ExtractFile(  
    INT nMessagePart,  
    LPCTSTR lpszFileName  
);  
  
BOOL ExtractFile(  
    LPCTSTR lpszAttachment,  
    LPCTSTR lpszFileName  
);  
  
BOOL ExtractFile(  
    LPCTSTR lpszFileName  
);
```

The **ExtractFile** method extracts a file attachment from the message and stores it on the local system.

Parameters

nMessagePart

An integer value that specifies the message part that contains the file attachment. This value may be -1, in which case the current message part will be used.

lpszAttachment

A pointer to a string that specifies the file name for the attachment in the message. If the file name of the attachment is not known, this parameter can be NULL or point to an empty string.

lpszFileName

A pointer to a string that specifies the name of a file on the local system. If this parameter is NULL or points to an empty string, the value of the *lpszAttachment* parameter will specify the name of the file in the current working directory. If both the *lpszAttachment* and *lpszFileName* parameters are NULL, the method will fail.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

This method will store the contents of a file attachment in the current message part to the specified file on the local system. If a path is specified as part of the file name, it must exist and the current user must have the appropriate permissions to create the file. If a file with the same name already exists, it will be overwritten with the contents of the attachment. If the file attachment was encoded using base64 or uuencode, this method will automatically decode the contents of the attachment.

If the *nMessagePart* parameter is specified, then an attachment in that message part will be stored in the specified file. If the message part does not contain a file attachment, the method will fail.

If the *lpszAttachment* parameter is specified, the method will search the entire message for an attachment with the same file name. The search is not case-sensitive, however it must match the attachment file name completely. This method will not match partial file names or names that include wildcard characters. If a match is found, the contents of that attachment will be stored in the file specified by the *lpszFileName* parameter.

To extract all of the files attached to a message in a single method call, use the **ExtractAllFiles** method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

CMailMessage::FindAttachment Method

```
INT FindAttachment(  
    LPCTSTR lpszFileName  
);
```

The **FindAttachment** method searches the message for an attachment with the specified file name.

Parameters

lpszFileName

Pointer to a string that specifies the name of the file attachment to search for. This parameter should only specify a base file name; it should not include a file path and cannot be NULL.

Return Value

If the method succeeds, the return value is the message part number that contains an attachment that matches the specified file name. If the message does not contain an attachment with the specified file name, the method will return MIME_ERROR. To get extended error information, call **GetLastError**.

Remarks

This method will search the message for a attachment that matches the specified file name. The search is not case-sensitive, however it must match the attachment file name completely. This method will not match partial file names or names that include wildcard characters. To obtain a list of all of the files attached to a message, use the **EnumAttachments** method.

Example

```
// The name of the file attachment to search for  
LPCTSTR lpszFileName = _T("MyProject.docx");  
  
// Search for the attached file and store it on the local system  
INT nMessagePart = pMessage->FindAttachment(lpszFileName);  
if (nMessagePart != MIME_ERROR)  
{  
    pMessage->SetPart(nMessagePart);  
  
    if (pMessage->ExtractFile(lpszFileName) != MIME_ERROR)  
        _tprintf(_T("Saved file attachment %s\n"), lpszFileName);  
    else  
    {  
        _tprintf(_T("Unable to save file attachment %s\n"), lpszFileName);  
        return;  
    }  
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

CMailMessage::FormatDate Method

```
LPTSTR FormatDate(  
    LONG nSeconds,  
    LONG nTimezone,  
    LPTSTR lpszDate,  
    INT cchMaxDate  
);
```

```
LPTSTR FormatDate(  
    LONG nSeconds,  
    LPTSTR lpszDate,  
    INT cchMaxDate  
);
```

```
LPTSTR FormatDate(  
    LONG nSeconds,  
    LONG nTimezone,  
    CString& strDate  
);
```

```
LPTSTR FormatDate(  
    LONG nSeconds,  
    CString& strDate  
);
```

The **FormatDate** converts the specified date, expressed as the number of seconds since 1 January 1970, into a string compatible with the RFC 822 standard format for email messages.

Parameters

nSeconds

A long integer which specifies the number of seconds since 1 January 1970 00:00:00 UTC. This date is commonly called the epoch, and is the base date used by the standard C time methods. If the value of this parameter is zero, the current date and time is used.

nTimezone

A pointer to a long integer which is set to the difference in seconds between the specified date's timezone and Coordinated Universal Time. A value of zero specifies Coordinated Universal Time, while a positive value specifies a timezone west of UTC, and a negative value specifies a timezone east of UTC. For example, the Eastern timezone would be specified as the value 18000 and the Pacific timezone would be the value 28800. If this argument is omitted from the method, then the current timezone is used.

lpszDate

A buffer which will contain the formatted date as a null-terminated string. This parameter cannot be a NULL pointer.

cchMaxDate

The maximum number of characters, including the terminating null character, which may be copied into the date string buffer.

Return Value

If the method succeeds, a pointer to the date string buffer is returned. If the method fails, a NULL pointer is returned. To get extended error information, call **GetLastError**.

Remarks

The date string is returned in a standard format as outlined in RFC 822, the document which describes the basic structure of Internet email messages. This format is as follows:

www, dd mmm yyyy hh:mm:ss [-]zzzz

Each part of the date string is defined as follows:

Format	Description
www	Weekday
dd	Day
mmm	Month
yyyy	Year
hh	Hour (24-hour clock)
mm	Minutes
ss	Seconds
zzzz	Timezone

The weekday and month are displayed using standard three-character English abbreviations. The timezone is displayed as the difference (in hours and minutes) between the specified timezone and Coordinated Universal Time. For example, if the timezone is eight hours west of Coordinated Universal Time, the *nTimezone* value would be 28800. This would be displayed as -0800 in the formatted date string.

Note that the format of the date string is defined by the RFC 822 standard, and is not affected by localization settings on the host system.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[ParseDate](#), [GetDate](#), [SetDate](#)

CMailMessage::GetAllHeaders Method

```
INT GetAllHeaders(  
    LPTSTR lpszHeaders,  
    INT nMaxLength  
);  
  
INT GetAllHeaders(  
    CString& strHeaders  
);
```

The **GetAllHeaders** method returns the complete RFC 822 header values in a string buffer.

Parameters

lpszHeaders

Pointer to string buffer which will contain the header values for the current message. This parameter may be NULL, in which case the method will calculate the number of characters needed to store the complete header block.

nMaxLength

An integer value which specifies the maximum number of characters that can be stored in the *lpszHeaders* string. If the *lpszHeaders* parameter is NULL, this value must be zero. If the *lpszHeaders* parameter is not NULL, this value must be large enough to store the entire list of addresses.

strHeaders

A **CString** object that will contain the header values for the current message. This version of the method is available if MFC or ATL is being used by the application, and the memory required to store the complete header block will be calculated automatically.

Return Value

If the method succeeds and the *lpszHeaders* parameter is NULL, the return value is the minimum number of characters that should be allocated to store all of the header values, including the terminating null character. If the *lpszHeaders* parameter is not NULL, then the return value is the number of characters copied into the string, not including the terminating null character. If the method fails, the return value is MIME_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetAllHeaders** method will return all of the RFC 822 header values in a string buffer. This includes the message headers that are most commonly referred to, such as the To, From and Subject headers. Each header and its value are separated by a colon, and terminated with a carriage return and linefeed (CRLF) pair.

The headers and their values returned by this method will not be identical to the header block in the original message. If a header value is split across multiple lines, this method will fold the text, returning the complete header value on a single line of text and removing any extraneous whitespace. If the header value has been encoded by the mail client, this method will return the decoded value, not the original encoded value.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[GetFirstHeader](#), [GetHeader](#), [GetNextHeader](#), [SetHeader](#)

CMailMessage::GetAllRecipients Method

```
INT GetAllRecipients(  
    LPCTSTR lpszExtraAddress,  
    LPTSTR lpszRecipients,  
    INT nMaxLength  
);  
  
INT GetAllRecipients(  
    CString& strRecipients,  
    LPCTSTR lpszExtraAddress  
);
```

The **GetAllRecipients** method returns a comma-separated list of recipient addresses in a string buffer.

Parameters

lpszExtraAddress

A pointer to a string which contains one or more additional email addresses that should be included in the list, in addition to those found in the message. If more than one address is specified, each address should be separated by a comma. This parameter may be NULL if there are no extra addresses to include in the recipient list.

lpszRecipients

Pointer to string buffer which will contain a comma-separated list of email addresses when the method returns. This parameter may be NULL, in which case the method will calculate the number of characters needed to store the complete list.

nMaxLength

An integer value which specifies the maximum number of characters that can be stored in the *lpszRecipients* string. If the *lpszRecipients* parameter is NULL, this value must be zero. If the *lpszRecipients* parameter is not NULL, this value must be large enough to store the entire list of addresses.

Return Value

If the method succeeds and the *lpszRecipients* parameter is NULL, the return value is the minimum number of characters that should be allocated to store the list recipient addresses, including the terminating null character. If the *lpszRecipients* parameter is not NULL, then the return value is the number of characters copied into the buffer, not including the terminating null character. If the method returns a value of zero, then the specified message has no recipients. If the method fails, the return value is MIME_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetAllRecipients** method is useful for creating a list of message recipients that can be passed to methods like **CSmtpClient::SendMessage**. If you wish to dynamically allocate the string buffer that will contain the list of recipients, then the *lpszRecipients* parameter should be NULL and the *nMaxLength* parameter should have a value of zero. The method will then return the recommended size of the buffer that should be allocated. This value is guaranteed to be large enough to store the entire list of message recipients, including the terminating null character.

Example

```
CString strRecipients;
```

```
if (pMessage->GetAllRecipients(strRecipients) < 1)
{
    // There are no recipients for the current message
    AfxMessageBox(IDS_ERROR_NO_RECIPIENTS);
    return;
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

CMailMessage::GetAttachedFileName Method

```
BOOL GetAttachedFileName(  
    LPTSTR lpszFileName,  
    INT cchFileName  
);  
  
BOOL GetAttachedFileName(  
    CString& strFileName  
);
```

The **GetAttachedFileName** method returns the file name for the attachment to the current message part.

Parameters

lpszFileName

Pointer to a buffer that will contain the current attachment file name as a string. An alternate form of this method accepts a **CString** object which will contain the file name when the method returns.

cchFileName

The maximum number of characters that may be copied into the buffer, including the terminating null character.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The method will first try to get the filename from the Content-Disposition header field. If this field does not exist, it then attempts to get the name from the Content-Type header field. If neither field exists, the method will fail.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[AttachFile](#), [GetHeader](#)

CMailMessage::GetBoundary Method

```
LPCTSTR GetBoundary();
```

The **GetBoundary** method returns a pointer to the boundary string used to separate the parts of a multipart message.

Parameters

None.

Return Value

If the method succeeds, the return value is a pointer to the boundary string. If the method fails, a NULL pointer is returned. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[CreatePart](#), [GetHeader](#), [GetPart](#)

CMailMessage::GetContentDigest Method

```
INT GetContentDigest(  
    LPTSTR lpszDigest,  
    INT cchDigest  
);  
  
INT GetContentDigest(  
    CString& strDigest  
);
```

The **GetContentDigest** method returns an encoded digest of the message.

Parameters

lpszDigest

Pointer to a string buffer to contain the MD5 digest for the specified message. An alternate form of this method accepts a **CString** object which will contain the digest when the method returns.

cchDigest

Maximum length of the digest string, in bytes.

Return Value

If the method succeeds, the return value is the length of the message digest string. A value of zero specifies that there is no MD5 digest for the current message. If the method fails, the return value is `MIME_ERROR`. To get extended error information, call **GetLastError**.

Remarks

This method returns the value of the Content-MD5 header field in the main body of the message. If the header exists, it contains the MD5 digest for the message as defined in RFC 1864.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csmsgv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

CMailMessage::GetContentLength Method

```
LONG GetContentLength();
```

The **GetContentLength** method returns the size of the current message part content in bytes.

Parameters

None.

Return Value

If the method succeeds, the return value is the content length. If the method fails, the return value is `MIME_ERROR`. To get extended error information, call **GetLastError**.

Remarks

This function will return the size of the content in the current message part as the number of bytes and does not account for any Unicode conversion of text. Exercise caution when using this function to determine the size of the buffer that should be allocated for a method like **GetText**. You should always allocate enough memory to accommodate any potential text conversion and decoding which may occur.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csmsgv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

See Also

[GetHeader](#), [GetPart](#), [GetText](#), [SetPart](#)

CMailMessage::GetDate Method

```
LPCTSTR GetDate(  
    BOOL bLocalize  
);
```

The **GetDate** method returns a pointer to a string that contains the message date and time.

Parameters

bLocalize

Boolean flag which specifies if the date and time should be localized for the current timezone.

Return Value

If the method succeeds, the return value is a pointer to the date and time string. If the method fails, it will return a NULL pointer. To get extended error information, call **GetLastError**.

Remarks

If no date has been specified in the message, the Date header field will be set to the current date and time, and that value will be returned. The date string returned by this method should never be directly modified by the application. Each call to this method will invalidate the previous value that was returned, so if you wish to save or modify the value, you should first make a private copy of the string.

To convert this date string to a long integer value that can be used with the standard C time methods, use the **ParseDate** method. Refer to the **FormatDate** method for information on the format of the date string.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

CMailMessage::GetErrorString Method

```
INT GetErrorString(  
    DWORD dwErrorCode,  
    LPTSTR lpszDescription,  
    INT cbDescription  
);
```

The **GetErrorString** method is used to return a description of a specific error code. Typically this is used in conjunction with the **GetLastError** method for use with warning dialogs or as diagnostic messages.

Parameters

dwErrorCode

The error code for which a description is returned.

lpszDescription

A pointer to the buffer that will contain a description of the specified error code. This buffer should be at least 128 characters in length.

cbDescription

The maximum number of characters that may be copied into the description buffer.

Return Value

If the method succeeds, the return value is the length of the description string. If the method fails, the return value is zero, meaning that no description exists for the specified error code. Typically this indicates that the error code passed to the method is invalid.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csmsgv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

See Also

CMailMessage::GetExportOptions Method

```
BOOL GetExportOptions(  
    LPDWORD LpdwOptions  
);
```

The **GetExportOptions** method returns a bitmask that describes the default message export options.

Parameters

LpdwOptions

Pointer to mask of attribute options. The mask is a combination of the following values:

Constant	Description
MIME_OPTION_DEFAULT	The default export options. The headers for the message are written out in a specific consistent order, with custom headers written to the end of the header block regardless of the order in which they were set or imported from another message. If the message contains Bcc, Received, Return-Path, Status or X400-Received header fields, they will not be exported.
MIME_OPTION_KEEPOORDER	The original order in which the message header fields were set or imported are preserved when the message is exported.
MIME_OPTION_ALLHEADERS	All headers, including the Bcc, Received, Return-Path, Status and X400-Received header fields will be exported. Normally these headers are not exported because they are only used by the mail transport system. This option can be useful when exporting a message to be stored on the local system, but should not be used when exporting a message to be delivered to another user.
MIME_OPTION_NOHEADERS	When exporting a message, the main header block will not be included. This can be useful when creating a multipart message for services which expect MIME formatted data, such as HTTP POST requests. This option should never be used for email messages being submitted using SMTP.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is 0. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

CMailMessage::GetFileContentType Method

```
UINT GetFileContentType(  
    LPCTSTR lpszFileName,  
    LPTSTR lpszContentType,  
    INT cchContentType  
);  
  
UINT GetFileContentType(  
    LPCTSTR lpszFileName,  
    CString& strContentType  
);
```

The **GetFileContentType** method returns the content type for the specified file.

Parameters

lpszFileName

Pointer to a string which specifies the name of the file for which content type information is returned.

lpszContentType

Pointer to a string buffer that will contain the MIME type for the specified file. This may be a NULL pointer, in which case this parameter is ignored. If a buffer is provided, it is recommended that it be at least 64 characters in length.

cchContentType

An integer which specifies the maximum number of characters, including the terminating null character, which may be copied into the string buffer.

Return Value

If the method succeeds, the return value is the content type of the specified file. If the method fails, the return value is MIME_CONTENT_UNKNOWN. To get extended error information, call **GetLastError**.

The following values may be returned by this method:

Constant	Description
MIME_CONTENT_UNKNOWN	The file content type is unknown. This value may be returned if the message handle is invalid, or if the file extension is unknown and the file could not be opened for read access.
MIME_CONTENT_APPLICATION	The file content is application specific. Examples of this type of file would be a Microsoft Word document or an executable program. This is also the default type for files which have an unrecognized file name extension and contain binary data.
MIME_CONTENT_AUDIO	The file is an audio file in one of several standard formats. Examples of this type of file would be a Windows (.wav) file or MPEG3 (.mp3) file.
MIME_CONTENT_IMAGE	The file is an image file in one of several standard formats. Examples of this type of file would be a GIF or JPEG image file.
MIME_CONTENT_TEXT	The file is a text file. This is also the default type for files which

	have an unrecognized file name extension and contain only printable text data.
MIME_CONTENT_VIDEO	The file is a video file in one of several standard formats. Examples of this type of file would be a Windows (.avi) or Quicktime (.mov) video file.

Remarks

The content type for a given file is determined based on the file name extension, or if the extension is not recognized, the actual contents of the file. On 32-bit platforms, the system registry is used to determine the default content type values for a given extension. In all cases, file types that are explicitly set using the **SetFileContentType** method will override the default system values.

The content type string which is copied to the string buffer is the standard MIME content type description, which specifies a primary type and a subtype, separated by a slash. For example, a plain text file would have a content type of text/plain, while an HTML document would have a content type of text/html. Binary files may be associated with a specific application. For example, the content type for a Microsoft Word document is application/msword. Those binary files which are not associated with a specific application, or have an unrecognized file name extension, have a content type of application/octet-stream.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

CMailMessage::GetFirstHeader Method

```
BOOL GetFirstHeader(  
    LPTSTR lpszHeader,  
    INT cchMaxHeader,  
    LPTSTR lpszValue,  
    INT cchMaxValue  
);  
  
BOOL GetFirstHeader(  
    CString& strHeader,  
    CString& strValue  
);
```

The **GetFirstHeader** method returns the header field name and value for the first header in the current message part. This method is typically used in conjunction with **GetNextHeader** to enumerate all of the message header fields and their values in the current message part.

Parameters

lpszHeader

A pointer to a string buffer that will contain the the name of the first header in the current message part. This parameter cannot be a NULL pointer.

cchMaxHeader

An integer which specifies the maximum number of characters which may be copied into the buffer, including the terminating null character. This parameter must have a value greater than zero.

lpszValue

A pointer to a string buffer that will contain the value of the first header in the current message part. This parameter may be a NULL pointer, in which case the value of the header field is ignored.

cchMaxValue

An integer which specifies the maximum number of characters which may be copied into the buffer, including the terminating null character. If the *lpszValue* parameter is NULL, this parameter should have a value of zero.

Return Value

If the method succeeds, the return value is non-zero. If no headers exist for the current message part, or the handle to the message is invalid, the method will return zero. To get extended error information, call **GetLastError**.

Remarks

Each part in a multipart message has one or more header fields. To obtain header values for the main message, rather than the message attachments, the current part number must be set to zero using the **SetPart** method.

The header fields from an imported message may not be returned in the same order as which they appear in the message. An application should never make an assumption about the order in which one or more header fields are defined.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

CMailMessage::GetHandle Method

```
HMESSAGE GetHandle();
```

The **GetHandle** method returns the message handle associated with the current instance of the class.

Parameters

None.

Return Value

This method returns the message handle associated with the current instance of the class object. If there is no current message, the value `INVALID_MESSAGE` will be returned.

Remarks

This method is used to obtain the message handle created by the class for use with the SocketTools API.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csmsgv10.lib`

See Also

CMailMessage::GetHeader Method

```
INT GetHeader(  
    INT nMessagePart,  
    LPCTSTR lpszHeader,  
    LPTSTR lpszValue,  
    INT nMaxValue  
);
```

```
INT GetHeader(  
    LPCTSTR lpszHeader,  
    LPTSTR lpszValue,  
    INT nMaxValue  
);
```

```
INT GetHeader(  
    INT nMessagePart,  
    LPCTSTR lpszHeader,  
    CString& strValue  
);
```

```
INT GetHeader(  
    LPCTSTR lpszHeader,  
    CString& lpszValue  
);
```

The **GetHeader** copies the value of the specified header into a string buffer.

Parameters

nMessagePart

An integer value which specifies which part of the message to return the header value from. A value of zero returns a header value from the main message header, while a value greater than zero returns the header value from that specific part of a multipart message. A value of -1 specifies that the header value should be returned from the current message part. If this argument is omitted, the value will be returned from the current message part.

lpszHeader

A pointer to a string which specifies the message header.

lpszValue

A pointer to a string buffer which will contain the value of the specified header when the method returns. If this parameter is NULL, the method will return the length of the header value without copying the data. This is useful for determining the length of a header value so that a string buffer can be allocated and passed to a subsequent call to the method. In alternate forms of this method, a **CString** object may be specified which will contain the header field value when the method returns.

nMaxValue

An integer value which specifies the maximum number of characters that can be copied to the string buffer, including the terminating null character. If the *lpszValue* parameter is NULL, this value should be zero.

Return Value

If the method succeeds, the return value is the number of bytes copied into the string buffer, not including the terminating null byte. If the *lpszValue* parameter is NULL, the return value is the

length of the header value. If the header field does not exist, a value of zero is returned. If an invalid pointer or message part is specified, a value of MIME_ERROR is returned. To get extended error information, call **GetLastError**.

Example

```
CMailMessage *pMessage = new CMailMessage();
CString strSubject;

// Compose a test message
pMessage->ComposeMessage(_T("Bob Jones <bob@example.com>"),
                        _T("Tom Smith <tom@example.com>"),
                        NULL,
                        _T("This is a test message"),
                        _T("This is a test, this is only a test.));

// Change the subject of the message
if (pMessage->GetHeader(0, _T("Subject"), strSubject))
{
    strSubject = _T("Re: ") + strSubject;
    pMessage->SetHeader(0, _T("Subject"), strSubject);
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

CMailMessage::GetLastError Method

```
DWORD GetLastError();  
  
DWORD GetLastError(  
    CString& strDescription  
);
```

Parameters

strDescription

A string which will contain a description of the last error code value when the method returns. If no error has been set, or the last error code has been cleared, this string will be empty.

Return Value

The return value is the last error code value for the current thread. Functions set this value by calling the **SetLastError** method. The Return Value section of each reference page notes the conditions under which the method sets the last error code.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. You should call the **GetLastError** method immediately when a method's return value indicates that an error has occurred. That is because some methods call **SetLastError(0)** when they succeed, clearing the error code set by the most recently failed method.

Most methods will set the last error code value when they fail; a few methods set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_MESSAGE or MIME_ERROR. Those methods which call **SetLastError** when they succeed are noted on the method reference page.

The description of the error code is the same string that is returned by the **GetErrorString** method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmsgv10.lib

See Also

[GetErrorString](#), [SetLastError](#), [ShowError](#)

CMailMessage::GetMessageSize Method

```
DWORD GetMessageSize(  
    DWORD dwOptions  
);
```

The **GetMessageSize** method returns the size of the complete message in bytes.

Parameters

dwOptions

An optional unsigned integer value which specifies how the size of the message should be calculated, based on what header fields should be included. These are the same options used when exporting a message to a file or memory buffer. The following values may be combined using a bitwise Or operator:

Constant	Description
MIME_OPTION_DEFAULT	The default export options. The headers for the message are written out in a specific consistent order, with custom headers written to the end of the header block regardless of the order in which they were set or imported from another message. If the message contains Bcc, Received, Return-Path, Status or X400-Received header fields, they will not be exported.
MIME_OPTION_ALLHEADERS	All headers, including the Received, Return-Path, Status and X400-Received header fields will be exported. Normally these headers are not exported because they are only used by the mail transport system. This option can be useful when exporting a message to be stored on the local system, but should not be used when exporting a message to be delivered to another user.

Return Value

If the method succeeds, the return value is the size of the current message in bytes. If an error occurs, the method will return `MIME_ERROR`. To get extended error information, call **GetLastError**.

Remarks

This method returns the size of the complete message, including all headers, the message body and any attachments. It can be used to determine the minimum amount of memory that should be allocated to export the message to a memory buffer using the **ExportMessage** method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csmsgv10.lib`

See Also

CMailMessage::GetNextHeader Method

```
BOOL GetNextHeader(  
    LPTSTR lpszHeader,  
    INT cchMaxHeader,  
    LPTSTR lpszValue,  
    INT cchMaxValue  
);
```

```
BOOL GetNextHeader(  
    CString& strHeader,  
    CString& strValue  
);
```

The **GetNextHeader** method returns the header field name and value for the next header in the current message part. This method is typically used in conjunction with **GetFirstHeader** to enumerate all of the message header fields and their values in the current message part.

Parameters

lpszHeader

A pointer to a string buffer that will contain the name of the next header in the current message part. This parameter cannot be a NULL pointer.

cchMaxHeader

An integer which specifies the maximum number of characters which may be copied into the buffer, including the terminating null character. This parameter must have a value greater than zero.

lpszValue

A pointer to a string buffer that will contain the value of the next header in the current message part. This parameter may be a NULL pointer, in which case the value of the header field is ignored.

cchMaxValue

An integer which specifies the maximum number of characters which may be copied into the buffer, including the terminating null character. If the *lpszValue* parameter is NULL, this parameter should have a value of zero.

Return Value

If the method succeeds, the return value is non-zero. If no more headers exist for the current message part, or the handle to the message is invalid, the method will return zero. To get extended error information, call **GetLastError**.

Remarks

Each part in a multipart message has one or more header fields. To obtain header values for the main message, rather than the message attachments, the current part number must be set to zero using the **SetPart** method.

The header fields from an imported message may not be returned in the same order as which they appear in the message. An application should never make an assumption about the order in which one or more header fields are defined, with the following exception:

If an imported message has multiple Received headers, then those headers will be returned by **GetNextHeader** in the order in which they appeared in the original message. Note that if

GetHeader is used to retrieve the Received header, the first Received header in the message will be returned.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

CMailMessage::GetPart Method

```
INT GetPart();
```

The **GetPart** method returns the current message part index for the specified message.

Parameters

None.

Return Value

If the method succeeds, the return value is the message part index. If the method fails, the return value is MIME_ERROR. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmsgv10.lib

See Also

[CreatePart](#), [DeletePart](#), [GetPartCount](#), [SetPart](#)

CMailMessage::GetPartCount Method

```
INT GetPartCount();
```

The **GetPartCount** method returns the total number of message parts for the specified message. Each message consists of at least one part.

Parameters

None.

Return Value

If the method succeeds, the return value is the number of message parts. If the method fails, the return value is MIME_ERROR. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmsgv10.lib

See Also

[CreatePart](#), [GetPart](#), [SetPart](#)

CMailMessage::GetSender Method

```
INT GetSender(  
    LPCTSTR lpszSender,  
    INT nMaxLength  
);  
  
INT GetSender(  
    CString& strSender  
);
```

The **GetSender** method returns the email address of the message sender in the specified string buffer.

Parameters

lpszSender

A pointer to a string buffer that will contain the email address of the message sender when the method returns. In alternate forms of this method, a **CString** object may be specified which will contain the email address when the method returns.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied to the string buffer, including the terminating null character. It is recommended that the maximum length be at least 64 characters.

Return Value

If the method succeeds, the return value is the number of bytes copied to the string buffer. If an error occurs, the method will return MIME_ERROR. To get extended error information, call **GetLastError**.

Remarks

This method attempts to determine the email address of the sender that originated the message. It will first check for the presence of a Sender or X-Sender header value. If these headers are not defined, it will use the value of the From header field. It will only return successfully if a valid email address can be found.

If the method succeeds, the string buffer that is provided will only contain an email address. It will not contain the display name of the user associated with the address or any extraneous comments that are included in quotes or parenthesis.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[EnumHeaders](#), [GetFirstHeader](#), [GetHeader](#), [GetPart](#), [GetNextHeader](#), [ParseHeader](#), [SetHeader](#), [SetPart](#)

CMailMessage::GetText Method

```
LONG GetText(  
    LPTSTR lpszBuffer,  
    LONG nMaxLength,  
    LONG nOffset  
);  
  
LONG GetText(  
    CString& strBuffer,  
    LONG nOffset  
);
```

The **GetText** method copies the text of the current message part to the specified buffer.

Parameters

lpszBuffer

A pointer to a string buffer that will receive a copy of the message text when the method returns.

nMaxLength

The maximum number of bytes to copy into the buffer. The size of the buffer provided must be larger than the content length for the current message part.

nOffset

The byte offset from the beginning of the message. A value of zero specifies the first character in the body of the message part.

Return Value

If the method succeeds, the return value is number of bytes copied into the buffer. If the method fails, the return value is MIME_ERROR. To get extended error information, call **GetLastError**.

Remarks

If your project targets a multi-byte character set, this method will always return the message contents as UTF-8 text, regardless of the original character set specified in the message itself. This ensures that characters in the original text are preserved, regardless of the default ANSI code page on the local system. It is recommended you build your project to use Unicode whenever possible. If your application must use ANSI, you can use the **LocalizeText** method to convert the Unicode text to a specific character set.

You should not determine the maximum size of the output buffer using the **GetContentLength** method. That method returns the content size in bytes as it is stored in the message, and does not account for any character encoding or Unicode conversion which may be required. The content length can be used to estimate the amount of text stored in the message part, but you should always allocate a buffer which is larger than the length specified in the message.

If the *nMaxLength* parameter does not specify a buffer size large enough to store the contents of the current message part, this method will fail and the last error code will be set to ST_ERROR_BUFFER_TOO_SMALL. Your application must ensure the buffer is large enough to contain the complete message text and a terminating NUL character.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

CMailMessage::ImportMessage Method

```
BOOL ImportMessage(  
    LPCTSTR lpszFileName  
);
```

```
BOOL ImportMessage(  
    LPCTSTR lpszMessage,  
    INT nLength  
);
```

The **ImportMessage** method imports the message from a file or a string buffer in memory, replacing the current message contents.

Parameters

lpszFileName

A pointer to a string which specifies the name of the file that contains the message to be imported.

lpszMessage

A pointer to a string which contains the message to be imported.

nLength

An integer value which specifies the number of bytes to read from the string buffer. If this argument is -1, then the entire contents of the string up to the terminating null character will be imported.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[ExportMessage](#), [ParseBuffer](#)

CMailMessage::IsInitialized Method

```
BOOL IsInitialized();
```

The **IsInitialized** method returns whether or not the class object has been successfully initialized.

Return Value

This method returns a non-zero value if the class object has been successfully initialized. A return value of zero indicates that the runtime license key could not be validated.

Remarks

When an instance of the class is created, the class constructor will attempt to initialize the component with the runtime license key that was created when SocketTools was installed. If the constructor is unable to validate the license key the initialization will fail.

If SocketTools was installed with an evaluation license, the application cannot be redistributed to another system. The class object will fail to initialize if the application is executed on another system, or if the evaluation period has expired. To redistribute your application, you must purchase a development license which will include the runtime key that is needed to redistribute your software to other systems. Refer to the Developer's Guide for more information.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmsgv10.lib

See Also

[CMailMessage](#)

CMailMessage::LocalizeText Method

```
LONG LocalizeText(  
    LPCTSTR lpszInput,  
    LONG cchInput,  
    LPBYTE lpOutput,  
    LONG cbOutput,  
    UINT nCharacterSet  
);
```

The **LocalizeText** method converts a Unicode string to its ANSI equivalent using the specified character set.

Parameters

lpszInput

A pointer to a null terminated string which contains the Unicode text which should be localized. If the ANSI version of this function is called, the input text must be in UTF-8 format or the function will fail. This parameter cannot be a NULL pointer.

cchInput

An integer value which specifies the number of characters of text in the input string which should be localized. If this value is -1, the entire length of the string up to the terminating null will be decoded.

lpOutput

A pointer to a byte buffer which will contain the localized ANSI version of the input text. This parameter cannot be a NULL pointer.

cbOutput

An integer value which specifies the maximum number of bytes which can be copied into the output buffer. The buffer must be large enough to store all of the localized text. This value must be greater than zero.

nCharacterSet

An optional numeric identifier which specifies the [character set](#) to use when localizing the text. If this parameter is omitted, the locale for the current thread will be used when localizing the text.

Return Value

If the input text can be successfully localized, the return value is the number of bytes copied into the output buffer. If the function returns zero, then no text was localized. If the function fails, the return value is MIME_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **LocalizeText** method enables the application to localize a Unicode string, returning the ANSI version of that text using the specified character set. Because library handles all text as Unicode internally, the ANSI functions in this library will always return UTF-8 encoded text. This method allows you to easily convert that UTF-8 text to another supported character set.

If the ANSI version of this function is called, the input text must use UTF-8 character encoding or the method will fail with the last error set to ST_ERROR_INVALID_CHARACTER_SET.

If the *nCharacterSet* parameter is MIME_CHARSET_DEFAULT or MIME_CHARSET_UNKNOWN the input text will be converted to the default ANSI code page for the current thread locale. If there are characters in the Unicode input text which cannot be converted to an ANSI equivalent using

the specified character set, those characters will be replaced by the default character for your locale, typically a question mark symbol. You cannot specify `MIME_CHARSET_UTF16` as the character set.

This method will always attempt to ensure that the output buffer is terminated with an extra null byte so it is easier to work with as a standard C-style null terminated string. However, if the output buffer is not large enough to accommodate the extra null byte, it will not be copied. It is always recommended that your output buffer be somewhat larger than the length of the original input text to account for multi-byte character sequences. If the output buffer is not large enough to contain the entire localized text, no bytes will be copied to the output buffer and the function will fail with the last error set to `ST_ERROR_BUFFER_TOO_SMALL`.

This function is only required if your application needs to localize the UTF-8 text returned by another function and convert it to a specific 8-bit ANSI character set. For example, if you have an application which calls the ANSI version of **MimeGetMessageText**, it will return the message contents as UTF-8 text. If you need to display that text as localized ANSI, you can call this function to convert the UTF-8 text to your current locale or a specific character set.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csmsgv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

[MimeSetMessageText](#)

CMailMessage::ParseAddress Method

```
INT ParseAddress(  
    LPCTSTR lpszString,  
    LPCTSTR lpszDomain,  
    LPTSTR lpszAddress,  
    INT nMaxLength  
);
```

```
INT ParseAddress(  
    LPCTSTR lpszString,  
    LPTSTR lpszAddress,  
    INT nMaxLength  
);
```

```
INT ParseAddress(  
    LPCTSTR lpszString,  
    CString& strAddress  
);
```

The **ParseAddress** method parses a string for an email address, copying the address to the specified buffer.

Parameters

lpszString

A pointer to a string which contains the email address to parse.

lpszDomain

A pointer to a string which specifies a default domain for the address. This parameter may be NULL or point to an empty string if no default domain is required.

lpszAddress

A pointer to a string buffer which will contain the parsed email address when the method returns. It is recommended that this buffer be at least 128 characters in length.

nMaxLength

The maximum number of characters which can be copied into the string buffer, including the terminating null character.

Return Value

If the method succeeds, the return value is the length of the address. If the method fails, the return value is MIME_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **ParseAddress** method is useful for parsing the email addresses that may be specified in various header fields in the message. In many cases, the addresses have additional comment characters which are not part of the address itself. For example, one common format used is as follows:

```
"User Name" <user@domain.com>
```

In this case, the email address is enclosed in angle brackets and the name outside of the brackets is considered to be a comment which is not part of the address itself. Another common format is:

```
user@domain.com (User Name)
```

In this case, there is the address followed by a comment which is enclosed in parenthesis. The

ParseAddress method recognizes both formats, and when passed either string, would return the following address:

user@domain.com

If there was no domain specified in the address, that is just a user name was specified, then the value the *lpzDomain* parameter is added to the address.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[ExportMessage](#), [ExtractFile](#), [ImportMessage](#)

CMailMessage::ParseBuffer Method

```
BOOL ParseBuffer(  
    LPCTSTR lpszBuffer,  
    INT cbBuffer  
);
```

The **ParseBuffer** method parses the contents of the specified buffer and adds the contents to the message.

Parameters

lpszBuffer

Pointer to a buffer that contains the text to be added to the message contents.

cbBuffer

The length of the specified buffer. If this value is -1, all characters in the string up to the terminating null character will be parsed.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

This method is useful when the application needs to parse an arbitrary block of text and add it to the specified message. If the buffer contains header fields, the values will be added to the message header. Once the end of the header block is detected, all subsequent text is added to the body of the message.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

CMailMessage::ParseDate Method

```
BOOL ParseDate(  
    LPCTSTR lpszDate,  
    LPLONG lpnSeconds,  
    LPLONG lpnTimezone,  
    BOOL bLocalize  
);
```

The **ParseDate** method parses a date string, returning the number of seconds since 1 January 1970 and the difference in seconds between the specified timezone and coordinated universal time. If the string does not specify a timezone, the local timezone is used.

Parameters

lpszDate

A pointer to a string which specifies the date to be parsed. The date string must be in the standard format defined by RFC 822.

lpnSeconds

A pointer to a long integer which is set to the number of seconds since 1 January 1970 00:00:00 UTC. This date is commonly called the epoch, and is the base date used by the standard C time methods. This pointer may be NULL, in which case the parameter is ignored.

lpnTimezone

A pointer to a long integer which is set to the difference in seconds between the specified date's timezone and coordinated universal time (also known as Greenwich Mean Time). This pointer may be NULL, in which case the parameter is ignored.

bLocalize

A boolean flag which determines if the date should be localized to the current timezone, regardless of the timezone specified in the date string. A non-zero value specifies the timezone for the local system will be used, adjusted for daylight savings time if applicable.

Return Value

If the date could be successfully parsed, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

This method is not a general purpose date parsing function, and may not be capable of parsing dates for a specific locale. The date and time should be in a standard format as outlined in RFC 822, which describes the basic structure of Internet email messages. For a description of the date string format, refer to the **MimeFormatDate** function.

If the date and time does not include any timezone information, Coordinated Universal Time (UTC) will be used by default. This is an important consideration if you use this function to parse input from a user, because in most cases they will not provide a timezone and will assume the date and time they enter is for their current timezone.

The value of the *bLocalize* parameter will only change the number of seconds offset by the current timezone and does not affect the value returned in the *lpnSeconds* parameter. If the date is localized, the timezone offset will be adjusted for daylight savings if it was in effect at the time.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[FormatDate](#), [GetDate](#), [SetDate](#)

CMailMessage::ParseHeader Method

```
BOOL ParseHeader(  
    LPCTSTR lpszBuffer  
);
```

The **ParseHeader** method parses a line of text and adds the header and value to the current message.

Parameters

lpszBuffer

Pointer to a string which contains the header and value to be added to the message.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

This method is used to parse a line of text that is part of a message header. The string must consist of a header name, followed by a colon, followed by the header value. The header name may only consist of printable characters, and may not contain whitespace (space, tab, carriage return or linefeed characters).

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[ImportMessage](#), [ParseBuffer](#)

CMailMessage::SetDate Method

```
BOOL SetDate(  
    LPCTSTR lpszDate,  
    BOOL bLocalize  
);
```

The **SetDate** method sets the date and time in the header for the specified message.

Parameters

lpszDate

Pointer to a string which specifies the date and time. If this parameter specifies a zero-length string or a NULL pointer, the current date and time will be used.

bLocalize

Boolean flag that specifies the date and time should be localized for the current timezone.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The date string should be in a standard format as outlined in RFC 822, the document which describes the basic structure of Internet email messages. For a description of the date string format, refer to the **FormatDate** method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[FormatDate](#), [GetDate](#), [GetHeader](#), [ParseDate](#), [SetHeader](#)

CMailMessage::SetExportOptions Method

```
BOOL SetExportOptions(  
    DWORD dwOptions  
);
```

The **SetExportOptions** method specifies a bitmask that describes current message export options.

Parameters

dwOptions

Mask of attribute options. The mask is a combination of the following values:

Constant	Description
MIME_OPTION_DEFAULT	The default export options. The headers for the message are written out in a specific consistent order, with custom headers written to the end of the header block regardless of the order in which they were set or imported from another message. If the message contains Bcc, Received, Return-Path, Status or X400-Received header fields, they will not be exported.
MIME_OPTION_KEEPOORDER	The original order in which the message header fields were set or imported are preserved when the message is exported.
MIME_OPTION_ALLHEADERS	All headers, including the Bcc, Received, Return-Path, Status and X400-Received header fields will be exported. Normally these headers are not exported because they are only used by the mail transport system. This option can be useful when exporting a message to be stored on the local system, but should not be used when exporting a message to be delivered to another user.
MIME_OPTION_NOHEADERS	When exporting a message, the main header block will not be included. This can be useful when creating a multipart message for services which expect MIME formatted data, such as HTTP POST requests. This option should never be used for email messages being submitted using SMTP.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

By default, the Received and Return-Path headers are not exported. In addition, the order of the headers in an exported message is undefined. This is reasonable behavior for most mail clients, but may not be appropriate for applications which need access to all of the header fields.

Example

```
pMessage->SetExportOptions(MIME_EXPORT_OPTIONS_ALL |
                           MIME_EXPORT_OPTIONS_KEEP_ORDER);

if (pMessage->Import(lpszFileName))
{
    // Process the message and make any modifications
    // then write the message back out, preserving all
    // of the headers in their original order
    bResult = pMessage->Export(lpszFileName);
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[ExportMessage](#), [ImportMessage](#), [GetExportOptions](#)

CMailMessage::SetFileContentType Method

```
BOOL SetFileContentType(  
    UINT nContentType,  
    LPCTSTR lpszSubtype,  
    LPCTSTR lpszExtension  
);
```

The **SetFileContentType** method associates a per-message content type with a given file name extension. This association is specific to the message, and is not shared by other messages that may be opened by the process.

Parameters

nContentType

An identifier which specifies the primary content type. It may be one of the following values:

Constant	Description
MIME_CONTENT_UNKNOWN	The default content type for the specified extension should be used. This value should only be used to delete a previously defined content type.
MIME_CONTENT_APPLICATION	The file content is application specific. Examples of this type of file would be a Microsoft Word document or an executable program. This is also the default type for files which have an unrecognized file name extension and contain binary data.
MIME_CONTENT_AUDIO	The file is an audio file in one of several standard formats. Examples of this type of file would be a Windows (.wav) file or MPEG3 (.mp3) file.
MIME_CONTENT_IMAGE	The file is an image file in one of several standard formats. Examples of this type of file would be a GIF or JPEG image file.
MIME_CONTENT_TEXT	The file is a text file. This is also the default type for files which have an unrecognized file name extension and contain only printable text data.
MIME_CONTENT_VIDEO	The file is a video file in one of several standard formats. Examples of this type of file would be a Windows (.avi) or Quicktime (.mov) video file.

lpszSubtype

A pointer to a string which specifies the MIME subtype. This parameter may be NULL if the content type association is being deleted.

lpszExtension

A pointer to a string which specifies the file name extension that will be associated with the MIME content type.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **SetFileContentType** method allows an application to specify a content type for a given file extension, and is typically used to define custom content types for file attachments. The content type will override any default content types associated with the extension, as well as allow new content types to be defined for application-specific files.

Example

In the following example, the file extension ".dat" is associated with a custom content type, a file is attached to the message and then the custom content type is deleted. Note that because the primary content type designates the file as an application specific (non-text) file, it will be automatically encoded when attached to a message:

```
bResult = pMessage->SetFileContentType(
    MIME_CONTENT_APPLICATION,
    _T("octet-stream"), _T("dat"));

if (bResult)
{
    bResult = pMessage->AttachFile(lpszFileName, MIME_ATTACH_DEFAULT);
    pMessage->SetFileContentType(MIME_CONTENT_UNKNOWN, NULL, _T("dat"));
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[AttachData](#), [AttachFile](#), [GetFileContentType](#)

CMailMessage::SetHeader Method

```
BOOL SetHeader(  
    INT nMessagePart,  
    LPCTSTR lpszHeader,  
    LPCTSTR lpszValue  
);
```

```
BOOL SetHeader(  
    LPCTSTR lpszHeader,  
    LPCTSTR lpszValue  
);
```

The **SetHeader** method adds or updates a header field in the specified message.

Parameters

nMessagePart

An integer value which specifies which part of the message the header should be set or modified in. A value of zero sets a header value in the main message header block, while a value greater than zero sets the header value in that specific part of a multipart message. If this argument is omitted or a value of -1 is specified, the header value will be set in the current message part.

lpszHeader

Pointer to a string which specifies the header field that will be added or updated.

lpszValue

Pointer to a string which specifies the value for the header field. This pointer may be NULL, which causes the header field to be removed from the message.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[EnumHeaders](#), [GetFirstHeader](#), [GetHeader](#), [GetPart](#), [GetNextHeader](#), [SetPart](#), [SetText](#)

CMailMessage::SetLastError Method

```
VOID SetLastError(  
    DWORD dwErrorCode  
);
```

The **SetLastError** method sets the last error code for the current thread. This method is typically used to clear the last error by specifying a value of zero as the parameter.

Parameters

dwErrorCode

Specifies the last error code for the current thread.

Return Value

None.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. Most methods will set the last error code value when they fail; a few methods set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_MESSAGE or MIME_ERROR. Those methods which call **SetLastError** when they succeed are noted on the method reference page.

Applications can retrieve the value saved by this method by using the **GetLastError** method. The use of **GetLastError** is optional; an application can call the method to determine the specific reason for a method failure.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmsgv10.lib

See Also

[GetErrorString](#), [GetLastError](#), [ShowError](#)

CMailMessage::SetPart Method

```
INT SetPart(  
    INT nNewPart  
);
```

The **SetPart** method sets the current message part index for the specified message.

Parameters

nNewPart

The new message part index. A value of zero specifies the main message part.

Return Value

If the method succeeds, the return value is the previous message part index. If the method fails, the return value is MIME_ERROR. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[GetPart](#), [GetPartCount](#), [SetHeader](#)

CMailMessage::SetText Method

```
LONG SetText(  
    LONG nOffset,  
    LPCTSTR lpszText  
);  
  
LONG SetText(  
    LPCTSTR lpszText  
);
```

The **SetText** method copies the specified text into the body of the current message part.

Parameters

nOffset

The offset into the body of the message part. A value of -1 specifies that the text will be appended to the message body. If this argument is omitted, the current message text is replaced with the contents of the *lpszText* argument.

lpszText

A pointer to a string which specifies the text to be copied to the current message part at the given offset.

Return Value

If the method succeeds, the return value is the number of bytes copied into the message. A return value of zero indicates that no text could be copied into the current message part. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

CMailMessage::ShowError Method

```
INT ShowError(  
    LPCTSTR lpszAppTitle,  
    UINT uType,  
    DWORD dwErrorCode  
);
```

The **ShowError** method displays a message box which describes the specified error.

Parameters

lpszAppTitle

A pointer to a string which specifies the title of the message box that is displayed. If this argument is NULL or omitted, then the default title of "Error" will be displayed.

uType

An unsigned integer which specifies the type of message box that will be displayed. This is the same value that is used by the **MessageBox** method in the Windows API. If a value of zero is specified, then a message box with a single OK button will be displayed. Refer to that method for a complete list of options.

dwErrorCode

Specifies the error code that will be used when displaying the message box. If this argument is zero, then the last error that occurred in the current thread will be displayed.

Return Value

If the method is successful, the return value will be the return value from the **MessageBox** function. If the method fails, it will return a value of zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

CMailMessage Character Sets

Constant	Value	Name	Code Page	Description
MIME_CHARSET_USASCII	1	us-ascii	20127	A character set which defines 7-bit printable characters with values ranging from 20h to 7Eh. An application that uses this character set has the broadest compatibility with most mail servers (MTAs) because it does not require the server to handle 8-bit characters correctly when the message is delivered.
MIME_CHARSET_ISO8859_1	2	iso-8859-1	28591	A character set for most western European languages such as English, French, Spanish and German. This character set is also commonly referred to as Latin-1. This character set is similar to Windows code page 1252 (Windows-1252), however there are differences such as the Euro symbol.
MIME_CHARSET_ISO8859_2	3	iso-8859-2	28592	A character set for most central and eastern European languages such as Czech, Hungarian, Polish and Romanian. This character set is also commonly referred to as Latin-2. This character set is similar to Windows code page 1250, however the characters are arranged differently.
MIME_CHARSET_ISO8859_3	12	iso-8859-3	28593	A character set for southern European languages such as Maltese and Esperanto. This character set was also used with the Turkish language, but it was superseded by ISO 8859-9 which is the preferred character set for Turkish. This character set is not widely used in mail messages and it is recommended that you use UTF-8 instead.
MIME_CHARSET_ISO8859_4	13	iso-8859-4	28594	A character set for northern European languages such as

				Latvian, Lithuanian and Greenlandic. This character set is not widely used in mail messages and it is recommended that you use UTF-8 instead.
MIME_CHARSET_ISO8859_5	4	iso-8859-5	28595	A character set for Cyrillic languages such as Russian, Bulgarian and Serbian. This character set was never widely adopted and most mail messages use either KOI8 or UTF-8 encoding.
MIME_CHARSET_ISO8859_6	5	iso-8859-6	28596	A character set for Arabic languages. Note that the application is responsible for displaying text that uses this character set. In particular, any display engine needs to be able to handle the reverse writing direction and analyze the context of the message to correctly combine the glyphs.
MIME_CHARSET_ISO8859_7	6	iso-8859-7	28597	A character set for the Greek language. This character set is also commonly referred to as Latin/Greek. This character set is no longer widely used and has largely been replaced with UTF-8 which provides more complete coverage of the Greek alphabet.
MIME_CHARSET_ISO8859_8	7	iso-8859-8	28598	A character set for the Hebrew language. Note that similar to Arabic, Hebrew uses a reverse writing direction. An application which displays this character should be capable of processing bi-directional text where a single message may include both right-to-left and left-to-right languages, such as Hebrew and English. In most cases it is recommended that you use UTF-8 instead of this character set.
MIME_CHARSET_ISO8859_9	8	iso-8859-9	28599	A character set for the Turkish language. This character set is

				also commonly referred to as Latin-5. This character set is nearly identical to ISO 8859-1, except that it replaces certain Icelandic characters with Turkish characters.
MIME_CHARSET_ISO8859_10	14	iso-8859-10	28600	A character set for the Danish, Icelandic, Norwegian and Swedish languages. This character set is also commonly referred to as Latin-6 and is similar to ISO 8859-4.
MIME_CHARSET_ISO8859_13	15	iso-8859-13	28603	A character set for Baltic languages. This character set is also commonly referred to as Latin-7. This character set is similar to ISO 8859-4, except it adds certain Polish characters and does not support Nordic languages.
MIME_CHARSET_ISO8859_14	16	iso-8859-14	28604	A character set for Gaelic languages such as Irish, Manx and Scottish Gaelic. This character set is also commonly referred to as Latin-8. This character set replaced ISO 8859-12 which was never fully implemented.
MIME_CHARSET_ISO8859_15	17	iso-8859-15	28605	A character set for western European languages. This character set is also commonly referred to as Latin-9 and is nearly identical to ISO8859-1 except that it replaces lesser-used symbols with the Euro sign and some letters.
MIME_CHARSET_ISO2022_JP	18	iso-2022-jp	50222	A multi-byte character encoding for Japanese that is widely used with mail messages. This is a 7-bit encoding where all characters start with ASCII and uses escape sequences to switch to the double-byte character sets.
MIME_CHARSET_ISO2022_KR	19	iso-2022-kr	50225	A multi-byte character encoding for Korean which encodes both ASCII and Korean

				double-byte characters. This is a 7-bit encoding which uses the shift in and shift out control characters to switch to the double-byte character set.
MIME_CHARSET_ISO2022_CN	20	x-cp50227	50227	A multi-byte character encoding for Simplified Chinese which encodes both ASCII and Chinese double-byte characters. This is a 7-bit encoding which uses the shift in and shift out control characters to switch to the double-byte character set.
MIME_CHARSET_KOI8R	21	koi8-r	20866	A character set for Russian using the Cyrillic alphabet. This character set also covers the Bulgarian language. Most mail messages in the Russian language use this character set or UTF-8 instead of ISO 8859-5, which was never widely adopted.
MIME_CHARSET_KOI8U	22	koi8-u	21866	A character set for Ukrainian using the Cyrillic alphabet. This character set is similar to the KOI8-R character set, but replaces certain symbols with Ukrainian letters. Most mail messages in the Ukrainian language use this character set or UTF-8 instead of ISO 8859-5, which was never widely adopted.
MIME_CHARSET_GB2312	23	x-cp20936	20936	A multi-byte character encoding which can represent ASCII and simplified Chinese characters. It has been superseded by GB18030, however it remains widely used in China.
MIME_CHARSET_GB18030	24	gb18030	54936	A Unicode transformation format which can represent all Unicode code points and supports both simplified and traditional Chinese characters. It is backwards compatible with GB2312 and supersedes that

				character set.
MIME_CHARSET_BIG5	25	big5	950	A multi-byte character set that supports both ASCII characters and traditional Chinese characters. It is widely used in Taiwan, Hong Kong and Macau. It is no longer commonly used in China, which has developed GB18030 as a standard encoding. Microsoft's implementation of Big5 on Windows does not support all of the extensions and is missing certain code points.
MIME_CHARSET_UTF7	9	utf-7	65000	A Unicode transformation format that uses variable-length character encoding to represent Unicode text as a stream of ASCII characters that are safe to transport between mail servers that only support 7-bit printable characters. It is primarily used as an alternative to UTF-8 when quoted-printable or base64 encoding is not desired.
MIME_CHARSET_UTF8	10	utf-8	65001	A Unicode transformation format that uses multi-byte character sequences to represent Unicode text. It is backwards compatible with the ASCII character set, however because it uses 8-bit text, it is recommended that you use either quoted-printable or base64 encoding to ensure compatibility with mail servers that do not support 8-bit characters.
MIME_CHARSET_UTF16	11	utf-16le	N/A	A 16-bit Unicode format that represents each character as a 16-bit value in little endian byte order. This character set is not widely used in mail messages and it is recommended that you use UTF-8 instead. UTF-16 characters in big endian byte order are not supported.

Remarks

When composing a new message, it is recommended that you always use UTF-8 as the character set encoding which ensures broad compatibility with most applications. The other character sets are primarily used when parsing messages generated by other applications. Internally, all message headers and text are processed as UTF-8. If you compile your application using a multi-byte (ANSI) character set, header values and message text will always be returned to your application as UTF-8 encoded Unicode, regardless of the original character set used in the message.

In addition to the character sets listed above, the class will recognize additional character sets which correspond to specific Windows code pages, as well several variants. These additional character sets are included for compatibility with other applications; they are not defined because they should not be used when composing new messages.

It is important to note that while certain Windows character sets are similar to standard ISO character sets, they are not identical. For example, although the Windows-1252 character set is nearly identical to ISO 8859-1, they are not interchangeable. Some legacy applications make the error of representing Windows ANSI character sets as 8-bit ISO character sets, which can result in errors when converting them to Unicode. This is something to be aware of when encoding and decoding text generated by older applications. Before the widespread adoption of UTF-8, it was particularly common for legacy Windows mail clients to default to using Windows-1252 for text and label it as using ISO 8859-1.

Although the **CMailMessage** class supports UTF-16, it is recommended you use UTF-8 instead. Text which uses UTF-16 will always be base64 encoded, and some mail clients may not recognize it as a valid character set. If the message does not specify if big endian or little endian byte order is used, the class will default to little endian. When UTF-16 is used when composing a new message, it will always use little endian byte order.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Message Store Class Library

Store a collection of email messages on the local system.

Reference

- [Class Methods](#)
- [Error Codes](#)

Library Information

Class Name	CMessageStore
File Name	CSMSGV10.DLL
Version	10.0.1468.2518
LibID	E6D79220-7873-4170-BF39-5D7A0049655C
Import Library	CSMSGV10.LIB
Dependencies	None

Overview

The Message Store class library provides an interface for managing a local message storage file that can be used to store and retrieve multiple messages. Functions are provided to open and create storage files, add, remove and extract messages from storage, and search the stored messages for specific header field values.

SocketTools also includes a class library for managing individual messages. For more information, refer to the [CMailMessage](#) class.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). If you are using Visual C++ 6.0 it is required that you have Service Pack 6 (SP6) installed. You should install all updates for your development tools and have the current Windows SDK installed. The minimum recommended version of Visual Studio is Visual Studio 2010.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are using Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. It is recommended that you install the current service pack and all critical updates available for your version of the operating system.

This product includes both 32-bit and 64-bit libraries. Native 64-bit CPU support requires the 64-bit version of Windows 7 or later versions of the Windows operating system.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

Message Store Class Methods

Class	Description
CMessageStore	Constructor which initializes the current instance of the class
~CMessageStore	Destructor which releases resources allocated by the class
Method	Description
AttachHandle	Attach the specified message handle to this instance of the class
CloseFile	Close the current message storage file
CopyFile	Duplicate the contents of the current message store in a new file
DeleteMessage	Remove the specified message from the current message store
DetachHandle	Detach the handle for the current instance of this class
FindMessage	Search for a message in the current message store
GetHandle	Return the message handle used by this instance of the class
GetErrorString	Return a description for the specified error code
GetLastError	Return the last error code
GetMessage	Retrieve a message from the current message store
GetMessageCount	Return the number of messages in the current message store
IsInitialized	Determine if the class has been successfully initialized
OpenFile	Open the specified message storage file
PurgeFile	Purge all deleted messages from the current message store
ReplaceMessage	Replace the specified message in the current message store
SetLastError	Set the last error code
ShowError	Display a message box with a description of the specified error
StoreMessage	Store the specified message in the current message store

CMessageStore::CMessageStore Method

`CMessageStore();`

The **CMessageStore** constructor initializes the class library and validates the license key at runtime.

Remarks

If the constructor fails to validate the runtime license, subsequent methods in this class will fail. If the product is installed with an evaluation license, then the application will only function on the development system and cannot be redistributed.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmsgv10.lib

See Also

[~CMessageStore](#), [IsInitialized](#)

CMessageStore::~CMessageStore

`~CMessageStore();`

The **CMessageStore** destructor releases resources allocated by the current instance of the **CMessageStore** object. It also uninitialized the library if there are no other concurrent uses of the class.

Remarks

When a **CMessageStore** object goes out of scope, the destructor is automatically called to allow the library to free any resources allocated on behalf of the process. All handles that were created for the session are destroyed.

The destructor is not called explicitly by the application.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

CMessageStore::AttachHandle Method

```
VOID AttachHandle(  
    HMESSAGESTORE hStorage  
);
```

The **AttachHandle** method attaches the specified message store to the current instance of the class.

Parameters

hStorage

The handle to the message store that will be attached to the current instance of the class object.

Return Value

None.

Remarks

This method is used to attach a message store handle created outside of the class using the SocketTools API. Once the handle is attached to the class, the other class member functions may be used with that message store.

If a message store handle already has been created for the class, that handle will be released when the new handle is attached to the class object. If you want to prevent the previous message store from being closed, you must call the **DetachHandle** method. Failure to release the detached handle may result in a resource leak in your application.

Note that the *hStorage* parameter is presumed to be a valid message store handle and no checks are performed to ensure that the handle is valid. Specifying an invalid message store handle will cause subsequent method calls to fail.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmsgv10.lib

See Also

[DetachHandle](#), [GetHandle](#)

CMessageStore::CloseFile Method

```
BOOL CloseFile(  
    BOOL bPurgeMessages  
);
```

The **CloseFile** method closes the current message store.

Parameters

bPurgeMessages

An integer value which specifies if deleted messages are purged from the message store. A non-zero value specifies that all messages marked for deletion will be removed from the message store. A value of zero specifies that deleted messages will not be removed from the store.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **CloseFile** method closes the storage file that was previously opened, releasing all of the memory allocated for the message store and optionally purging all deleted messages. Note that the current message store will be closed by the class destructor when the class object is deleted or goes out of scope.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmsgv10.lib

See Also

[CopyFile](#), [OpenFile](#), [PurgeFile](#)

CMessageStore::CopyFile Method

```
BOOL CopyFile(  
    LPCTSTR lpszFileName  
);
```

The **CopyFile** method duplicates the contents of the current message store in a new file.

Parameters

lpszFileName

A pointer to a string which specifies the name of the file that the messages will be copied to. This parameter cannot be NULL and must specify a valid file path and name.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **MimeGetLastError**.

Remarks

The **CopyFile** method is used to create a copy of the current message store in a new file. If the file does not exist, it will be created. If the file already exists, then the contents will be overwritten with the contents of the message store.

Messages that have been marked for deletion are not copied to the new message store file.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[CloseFile](#), [OpenFile](#), [PurgeFile](#)

CMessageStore::DeleteMessage Method

```
BOOL DeleteMessage(  
    LONG nMessageId  
);
```

The **DeleteMessage** method removes the specified message from the current message store.

Parameters

nMessageId

An integer value which identifies the message that is to be removed from the message store. Message numbers begin at one and increment for each message in the store.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **DeleteMessage** method marks the specified message for deletion from the storage file. When the message store is closed or purged, the message is removed from the file. Once a message has been marked for deletion, it may no longer be referenced by the application. For example, you cannot access the contents of a message that has been deleted.

The message store must be opened with write access. This method will fail if you attempt to delete a message from a storage file that has been opened for read-only access. If the application needs to delete messages in the message store, it is recommended that the file be opened for exclusive access using the MIME_STORAGE_LOCK option.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmsgv10.lib

See Also

CMessageStore::DetachHandle Method

```
HMESSAGESTORE DetachHandle();
```

The **DetachHandle** method detaches the client handle associated with the current instance of the class.

Parameters

None.

Return Value

This method returns the message store handle associated with the current instance of the class object. If there is no active client session, the value `INVALID_MESSAGESTORE` will be returned.

Remarks

This method is used to detach a message handle created by the class for use with the SocketTools API. Once the message handle is detached from the class, no other class member functions may be called. Note that the handle must be explicitly released at some later point by the process or a resource leak will occur.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csmsgv10.lib`

[AttachHandle](#), [GetHandle](#)

CMessageStore::FindMessage Method

```
LONG FindMessage(  
    LONG nMessageId,  
    LPCTSTR lpszHeaderName,  
    LPCTSTR lpszHeaderValue,  
    DWORD dwOptions  
);
```

The **FindMessage** method searches for a message in the current message store.

Parameters

nMessageId

An integer value which specifies the message number that should be used when starting the search. The first message in the message store has a value of one.

lpszHeaderField

A pointer to the string which specifies the name of the header field that should be searched. The header field name is not case sensitive. This parameter cannot be NULL.

lpszHeaderValue

A pointer to the string which specifies the header value that should be searched for. The search options can be used to specify if the search is case-sensitive, and whether the search should return partial matches to the string. This parameter cannot be NULL.

dwOptions

A value which specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
MIME_SEARCH_DEFAULT	Perform a complete match against the specified header value. The comparison is not case-sensitive.
MIME_SEARCH_CASE_SENSITIVE	The header field value comparison will be case-sensitive. Note that this does not affect header field names. Matches for header names are always case-insensitive.
MIME_SEARCH_PARTIAL_MATCH	Perform a partial match against the specified header value. It is recommended that this option be used when searching for matches to email addresses.
MIME_SEARCH_DECODE_HEADERS	Decode any encoded message headers before comparing them to the specified value. This option can increase the amount of time required to search the message store and should only be used when necessary.

Return Value

If the method succeeds, the return value is the number for the message which matches the search criteria. If the method fails, the return value is `MIME_ERROR`. To get extended error information,

call `GetLastError`.

Remarks

The **FindMessage** method is used to search the message store for a message which matches a specific header field value. For example, it can be used to find every message which is addressed to a specific recipient or has a subject which matches a particular string value.

Example

```
CMessageStore mailStorage;
LPCTSTR lpszHeader = _T("From");
LPCTSTR lpszAddress = _T("jsmith@example.com");
LONG nMessageId = 1;

if (! mailStorage.OpenFile(lpszFileName))
{
    // Unable to open the storage file
    return;
}

// Begin searching for messages from the specified sender
while (nMessageId != MIME_ERROR)
{
    nMessageId = mailStorage.FindMessage(nMessageId,
                                        lpszHeader,
                                        lpszAddress,
                                        MIME_SEARCH_PARTIAL_MATCH);

    if (nMessageId != MIME_ERROR)
    {
        CMailMessage mailMessage;

        // Get a copy of the message that was found
        if (mailStorage.GetMessage(nMessageId, mailMessage))
        {
            // Store the message in a file
            TCHAR szFileName[MAX_PATH];
            BOOL bExported;

            // Create a filename based on the message number
            wsprintf(szFileName, _T("msg%05ld.tmp"), nMessageId);

            // Export the message to a file
            bExported = mailMessage.ExportMessage(szFileName);
        }

        // Increase the message ID to resume the search at the next message
        nMessageId++;
    }
}

mailStorage.CloseFile();
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csmsgv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

CMessageStore::GetErrorString Method

```
INT GetErrorString(  
    DWORD dwErrorCode,  
    LPTSTR lpszDescription,  
    INT cbDescription  
);
```

The **GetErrorString** method is used to return a description of a specific error code. Typically this is used in conjunction with the **GetLastError** method for use with warning dialogs or as diagnostic messages.

Parameters

dwErrorCode

The error code for which a description is returned.

lpszDescription

A pointer to the buffer that will contain a description of the specified error code. This buffer should be at least 128 characters in length.

cbDescription

The maximum number of characters that may be copied into the description buffer.

Return Value

If the method succeeds, the return value is the length of the description string. If the method fails, the return value is zero, meaning that no description exists for the specified error code. Typically this indicates that the error code passed to the method is invalid.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csmsgv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

[GetLastError](#), [SetLastError](#)

CMessageStore::GetHandle Method

```
HMESSAGESTORE GetHandle();
```

The **GetHandle** method returns the message store handle associated with the current instance of the class.

Parameters

None.

Return Value

This method returns the message store handle associated with the current instance of the class object. If there is no current message, the value `INVALID_MESSAGESTORE` will be returned.

Remarks

This method is used to obtain the message store handle created by the class for use with the SocketTools API.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csmsgv10.lib`

See Also

[AttachHandle](#), [DetachHandle](#), [IsInitialized](#)

CMessageStore::GetLastError Method

```
DWORD GetLastError();  
  
DWORD GetLastError(  
    CString& strDescription  
);
```

Parameters

strDescription

A string which will contain a description of the last error code value when the method returns. If no error has been set, or the last error code has been cleared, this string will be empty.

Return Value

The return value is the last error code value for the current thread. Functions set this value by calling the **SetLastError** method. The Return Value section of each reference page notes the conditions under which the method sets the last error code.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. You should call the **GetLastError** method immediately when a method's return value indicates that an error has occurred. That is because some methods call **SetLastError(0)** when they succeed, clearing the error code set by the most recently failed method.

Most methods will set the last error code value when they fail; a few methods set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_MESSAGESTORE or MIME_ERROR. Those methods which call **SetLastError** when they succeed are noted on the method reference page.

The description of the error code is the same string that is returned by the **GetErrorString** method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmsgv10.lib

[GetErrorString](#), [SetLastError](#), [ShowError](#)

CMessageStore::GetMessage Method

```
BOOL GetMessage(  
    LONG nMessageId,  
    CMailMessage& mailMessage  
);  
  
HMESSAGE GetMessage(  
    LONG nMessageId,  
    DWORD dwOptions  
);
```

The **GetMessage** method retrieves a message from the current message store.

Parameters

nMessageId

An integer value which specifies the message number that should be retrieved. The first message in the message store has a value of one.

mailMessage

A **CMailMessage** object which will reference the message that is retrieved from the message store.

dwOptions

A value which specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
0	A shared message handle returned by the function. The contents of this message will be overwritten each time this function is called.
MIME_COPY_STORED_MESSAGE	A message handle is allocated for a copy of the message that is retrieved from the message store.

Return Value

If the first form of the method succeeds the return value is non-zero, otherwise the return value is zero. If the second form of the message succeeds it returns a message handle, otherwise it returns **INVALID_MESSAGE**. To get extended error information, call **GetLastError**.

Remarks

The second form of the **GetMessage** method returns a message handle for the specified message in the message store. If no options are specified, a temporary message handle is returned that is only valid until the next message is retrieved. If a multithreaded application changes the contents of the temporary message, it will change for all other threads that have obtained a message handle using this function.

If the application must have a unique copy of the message, the **MIME_COPY_STORED_MESSAGE** option should be specified. Instead of returning a handle to a shared message, the message is duplicated and a handle to that copy of the message is returned. If a reference to a **CMailMessage** object is passed to the first form of this method, this option is used to create a copy of the message.

Example

```
CMessageStore mailStorage;
LPCTSTR lpszHeader = _T("From");
LPCTSTR lpszAddress = _T("jsmith@example.com");
LONG nMessageId = 1;

if (! mailStorage.OpenFile(lpszFileName))
{
    // Unable to open the storage file
    return;
}

// Begin searching for messages from the specified sender
while (nMessageId != MIME_ERROR)
{
    nMessageId = mailStorage.FindMessage(nMessageId,
                                        lpszHeader,
                                        lpszAddress,
                                        MIME_SEARCH_PARTIAL_MATCH);

    if (nMessageId != MIME_ERROR)
    {
        CMailMessage mailMessage;

        // Get a copy of the message that was found
        if (mailStorage.GetMessage(nMessageId, mailMessage))
        {
            // Store the message in a file
            TCHAR szFileName[MAX_PATH];
            BOOL bExported;

            // Create a filename based on the message number
            wsprintf(szFileName, _T("msg%05ld.tmp"), nMessageId);

            // Export the message to a file
            bExported = mailMessage.ExportMessage(szFileName);
        }

        // Increase the message ID to resume the search at the next message
        nMessageId++;
    }
}

mailStorage.CloseFile();
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmsgv10.lib

See Also

[CMailMessage](#), [DeleteMessage](#), [FindMessage](#), [GetMessageCount](#), [StoreMessage](#)

CMessageStore::GetMessageCount Method

```
BOOL GetMessageCount(  
    LPLONG lpnLastMessage  
);
```

The **GetMessageCount** method returns the number of messages in the current message store.

Parameters

lpnLastMessage

A pointer to an integer which will contain the message number for the last message in the storage file. If this information is not required, a NULL pointer may be specified.

Return Value

If the method succeeds, the return value is the number of messages in the message store. If the method fails, the return value is MIME_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetMessageCount** method returns the number of messages in the message store. It is important to note that does not count those messages which have been marked for deletion. This means that the value returned by this function will decrease as messages are deleted.

The message number returned in the *lpnLastMessage* parameter will specify the total number of messages in the message store, including deleted messages.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[DeleteMessage](#), [FindMessage](#), [GetMessage](#)

CMessageStore::IsInitialized Method

```
BOOL IsInitialized();
```

The **IsInitialized** method returns whether or not the class object has been successfully initialized.

Return Value

This method returns a non-zero value if the class object has been successfully initialized. A return value of zero indicates that the runtime license key could not be validated.

Remarks

When an instance of the class is created, the class constructor will attempt to initialize the component with the runtime license key that was created when SocketTools was installed. If the constructor is unable to validate the license key the initialization will fail.

If SocketTools was installed with an evaluation license, the application cannot be redistributed to another system. The class object will fail to initialize if the application is executed on another system, or if the evaluation period has expired. To redistribute your application, you must purchase a development license which will include the runtime key that is needed to redistribute your software to other systems. Refer to the Developer's Guide for more information.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmsgv10.lib

[CMessageStore](#)

CMessageStore::OpenFile Method

```
BOOL OpenFile(  
    LPCTSTR lpszFileName,  
    DWORD dwOpenMode  
);
```

The **OpenFile** method opens the specified message storage file.

Parameters

lpszFileName

A pointer to a string which specifies the name of the storage file.

dwOpenMode

A value which specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
MIME_STORAGE_READ	The message store will be opened for read access. The contents of the message store can be accessed, but cannot be modified by the process unless it has also been opened for writing.
MIME_STORAGE_WRITE	The message store will be opened for writing. This mode also implies read access and must be specified if the application needs to modify the contents of the message store.
MIME_STORAGE_CREATE	The message store will be created if the storage file does not exist. If the file exists, it will be truncated. This mode implies read and write access.
MIME_STORAGE_LOCK	The message store will be opened so that it may only be accessed and modified by the current process.
MIME_STORAGE_COMPRESS	The contents of the message store are compressed. This option is automatically enabled if a compressed message store is opened for reading or writing.
MIME_STORAGE_MAILBOX	The message store should use the UNIX mbox format when reading and storing messages. This option is provided for backwards compatibility and is not recommended for general use.

Return Value

If the method succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **OpenFile** method opens a message storage file which contains one or more messages. If the storage file is opened for read access, the application can search the message store and extract messages but it cannot add or delete messages. To add new messages or delete existing messages from the store, it must be opened with write access.

The message store is designed to be a simple, effective way to store multiple messages together in a single file. When the message store is opened, the contents are indexed in memory. Although there is no specific limit to the number of messages that can be stored, there must be sufficient memory available to build an index of each message and its headers. If the application must store and manage a very large number of messages, it is recommended that you use a database rather than a flat-file message store.

Message Store Format

Each message is prefixed by a control sequence of five ASCII 01 characters followed by an ASCII 10 and ASCII 13 character. The messages themselves are stored unmodified in their original text format. The length of each message is calculated based on the location of the control sequence that delimits each message, and explicit message lengths are not stored in the file. This means that it is safe to manually change the message contents, as long as the message delimiters are preserved.

If the message store is compressed, the contents of the storage file are expanded when the file is opened and then re-compressed when the storage file is closed. Using the `MIME_STORAGE_COMPRESS` option reduces the size of the storage file and prevents the contents of the message store from being read using a text file editor. However, enabling compression will increase the amount of memory allocated by the library and can increase the amount of time that it takes to open and close the storage file.

The class also has a backwards compatibility mode where it will recognize storage files that use the UNIX mbox format. While this format is supported for accessing existing files, it is not recommended that you use it when creating new message stores or adding messages to an existing store. There are a number of different variants on the mbox format that have been used by different Mail Transfer Agents (MTAs) on the UNIX platform. For example, the `mboxrd` variant looks identical to the `mboxcl2` variant, and they are programmatically indistinguishable from one another, but they are not compatible. For this reason, the use of the mbox format is strongly discouraged.

Example

```
CMailMessage mailMessage;

// Compose a new message
mailMessage.ComposeMessage(lpszSender,
                           lpszRecipient,
                           NULL,
                           lpszSubject,
                           lpszMessage,
                           NULL,
                           MIME_CHARSET_DEFAULT,
                           MIME_ENCODING_DEFAULT);

CMessageStore mailStorage;

// Open the message storage file
if (mailStorage.OpenFile(lpszFileName, MIME_STORAGE_WRITE))
{
    // Store a copy of the message in the message store
    nMessageId = mailStorage.StoreMessage(mailMessage);

    if (nMessageId == MIME_ERROR)
    {
        // We were unable to store the message
    }
}
```

```
    }  
  
    // Close the message store  
    mailStorage.CloseFile();  
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[CloseFile](#), [FindMessage](#), [GetMessage](#), [GetMessageCount](#), [PurgeFile](#)

CMessageStore::PurgeFile Method

```
BOOL PurgeFile();
```

The **PurgeFile** method purges all deleted messages from the specified message store.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **PurgeFile** method purges all deleted messages from the message store. If the storage file has been opened in read-only mode or there are no messages marked for deletion, this method will take no action.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmsgv10.lib

See Also

[CopyFile](#), [DeleteMessage](#), [FindMessage](#), [GetMessage](#)

CMessageStore::ReplaceMessage Method

```
BOOL ReplaceMessage(  
    LONG nMessageId,  
    CMailMessage& mailMessage  
);
```

```
BOOL ReplaceMessage(  
    LONG nMessageId,  
    HMESSAGE hMessage  
);
```

The **MimeReplaceStoredMessage** function replaces the contents of the specified message in a message store.

Parameters

nMessageId

An integer value which specifies the message number that should be replaced.

mailMessage

A **CMailMessage** object which references the message that will be stored.

hMessage

Handle to the message that will be stored.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **MimeGetLastError**.

Remarks

The **ReplaceMessage** method replaces the specified message with a new message. The message number may be a message that has been previously marked for deletion. It is important to note that the change will not be reflected in the physical storage file until it has been closed. If the application needs to replace messages in the message store, it is recommended that the file be opened for exclusive access using the MIME_STORAGE_LOCK option.

Example

```
CMailMessage mailMessage;  
  
// Compose a new message  
mailMessage.ComposeMessage(lpszSender,  
                           lpszRecipient,  
                           NULL,  
                           lpszSubject,  
                           lpszMessage);  
  
CMessageStore mailStorage;  
  
if (mailStorage.OpenFile(lpszFileName, MIME_STORAGE_WRITE))  
{  
    LONG nLastMessage = 0;  
  
    // Get the last message number in the message store  
    mailStorage.GetMessageCount(&nLastMessage);
```

```
if (nLastMessage > 0)
{
    // Replace the last message in the message store
    if (!mailStorage.ReplaceMessage(nLastMessage, mailMessage))
    {
        // We were unable to replace the message
    }
}

// Close the message store
mailStorage.CloseFile();
}
```

Requirements

    DWORD dwErrorCode  
);
```

The **SetLastError** method sets the last error code for the current thread. This method is typically used to clear the last error by specifying a value of zero as the parameter.

Parameters

dwErrorCode

Specifies the last error code for the current thread.

Return Value

None.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. Most methods will set the last error code value when they fail; a few methods set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_MESSAGESTORE or MIME_ERROR. Those methods which call **SetLastError** when they succeed are noted on the method reference page.

Applications can retrieve the value saved by this method by using the **GetLastError** method. The use of **GetLastError** is optional; an application can call the method to determine the specific reason for a method failure.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmsgv10.lib

[GetErrorString](#), [GetLastError](#), [ShowError](#)

CMessageStore::ShowError Method

```
INT ShowError(  
    LPCTSTR lpszAppTitle,  
    UINT uType,  
    DWORD dwErrorCode  
);
```

The **ShowError** method displays a message box which describes the specified error.

Parameters

lpszAppTitle

A pointer to a string which specifies the title of the message box that is displayed. If this argument is NULL or omitted, then the default title of "Error" will be displayed.

uType

An unsigned integer which specifies the type of message box that will be displayed. This is the same value that is used by the **MessageBox** method in the Windows API. If a value of zero is specified, then a message box with a single OK button will be displayed. Refer to that method for a complete list of options.

dwErrorCode

Specifies the error code that will be used when displaying the message box. If this argument is zero, then the last error that occurred in the current thread will be displayed.

Return Value

If the method is successful, the return value will be the return value from the **MessageBox** function. If the method fails, it will return a value of zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmsgv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

CMessageStore::StoreMessage Method

```
LONG StoreMessage(  
    CMailMessage& mailMessage  
);  
  
LONG StoreMessage(  
    HMESSAGE hMessage  
);
```

The **StoreMessage** method stores the specified message in the current message store.

Parameters

hStorage

Handle to the message store.

mailMessage

A **CMailMessage** object which references the message that will be stored.

hMessage

Handle to the message that will be stored.

Return Value

If the method succeeds, the return value is the message number for the message that was just stored. If the method fails, the return value is `MIME_ERROR`. To get extended error information, call **GetLastError**.

Remarks

The **StoreMessage** method will always append the specified message to the storage file. If you want to replace a message in the message store, you should use the **DeleteMessage** method to mark the original message for deletion and then use **StoreMessage** to write the updated message to the message store.

Example

```
CMailMessage mailMessage;  
  
// Compose a new message  
mailMessage.ComposeMessage(lpszSender,  
                           lpszRecipient,  
                           NULL,  
                           lpszSubject,  
                           lpszMessage,  
                           NULL,  
                           MIME_CHARSET_DEFAULT,  
                           MIME_ENCODING_DEFAULT);  
  
CMessageStore mailStorage;  
  
// Open the message storage file  
if (mailStorage.OpenFile(lpszFileName, MIME_STORAGE_WRITE))  
{  
    // Store a copy of the message in the message store  
    nMessageId = mailStorage.StoreMessage(mailMessage);  
  
    if (nMessageId == MIME_ERROR)
```

```
{  
    // We were unable to store the message  
}  
  
// Close the message store  
mailStorage.CloseFile();  
}
```

Requirements

Time Protocol Class Library

Query a time server for the current time and synchronize the local system clock with that value.

Reference

- [Class Methods](#)
- [Data Structures](#)
- [Error Codes](#)

Library Information

Class Name	CNetworkTime
File Name	CSTIMV10.DLL
Version	10.0.1468.2518
LibID	7E65DD9F-5799-42FA-A72D-EC0B714E3021
Import Library	CSTIMV10.LIB
Dependencies	None
Standards	RFC 868

Overview

The Time Protocol class provides an interface for synchronizing the local system's time and date with that of a server. The time values returned are in Coordinated Universal and be adjusted for the local host's timezone. The library enables developers to query a server for the current time and then update the system clock if desired.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). If you are using Visual C++ 6.0 it is required that you have Service Pack 6 (SP6) installed. You should install all updates for your development tools and have the current Windows SDK installed. The minimum recommended version of Visual Studio is Visual Studio 2010.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are using Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. It is recommended that you install the current service pack and all critical updates available for your version of the operating system.

This product includes both 32-bit and 64-bit libraries. Native 64-bit CPU support requires the 64-bit version of Windows 7 or later versions of the Windows operating system.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

Time Protocol Class Methods

Class	Description
CNetworkTime	Constructor which initializes the current instance of the class
~CNetworkTime	Destructor which releases resources allocated by the class
Method	Description
ConvertTime	Convert between network and system time values
DisableTrace	Disable logging of socket function calls to the trace log
EnableTrace	Enable logging of socket function calls to a file
GetErrorString	Return a description for the specified error code
GetLastError	Return the last error code
GetTime	Return the current network time from the server
IsInitialized	Determine if the class has been successfully initialized
SetLastError	Set the last error code
SetTime	Set the local system time with the network time

CNetworkTime::CNetworkTime Method

```
CNetworkTime();
```

The **CNetworkTime** constructor initializes the class library and validates the license key at runtime.

Remarks

If the constructor fails to validate the runtime license, subsequent methods in this class will fail. If the product is installed with an evaluation license, then the application will only function on the development system and cannot be redistributed.

The constructor calls the **TimeInitialize** function to initialize the library, which dynamically loads other system libraries and allocates thread local storage. If you are using this class within another DLL, it is important that you do not create or destroy an instance of the class from within the **DllMain** function because it can result in deadlocks or access violation errors. You should not declare static or global instances of this class within another DLL if it is linked with the C runtime library (CRT) because it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstimv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[~CNetworkTime](#), [IsInitialized](#)

CNetworkTime::~~CNetworkTime

`~CNetworkTime();`

The **CNetworkTime** destructor releases resources allocated by the current instance of the **CNetworkTime** object. It also uninitialized the library if there are no other concurrent uses of the class.

Remarks

When a **CNetworkTime** object goes out of scope, the destructor is automatically called to allow the library to free any resources allocated on behalf of the process. Any pending blocking or asynchronous calls in this process are canceled without posting any notification messages, and all handles that were created for the client session are destroyed.

The destructor is not called explicitly by the application.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `cstimv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

[CNetworkTime](#)

CNetworkTime::ConvertTime Method

```
BOOL ConvertTime(  
    DWORD dwNetworkTime,  
    LPLONG lpnUnixTime  
);  
  
BOOL ConvertTime(  
    DWORD dwNetworkTime,  
    CTime& LocalTime  
);  
  
BOOL ConvertTime(  
    DWORD dwNetworkTime,  
    LPSYSTEMTIME lpSystemTime,  
    BOOL bLocalTime  
);  
  
BOOL ConvertTime(  
    LPSYSTEMTIME lpSystemTime,  
    LPDWORD lpdwNetworkTime  
);
```

The **ConvertTime** method converts between a 32-bit network time value and a SYSTEMTIME structure.

Parameters

dwNetworkTime

The network time to be converted.

lpnUnixTime

A pointer to a long integer which will contain the time in UNIX format. The value is the number of seconds since 1 January 1970 UTC and is commonly used with the standard C library time functions.

localTime

A **CTime** object which will contain the local time when the method returns.

lpSystemTime

A pointer to a **SYSTEMTIME** structure which will be modified for the specified network time.

bLocalTime

A boolean flag that is used to specify if the network time should be adjusted for the local timezone.

Return Value

If the network time could be converted, the method returns a non-zero value. If the network time cannot be converted, or the pointer to the SYSTEMTIME structure is invalid, the method will return zero.

Remarks

The network time value is a 32-bit number, represented as the number of seconds since midnight, 1 January 1900 UTC. It can represent a date and time up to the year 2036.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstimv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[GetTime](#), [SetTime](#)

CNetworkTime::DisableTrace Method

```
BOOL DisableTrace();
```

The **DisableTrace** method disables the logging of socket function calls to the trace log.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, a value of zero is returned.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstimv10.lib

See Also

[EnableTrace](#)

CNetworkTime::EnableTrace Method

```
BOOL EnableTrace(  
    LPCTSTR lpszTraceFile,  
    DWORD dwTraceFlags  
);
```

The **EnableTrace** method enables the logging of socket function calls to a file.

Parameters

lpszTraceFile

A pointer to a string which specifies the name of the trace log file. If this parameter is NULL or an empty string, the default file name **cstrace.log** is used. The file is stored in the directory specified by the TEMP environment variable, if it is defined; otherwise, the current working directory is used.

dwTraceFlags

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
TRACE_INFO	All function calls are written to the trace file. This is the default value.
TRACE_ERROR	Only those function calls which fail are recorded in the trace file.
TRACE_WARNING	Only those function calls which fail or return values which indicate a warning are recorded in the trace file.
TRACE_HEXDUMP	All functions calls are written to the trace file, plus all the data that is sent or received is displayed, in both ASCII and hexadecimal format.
TRACE_PROCESS	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for multithreaded applications that are using worker threads.

Return Value

If the method succeeds, the return value is non-zero. A return value of zero indicates an error. Failure typically indicates that the tracing library **cstrcv10.dll** cannot be loaded on the local system.

Remarks

When trace logging is enabled, the file is opened, appended to and closed for each socket function call. This makes it possible for an application to append its own logging information, however care should be taken to ensure that the file is closed before the next network operation is performed. To limit the size of the log files, enable and disable logging only around those sections of code that you wish to trace.

Note that the TRACE_HEXDUMP trace level generates very large log files since it includes all of the data exchanged between your application and the server.

Trace method logging is managed on a per-thread basis, not for each client handle. This means that all SocketTools libraries and components share the same settings in the current thread. If you

are using multiple SocketTools libraries or components in your application, you only need to enable logging once.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstimv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[DisableTrace](#)

CNetworkTime::GetErrorString Method

```
INT GetErrorString(  
    DWORD dwErrorCode,  
    LPTSTR lpszDescription,  
    INT cbDescription  
);  
  
INT GetErrorString(  
    DWORD dwErrorCode,  
    CString& strDescription  
);
```

The **GetErrorString** method is used to return a description of a specific error code. Typically this is used in conjunction with the **GetLastError** method for use with warning dialogs or as diagnostic messages.

Parameters

dwErrorCode

The error code for which a description is returned.

lpszDescription

A pointer to the buffer that will contain a description of the specified error code. This buffer should be at least 128 characters in length. An alternate form of the method accepts a **CString** variable which will contain the error description.

cbDescription

The maximum number of characters that may be copied into the description buffer.

Return Value

If the method succeeds, the return value is the length of the description string. If the method fails, the return value is zero, meaning that no description exists for the specified error code. Typically this indicates that the error code passed to the method is invalid.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cstimv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[GetLastError](#), [SetLastError](#), [ShowError](#)

CNetworkTime::GetLastError Method

```
DWORD GetLastError();  
  
DWORD GetLastError(  
    CString& strDescription  
);
```

Parameters

strDescription

A string which will contain a description of the last error code value when the method returns. If no error has been set, or the last error code has been cleared, this string will be empty.

Return Value

The return value is the last error code value for the current thread. Functions set this value by calling the **SetLastError** method. The Return Value section of each reference page notes the conditions under which the method sets the last error code.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. You should call the **GetLastError** method immediately when a method's return value indicates that an error has occurred. That is because some methods call **SetLastError(0)** when they succeed, clearing the error code set by the most recently failed method.

Most methods will set the last error code value when they fail; a few methods set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or TIME_ERROR. Those methods which call **SetLastError** when they succeed are noted on the method reference page.

The description of the error code is the same string that is returned by the **GetErrorString** method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cstimv10.lib

See Also

[GetErrorString](#), [SetLastError](#), [ShowError](#)

CNetworkTime::GetTime Method

```
BOOL GetTime(  
    LPCTSTR lpszRemoteHost,  
    UINT nRemotePort,  
    LPDWORD lpdwNetworkTime  
    UINT nTimeout  
);  
  
BOOL GetTime(  
    LPCTSTR lpszRemoteHost,  
    UINT nRemotePort,  
    LPSYSTEMTIME lpSystemTime  
    UINT nTimeout  
);  
  
BOOL GetTime(  
    LPCTSTR lpszRemoteHost,  
    UINT nRemotePort,  
    CTime& LocalTime  
    UINT nTimeout  
);
```

The **GetTime** method returns the network time from the specified host.

Parameters

lpszRemoteHost

A pointer to the name of the server. The host must be running a time server that complies with the specifications outlined in RFC 868.

nRemotePort

The port the time server is running on. A value of zero indicates that the default port number for the service should be used. By default, port 37 is used to connect to the time server.

lpdwNetworkTime

A pointer to an unsigned 32-bit integer which will contain the current network time when the method returns. Note that this value is not the same as UNIX time and cannot be used with the standard C time functions.

lpSystemTime

A pointer to a [SYSTEMTIME](#) structure that will contain the system time when the method returns. This structure can be used with many of the standard Windows API time-related functions.

localTime

A **CTime** object that will contain the local time when the method returns.

nTimeout

The number of seconds that the method will wait for a response from the server.

Return Value

If the method succeeds, it returns the number of seconds since midnight, 1 January 1900 UTC. If the method was unable to obtain the time from the specified host, it returns zero.

Remarks

The network time is a 32-bit number, represented as the number of seconds since midnight, 1 January 1900 UTC. It can represent a date and time up to the year 2036. It is important to note that the network time value is not the same as the UNIX time value that is used the standard C library time functions. To convert between network time and other time values, use the **ConvertTime** method.

In the United States, the National Institute of Standards and Technology (NIST) hosts a number of public servers which can be used to obtain the current time. The following table lists the current host names and addresses:

Server Name	IP Address	Location
time-a.nist.gov	129.6.15.28	Gaithersburg, Maryland
time-b.nist.gov	129.6.15.29	Gaithersburg, Maryland
time-nw.nist.gov	131.107.13.100	Redmond, Washington
time-a.timefreq.bldrdoc.gov	132.163.4.101	Boulder, Colorado
time-b.timefreq.bldrdoc.gov	132.163.4.102	Boulder, Colorado
time-c.timefreq.bldrdoc.gov	132.163.4.103	Boulder, Colorado

Time servers are also commonly maintained by Internet service providers and universities. If you are unable to obtain the time from a server, contact the system administrator to determine if they have the standard time service available on port 37.

Example

```
CNetworkTime netTime;
DWORD dwNetworkTime;

// Get the current time from a NIST time server
if (netTime.GetTime(_T("time-nw.nist.gov"), &dwNetworkTime))
{
    // Convert the network time value to a CTime object
    CTime localTime;
    netTime.ConvertTime(dwNetworkTime, localTime);

    // Format the time string and create a message to display
    // to the user, asking if they want to update the time
    CString strTime;
    strTime = localTime.Format(_T("%B %d, %Y %H:%M:%S"));

    CString strMessage;
    strMessage.Format(_T("Update system time to %s?"), (LPCTSTR)strTime);

    INT nResult;
    nResult = AfxMessageBox(strMessage, MB_YESNO|MB_ICONQUESTION);

    if (nResult == IDYES)
    {
        // Update the local system time with the network time
        if (netTime.SetTime(dwNetworkTime) == FALSE)
            netTime.ShowError();
    }
}
else
{
```

```
    netTime.ShowError();  
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstimv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[ConvertTime](#), [SetTime](#)

CNetworkTime::IsInitialized Method

```
BOOL IsInitialized();
```

The **IsInitialized** method returns whether or not the class object has been successfully initialized.

Parameters

None.

Return Value

This method returns a non-zero value if the class object has been successfully initialized. A return value of zero indicates that the runtime license key could not be validated or the networking library could not be loaded by the current process.

Remarks

When an instance of the class is created, the class constructor will attempt to initialize the component with the runtime license key that was created when SocketTools was installed. If the constructor is unable to validate the license key or load the networking libraries, this initialization will fail.

If SocketTools was installed with an evaluation license, the application cannot be redistributed to another system. The class object will fail to initialize if the application is executed on another system, or if the evaluation period has expired. To redistribute your application, you must purchase a development license which will include the runtime key that is needed to redistribute your software to other systems. Refer to the Developer's Guide for more information.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstimv10.lib

See Also

[CNetworkTime](#)

CNetworkTime::SetLastError Method

```
VOID SetLastError(  
    DWORD dwErrorCode  
);
```

The **SetLastError** method sets the error code for the current thread. This method is typically used to clear the last error by passing a value of zero as the parameter.

Parameters

dwErrorCode

Specifies the error code for the current thread.

Return Value

None.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. Most methods will set the last error code value when they fail; a few methods set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or TIME_ERROR. Those methods which call **SetLastError** when they succeed are noted on the method reference page.

Applications can retrieve the value saved by this method by using the **GetLastError** method. The use of **GetLastError** is optional; an application can call the method to determine the specific reason for a method failure.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cstimv10.lib

CNetworkTime::SetTime Method

```
BOOL SetTime(  
    DWORD dwNetworkTime  
);  
  
BOOL SetTime(  
    LPSYSTEMTIME lpSystemTime  
);
```

The **SetTime** method sets the local system clock to the specified date and time.

Parameters

dwNetworkTime

The date and time the system clock should be set to, represented as the number of seconds since midnight, 1 January 1900.

lpSystemTime

A pointer to a [SYSTEMTIME](#) structure that specifies the date and time that the local clock should be set to.

Return Value

If the method is able to update the local time, it returns a non-zero value. If the specified time is invalid, or the user does not have the access rights to change the system clock, the method returns zero.

Remarks

The network time value is an unsigned 32-bit integer which can represent a date and time up to the year 2036. It is important to note that this is not the same as the UNIX time value which is used by the standard C library.

You must have administrator privileges in order to set the system clock.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `cstimv10.lib`

CNetworkTime::ShowError Method

```
INT ShowError(  
    LPCTSTR lpszAppTitle,  
    UINT uType,  
    DWORD dwErrorCode  
);
```

The **ShowError** method displays a message box which describes the specified error.

Parameters

lpszAppTitle

A pointer to a string which specifies the title of the message box that is displayed. If this argument is NULL or omitted, then the default title of "Error" will be displayed.

uType

An unsigned integer which specifies the type of message box that will be displayed. This is the same value that is used by the **MessageBox** method in the Windows API. If a value of zero is specified, then a message box with a single OK button will be displayed. Refer to that method for a complete list of options.

dwErrorCode

Specifies the error code that will be used when displaying the message box. If this argument is zero, then the last error that occurred in the current thread will be displayed.

Return Value

If the method is successful, the return value will be the return value from the **MessageBox** function. If the method fails, it will return a value of zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cstimv10.lib

Unicode: Implemented as Unicode and ANSI versions.

Time Protocol Data Structures

- SYSTEMTIME

SYSTEMTIME Structure

The **SYSTEMTIME** structure represents a date and time using individual members for the month, day, year, weekday, hour, minute, second, and millisecond.

```
typedef struct _SYSTEMTIME
{
    WORD wYear;
    WORD wMonth;
    WORD wDayOfWeek;
    WORD wDay;
    WORD wHour;
    WORD wMinute;
    WORD wSecond;
    WORD wMilliseconds;
} SYSTEMTIME, *LPSYSTEMTIME;
```

Members

wYear

Specifies the current year. The year value must be greater than 1601.

wMonth

Specifies the current month. January is 1, February is 2 and so on.

wDayOfWeek

Specifies the current day of the week. Sunday is 0, Monday is 1 and so on.

wDay

Specifies the current day of the month

wHour

Specifies the current hour.

wMinute

Specifies the current minute

wSecond

Specifies the current second.

wMilliseconds

Specifies the current millisecond.

Requirements

Library Information

Class Name	CNntpClient
File Name	CSNWSV10.DLL
Version	10.0.1468.2518
LibID	F37CEE4C-BAFE-43B9-B224-80975DF553B2
Import Library	CSNWSV10.LIB
Dependencies	None
Standards	RFC 977, RFC 2980

Overview

The Network News Transfer Protocol (NNTP) is used with servers that provide news services. This is similar in functionality to bulletin boards or message boards, where topics are organized hierarchically into groups, called newsgroups. Users can browse and search for messages, called news articles, which have been posted by other users. On many servers, they can also post their own articles which can be read by others. The largest collection of public newsgroups available is called USENET, a world-wide distributed discussion system. In addition, there are a large number of smaller news servers. For example, Catalyst Development operates a news server which methods as a forum for technical questions and announcements.

The SocketTools library provides a comprehensive interface for accessing newsgroups, retrieving articles and posting new articles. In combination with the Mail Message library to process the news articles, SocketTools can be used to integrate newsgroup access with an existing email application, or you can implement your own full-featured newsgroup client.

This library supports secure connections using the standard SSL and TLS protocols.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). If you are using Visual C++ 6.0 it is required that you have Service Pack 6 (SP6) installed. You should install all updates for your development tools and have the current Windows SDK installed. The minimum recommended version of Visual Studio is Visual Studio 2010.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are using Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. It is recommended that you install the current service pack and all critical updates available for your version of the operating system.

This product includes both 32-bit and 64-bit libraries. Native 64-bit CPU support requires the 64-

bit version of Windows 7 or later versions of the Windows operating system.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

Network News Transfer Protocol Class Methods

Class	Description
CNntpClient	Constructor which initializes the current instance of the class
~CNntpClient	Destructor which releases resources allocated by the class
Method	Description
AttachHandle	Attach the specified client handle to this instance of the class
AttachThread	Attach the specified client handle to another thread
Authenticate	Authenticate the specified user on the news server
Cancel	Cancel the current blocking operation
CloseArticle	Close the article being posted to the current newsgroup
Command	Send a command to the server
Connect	Connect to the specified server
CreateArticle	Create a new article in the current newsgroup
CreateSecurityCredentials	Create a new security credentials structure
DeleteSecurityCredentials	Delete a previously created security credentials structure
DetachHandle	Detach the handle for the current instance of this class
DisableEvents	Disable asynchronous event notification
DisableTrace	Disable logging of socket function calls to the trace log
Disconnect	Disconnect from the current server
EnableEvents	Enable asynchronous event notification
EnableTrace	Enable logging of socket function calls to a file
FreezeEvents	Suspend asynchronous event processing
GetArticle	Copy the specified article to a local buffer
GetArticleHeaders	Return the contents of the specified article header
GetArticleMessageId	Return the message identifier for the specified article
GetArticleRange	Return the first and last article number for the current group
GetCurrentArticle	Return the current article number for the selected group
GetCurrentDate	Return the current date and time
GetErrorString	Return a description for the specified error code
GetFirstArticle	Return the first available article in the currently selected newsgroup
GetFirstGroup	Return the first available newsgroup from the server
GetHandle	Return the client handle used by this instance of the class
GetGroupName	Return the name of the currently selected newsgroup

GetGroupTitle	Return a description of the currently selected newsgroup
GetLastError	Return the last error code
GetMessageIdArticle	Return the article number for the specified message identifier
GetNextArticle	Return the next available article from the currently selected newsgroup
GetNextGroup	Return the next available newsgroup from the server
GetResultCode	Return the result code from the previous command
GetResultString	Return the result string from the previous command
GetSecurityInformation	Return security information about the current client connection
GetStatus	Return the current client status
GetTimeout	Return the number of seconds until an operation times out
GetTransferStatus	Return data transfer statistics
IsBlocking	Determine if the client is blocked, waiting for information
IsConnected	Determine if the client is connected to the server
IsInitialized	Determine if the class has been successfully initialized
IsReadable	Determine if data can be read from the server
IsWritable	Determine if data can be written to the server
ListArticles	Return a list of articles in the currently selected newsgroup
ListGroups	Return a list of newsgroups maintained by the server
NntpEventProc	Callback method that processes events generated by the client
OpenArticle	Open the specified article in the currently selected newsgroup
OpenNextArticle	Open the next available article
OpenPreviousArticle	Open the previous article
PostArticle	Post a new article to the news server
Read	Read data returned by the news server
RegisterEvent	Register an event callback function
Reset	Reset the client
SelectGroup	Select the specified newsgroup to retrieve articles from
SetLastError	Set the last error code
SetTimeout	Set the number of seconds until an operation times out
ShowError	Display a message box with a description of the specified error
StoreArticle	Store the specified article to a file on the local system
Write	Write data to the news server

CNntpClient::CNntpClient Method

CNntpClient();

The **CNntpClient** constructor initializes the class library and validates the license key at runtime.

Remarks

If the constructor fails to validate the runtime license, subsequent methods in this class will fail. If the product is installed with an evaluation license, then the application will only function on the development system and cannot be redistributed.

The constructor calls the **NntpInitialize** function to initialize the library, which dynamically loads other system libraries and allocates thread local storage. If you are using this class within another DLL, it is important that you do not create or destroy an instance of the class from within the **DllMain** function because it can result in deadlocks or access violation errors. You should not declare static or global instances of this class within another DLL if it is linked with the C runtime library (CRT) because it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnwsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[~CNntpClient](#), [IsInitialized](#)

CNntpClient::~CNntpClient

`~CNntpClient();`

The **CNntpClient** destructor releases resources allocated by the current instance of the **CNntpClient** object. It also uninitialized the library if there are no other concurrent uses of the class.

Remarks

When a **CNntpClient** object goes out of scope, the destructor is automatically called to allow the library to free any resources allocated on behalf of the process. Any pending blocking or asynchronous calls in this process are canceled without posting any notification messages, and all handles that were created for the client session are destroyed.

The destructor is not called explicitly by the application.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csnwsv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

See Also

[CNntpClient](#)

CNntpClient::AttachHandle Method

```
VOID AttachHandle(  
    HCLIENT hClient  
);
```

The **AttachHandle** method attaches the specified client handle to the current instance of the class.

Parameters

hClient

The handle to the client session that will be attached to the current instance of the class object.

Return Value

None.

Remarks

This method is used to attach a client handle created outside of the class using the SocketTools API. Once the client handle is attached to the class, the other class member functions may be used with that client session.

If a client handle already has been created for the class, that handle will be released when the new handle is attached to the class object. If you want to prevent the previous client session from being terminated, you must call the **DetachHandle** method. Failure to release the detached handle may result in a resource leak in your application.

Note that the *hClient* parameter is presumed to be a valid client handle and no checks are performed to ensure that the handle is valid. Specifying an invalid client handle will cause subsequent method calls to fail.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnwsv10.lib

See Also

[AttachThread](#), [DetachHandle](#), [GetHandle](#)

CNntpClient::AttachThread Method

```
DWORD AttachThread(  
    DWORD dwThreadId  
);
```

The **AttachThread** method attaches the specified client handle to another thread.

Parameters

dwThreadId

The ID of the thread that will become the new owner of the handle. A value of zero specifies that the current thread should become the owner of the client handle.

Return Value

If the method succeeds, the return value is the thread ID of the previous owner. If the method fails, the return value is NNTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

When a client handle is created, it is associated with the current thread that created it. Normally, if another thread attempts to perform an operation using that handle, an error is returned since it does not own the handle. This is used to ensure that other threads cannot interfere with an operation being performed by the owner thread. In some cases, it may be desirable for one thread in a client application to create the client handle, and then pass that handle to another worker thread. The **AttachThread** method can be used to change the ownership of the handle to the new worker thread. By preserving the return value from the method, the original owner of the handle can be restored before the worker thread terminates.

This method should be called by the new thread immediately after it has been created, and if the new thread does not release the handle itself, the ownership of the handle should be restored to the parent thread before it terminates. Under no circumstances should **AttachThread** be used to forcibly release a handle allocated by another thread while a blocking operation is in progress. To cancel an operation, use the **Cancel** method and then release the handle after the blocking method exits and control is returned to the current thread.

Note that the *dwThreadId* parameter is presumed to be a valid thread ID and no checks are performed to ensure that the thread actually exists. Specifying an invalid thread ID will orphan the client handle used by the class until the destructor is called.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnwsv10.lib

See Also

[AttachHandle](#), [Cancel](#), [Connect](#), [DetachHandle](#), [Disconnect](#), [GetHandle](#)

CNntpClient::Authenticate Method

```
INT Authenticate(  
    LPCTSTR lpszUserName,  
    LPCTSTR lpszPassword  
);
```

The **Authenticate** method is used to authenticate access to the news server. Not all news servers require authentication by the client.

Parameters

lpszUserName

Pointer to a string which specifies the user name required for authentication on the news server.

lpszPassword

Pointer to a string which specifies the password required for authentication on the news server.

Return Value

If the method succeeds, the return value is the server result code. If the method fails, the return value is NNTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

This method should only be called if the server requires authentication. Two authentication methods, "original" and "simple" authentication, are recognized by the library.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnwsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[Connect](#), [ListArticles](#), [ListGroupes](#)

CNntpClient::Cancel Method

```
INT Cancel();
```

The **Cancel** method cancels any outstanding blocking operation in the client, causing the blocking method to fail. The application may then retry the operation or terminate the client session.

Parameters

None.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is NNTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

When the **Cancel** method is called, the blocking method will not immediately fail. An internal flag is set which causes the blocking operation to exit with an error. This means that the application cannot cancel an operation and immediately perform some other operation. Instead it must allow the calling stack to unwind, returning back to the blocking operation before making any further function calls.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnwsv10.lib

See Also

[IsBlocking](#)

CNntpClient::CloseArticle Method

```
INT CloseArticle();
```

The **CloseArticle** method closes the current article that has been opened or created.

Parameters

None.

Return Value

If the method succeeds, the return value is the server result code. If the method fails, the return value is NNTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

If an article is being created, this method actually submits the article to the server. Note that the client application is responsible for generating the message headers as well as the body of the message. News articles conform to the same general characteristics of an email message.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnwsv10.lib

CNntpClient::Command Method

```
INT Command(  
    LPCTSTR lpszCommand,  
    LPCTSTR lpszParameter,  
    BOOL bMultiLine  
);
```

The **Command** method sends a command to the server, and returns the result code back to the caller. This method is typically used for site-specific commands not directly supported by the class.

Parameters

lpszCommand

The command which will be executed by the server.

lpszParameter

An optional command parameter. If the command requires more than one parameter, then they should be combined into a single string, with a space separating each parameter. If the command does not accept any parameters, this value may be NULL.

bMultiLine

An optional boolean argument used to specify if multiple lines of data will be returned by the server as the result of the command. Unlike a single line response, which consists of a result code and result string, a multi-line response consists of one or more lines of text, terminated by a special end-of-data marker. If this argument is omitted, *bMultiLine* is FALSE.

Return Value

If the method succeeds, the return value is the result code returned by the server. If the method fails, the return value is NNTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

A list of valid commands can be found in the technical specification for the protocol. Many servers will list supported commands when the HELP command is used.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnwsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[GetResultCode](#), [GetResultString](#)

CNntpClient::Connect Method

```
BOOL Connect(  
    LPCTSTR lpszRemoteHost,  
    UINT nRemotePort,  
    UINT nTimeout,  
    DWORD dwOptions,  
    HWND hEventWnd,  
    UINT uEventMsg  
);
```

The **Connect** method establishes a connection with the specified server and defines security related options to be used.

Parameters

lpszRemoteHost

A pointer to the name of the server to connect to; this may be a fully-qualified domain name or an IP address.

nRemotePort

The port number the server is listening on; a value of zero specifies that the default port number should be used. For standard connections, the default port number is NN. For secure connections, the default port number is NN.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
NNTP_OPTION_NONE	No connection options specified. A standard connection to the server will be established using the specified host name and port number.
NNTP_OPTION_TUNNEL	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established.
NNTP_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using either the SSL or TLS protocols.
NNTP_OPTION_SECURE	This option specifies the client should attempt to establish a secure connection with the server. Note that the server must support secure

	connections using either the SSL or TLS protocol.
NNTP_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
NNTP_OPTION_FREETHREAD	This option specifies that this instance of the class may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the class instance is synchronized across multiple threads.

hEventWnd

The handle to the event notification window. This window receives messages which notify the client of various asynchronous network events that occur. If this argument is NULL, then the client session will be blocking and no network events will be sent to the client.

uEventMsg

The message identifier that is used when an asynchronous network event occurs. This value should be greater than WM_USER as defined in the Windows header files. If the *hEventWnd* argument is NULL, this argument should be specified as WM_NULL.

Return Value

If the method succeeds, the return value is a non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The use of Windows event notification messages has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

To prevent this method from blocking the main user interface thread, the application should create a background worker thread and establish a connection by calling **Connect** in that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each client session.

If you specify an event notification window, then the client session will be asynchronous. When a message is posted to the notification window, the low word of the *lParam* parameter contains the event identifier. The high word of *lParam* contains the low word of the error code, if an error has occurred. The *wParam* parameter contains the client handle. One or more of the following event identifiers may be sent:

Constant	Description
NNTP_EVENT_CONNECT	The connection to the server has completed. The high word of the <i>lParam</i> parameter should be checked, since this notification message will be posted if an error has occurred.
NNTP_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.

NNTP_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
NNTP_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
NNTP_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
NNTP_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.
NNTP_EVENT_COMMAND	A command has been issued by the client and the server response has been received and processed. This event can be used to log the result codes and messages returned by the server in response to actions taken by the client.
NNTP_EVENT_PROGRESS	The client is in the process of sending or receiving a file on the data channel. This event is called periodically during a transfer so that the client can update any user interface components such as a status control or progress bar.

To cancel asynchronous notification and return the client to a blocking mode, use the **DisableEvents** methods.

It is recommended that you only establish an asynchronous connection if you understand the implications of doing so. In most cases, it is preferable to create a synchronous connection and create threads for each additional session if more than one active client session is required.

The *dwOptions* argument can be used to specify the threading model that is used by the library when a connection is established. By default, the class instance is initially attached to the thread that created it. From that point on, until the it is released, only the owner may call functions using that instance of the class. The ownership of the class instance may be transferred from one thread to another using the **AttachThread** method.

Specifying the NNTP_OPTION_FREETHREAD option enables any thread to call any method in that instance of the class, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the class instance is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same instance.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnwsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[CreateSecurityCredentials](#), [Disconnect](#), [GetSecurityInformation](#)

CNntpClient::CreateArticle Method

```
INT CreateArticle();
```

The **CreateArticle** method creates a new article in the current newsgroup.

Parameters

None.

Return Value

If the method succeeds, the return value is the server result code. If the method fails, the return value is NNTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

This method sends the POST command to the news server. Not all servers permit clients to post articles. The client application is responsible for generating the message headers as well as the body of the message. News articles conform to the same general characteristics of an email message.

The **CloseArticle** method must be called once the contents of the article has been written to the server.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnwsv10.lib

CNntpClient::CreateSecurityCredentials Method

```
BOOL CreateSecurityCredentials(  
    DWORD dwProtocol,  
    DWORD dwOptions,  
    LPCTSTR lpszUserName,  
    LPCTSTR lpszPassword,  
    LPCTSTR lpszCertStore,  
    LPCTSTR lpszCertName  
);  
  
BOOL CreateSecurityCredentials(  
    LPCTSTR lpszCertStore,  
    LPCTSTR lpszCertName  
);  
  
BOOL CreateSecurityCredentials(  
    LPCTSTR lpszCertName  
);
```

The **CreateSecurityCredentials** method establishes the security credentials for the client session.

Parameters

dwProtocol

A bitmask of supported security protocols. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_SSL	Either SSL 2.0 or SSL 3.0 should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, TLS will be excluded from the list of supported protocols. Both SSL 2.0 and 3.0 have been deprecated and will never be used unless explicitly specified. It is not recommended that you enable either of these protocols for secure connections because it will cause most servers to reject your connection request, even if a version of TLS is also specified.
SECURITY_PROTOCOL_TLS	Either the TLS 1.0, 1.1 or 1.2 protocol should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols.

	This may be necessary for some servers that reject any attempt to use the older SSL protocol and require that only TLS be used.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This is the recommended version of TLS to use with secure connections.

dwOptions

A value which specifies one or options. This member is constructed by using a bitwise operator with any of the following values:

Constant	Description
CREDENTIAL_STORE_CURRENT_USER	The library will attempt to open a store for the current user using the certificate store name provided in this structure. If no options are specified, then this is the default behavior.
CREDENTIAL_STORE_LOCAL_MACHINE	The library will attempt to open a local machine store using the certificate store name provided in this structure. If this option is specified, the library will always search for a local machine store before searching for the store by that name for the current user.
CREDENTIAL_STORE_FILENAME	The certificate store name is a file that contains the certificate and private key that will be used.

lpzUserName

A pointer to a string which specifies the certificate owner's username. A value of NULL specifies that no username is required. Currently this parameter is not used and any value specified will be ignored.

lpszPassword

A pointer to a string which specifies the certificate owner's password. A value of NULL specifies that no password is required. This parameter is only used if a PKCS12 (PFX) certificate file is specified and that certificate has been secured with a password. This value will be ignored the current user or local machine certificate store is specified.

lpszCertStore

A pointer to a string which specifies the name of the certificate store to open. A certificate store is a collection of certificates and their private keys, typically organized by how they are used. If this value is NULL or points to an empty string, the default certificate store "MY" will be used.

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as VeriSign and Thawte act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. This corresponds to the "Personal" store that is displayed by the certificate manager utility and is the default store used by the library.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as VeriSign and Thawte are installed as part of the operating system and periodically updated by Microsoft.

lpszCertName

A pointer to a null terminated string which specifies the name of the certificate to use. The function will first search the certificate store for a certificate with a matching "friendly name"; this is a name for the certificate that is assigned by the user. Note that the name must match completely, but the comparison is not case sensitive. If no matching certificate is found, the function will then attempt to find a certificate that has a matching common name (also called the certificate subject). This comparison is less stringent, and the first partial match will be returned. If this second search fails, the function will return an error indicating that the certificate could not be found.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Example

```
pClient->CreateSecurityCredentials(  
    SECURITY_PROTOCOL_DEFAULT,  
    0,  
    NULL,  
    NULL,  
    lpszCertStore,  
    lpszCertName);
```

```
bConnected = pClient->Connect(lpszHostName,  
                               NNTP_PORT_SECURE,  
                               NNTP_TIMEOUT,  
                               NNTP_OPTION_SECURE);
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnwsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[Connect](#), [DeleteSecurityCredentials](#), [GetSecurityInformation](#), [SECURITYCREDENTIALS](#)

CNntpClient::DeleteSecurityCredentials Method

```
VOID DeleteSecurityCredentials();
```

The **DeleteSecurityCredentials** method releases the security credentials for the current session.

Parameters

None.

Return Value

None.

Remarks

This method can be used to release the memory allocated to the client or server credentials after a secure connection has been terminated. The security credentials are released when the class destructor is called, so it is normally not required that the application explicitly call this method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnwsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[CreateSecurityCredentials](#)

CNntpClient::DetachHandle Method

```
HCLIENT DetachHandle();
```

The **DetachHandle** method detaches the client handle associated with the current instance of the class.

Parameters

None.

Return Value

This method returns the client handle associated with the current instance of the class object. If there is no active client session, the value `INVALID_CLIENT` will be returned.

Remarks

This method is used to detach a client handle created by the class for use with the SocketTools API. Once the client handle is detached from the class, no other class member functions may be called. Note that the handle must be explicitly released at some later point by the process or a resource leak will occur.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csnwsv10.lib`

[AttachHandle](#), [GetHandle](#)

CNntpClient::DisableEvents Method

```
INT DisableEvents();
```

The **DisableEvents** method disables the event notification mechanism, preventing subsequent event notification messages from being posted to the application's message queue.

This method has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Parameters

None.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is NNTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **DisableEvents** method is used to disable event message posting for the specified client session. Although this will immediately prevent any new events from being generated, it is possible that messages could be waiting in the message queue. Therefore, an application must be prepared to handle client event messages after this method has been called.

This method is automatically called if the client has event notification enabled, and the **Disconnect** method is called. The same issues regarding outstanding event messages also applies in this situation, requiring that the application handle event messages that may reference a client handle that is no longer valid.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnwsv10.lib

See Also

[EnableEvents](#), [RegisterEvent](#)

CNntpClient::DisableTrace Method

```
BOOL DisableTrace();
```

The **DisableTrace** method disables the logging of socket function calls to the trace log.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, a value of zero is returned.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnwsv10.lib

[Connect](#), [IsConnected](#)

CNntpClient::EnableEvents Method

```
INT EnableEvents(  
    HWND hEventWnd,  
    UINT uEventMsg  
);
```

The **EnableEvents** method enables event notifications using Windows messages.

This method has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Applications should use the **RegisterEvent** method to register an event handler which is invoked when an event occurs.

Parameters

hEventWnd

Handle to the window which will receive the client notification messages. This parameter must specify a valid window handle. If a NULL handle is specified, event notification will be disabled.

uEventMsg

The message that is received when a client event occurs. This value must be greater than 1024.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is NNTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **EnableEvents** method is used to request that notification messages be posted to the specified window whenever a client event occurs. This allows an application to monitor the status of different client operations, such as a file transfer.

The *wParam* argument will contain the client handle, the low word of the *lParam* argument will contain the event ID, and the high word will contain any error code. If no error has occurred, the high word will always have a value of zero. The following events may be generated:

Constant	Description
NNTP_EVENT_CONNECT	The connection to the server has completed. The high word of the <i>lParam</i> parameter should be checked, since this notification message will be posted if an error has occurred.
NNTP_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
NNTP_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
NNTP_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking

	operation. This event is only generated if the client is in asynchronous mode.
NNTP_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
NNTP_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.
NNTP_EVENT_COMMAND	A command has been issued by the client and the server response has been received and processed. This event can be used to log the result codes and messages returned by the server in response to actions taken by the client.
NNTP_EVENT_PROGRESS	The client is in the process of sending or receiving a file on the data channel. This event is called periodically during a transfer so that the client can update any user interface components such as a status control or progress bar.

It is not required that the client be placed in asynchronous mode in order to receive command and progress event notifications. To disable event notification, call the **DisableEvents** method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnews10.lib

[DisableEvents](#), [RegisterEvent](#)

CNntpClient::EnableTrace Method

```
BOOL EnableTrace(  
    LPCTSTR lpszTraceFile,  
    DWORD dwTraceFlags  
);
```

The **EnableTrace** method enables the logging of socket function calls to a file.

Parameters

lpszTraceFile

A pointer to a string which specifies the name of the trace log file. If this parameter is NULL or an empty string, the default file name **cstrace.log** is used. The file is stored in the directory specified by the TEMP environment variable, if it is defined; otherwise, the current working directory is used.

dwTraceFlags

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
TRACE_INFO	All function calls are written to the trace file. This is the default value.
TRACE_ERROR	Only those function calls which fail are recorded in the trace file.
TRACE_WARNING	Only those function calls which fail or return values which indicate a warning are recorded in the trace file.
TRACE_HEXDUMP	All functions calls are written to the trace file, plus all the data that is sent or received is displayed, in both ASCII and hexadecimal format.
TRACE_PROCESS	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for multithreaded applications that are using worker threads.

Return Value

If the method succeeds, the return value is non-zero. A return value of zero indicates an error. Failure typically indicates that the tracing library **cstrcv10.dll** cannot be loaded on the local system.

Remarks

When trace logging is enabled, the file is opened, appended to and closed for each socket function call. This makes it possible for an application to append its own logging information, however care should be taken to ensure that the file is closed before the next network operation is performed. To limit the size of the log files, enable and disable logging only around those sections of code that you wish to trace.

Note that the TRACE_HEXDUMP trace level generates very large log files since it includes all of the data exchanged between your application and the server.

Trace method logging is managed on a per-thread basis, not for each client handle. This means that all SocketTools libraries and components share the same settings in the current thread. If you

are using multiple SocketTools libraries or components in your application, you only need to enable logging once.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnwsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[DisableTrace](#)

CNntpClient::FreezeEvents Method

```
INT FreezeEvents(  
    BOOL bFreeze  
);
```

The **FreezeEvents** method is used to suspend and resume event handling by the client.

Parameters

bFreeze

A non-zero value specifies that event handling should be suspended by the client. A zero value specifies that event handling should be resumed.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is NNTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

This method should be used when the application does not want to process events, such as when a modal dialog is being displayed. When events are suspended, all client events are queued. If events are re-enabled at a later point, those queued events will be sent to the application for processing. Note that only one of each event will be generated. For example, if the client has suspended event handling, and four read events occur, once event handling is resumed only one of those read events will be posted to the client. This prevents the application from being flooded by a potentially large number of queued events.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnwsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

CNntpClient::GetArticle Method

```
INT GetArticle(  
    LONG nArticleId,  
    LPBYTE lpBuffer,  
    LPDWORD lpdwLength  
);
```

```
INT GetArticle(  
    LONG nArticleId,  
    HGLOBAL* lpBuffer,  
    LPDWORD lpdwLength  
);
```

```
INT GetArticle(  
    LONG nArticleId,  
    CString& strBuffer  
);
```

```
INT GetArticle(  
    LPCTSTR lpszMessageId,  
    LPBYTE lpBuffer,  
    LPDWORD lpdwLength  
);
```

```
INT GetArticle(  
    LPCTSTR lpszMessageId,  
    HGLOBAL* lpBuffer,  
    LPDWORD lpdwLength  
);
```

```
INT GetArticle(  
    LPCTSTR lpszMessageId,  
    CString& strBuffer  
);
```

The **GetArticle** method retrieves the specified article and copies the contents to a local buffer.

Parameters

nArticleId

An integer value which specifies the number of the article to retrieve from the server. This value must be greater than zero. Overloaded versions of this method also support article IDs that are 64-bit integers.

lpszMessageId

A pointer to a string which specifies the message ID of the article to retrieve from the server. This parameter cannot be NULL or specify an empty string.

lpBuffer

A pointer to a byte buffer which will contain the data transferred from the server, or a pointer to a global memory handle which will reference the data when the method returns.

lpdwLength

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the *lpBuffer* parameter. If the *lpBuffer* parameter points to a global memory handle, the length value should be initialized to zero. When the method returns, this value will be updated with the actual length of the file that was

downloaded.

Return Value

If the method succeeds, the return value is the server result code. If the method fails, the return value is NNTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetArticle** method is used to retrieve an article from the server and copy it into a local buffer. The method may be used in one of two ways, depending on the needs of the application. The first method is to pre-allocate a buffer large enough to store the contents of the article. In this case, the *lpBuffer* parameter will point to the buffer that was allocated, the value that the *lpdwLength* parameter points to should be initialized to the size of that buffer.

The second method that can be used is have the *lpBuffer* parameter point to a global memory handle which will contain the article data when the method returns. In this case, the value that the *lpdwLength* parameter points to must be initialized to zero. It is important to note that the memory handle returned by the method must be freed by the application, otherwise a memory leak will occur. See the example code below.

This method will cause the current thread to block until the complete article has been retrieved, a timeout occurs or the operation is canceled. During the transfer, the NNTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **EnableEvents**, or by registering a callback function using the **RegisterEvent** method.

To determine the current status of a transfer while it is in progress, use the **GetTransferStatus** method.

Example

```
HGLOBAL hgb1Buffer = (HGLOBAL)NULL;
LPBYTE lpBuffer = (LPBYTE)NULL;
DWORD cbBuffer = 0;

// Return the article into block of global memory allocated by
// the GlobalAlloc function; the handle to this memory will be
// returned in the hgb1Buffer parameter
nResult = pClient->GetArticle(nArticleId, &hgb1Buffer, &cbBuffer);

if (nResult != NNTP_ERROR)
{
    // Lock the global memory handle, returning a pointer to the
    // article text
    lpBuffer = (LPBYTE)GlobalLock(hgb1Buffer);

    // After the data has been used, the handle must be unlocked
    // and freed, otherwise a memory leak will occur
    GlobalUnlock(hgb1Buffer);
    GlobalFree(hgb1Buffer);
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnwsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

CNntpClient::GetArticleHeaders Method

```
INT GetArticleHeaders(  
    LONG nArticleId,  
    LPBYTE lpHeaders,  
    LPDWORD lpdwLength  
);
```

```
INT GetArticleHeaders(  
    LONG nArticleId,  
    HGLOBAL* lpHeaders,  
    LPDWORD lpdwLength  
);
```

```
INT GetArticleHeaders(  
    LONG nArticleId,  
    CString& strHeaders  
);
```

The **GetArticleHeaders** method retrieves the headers for the specified article from the server.

Parameters

nArticleId

Number of article to retrieve from the server. This value must be greater than zero. Overloaded versions of this method also support article IDs that are 64-bit integers.

lpHeaders

A pointer to a byte buffer which will contain the data transferred from the server, or a pointer to a global memory handle which will reference the data when the method returns.

lpdwLength

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the *lpHeaders* parameter. If the *lpHeaders* parameter points to a global memory handle, the length value should be initialized to zero. When the method returns, this value will be updated with the actual length of the message that was downloaded.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is NNTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetArticleHeaders** method is used to retrieve an article header block from the server and copy it into a local buffer. The method may be used in one of two ways, depending on the needs of the application. The first method is to pre-allocate a buffer large enough to store the contents of the file. In this case, the *lpHeaders* parameter will point to the buffer that was allocated, the value that the *lpdwLength* parameter points to should be initialized to the size of that buffer.

The second method that can be used is have the *lpHeaders* parameter point to a global memory handle which will contain the message headers when the method returns. In this case, the value that the *lpdwLength* parameter points to must be initialized to zero. It is important to note that the memory handle returned by the method must be freed by the application, otherwise a memory leak will occur.

This method will cause the current thread to block until the transfer completes, a timeout occurs

or the transfer is canceled. During the transfer, the NNTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **EnableEvents**, or by registering a callback function using the **RegisterEvent** method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnwsv10.lib

CNntpClient::GetArticleMessageId Method

```
INT GetArticleMessageId(  
    LONG nArticleId,  
    LPTSTR lpszMessageId,  
    INT cbMessageId  
);  
  
INT GetArticleMessageId(  
    LONG nArticleId,  
    CString& strMessageId  
);
```

The **GetArticleMessageId** method returns the message identifier for the specified article in the current newsgroup.

Parameters

nArticleId

Article number to retrieve the message identifier for. The value may be zero, in which case the current article number is used.

lpszMessageId

Pointer to a string buffer which will contain the message identifier for the specified article.

cbMessageId

Maximum number of characters that may be copied into the buffer, including the terminating null character.

Return Value

If the method succeeds, the return value is the length of the message identifier string. If the method fails, the return value is NNTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The message identifier is a string which can uniquely identify the message on the news server. This value may be used to retrieve the contents of the article.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnwsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[GetMessageIdArticle](#), [ListArticles](#)

CNntpClient::GetArticleRange Method

```
BOOL GetArticleRange(  
    LONG * lpnFirstArticle,  
    LONG * lpnLastArticle,  
    LONG * lpnArticleCount  
);  
  
BOOL GetArticleRange(  
    ULONGLONG * lpnFirstArticle,  
    ULONGLONG * lpnLastArticle  
    ULONGLONG * lpnArticleCount  
);
```

The **GetArticleRange** method returns the first and last article numbers for the currently selected newsgroup.

Parameters

lpnFirstArticle

Pointer to an integer that will contain the first article number in the currently selected newsgroup. If this parameter is NULL, it will be ignored.

lpnLastArticle

Pointer to an integer that will contain the last article number in the currently selected newsgroup. If this parameter is NULL, it will be ignored.

lpnArticleCount

Pointer to an integer that will contain the total number of articles in currently selected newsgroup. If this parameter is NULL, it will be ignored.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

It is possible that there will be gaps in the articles within the range of the first and last articles in the newsgroup. This may be due to a message being canceled or expired. If the server can potentially return very large ID values, it is recommended your application use ULONGLONGs (64-bit unsigned integers) instead of LONGs (32-bit signed integers) to store article numbers.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnwsv10.lib

CNntpClient::GetCurrentArticle Method

```
BOOL GetCurrentArticle(  
    LONG * lpnArticleId  
);  
  
BOOL GetCurrentArticle(  
    ULONGLONG * lpnArticleId  
);
```

The **GetCurrentArticle** method returns the current article number for the currently selected newsgroup.

Parameters

lpnArticleId

Pointer to an integer variable that will contain the current article number when the method returns.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

If the server can potentially return very large ID values, it is recommended your application use ULONGLONGs (64-bit unsigned integers) instead of LONGs (32-bit signed integers) to store article numbers.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnwsv10.lib

CNntpClient::GetCurrentDate Method

```
INT GetCurrentDate(  
    LPTSTR lpszDate,  
    INT nMaxLength  
);  
  
INT GetCurrentDate(  
    CString& strDate  
);
```

The **GetCurrentDate** method copies the current date and time to the specified buffer in a format that is commonly used in news articles. This date format should be used in all date-related fields in the message header.

Parameters

lpszDate

Pointer to a string buffer that will contain the current date and time when the method returns.

nMaxLength

The maximum number of characters that can be copied into the string buffer.

Return Values

If the method succeeds, the return value is the number of characters copied into the buffer, not including the null-terminator. If the method fails, the return value is NNTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The date value that is returned is adjusted for the local timezone.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnwsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

CNntpClient::GetErrorString Method

```
INT GetErrorString(  
    DWORD dwErrorCode,  
    LPTSTR lpszDescription,  
    INT cbDescription  
);  
  
INT GetErrorString(  
    DWORD dwErrorCode,  
    CString& strDescription  
);
```

The **GetErrorString** method is used to return a description of a specific error code. Typically this is used in conjunction with the **GetLastError** method for use with warning dialogs or as diagnostic messages.

Parameters

dwErrorCode

The error code for which a description is returned.

lpszDescription

A pointer to the buffer that will contain a description of the specified error code. This buffer should be at least 128 characters in length. An alternate form of the method accepts a **CString** variable which will contain the error description.

cbDescription

The maximum number of characters that may be copied into the description buffer.

Return Value

If the method succeeds, the return value is the length of the description string. If the method fails, the return value is zero, meaning that no description exists for the specified error code. Typically this indicates that the error code passed to the method is invalid.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnwsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

CNntpClient::GetFirstArticle Method

```
BOOL GetFirstArticle(  
    LPNEWSARTICLE lpArticle  
);  
  
BOOL GetFirstArticle(  
    LPNEWSARTICLEEX lpArticle  
);
```

The **GetFirstArticle** method returns information about the first article in the currently selected newsgroup.

Parameters

lpArticle

A pointer to a [NEWSARTICLE](#) or [NEWSARTICLEEX](#) structure which will contain information about the first article in the currently selected directory. If the server can potentially return very large article IDs, it is recommended that you use the **NEWSARTICLEEX** structure.

Return Value

If the method succeeds, the return value is non-zero. If there are no articles in the current newsgroup, or the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **GetFirstArticle** method returns information about the first article in the currently selected newsgroup. This method is used in conjunction with the **GetNextArticle** method to enumerate all of the articles in the newsgroup. Typically this is used to provide the user with a list of articles to access.

While the articles in the newsgroup are being listed, the client cannot retrieve the contents of a specific article. For example, the **GetArticle** method cannot be called while inside a loop calling **GetNextArticle**. The client should store those articles which it wants to retrieve in an array, and then once all of the articles have been listed, it can begin calling **NntpGetArticle** for each article number to retrieve the article text.

The date and time that the article was posted is returned in the *stPosted* member of the **NEWSARTICLE** structure. This value is returned in Universal Coordinated Time (UTC) and can be converted to local time using the **SystemTimeToTzSpecificLocalTime** function.

Example

```
// List all articles in the current group  
if (pClient->ListArticles() == NNTP_ERROR)  
    pClient->ShowError();  
else  
{  
    NEWSARTICLE newsArticle;  
    BOOL bResult;  
  
    // Get each article in the current newsgroup, printing the article  
    // number and the subject of the article  
    bResult = pClient->GetFirstArticle(&newsArticle);  
    while (bResult)  
    {
```

```
        _tprintf(_T("%ld %s\n"), newsArticle.nArticleId, newsArticle.szSubject);  
        bResult = pClient->GetNextArticle(&newsArticle);  
    }  
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csnwsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[GetArticle](#), [GetFirstGroup](#), [GetNextArticle](#), [GetNextGroup](#), [ListArticles](#), [ListGroup](#), [SelectGroup](#), [NEWSARTICLE](#), [NEWSGROUP](#)

CNntpClient::GetFirstGroup Method

```
BOOL GetFirstGroup(  
    LPNEWSGROUP LpGroup  
);  
  
BOOL GetFirstGroup(  
    LPNEWSGROUPEX LpGroup  
);
```

The **GetFirstGroup** method returns information about the first available newsgroup.

Parameters

lpGroup

A pointer to a [NEWSGROUP](#) or [NEWSGROUPEX](#) structure which will contain information about the first available newsgroup. If the server can potentially return very large article IDs, it is recommended that you use the [NEWSGROUPEX](#) structure.

Return Value

If the method succeeds, the return value is non-zero. If there are no newsgroups available, or the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **GetFirstGroup** method returns information about the first newsgroup on the server. This method is used in conjunction with the **GetNextGroup** method to enumerate all of the available newsgroups. Typically this is used to provide the user with a list of newsgroups to select.

While the the newsgroups are being listed, the client cannot select a newsgroup or retrieve the contents of a specific article. The client should store those newsgroups which it wants to retrieve articles from, and then once all of the newsgroups have been listed, it can then select each newsgroup and retrieve the available articles from that group.

Note that if no newsgroups are returned by the server, it may indicate that it requires the client to authenticate itself prior to requesting a list of groups or articles.

Example

```
// List all available newsgroups  
if (pClient->ListGroups() == NNTP_ERROR)  
    pClient->ShowError();  
else  
{  
    NEWSGROUP newsGroup;  
    BOOL bResult;  
  
    // Get each newsgroup, printing the article range and  
    // the name of the group  
    bResult = pClient->GetFirstGroup(&newsGroup);  
    while (bResult)  
    {  
        printf("%ld %ld %s\n", newsGroup.nFirstArticle,  
            newsGroup.nLastArticle,  
            newsGroup.szName);  
        bResult = pClient->GetNextGroup(&newsGroup);  
    }  
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnwsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

CNntpClient::GetGroupName Method

```
INT GetGroupName(  
    LPTSTR lpszGroupName,  
    INT nMaxLength  
);
```

```
INT GetGroupName(  
    CString& strGroupName  
);
```

The **GetGroupName** method returns the name of the currently selected newsgroup.

Parameters

lpszGroupName

Pointer to a string buffer that will contain the name of the currently selected newsgroup.

nMaxLength

The maximum number of characters that may be copied into the buffer, including the terminating null character.

Return Value

If the method succeeds, the return value is the length of the newsgroup name. If no newsgroup has been selected, the method will return a value of zero. If the method fails, the return value is NNTP_ERROR. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csnwsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[GetGroupTitle](#), [ListGroup](#), [SelectGroup](#)

CNntpClient::GetGroupTitle Method

```
INT GetGroupTitle(  
    LPTSTR lpszGroupTitle,  
    INT nMaxLength  
);  
  
INT GetGroupTitle(  
    CString& strGroupTitle  
);
```

The **GetGroupTitle** method returns a description of the currently selected newsgroup.

Parameters

lpszGroupTitle

Pointer to a string buffer that will contain a description of the currently selected newsgroup.

nMaxLength

The maximum number of characters that may be copied into the buffer, including the terminating null character.

Return Value

If the method succeeds, the return value is the length of the description. If no newsgroup has been selected, the method will return a value of zero. If the method fails, the return value is NNTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The news server must support the XGTITLE command so that the group description can be obtained when the newsgroup is selected. If this command is not recognized, then no description will be returned.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csnews10.lib

Unicode: Implemented as Unicode and ANSI versions.

CNntpClient::GetHandle Method

```
HCLIENT GetHandle();
```

The **GetHandle** method returns the client handle associated with the current instance of the class.

Parameters

None.

Return Value

This method returns the client handle associated with the current instance of the class object. If there is no active client session, the value `INVALID_CLIENT` will be returned.

Remarks

This method is used to obtain the client handle created by the class for use with the SocketTools API.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csnwsv10.lib`

CNntpClient::GetLastError Method

```
DWORD GetLastError();  
  
DWORD GetLastError(  
    CString& strDescription  
);
```

Parameters

strDescription

A string which will contain a description of the last error code value when the method returns. If no error has been set, or the last error code has been cleared, this string will be empty.

Return Value

The return value is the last error code value for the current thread. Functions set this value by calling the **SetLastError** method. The Return Value section of each reference page notes the conditions under which the method sets the last error code.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. You should call the **GetLastError** method immediately when a method's return value indicates that an error has occurred. That is because some methods call **SetLastError(0)** when they succeed, clearing the error code set by the most recently failed method.

Most methods will set the last error code value when they fail; a few methods set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or NNTP_ERROR. Those methods which call **SetLastError** when they succeed are noted on the method reference page.

The description of the error code is the same string that is returned by the **GetErrorString** method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnwsv10.lib

See Also

[GetErrorString](#), [SetLastError](#), [ShowError](#)

CNntpClient::GetMessageIdArticle Method

```
BOOL GetMessageIdArticle(  
    LPCTSTR LpszMessageId,  
    LONG * LpnMessageId  
);  
  
BOOL GetMessageIdArticle(  
    LPCTSTR LpszMessageId,  
    ULONGLONG * LpnMessageId  
);
```

The **GetMessageIdArticle** method returns the article number associated with the specified message identifier in the current newsgroup.

Parameters

lpszMessageId

A pointer to the message identifier string.

lpnArticleId

Pointer to an integer variable that will contain the article number associated with the message ID.

Return Value

If the method succeeds, the return value is the article number. If the method fails, the return value is NNTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

If the server can potentially return very large ID values, it is recommended your application use ULONGLONGs (64-bit unsigned integers) instead of LONGs (32-bit signed integers) to store article numbers.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csnwsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[GetArticleMessageId](#), [ListArticles](#)

CNntpClient::GetNextArticle Method

```
BOOL GetNextArticle(  
    LPNEWSARTICLE lpArticle  
);  
  
BOOL GetNextArticle(  
    LPNEWSARTICLEEX lpArticle  
);
```

The **GetNextArticle** method returns information about the next article in the currently selected newsgroup.

Parameters

lpArticle

A pointer to a [NEWSARTICLE](#) or [NEWSARTICLEEX](#) structure which will contain information about the next available article in the currently selected directory. If the server can potentially return very large article IDs, it is recommended that you use the **NEWSARTICLEEX** structure.

Return Value

If the method succeeds, the return value is non-zero. If there are no more articles in the current newsgroup, or the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **GetNextArticle** method returns information about the next available article in the currently selected newsgroup. This method is used in conjunction with the **GetFirstArticle** method to enumerate all of the articles in the newsgroup. Typically this is used to provide the user with a list of articles to access.

While the articles in the newsgroup are being listed, the client cannot retrieve the contents of a specific article. For example, the **GetArticle** method cannot be called while inside a loop calling **GetNextArticle**. The client should store those articles which it wants to retrieve in an array, and then once all of the articles have been listed, it can begin calling **NntpGetArticle** for each article number to retrieve the article text.

Example

```
// List all articles in the current group  
if (pClient->ListArticles() == NNTP_ERROR)  
    pClient->ShowError();  
else  
{  
    NEWSARTICLE newsArticle;  
    BOOL bResult;  
  
    // Get each article in the current newsgroup, printing the article  
    // number and the subject of the article  
    bResult = pClient->GetFirstArticle(&newsArticle);  
    while (bResult)  
    {  
        _tprintf(_T("%ld %s\n"), newsArticle.nArticleId, newsArticle.szSubject);  
        bResult = pClient->GetNextArticle(&newsArticle);  
    }  
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnwsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[GetArticle](#), [GetFirstArticle](#), [GetFirstGroup](#), [GetNextGroup](#), [ListArticles](#), [ListGroup](#), [SelectGroup](#), [NEWSARTICLE](#), [NEWSGROUP](#)

CNntpClient::GetNextGroup Method

```
BOOL GetNextGroup(  
    LPNEWSGROUP LpGroup  
);  
  
BOOL GetNextGroup(  
    LPNEWSGROUPEX LpGroup  
);
```

The **GetNextGroup** method returns information about the next available newsgroup.

Parameters

lpGroup

A pointer to a [NEWSGROUP](#) or [NEWSGROUPEX](#) structure which will contain information about the next available newsgroup. If the server can potentially return very large article IDs, it is recommended that you use the **NEWSGROUPEX** structure.

Return Value

If the method succeeds, the return value is non-zero. If there are no more newsgroups available, or the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **GetNextGroup** method returns information about the next newsgroup on the server. This method is used in conjunction with the **GetFirstGroup** method to enumerate all of the available newsgroups. Typically this is used to provide the user with a list of newsgroups to select.

While the the newsgroups are being listed, the client cannot select a newsgroup or retrieve the contents of a specific article. The client should store those newsgroups which it wants to retrieve articles from, and then once all of the newsgroups have been listed, it can then select each newsgroup and retrieve the available articles from that group.

Example

```
// List all available newsgroups  
if (pClient->ListGroups() == NNTP_ERROR)  
    pClient->ShowError();  
else  
{  
    NEWSGROUP newsGroup;  
    BOOL bResult;  
  
    // Get each newsgroup, printing the article range and  
    // the name of the group  
    bResult = pClient->GetFirstGroup(&newsGroup);  
    while (bResult)  
    {  
        printf("%ld %ld %s\n", newsGroup.nFirstArticle,  
            newsGroup.nLastArticle,  
            newsGroup.szName);  
        bResult = pClient->GetNextGroup(&newsGroup);  
    }  
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnwsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

CNntpClient::GetResultCode Method

```
INT GetResultCode();
```

The **GetResultCode** method reads the result code returned by the server in response to a command. The result code is a three-digit numeric code, and indicates if the operation succeeded, failed or requires additional action by the client.

Parameters

None.

Return Value

If the method succeeds, the return value is the result code. If the method fails, the return value is NNTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

Result codes are three-digit numeric values returned by the server. They may be broken down into the following ranges:

Value	Description
100-199	Positive preliminary result. This indicates that the requested action is being initiated, and the client should expect another reply from the server before proceeding.
200-299	Positive completion result. This indicates that the server has successfully completed the requested action.
300-399	Positive intermediate result. This indicates that the requested action cannot complete until additional information is provided to the server.
400-499	Transient negative completion result. This indicates that the requested action did not take place, but the error condition is temporary and may be attempted again.
500-599	Permanent negative completion result. This indicates that the requested action did not take place.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnwsv10.lib

See Also

[Command](#), [GetResultString](#)

CNntpClient::GetResultString Method

```
INT GetResultString(  
    LPTSTR lpszResult,  
    INT cbResult  
);
```

```
INT GetResultString(  
    CString& strResult  
);
```

The **GetResultString** method returns the last message sent by the server along with the result code.

Parameters

lpszResult

A pointer to the buffer that will contain the result string returned by the server. An alternate form of the method accepts a **CString** argument which will contain the result string returned by the server.

cbResult

The maximum number of characters that may be copied into the result string buffer, including the terminating null character.

Return Value

If the method succeeds, the return value is the length of the result string. If a value of zero is returned, this means that no result string was sent by the server. If the method fails, the return value is NNTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetResultString** method is most useful when an error occurs because the server will typically include a brief description of the cause of the error. This can then be parsed by the application or displayed to the user. The result string is updated each time the client sends a command to the server and then calls **GetResultCode** to obtain the result code for the operation.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csnews10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[Command](#), [GetResultCode](#)

CNntpClient::GetSecurityInformation Method

```
BOOL GetSecurityInformation(  
    LPSECURITYINFO LpSecurityInfo  
);
```

The **GetSecurityInformation** method returns security protocol, encryption and certificate information about the current client connection.

Parameters

LpSecurityInfo

A pointer to a [SECURITYINFO](#) structure which contains information about the current client connection. The *dwSize* member of this structure must be initialized to the size of the structure before passing the address of the structure to this method.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

This method is used to obtain security related information about the current client connection to the server. It can be used to determine if a secure connection has been established, what security protocol was selected, and information about the server certificate. Note that a secure connection has not been established, the *dwProtocol* structure member will contain the value SECURITY_PROTOCOL_NONE.

Example

The following example notifies the user if the connection is secure or not:

```
SECURITYINFO securityInfo;  
securityInfo.dwSize = sizeof(SECURITYINFO);  
  
if (pClient->GetSecurityInformation(&securityInfo))  
{  
    if (securityInfo.dwProtocol == SECURITY_PROTOCOL_NONE)  
    {  
        MessageBox(NULL, _T("The connection is not secure"),  
                    _T("Connection"), MB_OK);  
    }  
    else  
    {  
        if (securityInfo.dwCertStatus == SECURITY_CERTIFICATE_VALID)  
        {  
            MessageBox(NULL, _T("The connection is secure"),  
                        _T("Connection"), MB_OK);  
        }  
        else  
        {  
            MessageBox(NULL, _T("The server certificate not valid"),  
                        _T("Connection"), MB_OK);  
        }  
    }  
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnwsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[Connect](#), [CreateSecurityCredentials](#), [SECURITYINFO](#)

CNntpClient::GetStatus Method

INT GetStatus();

The **GetStatus** method the current status of the client session.

Parameters

None.

Return Value

If the method succeeds, the return value is the client status code. If the method fails, the return value is NNTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetStatus** method returns a numeric code which identifies the current state of the client session. The following values may be returned:

Value	Constant	Description
0	NNTP_STATUS_UNUSED	No connection has been established.
1	NNTP_STATUS_IDLE	The client is current idle and not sending or receiving data.
2	NNTP_STATUS_CONNECT	The client is establishing a connection with the server.
3	NNTP_STATUS_READ	The client is reading data from the server.
4	NNTP_STATUS_WRITE	The client is writing data to the server.
5	NNTP_STATUS_DISCONNECT	The client is disconnecting from the server.

In a multithreaded application, any thread in the current process may call this method to obtain status information for the specified client session. To obtain status information about a file transfer, use the **GetTransferStatus** method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnwsv10.lib

See Also

[IsBlocking](#), [IsInitialized](#), [IsReadable](#), [IsWritable](#)

CNntpClient::GetTimeout Method

```
INT GetTimeout();
```

The **GetTimeout** method returns the number of seconds the client will wait for a response from the server. Once the specified number of seconds has elapsed, the method will fail and return to the caller.

Parameters

None.

Return Value

If the method succeeds, the return value is the timeout period in seconds. If the method fails, the return value is NNTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The timeout value is only used with blocking client connections. A value of zero indicates that the default timeout period of 20 seconds should be used.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnwsv10.lib

See Also

CNntpClient::GetTransferStatus Method

```
INT GetTransferStatus(  
    LPNNTPTRANSFERSTATUS LpStatus  
);  
  
INT GetTransferStatus(  
    LPNNTPTRANSFERSTATUSEX LpStatus  
);
```

The **GetTransferStatus** method returns information about the current data transfer in progress.

Parameters

LpStatus

A pointer to an [NNTPTRANSFERSTATUS](#) or [NNTPTRANSFERSTATUSEX](#) structure which contains information about the status of the current data transfer. If the server can potentially return very large article IDs, it is recommended that you use the **NNTPTRANSFERSTATUSEX** structure.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is `NNTP_ERROR`. To get extended error information, call **GetLastError**.

Remarks

The **GetTransferStatus** method returns information about the current data transfer, including the average number of bytes transferred per second and the estimated amount of time until the transfer completes. If no article is currently being retrieved or submitted to the server, this function will return the status of the last successful data transfer made by the client.

In a multithreaded application, any thread in the current process may call this method to obtain status information for the specified client session.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csnwsv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

See Also

[EnableEvents](#), [GetStatus](#), [RegisterEvent](#)

CNntpClient::IsBlocking Method

BOOL IsBlocking();

The **IsBlocking** method is used to determine if the client is currently performing a blocking operation.

Parameters

None.

Return Value

If the client is performing a blocking operation, the method returns a non-zero value. If the client is not performing a blocking operation, or the client handle is invalid, the method returns zero.

Remarks

Because a blocking operation can allow the application to be re-entered (for example, by pressing a button while the operation is being performed), it is possible that another blocking method may be called while it is in progress. Since only one thread of execution may perform a blocking operation at any one time, an error would occur. The **IsBlocking** method can be used to determine if the client is already blocked, and if so, take some other action (such as warning the user that they must wait for the operation to complete).

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnwsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[Cancel](#), [GetStatus](#), [IsConnected](#), [IsInitialized](#), [IsReadable](#), [IsWritable](#), [Read](#), [Write](#)

CNntpClient::IsConnected Method

```
BOOL IsConnected();
```

The **IsConnected** method is used to determine if the client is currently connected to a server.

Parameters

None.

Return Value

If the client is connected to a server, the method returns a non-zero value. If the client is not connected, or the client handle is invalid, the method returns zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csnwsv10.lib

See Also

[GetStatus](#), [IsBlocking](#), [IsInitialized](#), [IsReadable](#), [IsWritable](#)

CNntpClient::IsInitialized Method

```
BOOL IsInitialized();
```

The **IsInitialized** method returns whether or not the class object has been successfully initialized.

Parameters

None.

Return Value

This method returns a non-zero value if the class object has been successfully initialized. A return value of zero indicates that the runtime license key could not be validated or the networking library could not be loaded by the current process.

Remarks

When an instance of the class is created, the class constructor will attempt to initialize the component with the runtime license key that was created when SocketTools was installed. If the constructor is unable to validate the license key or load the networking libraries, this initialization will fail.

If SocketTools was installed with an evaluation license, the application cannot be redistributed to another system. The class object will fail to initialize if the application is executed on another system, or if the evaluation period has expired. To redistribute your application, you must purchase a development license which will include the runtime key that is needed to redistribute your software to other systems. Refer to the Developer's Guide for more information.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnwsv10.lib

See Also

[CNntpClient](#), [IsBlocking](#), [IsConnected](#)

CNntpClient::IsReadable Method

```
BOOL IsReadable(  
    INT nTimeout,  
    LPDWORD lpdwAvail  
);
```

The **IsReadable** method is used to determine if data is available to be read from the server.

Parameters

nTimeout

Timeout for server response, in seconds. A value of zero specifies that the connection should be polled without blocking the current thread.

lpdwAvail

A pointer to an unsigned integer which will contain the number of bytes available to read. This parameter may be NULL if this information is not required.

Return Value

If the client can read data from the server within the specified timeout period, the method returns a non-zero value. If the client cannot read any data, the method returns zero.

Remarks

On some platforms, this value will not exceed the size of the receive buffer (typically 64K bytes). Because of differences between TCP/IP stack implementations, it is not recommended that your application exclusively depend on this value to determine the exact number of bytes available. Instead, it should be used as a general indicator that there is data available to be read.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnwsv10.lib

See Also

[GetStatus](#), [IsBlocking](#), [IsConnected](#), [IsInitialized](#), [IsWritable](#), [Write](#)

CNntpClient::IsWritable Method

```
BOOL IsWritable(  
    INT nTimeout  
);
```

The **IsWritable** method is used to determine if data can be written to the server.

Parameters

nTimeout

Timeout for server response, in seconds. A value of zero specifies that the connection should be polled without blocking the current thread.

Return Value

If the client can write data to the server within the specified timeout period, the method returns a non-zero value. If the client cannot write any data, the method returns zero.

Remarks

Although this method can be used to determine if some amount of data can be sent to the remote process it does not indicate the amount of data that can be written without blocking the client. In most cases, it is recommended that large amounts of data be broken into smaller logical blocks, typically some multiple of 512 bytes in length.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnwsv10.lib

See Also

[GetStatus](#), [IsBlocking](#), [IsConnected](#), [IsInitialized](#), [IsReadable](#), [Write](#)

CNntpClient::ListArticles Method

```
INT ListArticles(  
    LONG nFirstArticle,  
    LONG nLastArticle  
);  
  
INT ListArticles(  
    ULONGLONG nFirstArticle,  
    ULONGLONG nLastArticle  
);
```

The **ListArticles** method returns a list of articles in the currently selected newsgroup, within the specified article range.

Parameters

nFirstArticle

The first newsgroup article to be returned in the list. If this value is -1, the list will begin with the first available article in the newsgroup.

nLastArticle

The last newsgroup article to be returned in the list. If the value is -1, the list will end with the last available article in the newsgroup.

Return Value

If the method succeeds, the return value is the server result code. If the method fails, the return value is NNTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

It is possible that there will be gaps in the articles within the range of the first and last articles in the newsgroup. This may be due to a message being canceled or expired. Use the **GetFirstArticle** and **GetNextArticle** methods to read the list of articles returned by the server. If the server can potentially return very large ID values, it is recommended your application use ULONGLONGs (64-bit unsigned integers) instead of LONGs (32-bit signed integers) to store article numbers.

Example

```
// List all articles in the current group  
if (pClient->ListArticles() == NNTP_ERROR)  
    pClient->ShowError();  
else  
{  
    NEWSARTICLE newsArticle;  
    BOOL bResult;  
  
    // Get each article in the current newsgroup, printing the article  
    // number and the subject of the article  
    bResult = pClient->GetFirstArticle(&newsArticle);  
    while (bResult)  
    {  
        printf("%ld %s %s\n", newsArticle.nArticleId, newsArticle.szSubject);  
        bResult = pClient->GetNextArticle(&newsArticle);  
    }  
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnwsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

CNntpClient::ListGroup Method

```
INT ListGroups(  
    LPCTSTR lpszLastUpdated,  
    BOOL bLocalTime  
);
```

The **ListGroups** method instructs the server to begin sending a list of newsgroups that were created since the specified date.

Parameters

lpszLastUpdated

Pointer to a string which specifies the date and time that the list of newsgroups were last retrieved from the server. This parameter may be NULL or an empty string, in which case all available newsgroups will be listed by the server.

bLocalTime

A boolean value which indicates if the time specified in the *lpszLastUpdated* parameter is for the current timezone. If the value is non-zero, the time is assumed to be in the local timezone. If the value is zero, the time is assumed to be in Coordinated Universal Time (UTC).

Return Value

If the method succeeds, the return value is the server result code. If the method fails, the return value is NNTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **ListGroups** method is used in conjunction with the **GetFirstGroup** and **GetNextGroup** methods to enumerate all of the newsgroups that were added to the server since a specific date and time. Typically this is used to provide the user with a list of updated newsgroups to select. To list all of the newsgroups available on the server, omit the arguments to this method.

While the newsgroups are being listed, the client cannot select a newsgroup or retrieve the contents of a specific article. The client should store those newsgroups which it wants to retrieve articles from, and then once all of the newsgroups have been listed, it can then select each newsgroup and retrieve the available articles from that group.

Example

```
LPCTSTR lpszUpdated = _T("1/1/2004 12:00 AM");  
  
// List all newsgroups that were added after a specific date  
if (pClient->ListGroup(lpszUpdated, TRUE) == NNTP_ERROR)  
    pClient->ShowError();  
else  
{  
    NEWSGROUP newsGroup;  
    BOOL bResult;  
  
    // Get each newsgroup, printing the article range and  
    // the name of the group  
    bResult = pClient->GetFirstGroup(&newsGroup);  
    while (bResult)  
    {  
        printf("%ld %ld %s\n", newsGroup.nFirstArticle,  
              newsGroup.nLastArticle,
```

```
        newsGroup.szName);  
    bResult = pClient->GetNextGroup(&newsGroup);  
    }  
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csnwsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

CNntpClient::OpenArticle Method

```
INT OpenArticle(  
    LONG nArticleId  
);  
  
INT OpenArticle(  
    LPCTSTR lpszMessageId  
);
```

The **OpenArticle** method opens the specified article in the currently selected newsgroup.

Parameters

nArticleId

Number that specifies which article in the current newsgroup to retrieve. This value may be zero, which specifies that the current article should be returned.

lpszMessageId

Pointer to a string which contains the message identifier for the article in the current newsgroup.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is NNTP_ERROR. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnwsv10.lib

See Also

CNntpClient::OpenNextArticle Method

```
INT OpenNextArticle();
```

The **OpenNextArticle** method opens the next available article in the current newsgroup.

Parameters

None.

Return Value

If the method succeeds, the return value is the server result code. If the method fails, the return value is NNTP_ERROR. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnwsv10.lib

See Also

[CloseArticle](#), [GetArticle](#), [GetArticleRange](#), [GetCurrentArticle](#), [ListArticles](#), [OpenPreviousArticle](#), [Read](#)

CNntpClient::OpenPreviousArticle Method

```
INT OpenPreviousArticle();
```

The **OpenPreviousArticle** method opens the previous article in the current newsgroup.

Parameters

None.

Return Value

If the method succeeds, the return value is the server result code. If the method fails, the return value is NNTP_ERROR. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnwsv10.lib

See Also

CNntpClient::PostArticle Method

```
INT PostArticle(  
    LPCTSTR lpBuffer,  
    DWORD dwLength  
);
```

The **PostArticle** method post the contents of the specified buffer to the server as a new article in the current newsgroup.

Parameters

lpBuffer

A pointer to a character buffer which contains the article to be posted to the currently selected newsgroup.

dwLength

Specifies the length of the string which contains the article. If this parameter is -1, the actual length of the string is calculated by searching the buffer for a terminating null byte.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is NNTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **PostArticle** method is used to post the contents of the specified buffer to the server as a new article in the current newsgroup. Not all newsgroups permit new articles to be posted, and some newsgroups may require that you email the article to a moderator for approval instead of posting directly to the group. It may be required that the client authenticate itself using the **Authenticate** method prior to posting the article.

A news article is similar to an email message in that it contains one or more header fields, followed by an empty line, followed by the body of the article. Each line of text should be terminated by a carriage return/linefeed sequence of characters. The Mail Message library can be used to compose a message if needed. Note that the article header must contain a header field named "Newsgroups" with a value that specifies the newsgroup or newsgroups the article is being posted to. If this header field is missing, the news server will reject the article.

This method will cause the current thread to block until the transfer has completed, a timeout occurs or the transfer is canceled. During the transfer, the HTTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **EnableEvents**, or by registering a callback function using the **RegisterEvent** method.

To determine the current status of a transfer while it is in progress, use the **GetTransferStatus** method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnwsv10.lib

See Also

CNntpClient::Read Method

```
INT Read(  
    LPBYTE lpBuffer,  
    INT cbBuffer  
);  
  
INT Read(  
    CString& strBuffer,  
    INT cbBuffer  
);
```

The **Read** method reads the specified number of bytes from the client socket and copies them into the buffer. The data may be of any type, and is not terminated with a null character.

Parameters

lpBuffer

Pointer to the buffer in which the data will be copied. An alternate form of this method allows a **CString** variable to be passed and data read from the socket will be returned in that string.

cbBuffer

The maximum number of bytes to read and copy into the specified buffer. This value must be greater than zero.

Return Value

If the method succeeds, the return value is the number of bytes actually read. A return value of zero indicates that the server has closed the connection and there is no more data available to be read. If the method fails, the return value is NNTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

When **Read** is called and the client is in non-blocking mode, it is possible that the method will fail because there is no available data to read at that time. This should not be considered a fatal error. Instead, the application should simply wait to receive the next asynchronous notification that data is available.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnwsv10.lib

See Also

[EnableEvents](#), [IsBlocking](#), [IsReadable](#), [IsWritable](#), [RegisterEvent](#), [Write](#)

CNntpClient::RegisterEvent Method

```
INT RegisterEvent(  
    UINT nEventId,  
    NNTPEVENTPROC lpEventProc,  
    DWORD_PTR dwParam  
);
```

The **RegisterEvent** method registers an event handler for the specified event.

Parameters

nEventId

An unsigned integer which specifies which event should be registered with the specified callback function. One of the following values may be used:

Constant	Description
NNTP_EVENT_CONNECT	The connection to the server has completed.
NNTP_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
NNTP_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
NNTP_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
NNTP_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
NNTP_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.
NNTP_EVENT_COMMAND	A command has been issued by the client and the server response has been received and processed. This event can be used to log the result codes and messages returned by the server in response to actions taken by the client.
NNTP_EVENT_PROGRESS	The client is in the process of sending or receiving a file on the data channel. This event is called periodically during a transfer so that the client can update any user interface components such as a status control or progress bar.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **NntpEventProc** callback function. If this parameter is NULL, the callback for the specified event is disabled.

dwParam

A user-defined integer value that is passed to the callback function. If the application targets the x86 (32-bit) platform, this parameter must be a 32-bit unsigned integer. If the application targets the x64 (64-bit) platform, this parameter must be a 64-bit unsigned integer.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is NNTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **RegisterEvent** method associates a callback function with a specific event. The event handler is an **NntpEventProc** function that is invoked when the event occurs. Arguments are passed to the function to identify the client session, the event type and the user-defined value specified when the event handler is registered. If the event occurs because of an error condition, the error code will be provided to the handler.

This method is typically used to register an event handler that is invoked while a news article is being uploaded or downloaded. The NNTP_EVENT_PROGRESS event will only be generated periodically during the transfer to ensure the application is not flooded with event notifications. It is guaranteed that at least one NNTP_EVENT_PROGRESS notification will occur at the beginning of the transfer, and one at the end of the transfer when it has completed.

The callback function specified by the *lpEventProc* parameter must be declared using the **__stdcall** calling convention. This ensures the arguments passed to the event handler are pushed on to the stack in the correct order. Failure to use the correct calling convention will corrupt the stack and cause the application to terminate abnormally.

The *dwParam* parameter is commonly used to identify the class instance which is associated with the event that has occurred. Applications will cast the **this** pointer to a DWORD_PTR value when calling this function, and then the event handler will cast it back to a pointer to the class instance. This gives the handler access to the class member variables and methods.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csnwsv10.lib

See Also

[DisableEvents](#), [EnableEvents](#), [FreezeEvents](#), [NntpEventProc](#)

CNntpClient::Reset Method

```
INT Reset();
```

The **Reset** method resets the client state and resynchronizes with the server. This method is typically called after an unexpected error has occurred, or an operation has been canceled.

Parameters

None.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is NNTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The client cannot be reset while it is in a blocked state.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csnwsv10.lib

See Also

[Cancel](#), [IsBlocking](#)

CNntpClient::SelectGroup Method

```
INT SelectGroup(  
    LPCTSTR lpszGroupName  
);
```

The **SelectGroup** method selects the specified newsgroup from which articles will be retrieved.

Parameters

lpszGroupName

Pointer to a string which specifies the newsgroup to be selected. This value may be NULL, in which case the current newsgroup is unchanged, but the article count is updated.

Return Value

If the method succeeds, the return value is the server result code. If the method fails, the return value is NNTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

This method selects the newsgroup and obtains a description and the first and last article numbers for that group.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnwsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[GetGroupName](#), [GetGroupTitle](#), [ListGroup](#)s

CNntpClient::SetLastError Method

```
VOID SetLastError(  
    DWORD dwErrorCode  
);
```

The **SetLastError** method sets the last error code for the current thread. This method is typically used to clear the last error by specifying a value of zero as the parameter.

Parameters

dwErrorCode

Specifies the last error code for the current thread.

Return Value

None.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. Most methods will set the last error code value when they fail; a few methods set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or NNTP_ERROR. Those methods which call **SetLastError** when they succeed are noted on the method reference page.

Applications can retrieve the value saved by this method by using the **GetLastError** method. The use of **GetLastError** is optional; an application can call the method to determine the specific reason for a method failure.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csnwsv10.lib

See Also

[GetErrorString](#), [GetLastError](#), [ShowError](#)

CNntpClient::SetTimeout Method

```
INT SetTimeout(  
    UINT nTimeout  
);
```

The **SetTimeout** method sets the number of seconds the client will wait for a response from the server. Once the specified number of seconds has elapsed, the method will fail and return to the caller.

Parameters

nTimeout

The number of seconds to wait for a blocking operation to complete.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is NNTP_ERROR. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnwsv10.lib

See Also

[Connect](#), [GetTimeout](#), [IsReadable](#), [IsWritable](#), [Read](#), [Write](#)

CNntpClient::ShowError Method

```
INT ShowError(  
    LPCTSTR lpszAppTitle,  
    UINT uType,  
    DWORD dwErrorCode  
);
```

The **ShowError** method displays a message box which describes the specified error.

Parameters

lpszAppTitle

A pointer to a string which specifies the title of the message box that is displayed. If this argument is NULL or omitted, then the default title of "Error" will be displayed.

uType

An unsigned integer which specifies the type of message box that will be displayed. This is the same value that is used by the **MessageBox** method in the Windows API. If a value of zero is specified, then a message box with a single OK button will be displayed. Refer to that method for a complete list of options.

dwErrorCode

Specifies the error code that will be used when displaying the message box. If this argument is zero, then the last error that occurred in the current thread will be displayed.

Return Value

If the method is successful, the return value will be the return value from the **MessageBox** function. If the method fails, it will return a value of zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csnwsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[GetErrorString](#), [GetLastError](#), [SetLastError](#)

CNntpClient::StoreArticle Method

```
INT StoreArticle(  
    LONG nArticleId,  
    LPCTSTR lpszFileName  
);
```

The **StoreMessage** method retrieves an article from the current newsgroup and stores it in a local file.

Parameters

nArticleId

Number of the article to retrieve. This value must be greater than zero.

lpszFileName

Pointer to a string which specifies the file that the article will be stored in. If the file does not exist, it will be created. If the file does exist, it will be overwritten with the contents of the article.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is NNTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **StoreArticle** method provides a method of retrieving and storing an article on the local system. The contents of the article is stored as a text file, using the specified file name. This method always causes the caller to block until the entire message has been retrieved, even if the client has been put in asynchronous mode.

If event handling is enabled, the NNTP_EVENT_PROGRESS event will fire periodically during the transfer of the article to the local system. An application can determine how much of the article has been retrieved by calling the **GetTransferStatus** method.

To retrieve the message into a global memory buffer so that it can be passed to the MIME library, use the **GetArticle** method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csnwsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[GetArticle](#), [GetArticleHeaders](#), [GetTransferStatus](#)

CNntpClient::Write Method

```
INT Write(  
    LPBYTE lpBuffer,  
    INT cbBuffer  
);  
  
INT Write(  
    LPCTSTR lpszBuffer  
    INT cbBuffer  
);
```

The **Write** method sends the specified number of bytes to the server.

Parameters

lpBuffer

The pointer to the buffer which contains the data that is to be sent to the server. In an alternate form of the method, the pointer is to a string.

cbBuffer

The number of bytes to send from the specified buffer. This value must be greater than zero, unless a pointer to a string buffer is passed as the parameter. In that case, if the value is -1, all of the characters in the string, up to but not including the terminating null character, will be sent to the server.

Return Value

If the method succeeds, the return value is the number of bytes actually written. If the method fails, the return value is NNTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The return value may be less than the number of bytes specified by the *cbBuffer* parameter. In this case, the data has been partially written and it is the responsibility of the client application to send the remaining data at some later point. For non-blocking clients, the client must wait for the next asynchronous notification message before it resumes sending data.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnwsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

Network News Transfer Protocol Data Structures

- NEWSARTICLE
- NEWSGROUP
- NNTPTRANSFERSTATUS
- SECURITYCREDENTIALS
- SECURITYINFO
- SYSTEMTIME

NEWSARTICLE Structure

This structure is used by the [GetFirstArticle](#) and [GetNextArticle](#) methods to return information about articles in the currently selected directory.

```
typedef struct _NEWSARTICLE
{
    LONG        nArticleId;
    LONG        nBytes;
    LONG        nLines;
    TCHAR       szSubject[NNTP_MAXSUBJLEN];
    TCHAR       szAuthor[NNTP_MAXAUTHLEN];
    TCHAR       szMessageId[NNTP_MAXMSGIDLEN];
    TCHAR       szReferences[NNTP_MAXREFLEN];
    SYSTEMTIME  stPosted;
} NEWSARTICLE, *LPNEWSARTICLE;
```

Members

nArticleId

A long integer which specifies the article number.

nBytes

The length of the news article in bytes.

nLines

The length of the news article specified as the number of lines of text.

szSubject

A pointer to a string which specifies the subject of the article.

szAuthor

A pointer to a string which specifies the email address of the user who posted the article.

szMessageId

A pointer to a string which specifies the message ID for the article.

szReferences

A pointer to a string which specifies references to the article.

stPosted

A SYSTEMTIME structure which specifies when the article was posted in Universal Coordinated Time (UTC).

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csnews10.lib

Unicode: Implemented as Unicode and ANSI versions.

NEWSGROUP Structure

This structure is used by the [GetFirstGroup](#) and [GetNextGroup](#) methods to return information about available newsgroups.

```
typedef struct _NEWSGROUP
{
    LONG        nFirstArticle;
    LONG        nLastArticle;
    DWORD       dwAccess;
    TCHAR       szName[NNTP_MAXGRPNAMELEN];
} NEWSGROUP, *LPNEWSGROUP;
```

Members

nFirstArticle

A long integer which specifies the article number of the first available article in the newsgroup.

nLastArticle

A long integer which specifies the article number of the last available article in the newsgroup. Note that posted articles may not be contiguous in the range between the first and last article numbers. Some servers may assign numbers in a different order than the articles were posted, or there may be gaps where articles have been removed.

dwAccess

An unsigned integer which specifies the access mode for the group. It may be one of the following values:

Constant	Description
NNTP_GROUP_READONLY	The group is read-only and cannot be modified. Attempts to post articles to the newsgroup will result in an error.
NNTP_GROUP_READWRITE	Articles can be posted to the newsgroup. Even though a newsgroup is read-write, it may require that the client authenticate before being given permission to post articles to the server.
NNTP_GROUP_MODERATED	The newsgroup is moderated and articles can only be posted by the group moderator. To request that an article be posted to the newsgroup, you must email the message to the moderator.

szName

A pointer to a string which specifies the name of the newsgroup.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csnews10.lib

Unicode: Implemented as Unicode and ANSI versions.

NNTPTTRANSFERSTATUS Structure

This structure is used by the [GetTransferStatus](#) method to return information about an article transfer in progress.

```
typedef struct _NNTPTTRANSFERSTATUS
{
    UINT    nArticleId;
    DWORD   dwBytesTotal;
    DWORD   dwBytesCopied;
    DWORD   dwBytesPerSecond;
    DWORD   dwTimeElapsed;
    DWORD   dwTimeEstimated;
} NNTPTTRANSFERSTATUS, *LPNNTPTTRANSFERSTATUS;
```

Members

nArticleId

The article ID of the current article that is being transferred. If an article is being posted, this member will be set to zero.

dwBytesTotal

The total number of bytes that will be transferred. If the article is being copied from the server to the local host, this is the size of the article on the server. If the article is being posted to the server, it is the size of article on the local system. If the article size cannot be determined, this value will be zero.

dwBytesCopied

The total number of bytes that have been copied.

dwBytesPerSecond

The average number of bytes that have been copied per second.

dwTimeElapsed

The number of seconds that have elapsed since the transfer started.

dwTimeEstimated

The estimated number of seconds until the transfer is completed. This is based on the average number of bytes transferred per second.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

SECURITYCREDENTIALS Structure

The **SECURITYCREDENTIALS** structure specifies the information needed by the library to specify additional security credentials, such as a client certificate or private key, when establishing a secure connection.

```
typedef struct _SECURITYCREDENTIALS
{
    DWORD    dwSize;
    DWORD    dwProtocol;
    DWORD    dwOptions;
    DWORD    dwReserved;
    LPCTSTR  lpszHostName;
    LPCTSTR  lpszUserName;
    LPCTSTR  lpszPassword;
    LPCTSTR  lpszCertStore;
    LPCTSTR  lpszCertName;
    LPCTSTR  lpszKeyFile;
} SECURITYCREDENTIALS, *LPSECURITYCREDENTIALS;
```

Members

dwSize

Size of this structure. If the structure is being allocated dynamically, this member must be set to the size of the structure and all other unused structure members must be initialized to a value of zero or NULL.

dwProtocol

A bitmask of supported security protocols. The value of this structure member is constructed by using a bitwise operator with any of the following values:

Constant	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_SSL	Either SSL 2.0 or SSL 3.0 should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, TLS will be excluded from the list of supported protocols. Both SSL 2.0 and 3.0 have been deprecated and will never be used unless explicitly specified. It is not recommended that you enable either of these protocols for secure connections because it will cause most servers to reject your connection request, even if a version of TLS is also specified.
SECURITY_PROTOCOL_TLS	Either the TLS 1.0, 1.1 or 1.2 protocol should be used when establishing a secure connection. The correct protocol is automatically selected, based on

	what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers that reject any attempt to use the older SSL protocol and require that only TLS be used.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This is the recommended version of TLS to use with secure connections.

dwOptions

A value which specifies one or options. This member is constructed by using a bitwise operator with any of the following values:

Constant	Description
CREDENTIAL_STORE_CURRENT_USER	The library will attempt to open a store for the current user using the certificate store name provided in this structure. If no options are specified, then this is the default behavior.
CREDENTIAL_STORE_LOCAL_MACHINE	The library will attempt to open a local machine store using the certificate store name provided in this structure. If this option is specified, the library will always search for a local machine store before searching for the store by that name for the current user.
CREDENTIAL_STORE_FILENAME	The certificate store name is a file that contains the certificate and private key that

will be used.

dwReserved

This structure member is reserved for future use and should always be initialized to zero.

lpszHostName

A pointer to a null terminated string which specifies the hostname that will be used when validating the server certificate. If this member is NULL, then the server certificate will be validated against the hostname used to establish the connection.

lpszUserName

A pointer to a null terminated string which identifies the owner of client certificate. Currently this member is not used by the library and should always be initialized as a NULL pointer.

lpszPassword

A pointer to a null terminated string which specifies the password needed to access the certificate. Currently this member is only used if the CREDENTIAL_STORE_FILENAME option has been specified. If there is no password associated with the certificate, then this member should be initialized as a NULL pointer.

lpszCertStore

A pointer to a null terminated string which specifies the name of the certificate store to open. A certificate store is a collection of certificates and their private keys, typically organized by how they are used. If this value is NULL or points to an empty string, the default certificate store "MY" will be used.

Store Name	Description
------------	-------------

CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as VeriSign and Thawte act as certification authorities.
----	---

MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. This corresponds to the "Personal" store that is displayed by the certificate manager utility and is the default store used by the library.
----	--

ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as VeriSign and Thawte are installed as part of the operating system and periodically updated by Microsoft.
------	--

lpszCertName

A pointer to a null terminated string which specifies the name of the certificate to use. The library will first search the certificate store for a certificate with a matching "friendly name"; this is a name for the certificate that is assigned by the user. Note that the name must match completely, but the comparison is not case sensitive. If no matching certificate is found, the library will then attempt to find a certificate that has a matching common name (also called the certificate subject). This comparison is less stringent, and the first partial match will be returned. If this second search fails, the library will return an error indicating that the certificate could not be found. If the SECURITY_PROTOCOL_SSH protocol has been specified, this member should be NULL.

lpszKeyFile

A pointer to a null terminated string which specifies the name of the file which contains the private key required to establish the connection. This member is only used for SSH connections

and should always be NULL when establishing a secure connection using SSL or TLS.

Remarks

A client application only needs to create this structure if the server requires that the client provide a certificate as part of the process of negotiating the secure session. If a certificate is required, note that it must have a private key associated with it. Attempting to use a certificate that does not have a private key will result in an error during the connection process indicating that the client credentials could not be established.

If you are using a local certificate store, with the certificate and private key stored in the registry, you can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU:" for the current user, or "HKLM:" for the local machine. For example, a certificate store name of "HKLM:MY" would specify the personal certificate store for the local machine, rather than the current user. If neither prefix is specified, then it will default to the certificate store for the current user. You can manage these certificates using the CertMgr.msc Microsoft Management Console (MMC) snap-in.

It is possible to load the certificate from a file rather than from current user's certificate store. The *dwOptions* member should be set to CREDENTIAL_STORE_FILENAME and the *lpzCertStore* member should specify the name of the file that contains the certificate and its private key. The file must be in Private Information Exchange (PFX) format, also known as PKCS#12. These certificate files typically have an extension of .pfx or .p12. Note that if a password was specified when the certificate file was created, it must be provided in the *lpzPassword* member or the library will be unable to access the certificate.

Note that the *lpzUserName* and *lpzPassword* members are values which are used to access the certificate store or private key file. They are not the credentials which are used when establishing the connection with the remote host or authenticating the client session.

The TLS 1.1 and TLS 1.2 protocols are only supported on Windows 7, Windows Server 2008 R2 and later versions of the platform. If these options are specified and the application is running on Windows XP or Windows Vista, the protocol version will be downgraded to TLS 1.0 for backwards compatibility with those platforms.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cstools10.h

Unicode: Implemented as Unicode and ANSI versions.

SECURITYINFO Structure

This structure contains information about a secure connection that has been established.

```
typedef struct _SECURITYINFO
{
    DWORD        dwSize;
    DWORD        dwProtocol;
    DWORD        dwCipher;
    DWORD        dwCipherStrength;
    DWORD        dwHash;
    DWORD        dwHashStrength;
    DWORD        dwKeyExchange;
    DWORD        dwCertStatus;
    SYSTEMTIME   stCertIssued;
    SYSTEMTIME   stCertExpires;
    LPCTSTR      lpszCertIssuer;
    LPCTSTR      lpszCertSubject;
    LPCTSTR      lpszFingerprint;
} SECURITYINFO, *LPSECURITYINFO;
```

Members

dwSize

Specifies the size of the data structure. This member must always be initialized to **sizeof(SECURITYINFO)** prior to passing the address of this structure to the function. Note that if this member is not initialized, an error will be returned indicating that an invalid parameter has been passed to the function.

dwProtocol

A numeric value which specifies the protocol that was selected to establish the secure connection. One of the following values will be returned:

Constant	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_SSL	Either SSL 2.0 or SSL 3.0 should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, TLS will be excluded from the list of supported protocols. Both SSL 2.0 and 3.0 have been deprecated and will never be used unless explicitly specified. It is not recommended that you enable either of these protocols for secure connections because it will cause most servers to reject your connection request, even if a version of TLS is also specified.
SECURITY_PROTOCOL_TLS	Either the TLS 1.0, 1.1 or 1.2 protocol should be used when establishing a secure connection. The

	<p>correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers that reject any attempt to use the older SSL protocol and require that only TLS be used.</p>
SECURITY_PROTOCOL_TLS10	<p>The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.</p>
SECURITY_PROTOCOL_TLS11	<p>The TLS 1.1 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.</p>
SECURITY_PROTOCOL_TLS12	<p>The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This is the recommended version of TLS to use with secure connections.</p>

dwCipher

A numeric value which specifies the cipher that was selected when establishing the secure connection. One of the following values will be returned:

Constant	Description
SECURITY_CIPHER_RC2	The RC2 block cipher was selected. This is a variable key length cipher which supports keys between 40 and 128 bits, in 8-bit increments.
SECURITY_CIPHER_RC4	The RC4 stream cipher was selected. This is a variable key length cipher which supports keys between 40 and 128 bits, in 8-bit increments.
SECURITY_CIPHER_RC5	The RC5 block cipher was selected. This is a variable key length cipher which supports keys up to 2040 bits, in 8-bit increments.
SECURITY_CIPHER_DES	The DES (Data Encryption Standard) block cipher was selected. This is a fixed key length cipher, using 56-bit

	keys.
SECURITY_CIPHER_DES3	The Triple DES block cipher was selected. This cipher encrypts the data three times using different keys, effectively providing a 168-bit length key.
SECURITY_CIPHER_DESX	A variant of the DES block cipher which XORs an extra 64-bits of the key before and after the plaintext has been encrypted, increasing the key size to 184 bits.
SECURITY_CIPHER_AES	The Advanced Encryption Standard cipher (also known as the Rijndael cipher) is a fixed block size cipher which use a key size of 128, 192 or 256 bits. This cipher is supported on Windows XP SP3 and later versions of the operating system.
SECURITY_CIPHER_SKIPJACK	The Skipjack block cipher was selected. This is a fixed key length cipher, using 80-bit keys.
SECURITY_CIPHER_BLOWFISH	The Blowfish block cipher was selected. This is a variable key length cipher up to 448 bits, using a 64-bit block size.

dwCipherStrength

A numeric value which specifies the strength (the length of the cipher key in bits) of the cipher that was selected. Typically this value will be 128 or 256. 40-bit and 56-bit key lengths are considered weak encryption, and subject to brute force attacks. 128-bit and 256-bit key lengths are considered to be secure, and are the recommended key length for secure communications.

dwHash

A numeric value which specifies the hash algorithm which was selected. One of the following values will be returned:

Constant	Description
SECURITY_HASH_MD5	The MD5 algorithm was selected. Its use has been deprecated and is no longer considered to be cryptographically secure.
SECURITY_HASH_SHA1	The SHA-1 algorithm was selected. Its use has been deprecated and is no longer considered to be cryptographically secure.
SECURITY_HASH_SHA256	The SHA-256 algorithm was selected.
SECURITY_HASH_SHA384	The SHA-384 algorithm was selected.
SECURITY_HASH_SHA512	The SHA-512 algorithm was selected.

dwHashStrength

A numeric value which specifies the strength (the length in bits) of the message digest that was selected.

dwKeyExchange

A numeric value which specifies the key exchange algorithm which was selected. One of the following values will be returned:

--	--

Constant	Description
SECURITY_KEYEX_RSA	The RSA public key algorithm was selected.
SECURITY_KEYEX_KEA	The Key Exchange Algorithm (KEA) was selected. This is an improved version of the Diffie-Hellman public key algorithm.
SECURITY_KEYEX_DH	The Diffie-Hellman key exchange algorithm was selected.
SECURITY_KEYEX_ECDH	The Elliptic Curve Diffie-Hellman key exchange algorithm was selected. This is a variant of the Diffie-Hellman algorithm which uses elliptic curve cryptography. This key exchange algorithm is only supported on Windows XP SP3 and later versions of the operating system.

dwCertStatus

A numeric value which specifies the status of the certificate returned by the secure server. This member only has meaning for connections using the SSL or TLS protocols. One of the following values will be returned:

Constant	Description
SECURITY_CERTIFICATE_VALID	The certificate is valid.
SECURITY_CERTIFICATE_NOMATCH	The certificate is valid, but the domain name does not match the common name in the certificate.
SECURITY_CERTIFICATE_EXPIRED	The certificate is valid, but has expired.
SECURITY_CERTIFICATE_REVOKED	The certificate has been revoked and is no longer valid.
SECURITY_CERTIFICATE_UNTRUSTED	The certificate or certificate authority is not trusted on the local system.
SECURITY_CERTIFICATE_INVALID	The certificate is invalid. This typically indicates that the internal structure of the certificate has been damaged.

stCertIssued

A structure which contains the date and time that the certificate was issued by the certificate authority. If the issue date cannot be determined for the certificate, the SYSTEMTIME structure members will have zero values. This member only has meaning for connections using the SSL or TLS protocols.

stCertExpires

A structure which contains the date and time that the certificate expires. If the expiration date cannot be determined for the certificate, the SYSTEMTIME structure members will have zero values. This member only has meaning for connections using the SSL or TLS protocols.

lpszCertIssuer

A pointer to a string which contains information about the organization that issued the certificate. This string consists of one or more comma-separated tokens. Each token consists of an identifier, followed by an equal sign and a value. If the certificate issuer could not be determined, this member may be NULL. This member only has meaning for connections using the SSL or TLS protocols.

lpszCertSubject

A pointer to a string which contains information about the organization that the certificate was issued to. This string consists of one or more comma-separated tokens. Each token consists of an identifier, followed by an equal sign and a value. If the certificate subject could not be determined, this member may be NULL. This member only has meaning for connections using the SSL or TLS protocols.

lpszFingerprint

A pointer to a string which contains a sequence of hexadecimal values that uniquely identify the server. This member is only used when a connection has been established using the Secure Shell (SSH) protocol.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Unicode: Implemented as Unicode and ANSI versions.

SYSTEMTIME Structure

The **SYSTEMTIME** structure represents a date and time using individual members for the month, day, year, weekday, hour, minute, second, and millisecond.

```
typedef struct _SYSTEMTIME
{
    WORD wYear;
    WORD wMonth;
    WORD wDayOfWeek;
    WORD wDay;
    WORD wHour;
    WORD wMinute;
    WORD wSecond;
    WORD wMilliseconds;
} SYSTEMTIME, *LPSYSTEMTIME;
```

Members

wYear

Specifies the current year. The year value must be greater than 1601.

wMonth

Specifies the current month. January is 1, February is 2 and so on.

wDayOfWeek

Specifies the current day of the week. Sunday is 0, Monday is 1 and so on.

wDay

Specifies the current day of the month

wHour

Specifies the current hour.

wMinute

Specifies the current minute

wSecond

Specifies the current second.

wMilliseconds

Specifies the current millisecond.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include windows.h.

News Feed Class Library

Retrieve and process the contents of a syndicated news feed.

Reference

- [Class Methods](#)
- [Data Structures](#)
- [Error Codes](#)

Library Information

Class Name	CNewsFeed
File Name	CSRSSV10.DLL
Version	10.0.1468.2518
LibID	1F65A283-7BC8-4F5B-B739-D211EAF1CA35
Import Library	CSRSSV10.LIB
Dependencies	None

Overview

Really Simple Syndication (RSS) is a collection of standardized formats that are used to publish information about content that is frequently changed. A news feed is published in XML format, which contains one or more items that includes summary text, hyperlinks to source content and additional metadata that is used to describe the item. News feeds can be used for a variety of purposes, including providing updates for weblogs, news headlines, video and audio content. RSS can also be used for other purposes, such as a software updates, where new updates are listed as items in the feed.

News feeds can be accessed remotely from a web server, or locally as an XML formatted text file. The source of the feed is determined by the URI scheme that is specified. If the http or https scheme is specified, then the feed is retrieved from a web server. If the file scheme is used, the feed is considered to be local and is accessed from the disk or local network. The CNewsFeed class provides an interface that enables you to open a feed by URL and iterate through each of the items in the feed or search for a specific feed item. The class also provides a method that can be used to parse a string that contains XML data in RSS format, where the feed may have been retrieved from other sources such as a database.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). If you are using Visual C++ 6.0 it is required that you have Service Pack 6 (SP6) installed. You should install all updates for your development tools and have the current Windows SDK installed. The minimum recommended version of Visual Studio is Visual Studio 2010.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are using Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. It is recommended that you install the current service pack and all critical updates available for your version of the operating system.

This product includes both 32-bit and 64-bit libraries. Native 64-bit CPU support requires the 64-

bit version of Windows 7 or later versions of the Windows operating system.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

News Feed Class Methods

Class	Description
CNewsFeed	Constructor which initializes the current instance of the class
~CNewsFeed	Destructor which releases resources allocated by the class
Method	Description
AttachHandle	Attach the specified client handle to this instance of the class
CloseFeed	Close the specified news feed and release memory allocated for the channel
DetachHandle	Detach the handle for the current instance of this class
DisableTrace	Disable logging of network function calls
EnableTrace	Enable logging of network function calls to a text file
FindItem	Find a specific news feed item using its unique identifier (GUID) property
GetErrorString	Return a description for the specified error code
GetFirstItem	Return information about the first item in the news feed channel
GetHandle	Return the client handle used by this instance of the class
GetItem	Return information about the specified news feed item
GetItemCount	Return the number of news feed items in the channel
GetItemProperty	Return the value of the specified news feed item property or attribute
GetItemText	Return the text description of the specified news feed item
GetLastError	Return the last error code
GetNextItem	Return information about the next item in the news feed channel
IsInitialized	Determine if the class has been successfully initialized
OpenFeed	Open the specified news feed and return information about the channel
ParseFeed	Parse the contents of a string and return information about the channel
RefreshFeed	Refresh the specified news feed, updating the items in the channel
SetLastError	Set the last error code
ShowError	Display a message box with a description of the specified error
StoreFeed	Store the contents of the specified news feed in an XML formatted text file
ValidateFeed	Validate the contents of the specified news feed, returning the number of items in the feed

CNewsFeed::CNewsFeed Method

`CNewsFeed()`;

The **CNewsFeed** constructor initializes the class library and validates the license key at runtime.

Remarks

If the constructor fails to validate the runtime license, subsequent methods in this class will fail. If the product is installed with an evaluation license, then the application will only function on the development system and cannot be redistributed.

The constructor calls the **RssInitialize** function to initialize the library, which dynamically loads other system libraries and allocates thread local storage. If you are using this class within another DLL, it is important that you do not create or destroy an instance of the class from within the **DllMain** function because it can result in deadlocks or access violation errors. You should not declare static or global instances of this class within another DLL if it is linked with the C runtime library (CRT) because it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csrsv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

See Also

[~CNewsFeed, IsInitialized](#)

CNewsFeed::~CNewsFeed

`~CNewsFeed();`

The **CNewsFeed** destructor releases resources allocated by the current instance of the **CNewsFeed** object. It also uninitialized the library if there are no other concurrent uses of the class.

Remarks

When a **CNewsFeed** object goes out of scope, the destructor is automatically called to allow the library to free any resources allocated on behalf of the process. Any pending blocking or asynchronous calls in this process are canceled without posting any notification messages, and all handles that were created for the client session are destroyed.

The destructor is not called explicitly by the application.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csrsv10.lib`

See Also

[CNewsFeed](#)

CNewsFeed::AttachHandle Method

```
VOID AttachHandle(  
    HCHANNEL hChannel  
);
```

The **AttachHandle** method attaches the specified handle to the current instance of the class.

Parameters

hChannel

The handle to the channel that will be attached to the current instance of the class object.

Return Value

None.

Remarks

This method is used to attach a handle created outside of the class using the SocketTools API. Once the handle is attached to the class, the other class member functions may be used with that news feed channel.

If a handle already has been created for the class, that handle will be released when the new handle is attached to the class object. If you want to prevent the previous news feed channel from being closed, you must call the **DetachHandle** method. Failure to close the detached handle may result in a resource leak in your application.

Note that the *hChannel* parameter is presumed to be valid and no checks are performed to ensure its validity. Specifying an invalid handle value will cause subsequent method calls to fail.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csrssv10.lib

See Also

[DetachHandle](#), [GetHandle](#)

CNewsFeed::CloseFeed Method

```
BOOL CloseFeed();
```

The **CloseFeed** method closes the specified news feed and releases memory allocated for the channel.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **CloseFeed** method must be called whenever the application has completed processing the news feed. It is important to note that the memory allocated for the channel will be released when this function is called, which means that any data referenced in the `RSSCHANNEL` and `RSSCHANNELITEM` structures will no longer be valid and must not be used by the application after the feed has been closed.

This method can fail if the feed is currently being updated, such as when the **RefreshFeed** method is called. In this case, the channel handle will not be released and the application must attempt to close the feed at a later time.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csrsv10.lib`

See Also

[OpenFeed](#) [ParseFeed](#) [StoreFeed](#)

CNewsFeed::DetachHandle Method

```
HCHANNEL DetachHandle();
```

The **DetachHandle** method detaches the handle associated with the current instance of the class.

Parameters

None.

Return Value

This method returns the handle associated with the current instance of the class object. If there is no open news feed, the value `INVALID_CHANNEL` will be returned.

Remarks

This method is used to detach a handle created by the class for use with the SocketTools API. Once the handle is detached from the class, no other class member functions may be called. Note that the handle must be explicitly closed at some later point by the process or a resource leak will occur.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csrsv10.lib`

See Also

[AttachHandle](#), [GetHandle](#)

CNewsFeed::DisableTrace Method

```
BOOL DisableTrace();
```

The **DisableTrace** method disables the logging of socket function calls to the trace log.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, a value of zero is returned.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csrssv10.lib

See Also

[EnableTrace](#)

CNewsFeed::EnableTrace Method

```
BOOL EnableTrace(  
    LPCTSTR lpszTraceFile,  
    DWORD dwTraceFlags  
);
```

The **EnableTrace** method enables the logging of socket function calls to a file.

Parameters

lpszTraceFile

A pointer to a string which specifies the name of the trace log file. If this parameter is NULL or an empty string, the default file name **cstrace.log** is used. The file is stored in the directory specified by the TEMP environment variable, if it is defined; otherwise, the current working directory is used.

dwTraceFlags

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
TRACE_INFO	All function calls are written to the trace file. This is the default value.
TRACE_ERROR	Only those function calls which fail are recorded in the trace file.
TRACE_WARNING	Only those function calls which fail or return values which indicate a warning are recorded in the trace file.
TRACE_HEXDUMP	All functions calls are written to the trace file, plus all the data that is sent or received is displayed, in both ASCII and hexadecimal format.
TRACE_PROCESS	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for multithreaded applications that are using worker threads.

Return Value

If the method succeeds, the return value is non-zero. A return value of zero indicates an error. Failure typically indicates that the tracing library **cstrcv10.dll** cannot be loaded on the local system.

Remarks

When trace logging is enabled, the file is opened, appended to and closed for each socket function call. This makes it possible for an application to append its own logging information, however care should be taken to ensure that the file is closed before the next network operation is performed. To limit the size of the log files, enable and disable logging only around those sections of code that you wish to trace.

Note that the TRACE_HEXDUMP trace level generates very large log files since it includes all of the data exchanged between your application and the server.

Trace method logging is managed on a per-thread basis, not for each client handle. This means that all SocketTools libraries and components share the same settings in the current thread. If you

are using multiple SocketTools libraries or components in your application, you only need to enable logging once.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csrsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[DisableTrace](#)

CNewsFeed::FindItem Method

```
BOOL FindItem(  
    LPCTSTR lpszValue,  
    DWORD dwOptions,  
    LPRSSCHANNELITEM lpItem  
);
```

```
BOOL FindItem(  
    LPCTSTR lpszValue,  
    LPRSSCHANNELITEM lpItem  
);
```

The **FindItem** method searches for an item in the news feed channel which matches the unique identifier (GUID) value and returns information about that item.

Parameters

lpszValue

A pointer to a string which specifies the value of the item being searched for. This value should uniquely identify the item in the feed, and this parameter cannot be an empty string or NULL pointer.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
RSS_FIND_GUID	Search the feed for items with a matching GUID property value. This is the default option, and is the only item property that is guaranteed to be unique in the feed. The search is case-sensitive, requiring that the <i>lpszValue</i> parameter match the property value exactly.
RSS_FIND_LINK	Search the feed for items with a matching link property value. For feeds that do not specify a GUID property, this is the recommended option for searching for an item. The search is not case-sensitive.
RSS_FIND_TITLE	Search the feed for items with a matching title. This option should not be used if you must ensure that the item returned is unique in the feed because there may be multiple items with the same title in the feed. The search is not case-sensitive.
RSS_FIND_PUBDATE	Search the feed for items with a matching publishing date. This option should not be used if you must ensure that the item returned is unique in the feed because more than one item may have the same publishing date. The format of the date string must match the standard format used with the RSS protocol and the match is not case-sensitive.

lpItem

A pointer to a **RSSCHANNELITEM** structure which contains information about the specified item in the news feed. This structure is initialized by the method and the parameter can never

be specified as a NULL pointer.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

It is recommended that you use the `RSS_FIND_GUID` option with news feeds that are using version 2.0 or later of the RSS specification. If the feed uses an earlier version, items may not include a GUID property. It is also possible that a feed may omit the GUID property even though it is considered a requirement for the current RSS specification. For the broadest compatibility with all news feeds, an application should not depend on being able to search for a specific news feed item by its GUID.

Only the GUID property is guaranteed to be unique in the feed. If the feed does not specify GUIDs for the news items, the application must use an alternate criteria such as the item hyperlink or publishing date. If there are multiple items that match the *lpzValue* value, the first matching item will be returned.

The data referenced in the **RSSCHANNELITEM** structure should be considered read-only and never modified by the application. Not all members of the structure may contain valid values, in which case those members will either have a value of zero or will specify NULL pointers. When the feed is closed, the members of this structure will no longer be valid, and therefore should never be stored by the application. If the application needs to store or modify this information, it should create its own private copy of the data.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csrsv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

See Also

CNewsFeed::GetErrorString Method

```
INT GetErrorString(  
    DWORD dwErrorCode,  
    LPTSTR lpszDescription,  
    INT cbDescription  
);  
  
INT GetErrorString(  
    DWORD dwErrorCode,  
    CString& strDescription  
);
```

The **GetErrorString** method is used to return a description of a specific error code. Typically this is used in conjunction with the **GetLastError** method for use with warning dialogs or as diagnostic messages.

Parameters

dwErrorCode

The error code for which a description is returned.

lpszDescription

A pointer to the buffer that will contain a description of the specified error code. This buffer should be at least 128 characters in length. An alternate form of the method accepts a **CString** variable which will contain the error description.

cbDescription

The maximum number of characters that may be copied into the description buffer.

Return Value

If the method succeeds, the return value is the length of the description string. If the method fails, the return value is zero, meaning that no description exists for the specified error code. Typically this indicates that the error code passed to the method is invalid.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csrssv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

CNewsFeed::GetFirstItem Method

```
BOOL GetFirstItem(  
    LPRSSCHANNELITEM LpItem  
);
```

The **GetFirstItem** method returns information about the first item in the news feed channel.

Parameters

lpItem

A pointer to a **RSSCHANNELITEM** structure which contains information about the first item in the news feed. This structure is initialized by the method and the parameter can never be specified as a NULL pointer.

Return Value

If the method succeeds, it returns a non-zero value. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **GetFirstItem** method is used in conjunction with the **GetNextItem** method to enumerate the available items in the specified news feed channel. If this method fails, it typically indicates that the channel does not contain any valid news items or that the format of the news feed is invalid.

The data referenced in the **RSSCHANNELITEM** structure should be considered read-only and never modified by the application. Not all members of the structure may contain valid values, in which case those members will either have a value of zero or will specify NULL pointers. When the feed is closed, the members of this structure will no longer be valid, and therefore should never be stored by the application. If the application needs to store or modify this information, it should create its own private copy of the data.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstoools10.h

Import Library: csrssv10.lib

Unicode: Implemented as Unicode and ANSI versions.

CNewsFeed::GetHandle Method

```
HCHANNEL GetHandle();
```

The **GetHandle** method returns the handle associated with the current instance of the class.

Parameters

None.

Return Value

This method returns the handle associated with the current instance of the class object. If there is no open news feed, the value `INVALID_CHANNEL` will be returned.

Remarks

This method is used to obtain the handle created by the class for use with the SocketTools API.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csrsv10.lib`

See Also

CNewsFeed::GetItem Method

```
BOOL GetItem(  
    UINT nItemId,  
    LPRSSCHANNELITEM lpItem  
);
```

The **GetItem** method returns information about the specified item in the news feed channel.

Parameters

nItemId

An integer value which identifies the news feed item. The first item identifier in the news feed has a value of one, and that value is incremented for each additional item in the feed. If this parameter is zero or specifies a value larger than the number of items in the feed, this method will fail.

lpItem

A pointer to a **RSSCHANNELITEM** structure which contains information about the specified item in the news feed. This structure is initialized by the method and the parameter can never be specified as a NULL pointer.

Return Value

If the method succeeds, it returns a non-zero value. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **GetItem** method is used to return information about a specific item in the news feed. If this method fails, it typically indicates that the item ID is invalid or that the feed does not contain any valid news items. The **GetItemCount** method can be used to determine the number of items contained in the feed channel.

The data referenced in the **RSSCHANNELITEM** structure should be considered read-only and never modified by the application. Not all members of the structure may contain valid values, in which case those members will either have a value of zero or will specify NULL pointers. When the feed is closed, the members of this structure will no longer be valid, and therefore should never be stored by the application. If the application needs to store or modify this information, it should create its own private copy of the data.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csrssv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[FindItem](#), [GetFirstItem](#), [GetItemCount](#), [GetItemProperty](#), [GetItemText](#), [GetNextItem](#), [RSSCHANNELITEM](#)

CNewsFeed::GetItemCount Method

```
INT GetItemCount();
```

The **GetItemCount** method returns the number of items in the news feed channel.

Parameters

None.

Return Value

If the method succeeds, the return value is the number of items in the news feed. A value of zero indicates that the feed channel is empty. If the method fails, the return value is `RSS_ERROR`. To get extended error information, call **GetLastError**.

Remarks

The **GetItemCount** method is used to determine the number of items that are contained in the news feed channel, and therefore determine the maximum value of the item identifier which can be used to reference a specific item in the feed. This value is the same as the value specified by the *nItemCount* member of the **RSSCHANNEL** structure.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csrsv10.lib`

See Also

[FindItem](#), [GetItem](#), [GetItemProperty](#), [GetItemText](#), [RSSCHANNEL](#)

CNewsFeed::GetItemProperty Method

```
INT GetItemProperty(  
    UINT nItemId,  
    LPCTSTR lpszProperty,  
    LPCTSTR lpszAttribute,  
    LPTSTR lpszValue,  
    INT nMaxLength  
);
```

```
INT GetItemProperty(  
    UINT nItemId,  
    LPCTSTR lpszProperty,  
    LPCTSTR lpszAttribute,  
    CString& strValue  
);
```

The **GetItemProperty** method is used to return the value of a property for the specified item in the news feed channel.

Parameters

nItemId

An integer value which identifies the news feed item. The first item identifier in the news feed has a value of one, and that value is incremented for each additional item in the feed. If this parameter is zero or specifies a value larger than the number of items in the feed, this method will fail.

lpszProperty

A pointer to a string which specifies the name of the item property. This parameter cannot point to an empty string or specify a NULL pointer.

lpszAttribute

A pointer to a string which specifies the name of an attribute for the property. If this parameter is an empty string or NULL pointer, the method will return the value of the property, rather than an attribute of the specified property.

lpszValue

A pointer to a string buffer which will contain the value of the specified item property or attribute. This string should be large enough to contain the property value. If this parameter is a NULL pointer, it will be ignored and the method will only return the length of value for the specified property.

nMaxLength

The maximum number of characters that may be copied into the property value buffer. If the value of this parameter is zero, then the *lpszValue* parameter is ignored and the method will only return the length of the value for the specified property.

Return Value

If the method succeeds, the return value is the length of the property value string. A return value of zero indicates that the property does not contain any value. If the method fails, the return value is `RSS_ERROR`. To get extended error information, call **GetLastError**.

Remarks

The **GetItemProperty** method is primarily used with custom item properties that may be used

with extensions to the news feed. The standard properties for an item such as the title, link and description can be obtained using **GetItem** and related methods. However, if items in the feed contain custom properties that are not part of the standard RSS format, this method can be used to obtain those values.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csrsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[FindItem](#), [GetItem](#), [GetItemText](#), [RSSCHANNELITEM](#)

CNewsFeed::GetItemText Method

```
INT GetItemText(  
    UINT nItemId,  
    LPTSTR lpszBuffer,  
    INT nMaxLength  
);
```

```
INT GetItemText(  
    UINT nItemId,  
    CString& strBuffer  
);
```

The **GetItemText** method is used to return a copy of an item's description.

Parameters

nItemId

An integer value which identifies the news feed item. The first item identifier in the news feed has a value of one, and that value is incremented for each additional item in the feed. If this parameter is zero or specifies a value larger than the number of items in the feed, this method will fail.

lpszBuffer

A pointer to a string buffer which will contain the value of the item description. If this parameter is a NULL pointer, it will be ignored and the method will only return the length of the item description.

nMaxLength

The maximum number of characters that may be copied into the description buffer. If the value of this parameter is zero, then the *lpszValue* parameter is ignored and the method will only return the length of the item description.

Return Value

If the method succeeds, the return value is the length of the item description. A return value of zero indicates that the item does not have a description. If the method fails, the return value is `RSS_ERROR`. To get extended error information, call **GetLastError**.

Remarks

The **GetItemText** function is used to obtain a copy of the string that describes the specified item. Typically this is text that provides a summary of the news feed item and is used in conjunction with the item's title and hyperlink to additional content.

The content of an item description is typically either plain text or HTML formatted text. It is the responsibility of the application to display the content in a format is appropriate for the end-user.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csrsvg10.lib`

Unicode: Implemented as Unicode and ANSI versions.

[FindItem](#), [GetItem](#), [GetItemProperty](#), [RSSCHANNELITEM](#)

CNewsFeed::GetLastError Method

```
DWORD GetLastError();  
  
DWORD GetLastError(  
    CString& strDescription  
);
```

Parameters

strDescription

A string which will contain a description of the last error code value when the method returns. If no error has been set, or the last error code has been cleared, this string will be empty.

Return Value

The return value is the last error code value for the current thread. Functions set this value by calling the **SetLastError** method. The Return Value section of each reference page notes the conditions under which the method sets the last error code.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. You should call the **GetLastError** method immediately when a method's return value indicates that an error has occurred. That is because some methods call **SetLastError(0)** when they succeed, clearing the error code set by the most recently failed method.

Most methods will set the last error code value when they fail; a few methods set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or RSS_ERROR. Those methods which call **SetLastError** when they succeed are noted on the method reference page.

The description of the error code is the same string that is returned by the **GetErrorString** method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csrsv10.lib

See Also

[GetErrorString](#), [SetLastError](#), [ShowError](#)

CNewsFeed::GetNextItem Method

```
BOOL GetNextItem(  
    LPRSSCHANNELITEM LpItem  
);
```

The **GetNextItem** method returns information about the next item in the news feed channel.

Parameters

LpItem

A pointer to a **RSSCHANNELITEM** structure which contains information about the next item in the news feed. This structure is initialized by the method and the parameter can never be specified as a NULL pointer.

Return Value

If the method succeeds, it returns a non-zero value. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **GetNextItem** method is used in conjunction with the **GetFirstItem** method to enumerate the available items in the specified news feed channel. If this method fails, it typically indicates that there are no more items in the news feed channel.

The data referenced in the **RSSCHANNELITEM** structure should be considered read-only and never modified by the application. Not all members of the structure may contain valid values, in which case those members will either have a value of zero or will specify NULL pointers. When the feed is closed, the members of this structure will no longer be valid, and therefore should never be stored by the application. If the application needs to store or modify this information, it should create its own private copy of the data.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csrssv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[FindItem](#), [GetFirstItem](#), [GetItem](#), [GetItemProperty](#), [GetItemText](#), [RSSCHANNELITEM](#)

CNewsFeed::IsInitialized Method

```
BOOL IsInitialized();
```

The **IsInitialized** method returns whether or not the class object has been successfully initialized.

Parameters

None.

Return Value

This method returns a non-zero value if the class object has been successfully initialized. A return value of zero indicates that the runtime license key could not be validated or the networking library could not be loaded by the current process.

Remarks

When an instance of the class is created, the class constructor will attempt to initialize the component with the runtime license key that was created when SocketTools was installed. If the constructor is unable to validate the license key or load the networking libraries, this initialization will fail.

If SocketTools was installed with an evaluation license, the application cannot be redistributed to another system. The class object will fail to initialize if the application is executed on another system, or if the evaluation period has expired. To redistribute your application, you must purchase a development license which will include the runtime key that is needed to redistribute your software to other systems. Refer to the Developer's Guide for more information.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csrssv10.lib

See Also

[CNewsFeed](#)

CNewsFeed::OpenFeed Method

```
BOOL OpenFeed(  
    LPCTSTR lpszFeedUrl,  
    UINT nTimeout,  
    DWORD dwOptions,  
    LPRSSCHANNEL lpChannel  
);
```

```
BOOL OpenFeed(  
    LPCTSTR lpszFeedUrl,  
    UINT nTimeout,  
    LPRSSCHANNEL lpChannel  
);
```

```
BOOL OpenFeed(  
    LPCTSTR lpszFeedUrl,  
    LPRSSCHANNEL lpChannel  
);
```

The **OpenFeed** method is used to open a news feed and return a handle which can be used to access the individual news items in the feed.

Parameters

lpszFeedUrl

A pointer to a string which specifies the URL for the news feed. To access a news feed on a web server, a standard http or https URL may be specified. To access a file on the local system or network share, a file name or file URL may be specified.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation. This parameter is ignored if the *lpszFeedUrl* parameter specifies a local file name or URL.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
RSS_OPTION_NONE	No additional options are specified and the news feed is processed using relaxed rules when checking the validity of the feed. The library will attempt to automatically compensate for a feed that is malformed or does not strictly conform to the RSS standard.
RSS_OPTION_STRICT	The news feed content should be processed using strict rules to ensure that the feed meets the appropriate RSS standard specification and all feed property values are case-sensitive. By default, relaxed rules are used which allows the application to open a feed that may not strictly conform to the standard specification.

lpChannel

A pointer to an **RSSCHANNEL** structure which contains information about the news feed

channel such as the feed title, hyperlink and description. If the parameter is not NULL, the structure is initialized by the method. If the parameter is NULL, it is ignored and no information is returned.

Return Value

If the method succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

A news feed may be local or remote, depending on the URL that is specified. If a local file name or file URL is specified for the feed, then it is opened locally and no network access is required. If an http or https URL is specified, then **OpenFeed** will attempt to download the feed from the server and store it temporarily on the local system. Accessing a remote feed requires that the application has permission to establish a connection with the server and will cause the application to block until the feed has been downloaded, the operation times out or an error occurs.

Although the **OpenFeed** method will meet the needs of most applications, if you require more complex functionality such as retrieving the feed asynchronously in the background or event notifications for large transfers, you can use the SocketTools [Hypertext Transfer Protocol](#) API to download the news feed and then use the **ParseFeed** method to parse the contents.

The data referenced in the **RSSCHANNEL** structure should be considered read-only and never modified by the application. Not all members of the structure may contain valid values, in which case those members will either have a value of zero or will specify NULL pointers. When the feed is closed, the members of this structure will no longer be valid, and therefore should never be stored by the application. If the application needs to store or modify this information, it should create its own private copy of the data.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csrsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[CloseFeed](#), [ParseFeed](#), [RefreshFeed](#), [StoreFeed](#), [RSSCHANNEL](#)

CNewsFeed::ParseFeed Method

```
BOOL ParseFeed(  
    LPCTSTR lpszFeedXml,  
    DWORD dwOptions,  
    LPRSSCHANNEL lpChannel  
);
```

```
BOOL ParseFeed(  
    LPCTSTR lpszFeedXml,  
    LPRSSCHANNEL lpChannel  
);
```

The **ParseFeed** method is used to parse the contents of a news feed, returning a handle which can be used to access the individual news items in the feed.

Parameters

lpszFeedXml

A pointer to a string which contains the contents of the news feed. The string must contain XML formatted data that conforms to the RSS standard specification. This parameter cannot specify an empty string or a NULL pointer.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
RSS_OPTION_NONE	No additional options are specified.
RSS_OPTION_STRICT	The news feed content should be processed using strict rules to ensure that the feed meets the appropriate RSS standard specification and all feed property values are case-sensitive. By default, relaxed rules are used which allows the application to open a feed that may not strictly conform to the standard specification.

lpChannel

A pointer to an **RSSCHANNEL** structure which contains information about the news feed channel such as the feed title, hyperlink and description. If the parameter is not NULL, the structure is initialized by the method. If the parameter is NULL, it is ignored and no information is returned.

Return Value

If the method succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **ParseFeed** method is an alternative to the **OpenFeed** method, enabling the application to process a news feed from alternative sources such as a database or compressed file. It is important to note that the string which contains the news feed XML must be properly formatted and conform to the RSS standard specification.

The data referenced in the **RSSCHANNEL** structure should be considered read-only and never

modified by the application. Not all members of the structure may contain valid values, in which case those members will either have a value of zero or will specify NULL pointers. When the feed is closed, the members of this structure will no longer be valid, and therefore should never be stored by the application. If the application needs to store or modify this information, it should create its own private copy of the data.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csrssv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[CloseFeed](#), [OpenFeed](#), [RefreshFeed](#), [StoreFeed](#), [RSSCHANNEL](#)

CNewsFeed::RefreshFeed Method

```
BOOL RefreshFeed(  
    LPRSSCHANNEL lpChannel  
);
```

The **RefreshFeed** method reloads the news feed and updates the items in the channel.

Parameters

lpChannel

A pointer to an **RSSCHANNEL** structure which contains information about the news feed channel such as the feed title, hyperlink and description. If the parameter is not NULL, the structure is initialized by the method. If the parameter is NULL, it is ignored and no information is returned.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

When the **RefreshFeed** method is called, the news feed is reloaded from the original source and the items in the channel are updated. For news feeds that are frequently updated, the *nTimeToLive* member of the **RSSCHANNEL** structure can provide a hint to the application as to how frequently the feed should be refreshed.

If the news feed was originally opened using an http or https URL, this method will download the updated feed from the server and store it temporarily on the local system. Accessing a remote feed requires that the application has permission to establish a connection with the server and will cause the application to block until the feed has been downloaded, the operation times out or an error occurs. The same timeout period and options will be used as when the feed was originally opened.

The **RefreshFeed** method should only be used if the feed was opened using the **OpenFeed** method, otherwise the method will fail with an error indicating that the operation is not supported.

The data referenced in the **RSSCHANNEL** structure should be considered read-only and never modified by the application. The members of this structure returned by previous calls to either the **OpenFeed** or **RefreshFeed** methods will no longer be valid and should not be referenced. Likewise, the members of an **RSSCHANNELITEM** structure will no longer be valid after this method returns.

It is important that the application does not make any assumptions about the number of news items in the channel, or the content associated with those items after the **RefreshFeed** function has been called. For example, never assume that the number of items in the channel remains the same, or that the item IDs for each item remains the same. If you need to find a specific item in the news feed, use the **FindItem** method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csrssv10.lib

Unicode: Implemented as Unicode and ANSI versions.

CNewsFeed::SetLastError Method

```
VOID SetLastError(  
    DWORD dwErrorCode  
);
```

The **SetLastError** method sets the last error code for the current thread. This method is typically used to clear the last error by specifying a value of zero as the parameter.

Parameters

dwErrorCode

Specifies the last error code for the current thread.

Return Value

None.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. Most methods will set the last error code value when they fail; a few methods set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or RSS_ERROR. Those methods which call **SetLastError** when they succeed are noted on the method reference page.

Applications can retrieve the value saved by this method by using the **GetLastError** method. The use of **GetLastError** is optional; an application can call the method to determine the specific reason for a method failure.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csrssv10.lib

CNewsFeed::ShowError Method

```
INT ShowError(  
    LPCTSTR lpszAppTitle,  
    UINT uType,  
    DWORD dwErrorCode  
);
```

The **ShowError** method displays a message box which describes the specified error.

Parameters

lpszAppTitle

A pointer to a string which specifies the title of the message box that is displayed. If this argument is NULL or omitted, then the default title of "Error" will be displayed.

uType

An unsigned integer which specifies the type of message box that will be displayed. This is the same value that is used by the **MessageBox** method in the Windows API. If a value of zero is specified, then a message box with a single OK button will be displayed. Refer to that method for a complete list of options.

dwErrorCode

Specifies the error code that will be used when displaying the message box. If this argument is zero, then the last error that occurred in the current thread will be displayed.

Return Value

If the method is successful, the return value will be the return value from the **MessageBox** function. If the method fails, it will return a value of zero.

CNewsFeed::StoreFeed Method

```
BOOL StoreFeed(  
    LPCTSTR lpszFileName  
);
```

The **StoreFeed** method stores the contents of the news feed in an XML formatted text file.

Parameters

lpszFileName

A pointer to a string which specifies the name of the file on the local system. The contents of the news feed will be stored in this file. If the file does not exist, it will be created; otherwise it will overwrite the contents of the file.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

);
```

The **RssValidateFeed** method is used to validate a news feed, returning the number of items in the feed and the date it was last modified.

Parameters

lpszFeedUrl

A pointer to a string which specifies the URL for the news feed. To access a news feed on a web server, a standard http or https URL may be specified. To access a file on the local system or network share, a file name or file URL may be specified.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation. This parameter is ignored if the *lpszFeedUrl* parameter specifies a local file name or URL.

dwOptions

An unsigned integer that specifies one or more options. This parameter is reserved for future use and should always have a value of zero.

lpstModified

A pointer to a **SYSTEMTIME** structure which will specify the date that the feed was last modified when the method returns. If the parameter is NULL, it is ignored and no information is returned.

Return Value

If the method succeeds, the return value is the number of items in the news feed channel. If the method fails, the return value is **RSS_ERROR**. To get extended error information, call **RssGetLastError**.

Remarks

The **RssValidateFeed** method can be used to check that a news feed exists and is properly formatted. If the contents of the feed are valid, the method will return the number of items in the feed and the date that it was last modified. This can be useful for applications that want to periodically check a news feed and determine if the contents have changed.

The **SYSTEMTIME** structure that is populated by the method specifies the date when the feed was last modified. The method first checks the value of the `lastBuildDate` property of the feed channel. If that property is not defined, then it will use the value of the `pubDate` property. If neither are defined, then the structure members will have a value of zero.

The validation process imposes strict checks on the structure of the news feed and requires that it conform to the RSS specification. For example, the feed must have a title, link and description. Each item in the feed must have either a title or description, and the hyperlinks specified in the feed must be valid. If the feed XML is malformed, or a required property of the feed is invalid or missing, this method will fail.

If a news feed cannot be validated, it still may be possible to open the feed using the **OpenFeed** method. By default, relaxed rules are used when parsing the contents of the feed and it does not check to ensure all required properties are defined and have valid values.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csrsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

RSSCHANNEL Structure

This structure contains information about the properties of the news feed channel.

```
typedef struct _RSSCHANNEL
{
    UINT        nItemCount;
    UINT        nTimeToLive;
    WORD        wVersionMajor;
    WORD        wVersionMinor;
    DWORD       dwFlags;
    DWORD       dwReserved;
    LPCTSTR     lpszTitle;
    LPCTSTR     lpszLink;
    LPCTSTR     lpszDescription;
    LPCTSTR     lpszCategory;
    LPCTSTR     lpszLanguage;
    LPCTSTR     lpszCopyright;
    LPCTSTR     lpszEditor;
    LPCTSTR     lpszWebmaster;
    LPCTSTR     lpszGenerator;
    LPCTSTR     lpszImageLink;
    LPCTSTR     lpszImageTitle;
    LPCTSTR     lpszImageUrl;
    SYSTEMTIME  stPublished;
    SYSTEMTIME  stLastBuild;
} RSSCHANNEL, *LPRSSCHANNEL;
```

Members

nItemCount

An integer value which specifies number of news items in the channel.

nTimeToLive

An integer value which specifies the frequency in seconds at which the feed should be refreshed to obtain updated information. Not all feeds specify a time-to-live, in which case this member will have a value of zero.

wVersionMajor

A word value which specifies the major version number for the news feed.

wVersionMinor

A word value which specifies the minor version number for the news feed.

dwFlags

A value which specifies one or more option flags for the news feed channel. Currently there are no option flags defined and this member is reserved for future expansion.

dwReserved

A value reserved for future expansion.

lpszTitle

A pointer to a string which specifies the name of the channel. If the content of the news feed corresponds to a website, this is typically the same as the title of the website. If a title has not been specified, this member will be NULL. Note that a strictly conforming news feed requires a title.

lpszLink

A pointer to a string which specifies a URL to the website corresponding to the channel. Note that this is not the URL of the news feed itself. Typically it is a link to the home page of the site which owns the news feed. If a link has not been specified, this member will be NULL. Note that strictly conforming news feed requires a link.

lpszDescription

A pointer to a string which describes the channel. This provides an overview of the news feed and the type of information that is provided. If a description of the feed has not been specified, this member will be NULL. Note that a strictly conforming news feed requires a description.

lpszCategory

A pointer to a string which defines the category or categories that the channel belongs to. This property is optional and the category names themselves are user-defined. If a category has not been specified, this member will be NULL.

lpszLanguage

A pointer to a string which defines the language the channel is written in, using the standard language codes. This property is optional and if this member is NULL, the English language is typically presumed to be the default.

lpszCopyright

A pointer to a string which specifies a copyright notice for the content. If a copyright has not been specified, this member will be NULL.

lpszEditor

A pointer to a string which identifies the person responsible for managing the content of the news feed. If this property is defined, it is typically the name and email address of the feed editor. If an editor has not been specified, this member will be NULL.

lpszWebmaster

A pointer to a string which identifies the person responsible for technical issues related to the news feed. If this property is defined, it is typically the name and email address of a system administrator. If a webmaster has not been specified, this member will be NULL.

lpszGenerator

A pointer to a string which identifies the application that was used to create the news feed. If the application that generated the feed has not been specified, this member will be NULL.

lpszImageLink

A pointer to a string which specifies a URL to the website corresponding to the channel. In most cases, this is the same URL that is specified by the *lpszLink* member. If an image link has not been specified, this member will be NULL.

lpszImageTitle

A pointer to a string which identifies the image associated with the channel. This is usually a brief description of the image, and may be the same as the value specified by the *lpszTitle* member. If an image title has not been specified, this member will be NULL.

lpszImageUrl

A pointer to a string which specifies a URL for the image associated with the channel. An application can download this image and display it with the contents of the news feed. If an image URL has not been specified, this member will be NULL.

stPublished

The date that the news feed was published. For example, a feed that is associated with a weekly print publication may update this value once per week. Note that this is not necessarily the date

that the feed was last modified. If the channel does not specify the publish date, this structure will contain all zeroes.

stLastBuild

The date that the content of the channel was last modified. If the channel does not specify the build date, this structure will contain all zeroes.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Unicode: Implemented as Unicode and ANSI versions.

RSSCHANNELITEM Structure

This structure contains information about the properties of an item in a news feed channel.

```
typedef struct _RSSCHANNELITEM
{
    UINT            nItemId;
    DWORD          dwFlags;
    DWORD          dwReserved;
    LPCTSTR        lpszTitle;
    LPCTSTR        lpszLink;
    LPCTSTR        lpszText;
    LPCTSTR        lpszGuid;
    LPCTSTR        lpszAuthor;
    LPCTSTR        lpszSource;
    LPCTSTR        lpszComments;
    LPCTSTR        lpszEnclosure;
    SYSTEMTIME     stPublished;
} RSSCHANNELITEM, *LPRSSCHANNELITEM;
```

Members

nItemId

An integer which identifies this item in the channel.

dwFlags

A value which specifies one or more option flags for the item. Currently there are no option flags defined and this member is reserved for future expansion.

dwReserved

A value reserved for future expansion.

lpszTitle

A pointer to a string which specifies the title of the item. If a title for the item has not been specified, this member will be NULL.

lpszLink

A pointer to a string which specifies a URL that typically links to additional information related to the item. If a link for the item has not been specified, this member will be NULL.

lpszText

A pointer to a string which specifies a summary or description of the item. This may contain either plain text or HTML formatted text, and there is no fixed limit to the length of the text. If no text has been specified for the item, this member will be NULL.

lpszGuid

A pointer to a string which uniquely identifies the item in the channel. If this property is defined, it is guaranteed to be a unique, persistent value. It is important to note that this string does not have to be a standard GUID reference number, it can be any unique string. In many cases it is the same value as the item hyperlink specified by the *lpszLink* member, although an application should never depend on this behavior. If there is no unique identifier associated with the item, this member will be NULL.

lpszAuthor

A pointer to a string which identifies the author of the item. If this property is defined, it is typically the name and email address of the person who created the content that the item links to. If the author is not specified, this member will be NULL.

lpszSource

A pointer to a string which identifies the source of the item, specified as a URL for the original news feed that contained it. This typically used to propagate credit for items that are aggregated by a third-party and re-published in their own channel. If the source is not specified, this member will be NULL.

lpszComments

A pointer to a string which specifies a URL that links to further discussion about the item. Typically this is a link to the comment area of a weblog or a forum topic specific to the item. If a comment link is not specified, this member will be NULL.

lpszEnclosure

A pointer to a string which specifies a URL that links to a file related to the item. This is similar to an attachment in an email message, however instead of the item containing the contents of the attached file, it only specifies a link to the file. Enclosures are most commonly used with podcasting where an item is linked to an audio or video file, however the link may reference any type of file. If there is no enclosure specified for the item, this member will be NULL.

stPublished

The date that the item was published. If the item does not specify the publish date, this structure will contain all zeroes.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Unicode: Implemented as Unicode and ANSI versions.

SYSTEMTIME Structure

The **SYSTEMTIME** structure represents a date and time using individual members for the month, day, year, weekday, hour, minute, second, and millisecond.

```
typedef struct _SYSTEMTIME
{
    WORD wYear;
    WORD wMonth;
    WORD wDayOfWeek;
    WORD wDay;
    WORD wHour;
    WORD wMinute;
    WORD wSecond;
    WORD wMilliseconds;
} SYSTEMTIME, *LPSYSTEMTIME;
```

Members

wYear

Specifies the current year. The year value must be greater than 1601.

wMonth

Specifies the current month. January is 1, February is 2 and so on.

wDayOfWeek

Specifies the current day of the week. Sunday is 0, Monday is 1 and so on.

wDay

Specifies the current day of the month

wHour

Specifies the current hour.

wMinute

Specifies the current minute

wSecond

Specifies the current second.

wMilliseconds

Specifies the current millisecond.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include windows.h.

Post Office Protocol Class Library

List and retrieve email messages from a mail server.

Reference

- [Class Methods](#)
- [Data Structures](#)
- [Error Codes](#)

Library Information

Class Name	CPopClient
File Name	CSPOPV10.DLL
Version	10.0.1468.2518
LibID	E4B30E06-4091-4A79-8A4C-17547C76A995
Import Library	CSPOPV10.LIB
Dependencies	None
Standards	RFC 1939

Overview

The Post Office Protocol (POP3) provides access to a user's new email messages on a mail server. Functions are provided for listing available messages and then retrieving those messages, storing them either in files or in memory. Once a user's messages have been downloaded to the local system, they are typically removed from the server. This is the most popular email protocol used by Internet Service Providers (ISPs) and the library provides a complete interface for managing a user's mailbox. This library is typically used in conjunction with the Mail Message library, which is used to process the messages that are retrieved from the server.

This library supports secure connections using the standard SSL and TLS protocols. Both implicit and explicit SSL connections can be established, enabling the library to work with a wide variety of servers.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). If you are using Visual C++ 6.0 it is required that you have Service Pack 6 (SP6) installed. You should install all updates for your development tools and have the current Windows SDK installed. The minimum recommended version of Visual Studio is Visual Studio 2010.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are using Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. It is recommended that you install the current service pack and all critical updates available for your version of the operating system.

This product includes both 32-bit and 64-bit libraries. Native 64-bit CPU support requires the 64-bit version of Windows 7 or later versions of the Windows operating system.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

Post Office Protocol Class Methods

Class	Description
CPopClient	Constructor which initializes the current instance of the class
~CPopClient	Destructor which releases resources allocated by the class
Method	Description
AttachHandle	Attach the specified client handle to this instance of the class
AttachThread	Attach the specified client handle to another thread
Cancel	Cancel the current blocking operation
ChangePassword	Change the specified mail account password
Command	Send a command to the server
Connect	Connect to the specified server
CreateSecurityCredentials	Allocate a structure to establish client security credentials
DeleteMessage	Delete the specified message from the mailbox
DeleteSecurityCredentials	Delete the specified client security credentials
DetachHandle	Detach the handle for the current instance of this class
DisableEvents	Disable the event notification mechanism
DisableTrace	Disable logging of socket function calls to the trace log
Disconnect	Disconnect from the current server
EnableEvents	Enable the client event notification mechanism
EnableTrace	Enable logging of socket function calls to a file
FreezeEvents	Suspend and resume event handling by the client
GetErrorString	Return a description for the specified error code
GetHandle	Return the client handle used by this instance of the class
GetHeaderValue	Return the value of the specified header field
GetLastError	Return the last error code
GetMessage	Retrieve the specified message from the server
GetMessageCount	Return the number of messages available in the mailbox
GetMessageHeaders	Retrieve the specified message header from the server
GetMessageId	Return the message ID string for the specified message
GetMessageSender	Return the address of the message sender
GetMessageSize	Return the size of the specified message
GetMessageUid	Return the unique identifier for the specified message
GetResultCode	Return the result code from the previous command

GetResultString	Return the result string from the previous command
GetSecurityInformation	Return security information about the current client connection
GetStatus	Return the current status of the client
GetTimeout	Return the number of seconds until an operation times out
GetTransferStatus	Return data transfer statistics
IsBlocking	Determine if the client is blocked, waiting for information
IsConnected	Determine if the client is connected to the server
IsInitialized	Determine if the class has been successfully initialized
IsReadable	Determine if data can be read from the server
IsWritable	Determine if data can be written to the server
Login	Login to the server
OpenMessage	Open the specified message for reading on the server
PopEventProc	Callback method that processes events generated by the client
Read	Read data returned by the server
RegisterEvent	Register an event handler for the specified event
Reset	Reset the client and return to a command state
SendMessage	Send a message through the mail server
SetLastError	Set the last error code
SetTimeout	Set the number of seconds until an operation times out
ShowError	Display a message box with a description of the specified error
StoreMessage	Store the contents of a message in the specified file
Write	Write data to the server

CPopClient::CPopClient Method

`CPopClient();`

The **CPopClient** constructor initializes the class library and validates the license key at runtime.

Remarks

If the constructor fails to validate the runtime license, subsequent methods in this class will fail. If the product is installed with an evaluation license, then the application will only function on the development system and cannot be redistributed.

The constructor calls the **PopInitialize** function to initialize the library, which dynamically loads other system libraries and allocates thread local storage. If you are using this class within another DLL, it is important that you do not create or destroy an instance of the class from within the **DllMain** function because it can result in deadlocks or access violation errors. You should not declare static or global instances of this class within another DLL if it is linked with the C runtime library (CRT) because it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cspopv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[~CPopClient](#), [IsInitialized](#)

CPopClient::~CPopClient

`~CPopClient();`

The **CPopClient** destructor releases resources allocated by the current instance of the **CPopClient** object. It also uninitialized the library if there are no other concurrent uses of the class.

Remarks

When a **CPopClient** object goes out of scope, the destructor is automatically called to allow the library to free any resources allocated on behalf of the process. Any pending blocking or asynchronous calls in this process are canceled without posting any notification messages, and all handles that were created for the client session are destroyed.

The destructor is not called explicitly by the application.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `cspopv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

See Also

[CPopClient](#)

CPopClient::AttachHandle Method

```
VOID AttachHandle(  
    HCLIENT hClient  
);
```

The **AttachHandle** method attaches the specified client handle to the current instance of the class.

Parameters

hClient

The handle to the client session that will be attached to the current instance of the class object.

Return Value

None.

Remarks

This method is used to attach a client handle created outside of the class using the SocketTools API. Once the client handle is attached to the class, the other class member functions may be used with that client session.

If a client handle already has been created for the class, that handle will be released when the new handle is attached to the class object. If you want to prevent the previous client session from being terminated, you must call the **DetachHandle** method. Failure to release the detached handle may result in a resource leak in your application.

Note that the *hClient* parameter is presumed to be a valid client handle and no checks are performed to ensure that the handle is valid. Specifying an invalid client handle will cause subsequent method calls to fail.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cspopv10.lib

See Also

[AttachThread](#), [DetachHandle](#), [GetHandle](#)

CPopClient::AttachThread Method

```
DWORD AttachThread(  
    DWORD dwThreadId  
);
```

The **AttachThread** method attaches the specified client handle to another thread.

Parameters

dwThreadId

The ID of the thread that will become the new owner of the handle. A value of zero specifies that the current thread should become the owner of the client handle.

Return Value

If the method succeeds, the return value is the thread ID of the previous owner. If the method fails, the return value is POP_ERROR. To get extended error information, call **GetLastError**.

Remarks

When a client handle is created, it is associated with the current thread that created it. Normally, if another thread attempts to perform an operation using that handle, an error is returned since it does not own the handle. This is used to ensure that other threads cannot interfere with an operation being performed by the owner thread. In some cases, it may be desirable for one thread in a client application to create the client handle, and then pass that handle to another worker thread. The **AttachThread** method can be used to change the ownership of the handle to the new worker thread. By preserving the return value from the method, the original owner of the handle can be restored before the worker thread terminates.

This method should be called by the new thread immediately after it has been created, and if the new thread does not release the handle itself, the ownership of the handle should be restored to the parent thread before it terminates. Under no circumstances should **AttachThread** be used to forcibly release a handle allocated by another thread while a blocking operation is in progress. To cancel an operation, use the **Cancel** method and then release the handle after the blocking method exits and control is returned to the current thread.

Note that the *dwThreadId* parameter is presumed to be a valid thread ID and no checks are performed to ensure that the thread actually exists. Specifying an invalid thread ID will orphan the client handle used by the class until the destructor is called.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cspopv10.lib

See Also

[AttachHandle](#), [Cancel](#), [Connect](#), [DetachHandle](#), [Disconnect](#), [GetHandle](#)

CPopClient::Cancel Method

```
INT Cancel();
```

The **Cancel** method cancels any outstanding blocking operation in the client, causing the blocking method to fail. The application may then retry the operation or terminate the client session.

Parameters

None.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is POP_ERROR. To get extended error information, call **GetLastError**.

Remarks

When the **Cancel** method is called, the blocking method will not immediately fail. An internal flag is set which causes the blocking operation to exit with an error. This means that the application cannot cancel an operation and immediately perform some other operation. Instead it must allow the calling stack to unwind, returning back to the blocking operation before making any further function calls.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cspopv10.lib

See Also

[IsBlocking](#)

CPOPClient::ChangePassword Method

```
BOOL ChangePassword(  
    LPCTSTR lpszUserName,  
    LPCTSTR lpszOldPassword,  
    LPCTSTR lpszNewPassword  
);
```

The **ChangePassword** method changes the account password for the specified user.

Parameters

lpszUserName

Pointer to a string which specifies the user name of the account who's password will be changed. It is not required that this be the same user name that was used to login to the mail server.

lpszOldPassword

Pointer to a string which specifies the current account password.

lpszNewPassword

Pointer to a string which specifies the new account password. When the method returns, the user's mailbox password will be set to this value.

Return Value

If the method succeeds, it will return a non-zero value. If the method fails, it will return zero. To get extended error information, call **GetLastError**.

Remarks

The **ChangePassword** method is used to change the password associated with the specified account on the server. The method establishes a connection to a separate service running on the server, and does not use the POP3 protocol. For this method to succeed, the server must be configured to allow password changes using the "poppass" service, running on port 106.

Because passwords are sent over the network as clear text, this service is considered to be insecure.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cspopv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[Connect](#), [Login](#)

CPOPClient::CloseMessage Method

```
INT CloseMessage(  
    HCLIENT hClient  
);
```

The **CloseMessage** method closes the current message that has been opened or created.

Parameters

hClient

Handle to the client session.

Return Value

If the method succeeds, the return value is the server result code. If the method fails, the return value is POP_ERROR. To get extended error information, call **GetLastError**.

Remarks

If an message is being created, this method actually submits the message to the server. Note that the client application is responsible for generating the message headers as well as the body of the message. News messages conform to the same general characteristics of an email message.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cspopv10.lib

See Also

[OpenMessage](#), [Read](#)

CPopClient::Command Method

```
INT Command(  
    LPCTSTR lpszCommand,  
    LPCTSTR lpszParameter,  
    BOOL bMultiLine  
);
```

The **Command** method sends a command to the server, and returns the result code back to the caller. This method is typically used for site-specific commands not directly supported by the class.

Parameters

lpszCommand

The command which will be executed by the server.

lpszParameter

An optional command parameter. If the command requires more than one parameter, then they should be combined into a single string, with a space separating each parameter. If the command does not accept any parameters, this value may be NULL.

bMultiLine

An optional boolean argument used to specify if multiple lines of data will be returned by the server as the result of the command. Unlike a single line response, which consists of a result code and result string, a multi-line response consists of one or more lines of text, terminated by a special end-of-data marker. If this argument is omitted, *bMultiLine* is FALSE.

Return Value

If the method succeeds, the return value is the result code returned by the server. If the method fails, the return value is POP_ERROR. To get extended error information, call **GetLastError**.

Remarks

A list of valid commands can be found in the technical specification for the protocol. Many servers will list supported commands when the HELP command is used.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cspopv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[GetResultCode](#), [GetResultString](#)

CPOPClient::Connect Method

```
BOOL Connect(  
    LPCTSTR lpszRemoteHost,  
    UINT nRemotePort,  
    UINT nTimeout,  
    DWORD dwOptions,  
    HWND hEventWnd,  
    UINT uEventMsg  
);
```

The **Connect** method is used to establish a connection with the server.

Parameters

lpszRemoteHost

A pointer to the name of the server to connect to; this may be a fully-qualified domain name or an IP address.

nRemotePort

The port number the server is listening on. A value of zero specifies that the default port number should be used. For standard connections, the default port number is 110. For secure connections, the default port number is 995. If the secure port number is specified, an implicit SSL/TLS connection will be established by default.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
POP_OPTION_NONE	No connection options specified. A standard connection to the server will be established using the specified host name and port number.
POP_OPTION_LINEBREAK	Message data that is received from the server is read as individual lines of text terminated by a carriage return and linefeed control sequence. This option can be useful for applications that need to use the lower level network I/O functions and must process the message text on a line-by-line basis. This option is not recommended for most applications because it can have a negative impact on performance when retrieving large messages from the server.
POP_OPTION_TUNNEL	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and

	remote port number, default capability selection and how the connection is established.
POP_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using either the SSL or TLS protocols.
POP_OPTION_SECURE	This option specifies that a secure connection should be established with the server and requires that the server support either the SSL or TLS protocol. This option is the same as specifying POP_OPTION_SECURE_EXPLICIT, which initiates the secure session using the STLS command.
POP_OPTION_SECURE_EXPLICIT	This option specifies the client should attempt to establish a secure connection with the server. The server must support secure connections using either the SSL or TLS protocol and the STLS command.
POP_OPTION_SECURE_IMPLICIT	This option specifies the client should attempt to establish a secure connection with the server. It should only be used when the server expects an implicit SSL connection or does not implement RFC 2595 where the STLS command is used to negotiate a secure connection with the server.
POP_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
POP_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
POP_OPTION_FREETHREAD	This option specifies that this instance of the class may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the class instance is synchronized across multiple threads.

hEventWnd

The handle to the event notification window. This window receives messages which notify the client of various asynchronous socket events that occur. If this argument is NULL, then the client

session will be blocking and no network events will be sent to the client.

uEventMsg

The message identifier that is used when an asynchronous socket event occurs. This value should be greater than WM_USER as defined in the Windows header files. If the *hEventWnd* argument is NULL, this argument should be specified as WM_NULL.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The use of Windows event notification messages has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

To prevent this method from blocking the main user interface thread, the application should create a background worker thread and establish a connection by calling **Connect** in that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each client session.

If you specify an event notification window, then the client session will be asynchronous. When a message is posted to the notification window, the low word of the *lParam* parameter contains the event identifier. The high word of *lParam* contains the low word of the error code, if an error has occurred. The *wParam* parameter contains the client handle. One or more of the following event identifiers may be sent:

Constant	Description
POP_EVENT_CONNECT	The connection to the server has completed. The high word of the <i>lParam</i> parameter should be checked, since this notification message will be posted if an error has occurred.
POP_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
POP_EVENT_READ	Data is available to read by the client. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the calling process is in asynchronous mode.
POP_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
POP_EVENT_TIMEOUT	The client has timed out while waiting for a response from the server. Note that under some circumstances this event can be generated for a non-blocking connection, such as when the client is establishing a secure connection.
POP_EVENT_CANCEL	The client has canceled the current operation.

POP_EVENT_COMMAND	The client has processed a command that was sent to the server. The result code and result string can be used to determine if the response to the command. The high word of the IParam parameter should be checked, since this notification message will also be posed if the command cannot be executed.
POP_EVENT_PROGRESS	This event notification is sent periodically during lengthy blocking operations, such as retrieving a complete message from the server.

To cancel asynchronous notification and return the client to a blocking mode, use the **DisableEvents** method.

It is recommended that you only establish an asynchronous connection if you understand the implications of doing so. In most cases, it is preferable to create a synchronous connection and create threads for each additional session if more than one active client session is required.

The *dwOptions* argument can be used to specify the threading model that is used by the library when a connection is established. By default, the class instance is initially attached to the thread that created it. From that point on, until the it is released, only the owner may call methods using that instance of the class. The ownership of the class instance may be transferred from one thread to another using the **AttachThread** method.

Specifying the POP_OPTION_FREETHREAD option enables any thread to call any method in that instance of the class, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the class instance is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same instance.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cspopv10.lib

Unicode: Implemented as Unicode and ANSI versions.

CPOPClient::CreateSecurityCredentials Method

```
BOOL CreateSecurityCredentials(  
    DWORD dwProtocol,  
    DWORD dwOptions,  
    LPCTSTR lpszUserName,  
    LPCTSTR lpszPassword,  
    LPCTSTR lpszCertStore,  
    LPCTSTR lpszCertName  
);  
  
BOOL CreateSecurityCredentials(  
    LPCTSTR lpszCertStore,  
    LPCTSTR lpszCertName  
);  
  
BOOL CreateSecurityCredentials(  
    LPCTSTR lpszCertName  
);
```

The **CreateSecurityCredentials** method establishes the security credentials for the client session.

Parameters

dwProtocol

A bitmask of supported security protocols. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_SSL	Either SSL 2.0 or SSL 3.0 should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, TLS will be excluded from the list of supported protocols. Both SSL 2.0 and 3.0 have been deprecated and will never be used unless explicitly specified. It is not recommended that you enable either of these protocols for secure connections because it will cause most servers to reject your connection request, even if a version of TLS is also specified.
SECURITY_PROTOCOL_TLS	Either the TLS 1.0, 1.1 or 1.2 protocol should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols.

	This may be necessary for some servers that reject any attempt to use the older SSL protocol and require that only TLS be used.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This is the recommended version of TLS to use with secure connections.

dwOptions

A value which specifies one or options. This member is constructed by using a bitwise operator with any of the following values:

Constant	Description
CREDENTIAL_STORE_CURRENT_USER	The library will attempt to open a store for the current user using the certificate store name provided in this structure. If no options are specified, then this is the default behavior.
CREDENTIAL_STORE_LOCAL_MACHINE	The library will attempt to open a local machine store using the certificate store name provided in this structure. If this option is specified, the library will always search for a local machine store before searching for the store by that name for the current user.
CREDENTIAL_STORE_FILENAME	The certificate store name is a file that contains the certificate and private key that will be used.

lpzUserName

A pointer to a string which specifies the certificate owner's username. A value of NULL specifies that no username is required. Currently this parameter is not used and any value specified will be ignored.

lpszPassword

A pointer to a string which specifies the certificate owner's password. A value of NULL specifies that no password is required. This parameter is only used if a PKCS12 (PFX) certificate file is specified and that certificate has been secured with a password. This value will be ignored the current user or local machine certificate store is specified.

lpszCertStore

A pointer to a string which specifies the name of the certificate store to open. A certificate store is a collection of certificates and their private keys, typically organized by how they are used. If this value is NULL or points to an empty string, the default certificate store "MY" will be used.

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as VeriSign and Thawte act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. This corresponds to the "Personal" store that is displayed by the certificate manager utility and is the default store used by the library.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as VeriSign and Thawte are installed as part of the operating system and periodically updated by Microsoft.

lpszCertName

A pointer to a null terminated string which specifies the name of the certificate to use. The function will first search the certificate store for a certificate with a matching "friendly name"; this is a name for the certificate that is assigned by the user. Note that the name must match completely, but the comparison is not case sensitive. If no matching certificate is found, the function will then attempt to find a certificate that has a matching common name (also called the certificate subject). This comparison is less stringent, and the first partial match will be returned. If this second search fails, the function will return an error indicating that the certificate could not be found.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Example

```
pClient->CreateSecurityCredentials(  
    SECURITY_PROTOCOL_DEFAULT,  
    0,  
    NULL,  
    NULL,  
    lpszCertStore,  
    lpszCertName);
```

```
bConnected = pClient->Connect(lpszHostName,  
                              POP_PORT_SECURE,  
                              POP_TIMEOUT,  
                              POP_OPTION_SECURE);
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cspopv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[Connect](#), [DeleteSecurityCredentials](#), [GetSecurityInformation](#), [SECURITYCREDENTIALS](#)

CPopClient::DeleteMessage Method

```
INT DeleteMessage(  
    UINT nMessage  
);
```

The **DeleteMessage** method marks the specified message for deletion from the mailbox.

Parameters

nMessage

Number of message to delete from the server. This value must be greater than zero. The first message in the mailbox is message number one.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is POP_ERROR. To get extended error information, call **GetLastError**.

Remarks

This method only marks the message for deletion. The message is not actually deleted until the user disconnects from the server. To prevent one or more marked messages from actually being deleted from the mailbox, call the **Reset** method to reset the client session.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cspopv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[GetMessage](#), [GetMessageCount](#), [Reset](#)

CPopClient::DeleteSecurityCredentials Method

```
VOID DeleteSecurityCredentials();
```

The **DeleteSecurityCredentials** method releases the security credentials for the current session.

Parameters

None.

Return Value

None.

Remarks

This method can be used to release the memory allocated to the client or server credentials after a secure connection has been terminated. The security credentials are released when the class destructor is called, so it is normally not required that the application explicitly call this method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cspopv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[CreateSecurityCredentials](#)

CPopClient::DetachHandle Method

```
HCLIENT DetachHandle();
```

The **DetachHandle** method detaches the client handle associated with the current instance of the class.

Parameters

None.

Return Value

This method returns the client handle associated with the current instance of the class object. If there is no active client session, the value `INVALID_CLIENT` will be returned.

Remarks

This method is used to detach a client handle created by the class for use with the SocketTools API. Once the client handle is detached from the class, no other class member functions may be called. Note that the handle must be explicitly released at some later point by the process or a resource leak will occur.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `cspopv10.lib`

[AttachHandle](#), [GetHandle](#)

CPopClient::DisableEvents Method

```
INT DisableEvents();
```

The **DisableEvents** method disables the event notification mechanism, preventing subsequent event notification messages from being posted to the application's message queue.

This method has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Parameters

None.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is POP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **DisableEvents** method is used to disable event message posting for the specified client session. Although this will immediately prevent any new events from being generated, it is possible that messages could be waiting in the message queue. Therefore, an application must be prepared to handle client event messages after this method has been called.

This method is automatically called if the client has event notification enabled, and the **Disconnect** method is called. The same issues regarding outstanding event messages also applies in this situation, requiring that the application handle event messages that may reference a client handle that is no longer valid.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cspopv10.lib

[EnableEvents](#), [RegisterEvent](#)

CPopClient::DisableTrace Method

```
BOOL DisableTrace();
```

The **DisableTrace** method disables the logging of socket function calls to the trace log.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, a value of zero is returned.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cspopv10.lib

[Connect](#), [IsConnected](#)

CPOPClient::EnableEvents Method

```
INT EnableEvents(  
    HWND hEventWnd,  
    UINT uEventMsg  
);
```

The **EnableEvents** method enables event notifications using Windows messages.

This method has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Applications should use the **RegisterEvent** method to register an event handler which is invoked when an event occurs.

Parameters

hEventWnd

Handle to the window which will receive the client notification messages. This parameter must specify a valid window handle. If a NULL handle is specified, event notification will be disabled.

uEventMsg

The message that is received when a client event occurs. This value must be greater than 1024.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is POP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **EnableEvents** method is used to request that notification messages be posted to the specified window whenever a client event occurs. This allows an application to monitor the status of different client operations, such as a file transfer.

The *wParam* argument will contain the client handle, the low word of the *lParam* argument will contain the event ID, and the high word will contain any error code. If no error has occurred, the high word will always have a value of zero. The following events may be generated:

Constant	Description
POP_EVENT_CONNECT	The connection to the server has completed. The high word of the <i>lParam</i> parameter should be checked, since this notification message will be posted if an error has occurred.
POP_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
POP_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
POP_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking

	operation. This event is only generated if the client is in asynchronous mode.
POP_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
POP_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.
POP_EVENT_COMMAND	A command has been issued by the client and the server response has been received and processed. This event can be used to log the result codes and messages returned by the server in response to actions taken by the client.
POP_EVENT_PROGRESS	The client is in the process of sending or receiving a file on the data channel. This event is called periodically during a transfer so that the client can update any user interface components such as a status control or progress bar.

It is not required that the client be placed in asynchronous mode in order to receive command and progress event notifications. To disable event notification, call the **DisableEvents** method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cspopv10.lib

See Also

[DisableEvents](#), [RegisterEvent](#)

CPopClient::EnableTrace Method

```
BOOL EnableTrace(  
    LPCTSTR lpszTraceFile,  
    DWORD dwTraceFlags  
);
```

The **EnableTrace** method enables the logging of socket function calls to a file.

Parameters

lpszTraceFile

A pointer to a string which specifies the name of the trace log file. If this parameter is NULL or an empty string, the default file name **cstrace.log** is used. The file is stored in the directory specified by the TEMP environment variable, if it is defined; otherwise, the current working directory is used.

dwTraceFlags

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
TRACE_INFO	All function calls are written to the trace file. This is the default value.
TRACE_ERROR	Only those function calls which fail are recorded in the trace file.
TRACE_WARNING	Only those function calls which fail or return values which indicate a warning are recorded in the trace file.
TRACE_HEXDUMP	All functions calls are written to the trace file, plus all the data that is sent or received is displayed, in both ASCII and hexadecimal format.
TRACE_PROCESS	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for multithreaded applications that are using worker threads.

Return Value

If the method succeeds, the return value is non-zero. A return value of zero indicates an error. Failure typically indicates that the tracing library **cstrcv10.dll** cannot be loaded on the local system.

Remarks

When trace logging is enabled, the file is opened, appended to and closed for each socket function call. This makes it possible for an application to append its own logging information, however care should be taken to ensure that the file is closed before the next network operation is performed. To limit the size of the log files, enable and disable logging only around those sections of code that you wish to trace.

Note that the TRACE_HEXDUMP trace level generates very large log files since it includes all of the data exchanged between your application and the server.

Trace method logging is managed on a per-thread basis, not for each client handle. This means that all SocketTools libraries and components share the same settings in the current thread. If you

are using multiple SocketTools libraries or components in your application, you only need to enable logging once.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cspopv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[DisableTrace](#)

CPopClient::FreezeEvents Method

```
INT FreezeEvents(  
    BOOL bFreeze  
);
```

The **FreezeEvents** method is used to suspend and resume event handling by the client.

Parameters

bFreeze

A non-zero value specifies that event handling should be suspended by the client. A zero value specifies that event handling should be resumed.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is POP_ERROR. To get extended error information, call **GetLastError**.

Remarks

This method should be used when the application does not want to process events, such as when a modal dialog is being displayed. When events are suspended, all client events are queued. If events are re-enabled at a later point, those queued events will be sent to the application for processing. Note that only one of each event will be generated. For example, if the client has suspended event handling, and four read events occur, once event handling is resumed only one of those read events will be posted to the client. This prevents the application from being flooded by a potentially large number of queued events.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cspopv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

CPopClient::GetErrorString Method

```
INT GetErrorString(  
    DWORD dwErrorCode,  
    LPTSTR lpszDescription,  
    INT cbDescription  
);  
  
INT GetErrorString(  
    DWORD dwErrorCode,  
    CString& strDescription  
);
```

The **GetErrorString** method is used to return a description of a specific error code. Typically this is used in conjunction with the **GetLastError** method for use with warning dialogs or as diagnostic messages.

Parameters

dwErrorCode

The error code for which a description is returned.

lpszDescription

A pointer to the buffer that will contain a description of the specified error code. This buffer should be at least 128 characters in length. An alternate form of the method accepts a **CString** variable which will contain the error description.

cbDescription

The maximum number of characters that may be copied into the description buffer.

Return Value

If the method succeeds, the return value is the length of the description string. If the method fails, the return value is zero, meaning that no description exists for the specified error code. Typically this indicates that the error code passed to the method is invalid.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstoools10.h

Import Library: cspopv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[GetLastError](#), [SetLastError](#), [ShowError](#)

CPopClient::GetHandle Method

```
HCLIENT GetHandle();
```

The **GetHandle** method returns the client handle associated with the current instance of the class.

Parameters

None.

Return Value

This method returns the client handle associated with the current instance of the class object. If there is no active client session, the value `INVALID_CLIENT` will be returned.

Remarks

This method is used to obtain the client handle created by the class for use with the SocketTools API.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `cspopv10.lib`

See Also

[AttachHandle](#), [DetachHandle](#), [IsInitialized](#)

CPopClient::GetHeaderValue Method

```
INT GetHeaderValue(  
    UINT nMessageId,  
    LPCTSTR lpszHeader,  
    LPTSTR lpszValue,  
    INT nMaxLength  
);
```

```
INT GetHeaderValue(  
    UINT nMessageId,  
    LPCTSTR lpszHeader,  
    CString& strValue  
);
```

The **GetHeaderValue** method returns the value of a header field in the specified message.

Parameters

nMessageId

Number of message to retrieve header value from. This value must be greater than zero. The first message in the mailbox is message number one.

lpszHeader

Pointer to a string which specifies the message header to retrieve. The colon should not be included in this string.

lpszValue

Pointer to a string buffer that will contain the value of the specified message header.

nMaxLength

The maximum number of characters that may be copied into the buffer, including the terminating null character.

Return Value

If the method succeeds, the method returns the length of the header field value. If the header field is not present in the message, the method will return a value of zero. If the method fails, the return value is POP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetHeaderValue** method returns the value of a header field from the specified message. This allows an application to be able to easily determine the value of a header (such as the sender, or the subject of the message) without downloading the entire message header and parsing the contents.

This method uses the XTND XLST command, which is an extension to the POP3 protocol. If this command is not supported by the server, the method will attempt to retrieve the entire message header and return the value for the specified header field. This enables an application to use this method even if the server does not support command extensions.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csppv10.lib

Unicode: Implemented as Unicode and ANSI versions.

CPopClient::GetLastError Method

```
DWORD GetLastError();  
  
DWORD GetLastError(  
    CString& strDescription  
);
```

Parameters

strDescription

A string which will contain a description of the last error code value when the method returns. If no error has been set, or the last error code has been cleared, this string will be empty.

Return Value

The return value is the last error code value for the current thread. Functions set this value by calling the **SetLastError** method. The Return Value section of each reference page notes the conditions under which the method sets the last error code.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. You should call the **GetLastError** method immediately when a method's return value indicates that an error has occurred. That is because some methods call **SetLastError(0)** when they succeed, clearing the error code set by the most recently failed method.

Most methods will set the last error code value when they fail; a few methods set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or POP_ERROR. Those methods which call **SetLastError** when they succeed are noted on the method reference page.

The description of the error code is the same string that is returned by the **GetErrorString** method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

[GetErrorString](#), [SetLastError](#), [ShowError](#)

CPOPClient::GetMessage Method

```
INT GetMessage(  
    LONG nMessageId,  
    LPBYTE lpBuffer,  
    LPDWORD lpdwLength  
);
```

```
INT GetMessage(  
    LONG nMessageId,  
    HGLOBAL* lpBuffer,  
    LPDWORD lpdwLength  
);
```

```
INT GetMessage(  
    LONG nMessageId,  
    CString& strBuffer  
);
```

The **GetMessage** method retrieves the specified message and copies the contents to a local buffer.

Parameters

nMessageId

Number of message to retrieve from the server. This value must be greater than zero.

lpBuffer

A pointer to a byte buffer which will contain the data transferred from the server, or a pointer to a global memory handle which will reference the data when the method returns.

lpdwLength

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the *lpBuffer* parameter. If the *lpBuffer* parameter points to a global memory handle, the length value should be initialized to zero. When the method returns, this value will be updated with the actual length of the file that was downloaded.

Return Value

If the method succeeds, the return value is the server result code. If the method fails, the return value is POP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetMessage** method is used to retrieve an message from the server and copy it into a local buffer. The method may be used in one of two ways, depending on the needs of the application. The first method is to pre-allocate a buffer large enough to store the contents of the message. In this case, the *lpBuffer* parameter will point to the buffer that was allocated, the value that the *lpdwLength* parameter points to should be initialized to the size of that buffer.

The second method that can be used is have the *lpBuffer* parameter point to a global memory handle which will contain the message data when the method returns. In this case, the value that the *lpdwLength* parameter points to must be initialized to zero. It is important to note that the memory handle returned by the method must be freed by the application, otherwise a memory leak will occur. See the example code below.

This method will cause the current thread to block until the complete message has been retrieved,

a timeout occurs or the operation is canceled. During the transfer, the POP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **EnableEvents**, or by registering a callback function using the **RegisterEvent** method.

To determine the current status of a transfer while it is in progress, use the **GetTransferStatus** method.

Example

```
HGLOBAL hgblBuffer = (HGLOBAL)NULL;
LPBYTE lpBuffer = (LPBYTE)NULL;
DWORD cbBuffer = 0;

// Return the message into block of global memory allocated by
// the GlobalAlloc function; the handle to this memory will be
// returned in the hgblBuffer parameter
nResult = pClient->GetMessage(nMessageId, &hgblBuffer, &cbBuffer);

if (nResult != POP_ERROR)
{
    // Lock the global memory handle, returning a pointer to the
    // message text
    lpBuffer = (LPBYTE)GlobalLock(hgblBuffer);

    // After the data has been used, the handle must be unlocked
    // and freed, otherwise a memory leak will occur
    GlobalUnlock(hgblBuffer);
    GlobalFree(hgblBuffer);
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cspopv10.lib

CPOPClient::GetMessageCount Method

```
INT GetMessageCount(  
    UINT *LpnLastMessage,  
    DWORD *LpdwMailboxSize  
);
```

The **GetMessageCount** method returns the number of messages available in the mailbox, the last valid message number in the mailbox and the current size of the mailbox in bytes.

Parameters

lpnLastMessage

Address of a variable that receives the number of the last valid message in the mailbox. If a NULL value is specified, this argument is ignored.

lpdwMailboxSize

Address of a variable that receives the current size of the mailbox. This value will decrease as messages are deleted. If a NULL value is specified, this argument is ignored.

Return Value

If the method succeeds, it returns the number of messages that are currently available. If no messages are available, either because the mailbox is empty or all of the messages have been deleted, this method will return zero. If the method fails, the return value is POP_ERROR. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cspopv10.lib

See Also

[DeleteMessage](#), [GetHeaderValue](#), [GetMessage](#), [GetMessageHeaders](#), [StoreMessage](#)

CPopClient::GetMessageHeaders Method

```
INT GetMessageHeaders(  
    LONG nMessageId,  
    LPBYTE lpHeaders,  
    LPDWORD lpdwLength  
);
```

```
INT GetMessageHeaders(  
    LONG nMessageId,  
    HGLOBAL* lpHeaders,  
    LPDWORD lpdwLength  
);
```

```
INT GetMessageHeaders(  
    LONG nMessageId,  
    CString& strHeaders  
);
```

The **GetMessageHeaders** method retrieves the headers for the specified message from the server.

Parameters

nMessageId

Number of message to retrieve from the server. This value must be greater than zero.

lpHeaders

A pointer to a byte buffer which will contain the data transferred from the server, or a pointer to a global memory handle which will reference the data when the method returns.

lpdwLength

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the *lpHeaders* parameter. If the *lpHeaders* parameter points to a global memory handle, the length value should be initialized to zero. When the method returns, this value will be updated with the actual length of the message that was downloaded.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is POP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetMessageHeaders** method is used to retrieve an message header block from the server and copy it into a local buffer. The method may be used in one of two ways, depending on the needs of the application. The first method is to pre-allocate a buffer large enough to store the contents of the file. In this case, the *lpHeaders* parameter will point to the buffer that was allocated, the value that the *lpdwLength* parameter points to should be initialized to the size of that buffer.

The second method that can be used is have the *lpHeaders* parameter point to a global memory handle which will contain the message headers when the method returns. In this case, the value that the *lpdwLength* parameter points to must be initialized to zero. It is important to note that the memory handle returned by the method must be freed by the application, otherwise a memory leak will occur.

This method will cause the current thread to block until the transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the POP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **EnableEvents**, or by registering a callback function using the **RegisterEvent** method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cspopv10.lib

See Also

[GetHeaderValue](#), [GetMessage](#), [GetMessageId](#), [OpenMessage](#)

CPopClient::GetMessageId Method

```
INT GetMessageId(  
    UINT nMessageId,  
    LPTSTR lpszMessageId,  
    INT nMaxLength  
);  
  
INT GetMessageId(  
    UINT nMessageId,  
    CString& strMessageId  
);
```

The **GetMessageId** method returns the message identifier for the specified message.

Parameters

nMessageId

Number of message to retrieve the unique identifier for. This value must be greater than zero. The first message in the mailbox is message number one.

lpszMessageId

Address of a string buffer to receive the message identifier. This should be at least 64 bytes in length. This argument may also be a **CString** object which will contain the message identifier when the method returns.

nMaxLength

The maximum length of the string buffer.

Return Value

If the method succeeds, the return value is the length of the unique identifier string. If the method fails, the return value is POP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetMessageId** method returns the message identifier from the Message-ID header of the specified message. The returned value is typically a string which specifies the domain, date and timestamp for the message that is created when the message is submitted to the mail server for delivery. To obtain a unique identifier for the message in the mailbox, it is recommended that you use the **GetMessageUid** method instead.

This method uses the XTND XLST command to obtain the value of the "Message-ID" header field. If this command is not supported by the server, the method will attempt to retrieve the entire message header and return the header value. This enables an application to use this method even if the server does not support command extensions.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cspopv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[GetHeaderValue](#), [GetMessage](#), [GetMessageHeaders](#), [GetMessageSender](#), [GetMessageUid](#)

CPopClient::GetMessageSender Method

```
INT GetMessageSender(  
    UINT nMessageId,  
    LPTSTR lpszAddress,  
    INT nMaxLength  
);
```

```
INT GetMessageSender(  
    UINT nMessageId,  
    CString& strAddress  
);
```

The **GetMessageSender** method returns the sender's address for the specified message.

Parameters

nMessageId

Number of message to retrieve header value from. This value must be greater than zero. The first message in the mailbox is message number one.

lpszAddress

Pointer to a string buffer that will contain the address of the message sender. This argument may also be a **CString** object which will contain the address when the method returns.

nMaxLength

The maximum number of characters that may be copied into the buffer, including the terminating null character.

Return Value

If the method succeeds, the method returns the length of the address. If the sender cannot be determined, the method will return a value of zero. If the method fails, the return value is POP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetMessageSender** method returns the email address of the user who sent the specified message. This allows an application to be able to easily determine the sender, without downloading the entire header block or contents of the message.

This method uses the XSENDER command, which is an extension to the POP3 protocol, to determine the address of the authenticated sender of the message. If the command is not supported, or the server was unable to authenticate the sender, the method will use the XTND XLST command to obtain the value of the "From" header field. If this command is not supported by the server, the method will attempt to retrieve the entire message header and return the value for the specified header field. This enables an application to use this method even if the server does not support command extensions.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cspopv10.lib

Unicode: Implemented as Unicode and ANSI versions.

Copyright © 2023 Catalyst Development Corporation. All rights reserved.

CPopClient::GetMessageSize Method

```
DWORD GetMessageSize(  
    UINT nMessageId  
);
```

The **GetMessageSize** method returns the size of the specified message.

Parameters

nMessageId

Number of message to retrieve size of. This value must be greater than zero. The first message in the mailbox is message number one.

Return Value

If the method succeeds, the return value is the size of the specified message in bytes. If the method fails, the return value is POP_ERROR. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cspopv10.lib

See Also

[GetHeaderValue](#), [GetMessageHeaders](#), [GetMessageId](#), [GetMessageSender](#), [GetTransferStatus](#)

CPopClient::GetMessageUid Method

```
INT GetMessageUid(  
    UINT nMessageId,  
    LPTSTR lpszMessageUID,  
    INT nMaxLength  
);  
  
INT GetMessageUid(  
    UINT nMessageId,  
    CString& strMessageUID  
);
```

The **GetMessageUid** method returns the unique identifier (UID) for the specified message in the current mailbox.

Parameters

nMessageId

Number of message to retrieve the unique identifier for. This value must be greater than zero. The first message in the mailbox is message number one.

lpszMessageUID

Address of a string buffer to receive the unique identifier for the specified message. This should be at least 64 bytes in length. This argument may also be a **CString** object which will contain the UID string when the method returns.

nMaxLength

The maximum length of the string buffer for the message UID.

Return Value

If the method succeeds, it returns a non-zero value. If no unique identifier is assigned to the message, the method will return zero. If an error occurs, the method returns POP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetMessageUid** method returns the unique message identifier for the specified message. The returned value is a string which can be used to uniquely identify a specific message in the mailbox across multiple client sessions. This is commonly used by mail clients to determine if they have already retrieved a message from the server in a previous session. The UID can also be used as a key or component of the file name to reference the message after it has been stored on the local system.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cspopv10.lib

See Also

[GetHeaderValue](#), [GetMessage](#), [GetMessageHeaders](#), [GetMessageId](#), [GetMessageSender](#)

CPopClient::GetResultCode Method

```
BOOL GetResultCode();
```

The **GetResultCode** method reads the result code returned by the server in response to a command. The result code is a boolean value, and indicates if the operation succeeded or failed.

Parameters

None.

Return Value

If the previous command was successful, the function returns a non-zero value. If the previous command failed, the function returns zero. To get extended error information, call **GetLastError**.

Remarks

Unlike most other Internet application protocols, the Post Office Protocol does not return numeric result codes to indicate success or failure. If a command is successful, the server will respond with the string "+OK" and this is indicated by the **GetResultCode** method returning a non-zero value. If the command fails, the server will respond with the string "-ERR" along with a description of the error, and this is indicated by the method returning a value of zero. The description of the error returned by the server can be obtained by calling the **GetResultString** method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cspopv10.lib

See Also

[Command](#), [GetResultString](#)

CPopClient::GetResultString Method

```
INT GetResultString(  
    LPTSTR lpszResult,  
    INT cbResult  
);
```

```
INT GetResultString(  
    CString& strResult  
);
```

The **GetResultString** method returns the last message sent by the server along with the result code.

Parameters

lpszResult

A pointer to the buffer that will contain the result string returned by the server. An alternate form of the method accepts a **CString** argument which will contain the result string returned by the server.

cbResult

The maximum number of characters that may be copied into the result string buffer, including the terminating null character.

Return Value

If the method succeeds, the return value is the length of the result string. If a value of zero is returned, this means that no result string was sent by the server. If the method fails, the return value is POP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetResultString** method is most useful when an error occurs because the server will typically include a brief description of the cause of the error. This can then be parsed by the application or displayed to the user. The result string is updated each time the client sends a command to the server and then calls **GetResultCode** to obtain the result code for the operation.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cspopv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[Command](#), [GetResultCode](#)

CPopClient::GetSecurityInformation Method

```
BOOL GetSecurityInformation(  
    LPSECURITYINFO LpSecurityInfo  
);
```

The **GetSecurityInformation** method returns security protocol, encryption and certificate information about the current client connection.

Parameters

LpSecurityInfo

A pointer to a [SECURITYINFO](#) structure which contains information about the current client connection. The *dwSize* member of this structure must be initialized to the size of the structure before passing the address of the structure to this method.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

This method is used to obtain security related information about the current client connection to the server. It can be used to determine if a secure connection has been established, what security protocol was selected, and information about the server certificate. Note that a secure connection has not been established, the *dwProtocol* structure member will contain the value SECURITY_PROTOCOL_NONE.

Example

The following example notifies the user if the connection is secure or not:

```
SECURITYINFO securityInfo;  
securityInfo.dwSize = sizeof(SECURITYINFO);  
  
if (pClient->GetSecurityInformation(&securityInfo))  
{  
    if (securityInfo.dwProtocol == SECURITY_PROTOCOL_NONE)  
    {  
        MessageBox(NULL, _T("The connection is not secure"),  
                    _T("Connection"), MB_OK);  
    }  
    else  
    {  
        if (securityInfo.dwCertStatus == SECURITY_CERTIFICATE_VALID)  
        {  
            MessageBox(NULL, _T("The connection is secure"),  
                        _T("Connection"), MB_OK);  
        }  
        else  
        {  
            MessageBox(NULL, _T("The server certificate not valid"),  
                        _T("Connection"), MB_OK);  
        }  
    }  
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cspopv10.lib

Unicode: Implemented as Unicode and ANSI versions.

CPopClient::GetStatus Method

INT GetStatus();

The **GetStatus** method the current status of the client session.

Parameters

None.

Return Value

If the method succeeds, the return value is the client status code. If the method fails, the return value is POP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetStatus** method returns a numeric code which identifies the current state of the client session. The following values may be returned:

Value	Constant	Description
0	POP_STATUS_UNUSED	No connection has been established.
1	POP_STATUS_IDLE	The client is current idle and not sending or receiving data.
2	POP_STATUS_CONNECT	The client is establishing a connection with the server.
3	POP_STATUS_READ	The client is reading data from the server.
4	POP_STATUS_WRITE	The client is writing data to the server.
5	POP_STATUS_DISCONNECT	The client is disconnecting from the server.

In a multithreaded application, any thread in the current process may call this method to obtain status information for the specified client session.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cspopv10.lib

See Also

[IsBlocking](#), [IsConnected](#), [IsReadable](#), [IsWritable](#)

CPopClient::GetTimeout Method

```
INT GetTimeout();
```

The **GetTimeout** method returns the number of seconds the client will wait for a response from the server. Once the specified number of seconds has elapsed, the method will fail and return to the caller.

Parameters

None.

Return Value

If the method succeeds, the return value is the timeout period in seconds. If the method fails, the return value is POP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The timeout value is only used with blocking client connections. A value of zero indicates that the default timeout period of 20 seconds should be used.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cspopv10.lib

See Also

[Connect](#), [IsReadable](#), [IsWritable](#), [Read](#), [SetTimeout](#), [Write](#)

CPOPClient::GetTransferStatus Method

```
INT GetTransferStatus(  
    LPPOPTRANSFERSTATUS lpStatus  
);
```

The **GetTransferStatus** method returns information about the current file transfer in progress.

Parameters

lpStatus

A pointer to an [POPTRANSFERSTATUS](#) structure which contains information about the status of the current file transfer.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is POP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetTransferStatus** method returns information about the current file transfer, including the average number of bytes transferred per second and the estimated amount of time until the transfer completes. If there is no file currently being transferred, this method will return the status of the last successful transfer made by the client.

In a multithreaded application, any thread in the current process may call this method to obtain status information for the specified client session.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cspopv10.lib

See Also

[EnableEvents](#), [GetStatus](#), [RegisterEvent](#)

CPopClient::IsBlocking Method

BOOL IsBlocking();

The **IsBlocking** method is used to determine if the client is currently performing a blocking operation.

Parameters

None.

Return Value

If the client is performing a blocking operation, the method returns a non-zero value. If the client is not performing a blocking operation, or the client handle is invalid, the method returns zero.

Remarks

Because a blocking operation can allow the application to be re-entered (for example, by pressing a button while the operation is being performed), it is possible that another blocking method may be called while it is in progress. Since only one thread of execution may perform a blocking operation at any one time, an error would occur. The **IsBlocking** method can be used to determine if the client is already blocked, and if so, take some other action (such as warning the user that they must wait for the operation to complete).

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cspopv10.lib

Unicode: Implemented as Unicode and ANSI versions.

CPopClient::IsConnected Method

```
BOOL IsConnected();
```

The **IsConnected** method is used to determine if the client is currently connected to a server.

Parameters

None.

Return Value

If the client is connected to a server, the method returns a non-zero value. If the client is not connected, or the client handle is invalid, the method returns zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cspopv10.lib

See Also

[GetStatus](#), [IsBlocking](#), [IsInitialized](#), [IsReadable](#), [IsWritable](#)

CPopClient::IsInitialized Method

```
BOOL IsInitialized();
```

The **IsInitialized** method returns whether or not the class object has been successfully initialized.

Parameters

None.

Return Value

This method returns a non-zero value if the class object has been successfully initialized. A return value of zero indicates that the runtime license key could not be validated or the networking library could not be loaded by the current process.

Remarks

When an instance of the class is created, the class constructor will attempt to initialize the component with the runtime license key that was created when SocketTools was installed. If the constructor is unable to validate the license key or load the networking libraries, this initialization will fail.

If SocketTools was installed with an evaluation license, the application cannot be redistributed to another system. The class object will fail to initialize if the application is executed on another system, or if the evaluation period has expired. To redistribute your application, you must purchase a development license which will include the runtime key that is needed to redistribute your software to other systems. Refer to the Developer's Guide for more information.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cspopv10.lib

See Also

[CPopClient](#), [IsBlocking](#), [IsConnected](#)

CPopClient::IsReadable Method

```
BOOL IsReadable(  
    INT nTimeout,  
    LPDWORD lpdwAvail  
);
```

The **IsReadable** method is used to determine if data is available to be read from the server.

Parameters

nTimeout

Timeout for server response, in seconds. A value of zero specifies that the connection should be polled without blocking the current thread.

lpdwAvail

A pointer to an unsigned integer which will contain the number of bytes available to read. This parameter may be NULL if this information is not required.

Return Value

If the client can read data from the server within the specified timeout period, the method returns a non-zero value. If the client cannot read any data, the method returns zero.

Remarks

On some platforms, this value will not exceed the size of the receive buffer (typically 64K bytes). Because of differences between TCP/IP stack implementations, it is not recommended that your application exclusively depend on this value to determine the exact number of bytes available. Instead, it should be used as a general indicator that there is data available to be read.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cspopv10.lib

See Also

CPopClient::IsWritable Method

```
BOOL IsWritable(  
    INT nTimeout  
);
```

The **IsWritable** method is used to determine if data can be written to the server.

Parameters

nTimeout

Timeout for server response, in seconds. A value of zero specifies that the connection should be polled without blocking the current thread.

Return Value

If the client can write data to the server within the specified timeout period, the method returns a non-zero value. If the client cannot write any data, the method returns zero.

Remarks

Although this method can be used to determine if some amount of data can be sent to the remote process it does not indicate the amount of data that can be written without blocking the client. In most cases, it is recommended that large amounts of data be broken into smaller logical blocks, typically some multiple of 512 bytes in length.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cspopv10.lib

CPopClient::Login Method

```
INT Login(  
    LPCTSTR lpszUserName,  
    LPCTSTR lpszPassword,  
    UINT nAuthType  
);
```

The **Login** method authenticates the specified user in on the server. This method must be called after the connection has been established, and before attempting to retrieve messages or perform any other method on the server.

Parameters

lpszUserName

A null terminated string which specifies the user name to be used to authenticate the current client session. For many service providers, the user name is the full email address of the user which owns the mailbox. In some cases, this may only be the portion of their email address before the domain name.

lpszPassword

A null terminated string which specifies the password to be used when authenticating the current client session. If you are using the POP_AUTH_XOAUTH2 or POP_AUTH_BEARER authentication methods, this parameter is not a password, instead it specifies the OAuth 2.0 bearer token provided by the mail service.

nAuthType

Identifies the type of authentication that should be used when the client logs in to the mail server. The following authentication methods are supported:

Constant	Description
POP_AUTH_DEFAULT	The default authentication scheme which sends the username and password as cleartext to the server. Because the user credentials are not encrypted, this method should only be used over a secure connection. This is the same as specifying POP_AUTH_PASS as the authentication method.
POP_AUTH_PASS	The username and password is sent to the server using the USER and PASS commands. This authentication method is supported by most servers and is the default authentication type. The credentials are not encrypted and this method should only be used over secure connections.
POP_AUTH_APOP	The APOP authentication method which uses an MD5 digest of the password. This method has been deprecated is not supported by all servers. It should only be used if required by legacy mail servers which do not support the SASL authentication methods.
POP_AUTH_LOGIN	This authentication type will use the LOGIN method to authenticate the client session. This encodes the username and password in a specific format, but the credentials are not encrypted. It should be used over a secure connection. The server must support the Simple Authentication and Security

	Layer (SASL) mechanism as defined in RFC 4422.
POP_AUTH_PLAIN	This authentication type will use the PLAIN method to authenticate the client session. This encodes the username and password in a specific format, but the credentials are not encrypted. It should be used over a secure connection. The server must support the PLAIN Simple Authentication and Security Layer (SASL) mechanism as defined in RFC 4616.
POP_AUTH_XOAUTH2	This authentication type will use the XOAUTH2 method to authenticate the client session. This authentication method does not require the user password, instead the <i>lpszPassword</i> parameter must specify the bearer token issued by the service provider. The application must provide a valid access token which has not expired, or this method will fail.
POP_AUTH_BEARER	This authentication type will use the OAUTHBEARER method to authenticate the client session as defined in RFC 7628. This authentication method does not require the user password, instead the <i>lpszPassword</i> parameter must specify the bearer token issued by the service provider. The application must provide a valid access token which has not expired, or this method will fail.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is POP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The POP_AUTH_LOGIN and POP_AUTH_PLAIN authentication methods require the mail server support the Simple Authentication and Security Layer (SASL) AUTH command as defined in RFC 5034. Most modern mail servers do support one or both of these methods, and they are generally preferred over the POP_AUTH_PASS method when possible. However, for backwards compatibility with legacy servers, the class will default to using POP_AUTH_PASS for client authentication.

You should only use an OAuth 2.0 authentication method if you understand the process of how to request the access token. Obtaining an access token requires registering your application with the mail service provider (e.g.: Microsoft or Google), getting a unique client ID associated with your application and then requesting the access token using the appropriate scope for the service. Obtaining the initial token will typically involve interactive confirmation on the part of the user, requiring they grant permission to your application to access their mail account.

The POP_AUTH_XOAUTH2 and POP_AUTH_BEARER authentication methods are similar, but they are not interchangeable. Both use an OAuth 2.0 bearer token to authenticate the client session, but they differ in how the token is presented to the server. It is currently preferable to use the XOAUTH2 method because it is more widely available and some service providers do not yet support the OAUTHBEARER method.

Your application should not store an OAuth 2.0 bearer token for later use. They have a relatively short lifespan, typically about an hour, and are designed to be used with that session. You should specify offline access as part of the OAuth 2.0 scope if necessary and store the refresh token provided by the service. The refresh token has a much longer validity period and can be used to obtain a new bearer token when needed.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cspopv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[Connect](#), [GetMessage](#), [GetMessageCount](#)

CPopClient::OpenMessage Method

```
INT OpenMessage(  
    UINT nMessageId  
);
```

The **OpenMessage** method opens the specified message for reading.

Parameters

nMessageId

Number that specifies which message to open. This value must be greater than zero. The first message in the mailbox is message one.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is POP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **OpenMessage** method is used to begin the process of reading the contents of a message from the server. Similar to how a file is opened and read, this method is followed by one or more calls to the **Read** method. When the entire contents of the message has been read, the **CloseMessage** method is used to close the message, completing the transaction on the server.

This is a lower-level method which enables the application to process the message as the contents are being returned by the server. In general, it is recommended that most applications use the **GetMessage** method instead, which provides a simpler interface for retrieving the contents of a message.

It is important to note that you cannot use this method to read the partial contents of a message. Opening a message on the server begins a process where the entire message contents must be read and the message closed before the next command can be issued to the server. If you only want to obtain the headers for a message, use the **GetMessageHeaders** method instead.

Example

```
// Connect to the mail server using the default settings  
if (popClient.Connect(strHostName))  
{  
    // Authenticate the user and display an error if the  
    // server does not accept the username or password  
    if (popClient.Login(strUserName, strPassword) == POP_ERROR)  
    {  
        popClient.ShowError();  
        popClient.Disconnect();  
        return;  
    }  
  
    // Open the specified message  
    if (popClient.OpenMessage(nMessageId) == POP_ERROR)  
    {  
        popClient.ShowError();  
        popClient.Disconnect();  
        return;  
    }  
  
    CString strMessage;
```

```

CString strBuffer;
INT nResult;

// Read the contents of the message in a loop; a return value
// of zero indicates that there is no more data to read
do
{
    if ((nResult = popClient.Read(strBuffer)) > 0)
        strMessage = strMessage + strBuffer;
}
while (nResult > 0);

// If an error occurred while reading reading the message,
// display an error message
if (nResult == POP_ERROR)
{
    popClient.ShowError();
    popClient.Disconnect();
    return;
}

// Close the message and disconnect from the server
popClient.CloseMessage();
popClient.Disconnect();
}

```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cspopv10.lib

[CloseMessage](#), [GetMessage](#), [GetMessageHeaders](#), [IsReadable](#), [Read](#)

CPopClient::Read Method

```
INT Read(  
    LPBYTE lpBuffer,  
    INT cbBuffer  
);  
  
INT Read(  
    CString& strBuffer,  
    INT cbBuffer  
);
```

The **Read** method reads the specified number of bytes from the client socket and copies them into the buffer. The data may be of any type, and is not terminated with a null character.

Parameters

lpBuffer

Pointer to the buffer in which the data will be copied. An alternate form of this method allows a **CString** variable to be passed and data read from the socket will be returned in that string.

cbBuffer

The maximum number of bytes to read and copy into the specified buffer. This value must be greater than zero.

Return Value

If the method succeeds, the return value is the number of bytes actually read. A return value of zero indicates that the server has closed the connection and there is no more data available to be read. If the method fails, the return value is POP_ERROR. To get extended error information, call **GetLastError**.

Remarks

When **Read** is called and the client is in non-blocking mode, it is possible that the method will fail because there is no available data to read at that time. This should not be considered a fatal error. Instead, the application should simply wait to receive the next asynchronous notification that data is available.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cspopv10.lib

[EnableEvents](#), [IsBlocking](#), [IsReadable](#), [IsWritable](#), [RegisterEvent](#), [Write](#)

CPopClient::RegisterEvent Method

```
INT RegisterEvent(  
    UINT nEventId,  
    POPEVENTPROC LpEventProc,  
    DWORD_PTR dwParam  
);
```

The **RegisterEvent** method registers an event handler for the specified event.

Parameters

nEventId

An unsigned integer which specifies which event should be registered with the specified callback function. One of the following values may be used:

Constant	Description
POP_EVENT_CONNECT	The connection to the server has completed.
POP_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
POP_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
POP_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
POP_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
POP_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.
POP_EVENT_COMMAND	A command has been issued by the client and the server response has been received and processed. This event can be used to log the result codes and messages returned by the server in response to actions taken by the client.
POP_EVENT_PROGRESS	The client is in the process of sending or receiving a file on the data channel. This event is called periodically during a transfer so that the client can update any user interface components such as a status control or progress bar.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more

information about the callback function, see the description of the **PopEventProc** callback function. If this parameter is NULL, the callback for the specified event is disabled.

dwParam

A user-defined integer value that is passed to the callback function. If the application targets the x86 (32-bit) platform, this parameter must be a 32-bit unsigned integer. If the application targets the x64 (64-bit) platform, this parameter must be a 64-bit unsigned integer.

Remarks

The **RegisterEvent** method associates a callback function with a specific event. The event handler is an **PopEventProc** function that is invoked when the event occurs. Arguments are passed to the function to identify the client session, the event type and the user-defined value specified when the event handler is registered. If the event occurs because of an error condition, the error code will be provided to the handler.

This method is typically used to register an event handler that is invoked while a message is being retrieved. The POP_EVENT_PROGRESS event will only be generated periodically during the transfer to ensure the application is not flooded with event notifications. It is guaranteed that at least one POP_EVENT_PROGRESS notification will occur at the beginning of the transfer, and one at the end of the transfer when it has completed.

The callback function specified by the *lpEventProc* parameter must be declared using the **__stdcall** calling convention. This ensures the arguments passed to the event handler are pushed on to the stack in the correct order. Failure to use the correct calling convention will corrupt the stack and cause the application to terminate abnormally.

The *dwParam* parameter is commonly used to identify the class instance which is associated with the event that has occurred. Applications will cast the **this** pointer to a DWORD_PTR value when calling this function, and then the event handler will cast it back to a pointer to the class instance. This gives the handler access to the class member variables and methods.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is POP_ERROR. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cspopv10.lib

See Also

[DisableEvents](#), [EnableEvents](#), [FreezeEvents](#), [PopEventProc](#)

CPopClient::Reset Method

```
BOOL Reset();
```

The **Reset** method resets the client state and resynchronizes with the server. This method is typically called after an unexpected error has occurred, or an operation has been canceled.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

This method will prevent any messages marked for deletion from actually being deleted from the mailbox. The client cannot be reset while the client is in a blocked state.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cspopv10.lib

See Also

[Cancel](#), [DeleteMessage](#), [IsBlocking](#)

CPopClient::SendMessage Method

```
INT SendMessage(  
    LPCTSTR lpszMessage,  
    INT nLength  
);
```

The **SendMessage** method sends a message to the specified recipients.

Parameters

lpszMessage

Pointer to a string buffer which contains the message to be submitted to the mail server for delivery.

nLength

The length of the string buffer. This specifies the number of characters to be written to the mail server. This value must be greater than zero. If this value is -1, then the length of the string up to the terminating null character is used.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is POP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **SendMessage** method sends a message through the POP3 server using the XTND XMIT command. The specified file must be in the standard format as described in RFC 822, with the recipient addresses specified in the To: and Cc: header fields. Some servers may support blind carbon copies by using addresses specified in a Bcc: header field, and then removing those addresses from the header before delivering the message.

Note that not all POP3 servers support this command, and it is recommended that you use the Simple Mail Transfer Protocol (SMTP) for general mail delivery purposes.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cspopv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[GetMessage](#), [StoreMessage](#)

CPopClient::SetLastError Method

```
VOID SetLastError(  
    DWORD dwErrorCode  
);
```

The **SetLastError** method sets the last error code for the current thread. This method is typically used to clear the last error by specifying a value of zero as the parameter.

Parameters

dwErrorCode

Specifies the last error code for the current thread.

Return Value

None.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. Most methods will set the last error code value when they fail; a few methods set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or POP_ERROR. Those methods which call **SetLastError** when they succeed are noted on the method reference page.

Applications can retrieve the value saved by this method by using the **GetLastError** method. The use of **GetLastError** is optional; an application can call the method to determine the specific reason for a method failure.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cspopv10.lib

See Also

[GetErrorString](#), [GetLastError](#), [ShowError](#)

CPopClient::SetTimeout Method

```
INT SetTimeout(  
    UINT nTimeout  
);
```

The **SetTimeout** method sets the number of seconds the client will wait for a response from the server. Once the specified number of seconds has elapsed, the method will fail and return to the caller.

Parameters

nTimeout

The number of seconds to wait for a blocking operation to complete.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is POP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The timeout value is only used with blocking client connections.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cspopv10.lib

CPopClient::ShowError Method

```
INT ShowError(  
    LPCTSTR lpszAppTitle,  
    UINT uType,  
    DWORD dwErrorCode  
);
```

The **ShowError** method displays a message box which describes the specified error.

Parameters

lpszAppTitle

A pointer to a string which specifies the title of the message box that is displayed. If this argument is NULL or omitted, then the default title of "Error" will be displayed.

uType

An unsigned integer which specifies the type of message box that will be displayed. This is the same value that is used by the **MessageBox** method in the Windows API. If a value of zero is specified, then a message box with a single OK button will be displayed. Refer to that method for a complete list of options.

dwErrorCode

Specifies the error code that will be used when displaying the message box. If this argument is zero, then the last error that occurred in the current thread will be displayed.

Return Value

If the method is successful, the return value will be the return value from the **MessageBox** function. If the method fails, it will return a value of zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cspopv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[GetErrorString](#), [GetLastError](#), [SetLastError](#)

CPopClient::StoreMessage Method

```
INT StoreMessage(  
    UINT nMessageId,  
    LPCTSTR lpszFileName  
);
```

The **StoreMessage** method stores a message in the specified file.

Parameters

nMessageId

Number of the message to retrieve. This value must be greater than zero. The first message in the mailbox is message number one.

lpszFileName

Pointer to a string which specifies the file that the message will be stored in. If an empty string or NULL pointer is passed as an argument, the message is copied to the system clipboard.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is POP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **StoreMessage** method provides a method of retrieving and storing a message on the local system. The contents of the message is stored as a text file, using the specified file name. This method always causes the caller to block until the entire message has been retrieved, even if the client has been put in asynchronous mode.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cspopv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[GetMessage](#), [GetMessageHeaders](#), [GetTransferStatus](#), [SendMessage](#)

CPopClient::Write Method

```
INT Write(  
    LPBYTE lpBuffer,  
    INT cbBuffer  
);  
  
INT Write(  
    LPCTSTR lpszBuffer  
    INT cbBuffer  
);
```

The **Write** method sends the specified number of bytes to the server.

Parameters

lpBuffer

The pointer to the buffer which contains the data that is to be sent to the server. In an alternate form of the method, the pointer is to a string.

cbBuffer

The number of bytes to send from the specified buffer. This value must be greater than zero, unless a pointer to a string buffer is passed as the parameter. In that case, if the value is -1, all of the characters in the string, up to but not including the terminating null character, will be sent to the server.

Return Value

If the method succeeds, the return value is the number of bytes actually written. If the method fails, the return value is POP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The return value may be less than the number of bytes specified by the *cbBuffer* parameter. In this case, the data has been partially written and it is the responsibility of the client application to send the remaining data at some later point. For non-blocking clients, the client must wait for the next asynchronous notification message before it resumes sending data.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cspopv10.lib

Unicode: Implemented as Unicode and ANSI versions.

Post Office Protocol Data Structures

- POPTRANSFERSTATUS
- SECURITYCREDENTIALS
- SECURITYINFO
- SYSTEMTIME

Copyright © 2023 Catalyst Development Corporation. All rights reserved.

POPTRANSFERSTATUS Structure

This structure is used by the [GetTransferStatus](#) method to return information about a message transfer in progress.

```
typedef struct _POPTRANSFERSTATUS
{
    UINT    nMessageId;
    DWORD   dwBytesTotal;
    DWORD   dwBytesCopied;
    DWORD   dwBytesPerSecond;
    DWORD   dwTimeElapsed;
    DWORD   dwTimeEstimated;
} POPTRANSFERSTATUS, *LPPOPTRANSFERSTATUS;
```

Members

nMessageId

The message ID of the current message that is being transferred.

dwBytesTotal

The total number of bytes that will be transferred. If the message is being copied from the server to the local host, this is the size of the message on the server. If the message is being posted to the server, it is the size of message on the local system. If the message size cannot be determined, this value will be zero.

dwBytesCopied

The total number of bytes that have been copied.

dwBytesPerSecond

The average number of bytes that have been copied per second.

dwTimeElapsed

The number of seconds that have elapsed since the transfer started.

dwTimeEstimated

The estimated number of seconds until the transfer is completed. This is based on the average number of bytes transferred per second.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

SECURITYCREDENTIALS Structure

The **SECURITYCREDENTIALS** structure specifies the information needed by the library to specify additional security credentials, such as a client certificate or private key, when establishing a secure connection.

```
typedef struct _SECURITYCREDENTIALS
{
    DWORD    dwSize;
    DWORD    dwProtocol;
    DWORD    dwOptions;
    DWORD    dwReserved;
    LPCTSTR  lpszHostName;
    LPCTSTR  lpszUserName;
    LPCTSTR  lpszPassword;
    LPCTSTR  lpszCertStore;
    LPCTSTR  lpszCertName;
    LPCTSTR  lpszKeyFile;
} SECURITYCREDENTIALS, *LPSECURITYCREDENTIALS;
```

Members

dwSize

Size of this structure. If the structure is being allocated dynamically, this member must be set to the size of the structure and all other unused structure members must be initialized to a value of zero or NULL.

dwProtocol

A bitmask of supported security protocols. The value of this structure member is constructed by using a bitwise operator with any of the following values:

Constant	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_SSL	Either SSL 2.0 or SSL 3.0 should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, TLS will be excluded from the list of supported protocols. Both SSL 2.0 and 3.0 have been deprecated and will never be used unless explicitly specified. It is not recommended that you enable either of these protocols for secure connections because it will cause most servers to reject your connection request, even if a version of TLS is also specified.
SECURITY_PROTOCOL_TLS	Either the TLS 1.0, 1.1 or 1.2 protocol should be used when establishing a secure connection. The correct protocol is automatically selected, based on

	what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers that reject any attempt to use the older SSL protocol and require that only TLS be used.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This is the recommended version of TLS to use with secure connections.

dwOptions

A value which specifies one or options. This member is constructed by using a bitwise operator with any of the following values:

Constant	Description
CREDENTIAL_STORE_CURRENT_USER	The library will attempt to open a store for the current user using the certificate store name provided in this structure. If no options are specified, then this is the default behavior.
CREDENTIAL_STORE_LOCAL_MACHINE	The library will attempt to open a local machine store using the certificate store name provided in this structure. If this option is specified, the library will always search for a local machine store before searching for the store by that name for the current user.
CREDENTIAL_STORE_FILENAME	The certificate store name is a file that contains the certificate and private key that

will be used.

dwReserved

This structure member is reserved for future use and should always be initialized to zero.

lpszHostName

A pointer to a null terminated string which specifies the hostname that will be used when validating the server certificate. If this member is NULL, then the server certificate will be validated against the hostname used to establish the connection.

lpszUserName

A pointer to a null terminated string which identifies the owner of client certificate. Currently this member is not used by the library and should always be initialized as a NULL pointer.

lpszPassword

A pointer to a null terminated string which specifies the password needed to access the certificate. Currently this member is only used if the CREDENTIAL_STORE_FILENAME option has been specified. If there is no password associated with the certificate, then this member should be initialized as a NULL pointer.

lpszCertStore

A pointer to a null terminated string which specifies the name of the certificate store to open. A certificate store is a collection of certificates and their private keys, typically organized by how they are used. If this value is NULL or points to an empty string, the default certificate store "MY" will be used.

Store Name	Description
------------	-------------

CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as VeriSign and Thawte act as certification authorities.
----	---

MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. This corresponds to the "Personal" store that is displayed by the certificate manager utility and is the default store used by the library.
----	--

ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as VeriSign and Thawte are installed as part of the operating system and periodically updated by Microsoft.
------	--

lpszCertName

A pointer to a null terminated string which specifies the name of the certificate to use. The library will first search the certificate store for a certificate with a matching "friendly name"; this is a name for the certificate that is assigned by the user. Note that the name must match completely, but the comparison is not case sensitive. If no matching certificate is found, the library will then attempt to find a certificate that has a matching common name (also called the certificate subject). This comparison is less stringent, and the first partial match will be returned. If this second search fails, the library will return an error indicating that the certificate could not be found. If the SECURITY_PROTOCOL_SSH protocol has been specified, this member should be NULL.

lpszKeyFile

A pointer to a null terminated string which specifies the name of the file which contains the private key required to establish the connection. This member is only used for SSH connections

and should always be NULL when establishing a secure connection using SSL or TLS.

Remarks

A client application only needs to create this structure if the server requires that the client provide a certificate as part of the process of negotiating the secure session. If a certificate is required, note that it must have a private key associated with it. Attempting to use a certificate that does not have a private key will result in an error during the connection process indicating that the client credentials could not be established.

If you are using a local certificate store, with the certificate and private key stored in the registry, you can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU:" for the current user, or "HKLM:" for the local machine. For example, a certificate store name of "HKLM:MY" would specify the personal certificate store for the local machine, rather than the current user. If neither prefix is specified, then it will default to the certificate store for the current user. You can manage these certificates using the CertMgr.msc Microsoft Management Console (MMC) snap-in.

It is possible to load the certificate from a file rather than from current user's certificate store. The *dwOptions* member should be set to CREDENTIAL_STORE_FILENAME and the *lpzCertStore* member should specify the name of the file that contains the certificate and its private key. The file must be in Private Information Exchange (PFX) format, also known as PKCS#12. These certificate files typically have an extension of .pfx or .p12. Note that if a password was specified when the certificate file was created, it must be provided in the *lpzPassword* member or the library will be unable to access the certificate.

Note that the *lpzUserName* and *lpzPassword* members are values which are used to access the certificate store or private key file. They are not the credentials which are used when establishing the connection with the remote host or authenticating the client session.

The TLS 1.1 and TLS 1.2 protocols are only supported on Windows 7, Windows Server 2008 R2 and later versions of the platform. If these options are specified and the application is running on Windows XP or Windows Vista, the protocol version will be downgraded to TLS 1.0 for backwards compatibility with those platforms.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include ctools10.h

Unicode: Implemented as Unicode and ANSI versions.

SECURITYINFO Structure

This structure contains information about a secure connection that has been established.

```
typedef struct _SECURITYINFO
{
    DWORD        dwSize;
    DWORD        dwProtocol;
    DWORD        dwCipher;
    DWORD        dwCipherStrength;
    DWORD        dwHash;
    DWORD        dwHashStrength;
    DWORD        dwKeyExchange;
    DWORD        dwCertStatus;
    SYSTEMTIME   stCertIssued;
    SYSTEMTIME   stCertExpires;
    LPCTSTR      lpszCertIssuer;
    LPCTSTR      lpszCertSubject;
    LPCTSTR      lpszFingerprint;
} SECURITYINFO, *LPSECURITYINFO;
```

Members

dwSize

Specifies the size of the data structure. This member must always be initialized to **sizeof(SECURITYINFO)** prior to passing the address of this structure to the function. Note that if this member is not initialized, an error will be returned indicating that an invalid parameter has been passed to the function.

dwProtocol

A numeric value which specifies the protocol that was selected to establish the secure connection. One of the following values will be returned:

Constant	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_SSL	Either SSL 2.0 or SSL 3.0 should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, TLS will be excluded from the list of supported protocols. Both SSL 2.0 and 3.0 have been deprecated and will never be used unless explicitly specified. It is not recommended that you enable either of these protocols for secure connections because it will cause most servers to reject your connection request, even if a version of TLS is also specified.
SECURITY_PROTOCOL_TLS	Either the TLS 1.0, 1.1 or 1.2 protocol should be used when establishing a secure connection. The

	<p>correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers that reject any attempt to use the older SSL protocol and require that only TLS be used.</p>
SECURITY_PROTOCOL_TLS10	<p>The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.</p>
SECURITY_PROTOCOL_TLS11	<p>The TLS 1.1 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.</p>
SECURITY_PROTOCOL_TLS12	<p>The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This is the recommended version of TLS to use with secure connections.</p>

dwCipher

A numeric value which specifies the cipher that was selected when establishing the secure connection. One of the following values will be returned:

Constant	Description
SECURITY_CIPHER_RC2	The RC2 block cipher was selected. This is a variable key length cipher which supports keys between 40 and 128 bits, in 8-bit increments.
SECURITY_CIPHER_RC4	The RC4 stream cipher was selected. This is a variable key length cipher which supports keys between 40 and 128 bits, in 8-bit increments.
SECURITY_CIPHER_RC5	The RC5 block cipher was selected. This is a variable key length cipher which supports keys up to 2040 bits, in 8-bit increments.
SECURITY_CIPHER_DES	The DES (Data Encryption Standard) block cipher was selected. This is a fixed key length cipher, using 56-bit

	keys.
SECURITY_CIPHER_DES3	The Triple DES block cipher was selected. This cipher encrypts the data three times using different keys, effectively providing a 168-bit length key.
SECURITY_CIPHER_DESX	A variant of the DES block cipher which XORs an extra 64-bits of the key before and after the plaintext has been encrypted, increasing the key size to 184 bits.
SECURITY_CIPHER_AES	The Advanced Encryption Standard cipher (also known as the Rijndael cipher) is a fixed block size cipher which use a key size of 128, 192 or 256 bits. This cipher is supported on Windows XP SP3 and later versions of the operating system.
SECURITY_CIPHER_SKIPJACK	The Skipjack block cipher was selected. This is a fixed key length cipher, using 80-bit keys.
SECURITY_CIPHER_BLOWFISH	The Blowfish block cipher was selected. This is a variable key length cipher up to 448 bits, using a 64-bit block size.

dwCipherStrength

A numeric value which specifies the strength (the length of the cipher key in bits) of the cipher that was selected. Typically this value will be 128 or 256. 40-bit and 56-bit key lengths are considered weak encryption, and subject to brute force attacks. 128-bit and 256-bit key lengths are considered to be secure, and are the recommended key length for secure communications.

dwHash

A numeric value which specifies the hash algorithm which was selected. One of the following values will be returned:

Constant	Description
SECURITY_HASH_MD5	The MD5 algorithm was selected. Its use has been deprecated and is no longer considered to be cryptographically secure.
SECURITY_HASH_SHA1	The SHA-1 algorithm was selected. Its use has been deprecated and is no longer considered to be cryptographically secure.
SECURITY_HASH_SHA256	The SHA-256 algorithm was selected.
SECURITY_HASH_SHA384	The SHA-384 algorithm was selected.
SECURITY_HASH_SHA512	The SHA-512 algorithm was selected.

dwHashStrength

A numeric value which specifies the strength (the length in bits) of the message digest that was selected.

dwKeyExchange

A numeric value which specifies the key exchange algorithm which was selected. One of the following values will be returned:

--	--

Constant	Description
SECURITY_KEYEX_RSA	The RSA public key algorithm was selected.
SECURITY_KEYEX_KEA	The Key Exchange Algorithm (KEA) was selected. This is an improved version of the Diffie-Hellman public key algorithm.
SECURITY_KEYEX_DH	The Diffie-Hellman key exchange algorithm was selected.
SECURITY_KEYEX_ECDH	The Elliptic Curve Diffie-Hellman key exchange algorithm was selected. This is a variant of the Diffie-Hellman algorithm which uses elliptic curve cryptography. This key exchange algorithm is only supported on Windows XP SP3 and later versions of the operating system.

dwCertStatus

A numeric value which specifies the status of the certificate returned by the secure server. This member only has meaning for connections using the SSL or TLS protocols. One of the following values will be returned:

Constant	Description
SECURITY_CERTIFICATE_VALID	The certificate is valid.
SECURITY_CERTIFICATE_NOMATCH	The certificate is valid, but the domain name does not match the common name in the certificate.
SECURITY_CERTIFICATE_EXPIRED	The certificate is valid, but has expired.
SECURITY_CERTIFICATE_REVOKED	The certificate has been revoked and is no longer valid.
SECURITY_CERTIFICATE_UNTRUSTED	The certificate or certificate authority is not trusted on the local system.
SECURITY_CERTIFICATE_INVALID	The certificate is invalid. This typically indicates that the internal structure of the certificate has been damaged.

stCertIssued

A structure which contains the date and time that the certificate was issued by the certificate authority. If the issue date cannot be determined for the certificate, the SYSTEMTIME structure members will have zero values. This member only has meaning for connections using the SSL or TLS protocols.

stCertExpires

A structure which contains the date and time that the certificate expires. If the expiration date cannot be determined for the certificate, the SYSTEMTIME structure members will have zero values. This member only has meaning for connections using the SSL or TLS protocols.

lpszCertIssuer

A pointer to a string which contains information about the organization that issued the certificate. This string consists of one or more comma-separated tokens. Each token consists of an identifier, followed by an equal sign and a value. If the certificate issuer could not be determined, this member may be NULL. This member only has meaning for connections using the SSL or TLS protocols.

lpszCertSubject

A pointer to a string which contains information about the organization that the certificate was issued to. This string consists of one or more comma-separated tokens. Each token consists of an identifier, followed by an equal sign and a value. If the certificate subject could not be determined, this member may be NULL. This member only has meaning for connections using the SSL or TLS protocols.

lpszFingerprint

A pointer to a string which contains a sequence of hexadecimal values that uniquely identify the server. This member is only used when a connection has been established using the Secure Shell (SSH) protocol.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Unicode: Implemented as Unicode and ANSI versions.

SYSTEMTIME Structure

The **SYSTEMTIME** structure represents a date and time using individual members for the month, day, year, weekday, hour, minute, second, and millisecond.

```
typedef struct _SYSTEMTIME
{
    WORD wYear;
    WORD wMonth;
    WORD wDayOfWeek;
    WORD wDay;
    WORD wHour;
    WORD wMinute;
    WORD wSecond;
    WORD wMilliseconds;
} SYSTEMTIME, *LPSYSTEMTIME;
```

Members

wYear

Specifies the current year. The year value must be greater than 1601.

wMonth

Specifies the current month. January is 1, February is 2 and so on.

wDayOfWeek

Specifies the current day of the week. Sunday is 0, Monday is 1 and so on.

wDay

Specifies the current day of the month

wHour

Specifies the current hour.

wMinute

Specifies the current minute

wSecond

Specifies the current second.

wMilliseconds

Specifies the current millisecond.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include windows.h.

Remote Command Protocol Class Library

Execute commands on a server or establish an interactive terminal session.

Reference

- [Class Methods](#)
- [Error Codes](#)

Library Information

Class Name	CRshClient
File Name	CSRSHV10.DLL
Version	10.0.1468.2518
LibID	4893754D-AF7A-4892-9320-D829EEC98DD6
Import Library	CSRSHV10.LIB
Dependencies	None
Standards	RFC 1282

Overview

The Remote Command protocol is used to execute a command on a server and return the output of that command to the client. This is most commonly used with UNIX based servers, although there are implementations of remote command servers for the Windows operating system. The library supports both the rcmd and rshell remote execution protocols and provides methods which can be used to search the data stream for specific sequences of characters. This makes it extremely easy to write Windows applications which serve as light-weight client interfaces to commands being executed on a UNIX server or another Windows system. The library can also be used to establish a remote terminal session using the rlogin protocol, which is similar to the Telnet protocol.

This class library should not be used when connecting to a server over the Internet because the user credentials are sent as unencrypted text. For secure remote command execution and interactive terminal sessions, it is recommended that you use the SocketTools Secure Shell (SSH) class instead.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). If you are using Visual C++ 6.0 it is required that you have Service Pack 6 (SP6) installed. You should install all updates for your development tools and have the current Windows SDK installed. The minimum recommended version of Visual Studio is Visual Studio 2010.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are using Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. It is recommended that you install the current service pack and all critical updates available for your version of the operating system.

This product includes both 32-bit and 64-bit libraries. Native 64-bit CPU support requires the 64-bit version of Windows 7 or later versions of the Windows operating system.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

Remote Command Protocol Class Methods

Class	Description
CRshClient	Constructor which initializes the current instance of the class
~CRshClient	Destructor which releases resources allocated by the class
Method	Description
AttachHandle	Attach the specified client handle to this instance of the class
AttachThread	Attach the specified client handle to another thread
Cancel	Cancel the current blocking operation
DetachHandle	Detach the handle for the current instance of this class
DisableEvents	Disable asynchronous event notification
DisableTrace	Disable logging of socket function calls to the trace log
Disconnect	Disconnect from the current server
EnableEvents	Enable asynchronous event notification
EnableTrace	Enable logging of socket function calls to a file
Execute	Execute a command on the server
FreezeEvents	Suspend asynchronous event processing
GetErrorString	Return a description for the specified error code
GetHandle	Return the client handle used by this instance of the class
GetLastError	Return the last error code
GetStatus	Return the current client status
GetTimeout	Return the number of seconds until an operation times out
IsBlocking	Determine if the client is blocked, waiting for information
IsConnected	Determine if the client is connected to the server
IsInitialized	Determine if the class has been successfully initialized
IsReadable	Determine if data can be read from the server
IsWritable	Determine if data can be written to the server
Login	Establish a login session with the specified server
Read	Read data returned by the server
RegisterEvent	Register an event callback function
RshEventProc	Callback method that processes events generated by the client
Search	Search for a specific character sequence in the data stream
SetLastError	Set the last error code
SetTimeout	Set the number of seconds until an operation times out
ShowError	Display a message box with a description of the specified error

Write	Write data to the server
-------	--------------------------

CRshClient::CRshClient

`CRshClient();`

The **CRshClient** constructor initializes the class library and validates the license key at runtime.

Remarks

If the constructor fails to validate the runtime license, subsequent methods in this class will fail. If the product is installed with an evaluation license, then the application will only function on the development system and cannot be redistributed.

The constructor calls the **RshInitialize** function to initialize the library, which dynamically loads other system libraries and allocates thread local storage. If you are using this class within another DLL, it is important that you do not create or destroy an instance of the class from within the **DllMain** function because it can result in deadlocks or access violation errors. You should not declare static or global instances of this class within another DLL if it is linked with the C runtime library (CRT) because it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csrshv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[~CRshClient](#), [IsInitialized](#)

CRshClient::~CRshClient

`~CRshClient();`

The **CRshClient** destructor releases resources allocated by the current instance of the **CRshClient** object. It also uninitialized the library if there are no other concurrent uses of the class.

Remarks

When a **CRshClient** object goes out of scope, the destructor is automatically called to allow the library to free any resources allocated on behalf of the process. Any pending blocking or asynchronous calls in this process are canceled without posting any notification messages, and all handles that were created for the client session are destroyed.

The destructor is not called explicitly by the application.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csrshv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[CRshClient](#)

CRshClient::AttachHandle

```
VOID AttachHandle(  
    HCLIENT hClient  
);
```

The **AttachHandle** method attaches the specified client handle to the current instance of the class.

Parameters

hClient

The handle to the client session that will be attached to the current instance of the class object.

Return Value

None.

Remarks

This method is used to attach a client handle created outside of the class using the SocketTools API. Once the client handle is attached to the class, the other class member functions may be used with that client session.

If a client handle already has been created for the class, that handle will be released when the new handle is attached to the class object. If you want to prevent the previous client session from being terminated, you must call the **DetachHandle** method. Failure to release the detached handle may result in a resource leak in your application.

Note that the *hClient* parameter is presumed to be a valid client handle and no checks are performed to ensure that the handle is valid. Specifying an invalid client handle will cause subsequent method calls to fail.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csrshv10.lib

See Also

[AttachThread](#), [DetachHandle](#), [GetHandle](#)

CRshClient::AttachThread

```
DWORD AttachThread(  
    DWORD dwThreadId  
);
```

The **AttachThread** method attaches the specified client handle to another thread.

Parameters

dwThreadId

The ID of the thread that will become the new owner of the handle. A value of zero specifies that the current thread should become the owner of the client handle.

Return Value

If the method succeeds, the return value is the thread ID of the previous owner. If the method fails, the return value is RSH_ERROR. To get extended error information, call **GetLastError**.

Remarks

When a client handle is created, it is associated with the current thread that created it. Normally, if another thread attempts to perform an operation using that handle, an error is returned since it does not own the handle. This is used to ensure that other threads cannot interfere with an operation being performed by the owner thread. In some cases, it may be desirable for one thread in a client application to create the client handle, and then pass that handle to another worker thread. The **AttachThread** method can be used to change the ownership of the handle to the new worker thread. By preserving the return value from the method, the original owner of the handle can be restored before the worker thread terminates.

This method should be called by the new thread immediately after it has been created, and if the new thread does not release the handle itself, the ownership of the handle should be restored to the parent thread before it terminates. Under no circumstances should **AttachThread** be used to forcibly release a handle allocated by another thread while a blocking operation is in progress. To cancel an operation, use the **Cancel** method and then release the handle after the blocking method exits and control is returned to the current thread.

Note that the *dwThreadId* parameter is presumed to be a valid thread ID and no checks are performed to ensure that the thread actually exists. Specifying an invalid thread ID will orphan the client handle used by the class until the destructor is called.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csrshv10.lib

See Also

[AttachHandle](#), [Cancel](#), [DetachHandle](#), [Disconnect](#), [Execute](#), [GetHandle](#), [Login](#)

CRshClient::Cancel

```
INT Cancel();
```

The **Cancel** method cancels any outstanding blocking operation in the client, causing the blocking method to fail. The application may then retry the operation or terminate the client session.

Parameters

None.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is RSH_ERROR. To get extended error information, call **GetLastError**.

Remarks

When the **Cancel** method is called, the blocking method will not immediately fail. An internal flag is set which causes the blocking operation to exit with an error. This means that the application cannot cancel an operation and immediately perform some other operation. Instead it must allow the calling stack to unwind, returning back to the blocking operation before making any further function calls.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csrshv10.lib

See Also

[IsBlocking](#)

CRshClient::DetachHandle

```
HCLIENT DetachHandle();
```

The **DetachHandle** method detaches the client handle associated with the current instance of the class.

Parameters

None.

Return Value

This method returns the client handle associated with the current instance of the class object. If there is no active client session, the value `INVALID_CLIENT` will be returned.

Remarks

This method is used to detach a client handle created by the class for use with the SocketTools API. Once the client handle is detached from the class, no other class member functions may be called. Note that the handle must be explicitly released at some later point by the process or a resource leak will occur.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csrshv10.lib`

See Also

[AttachHandle](#), [GetHandle](#)

CRshClient::DisableEvents

```
INT DisableEvents();
```

The **DisableEvents** method disables the event notification mechanism, preventing subsequent event notification messages from being posted to the application's message queue.

This method has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Parameters

None.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is RSH_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **DisableEvents** method is used to disable event message posting for the specified client session. Although this will immediately prevent any new events from being generated, it is possible that messages could be waiting in the message queue. Therefore, an application must be prepared to handle client event messages after this method has been called.

This method is automatically called if the client has event notification enabled, and the **Disconnect** method is called. The same issues regarding outstanding event messages also applies in this situation, requiring that the application handle event messages that may reference a client handle that is no longer valid.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csrshv10.lib

See Also

[EnableEvents](#), [RegisterEvent](#)

CRshClient::DisableTrace

```
BOOL DisableTrace();
```

The **DisableTrace** method disables the logging of socket function calls to the trace log.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, a value of zero is returned.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csrshv10.lib

See Also

[EnableTrace](#)

CRshClient::Disconnect

VOID Disconnect();

The **Disconnect** method terminates the connection with the server, closing the socket and releasing the memory allocated for the client session.

Parameters

None.

Return Value

None.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csrshv10.lib

See Also

[Execute](#), [Login](#)

CRshClient::EnableEvents

```
INT EnableEvents(  
    HWND hEventWnd,  
    UINT uEventMsg  
);
```

The **EnableEvents** method enables event notifications using Windows messages.

This method has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Applications should use the **RegisterEvent** method to register an event handler which is invoked when an event occurs.

Parameters

hEventWnd

Handle to the window which will receive the client notification messages. This parameter must specify a valid window handle. If a NULL handle is specified, event notification will be disabled.

uEventMsg

The message that is received when a client event occurs. This value must be greater than 1024.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is RSH_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **EnableEvents** method is used to request that notification messages be posted to the specified window whenever a client event occurs. This allows an application to monitor the status of different client operations, such as a file transfer.

The *wParam* argument will contain the client handle, the low word of the *lParam* argument will contain the event ID, and the high word will contain any error code. If no error has occurred, the high word will always have a value of zero. The following events may be generated:

Constant	Description
RSH_EVENT_CONNECT	The connection to the server has completed. The high word of the <i>lParam</i> parameter should be checked, since this notification message will be posted if an error has occurred.
RSH_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
RSH_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
RSH_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking

	operation. This event is only generated if the client is in asynchronous mode.
RSH_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
RSH_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and reconnect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.

To disable event notification, call the **DisableEvents** method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csrshv10.lib

See Also

[DisableEvents](#), [RegisterEvent](#)

CRshClient::EnableTrace

```
BOOL EnableTrace(  
    LPCTSTR lpszTraceFile,  
    DWORD dwTraceFlags  
);
```

The **EnableTrace** method enables the logging of socket function calls to a file.

Parameters

lpszTraceFile

A pointer to a string which specifies the name of the trace log file. If this parameter is NULL or an empty string, the default file name **cstrace.log** is used. The file is stored in the directory specified by the TEMP environment variable, if it is defined; otherwise, the current working directory is used.

dwTraceFlags

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
TRACE_INFO	All function calls are written to the trace file. This is the default value.
TRACE_ERROR	Only those function calls which fail are recorded in the trace file.
TRACE_WARNING	Only those function calls which fail or return values which indicate a warning are recorded in the trace file.
TRACE_HEXDUMP	All functions calls are written to the trace file, plus all the data that is sent or received is displayed, in both ASCII and hexadecimal format.
TRACE_PROCESS	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for multithreaded applications that are using worker threads.

Return Value

If the method succeeds, the return value is non-zero. A return value of zero indicates an error. Failure typically indicates that the tracing library **cstrcv10.dll** cannot be loaded on the local system.

Remarks

When trace logging is enabled, the file is opened, appended to and closed for each socket function call. This makes it possible for an application to append its own logging information, however care should be taken to ensure that the file is closed before the next network operation is performed. To limit the size of the log files, enable and disable logging only around those sections of code that you wish to trace.

Note that the TRACE_HEXDUMP trace level generates very large log files since it includes all of the data exchanged between your application and the server.

Trace method logging is managed on a per-thread basis, not for each client handle. This means that all SocketTools libraries and components share the same settings in the current thread. If you

are using multiple SocketTools libraries or components in your application, you only need to enable logging once.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csrshv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[DisableTrace](#)

CRshClient::Execute

```
BOOL Execute(  
    LPCTSTR lpszRemoteHost,  
    LPCTSTR lpszUserName,  
    LPCTSTR lpszPassword,  
    LPCTSTR lpszCommand,  
    UINT nRemotePort,  
    UINT nTimeout,  
    DWORD dwOptions,  
    HWND hEventWnd,  
    UINT uEventMsg  
);
```

```
BOOL Execute(  
    LPCTSTR lpszRemoteHost,  
    LPCTSTR lpszUserName,  
    LPCTSTR lpszCommand,  
    UINT nRemotePort,  
    UINT nTimeout,  
    DWORD dwOptions,  
    HWND hEventWnd,  
    UINT uEventMsg  
);
```

The **Execute** method is used to establish a connection with the server and execute the specified command.

Parameters

lpszRemoteHost

A pointer to the name of the server to connect to; this may be a fully-qualified domain name or an IP address.

lpszUserName

A pointer to a string which specifies the username used to authenticate the client session.

lpszPassword

A pointer to a string which specifies the password used to authenticate the client session.

lpszCommand

A pointer to a string which specifies the command to execute on the server.

nRemotePort

The port number the server is listening on. One of the following values should be used:

Constant	Description
RSH_PORT_REXEC	A connection is established with the server using port 512, the rexec service. This service requires that the client provide a username and password to execute the specified command. This is the default port used when calling the version of the method which specifies a password.
RSH_PORT_RSHELL	A connection is established with the server using port 514, the rshell service. This service uses host equivalence to authenticate the user. With host equivalence, the server considers the client to

be equivalent to itself, and as long as the specified user exists on the server, the client is permitted to execute commands on behalf of the user without requiring a password. Host equivalence is configured by the server administrator. This is the default port used when calling the version of the method that does not specify a password.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
RSH_OPTION_RESERVEDPORT	This option specifies that a reserved port should be used to establish the connection. Reserved ports are those port numbers which are less than 1024. This option should be specified when connecting on the RSH_PORT_RSHELL port.
RSH_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
RSH_OPTION_FREETHREAD	This option specifies that this instance of the class may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the class instance is synchronized across multiple threads.

hEventWnd

The handle to the event notification window. This window receives messages which notify the client of various asynchronous network events that occur. If this argument is NULL, then the client session will be blocking and no network events will be sent to the client.

uEventMsg

The message identifier that is used when an asynchronous network event occurs. This value should be greater than WM_USER as defined in the Windows header files. If the *hEventWnd* argument is NULL, this argument should be specified as WM_NULL.

Return Value

If the method succeeds, the return value non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The use of Windows event notification messages has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

To prevent this method from blocking the main user interface thread, the application should create a background worker thread and establish a connection by calling **Execute** in that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each client session.

If you specify an event notification window, then the client session will be asynchronous. When a message is posted to the notification window, the low word of the *lParam* parameter contains the event identifier. The high word of *lParam* contains the low word of the error code, if an error has occurred. The *wParam* parameter contains the client handle. One or more of the following event identifiers may be sent:

Constant	Description
RSH_EVENT_CONNECT	The connection to the server has completed. The high word of the <i>lParam</i> parameter should be checked, since this notification message will be posted if an error has occurred.
RSH_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
RSH_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
RSH_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
RSH_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
RSH_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.

To cancel asynchronous notification and return the client to a blocking mode, use the **DisableEvents** method.

It is recommended that you only establish an asynchronous connection if you understand the implications of doing so. In most cases, it is preferable to create a synchronous connection and create threads for each additional session if more than one active client session is required.

The *dwOptions* argument can be used to specify the threading model that is used by the library when a connection is established. By default, the class instance is initially attached to the thread

that created it. From that point on, until the it is released, only the owner may call methods using that instance of the class. The ownership of the class instance may be transferred from one thread to another using the **AttachThread** method.

Specifying the POP_OPTION_FREETHREAD option enables any thread to call any method in that instance of the class, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the class instance is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same instance.

Example

The following example demonstrates connecting to a server, executing a command on the server, reading the output and storing it in a string. This uses the rexec service on port 512, and requires a username and password.

```
CRshClient rshClient;
BOOL bConnected;

// Establish a connection with the server and execute
// the command as the specified user
bConnected = rshClient.Execute(strHostName,
                              strUserName,
                              strPassword,
                              strCommand);

// If the connection could not be established or the command
// could not be executed, display an error message
if (bConnected == FALSE)
{
    rshClient.ShowError();
    return;
}

CString strBuffer;
CString strResult;
INT nResult;

// Read the output from the command and store it in the strResult
// string; note that a UNIX server terminates each line of output
// with a bare linefeed, which is something that should be kept
// in mind when parsing the string
do
{
    if ((nResult = rshClient.Read(strBuffer)) > 0)
        strResult += strBuffer;
}
while (nResult > 0);

// If there was an error reading the output from the server, then
// display the error and disconnect
if (nResult == RSH_ERROR)
{
    rshClient.ShowError();
    rshClient.Disconnect();
    return;
}
```

```
rshClient.Disconnect();
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csrshv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[Disconnect](#), [Login](#)

CRshClient::FreezeEvents

```
INT FreezeEvents(  
    BOOL bFreeze  
);
```

The **FreezeEvents** method is used to suspend and resume event handling by the client.

Parameters

bFreeze

A non-zero value specifies that event handling should be suspended by the client. A zero value specifies that event handling should be resumed.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is RSH_ERROR. To get extended error information, call **GetLastError**.

Remarks

This method should be used when the application does not want to process events, such as when a modal dialog is being displayed. When events are suspended, all client events are queued. If events are re-enabled at a later point, those queued events will be sent to the application for processing. Note that only one of each event will be generated. For example, if the client has suspended event handling, and four read events occur, once event handling is resumed only one of those read events will be posted to the client. This prevents the application from being flooded by a potentially large number of queued events.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csrshv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

CRshClient::GetErrorString

```
INT GetErrorString(  
    DWORD dwErrorCode,  
    LPTSTR lpszDescription,  
    INT cbDescription  
);  
  
INT GetErrorString(  
    DWORD dwErrorCode,  
    CString& strDescription  
);
```

The **GetErrorString** method is used to return a description of a specific error code. Typically this is used in conjunction with the **GetLastError** method for use with warning dialogs or as diagnostic messages.

Parameters

dwErrorCode

The error code for which a description is returned.

lpszDescription

A pointer to the buffer that will contain a description of the specified error code. This buffer should be at least 128 characters in length. An alternate form of the method accepts a **CString** variable which will contain the error description.

cbDescription

The maximum number of characters that may be copied into the description buffer.

Return Value

If the method succeeds, the return value is the length of the description string. If the method fails, the return value is zero, meaning that no description exists for the specified error code. Typically this indicates that the error code passed to the method is invalid.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csrshv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[GetLastError](#), [SetLastError](#), [ShowError](#)

CRshClient::GetHandle

```
HCLIENT GetHandle();
```

The **GetHandle** method returns the client handle associated with the current instance of the class.

Parameters

None.

Return Value

This method returns the client handle associated with the current instance of the class object. If there is no active client session, the value `INVALID_CLIENT` will be returned.

Remarks

This method is used to obtain the client handle created by the class for use with the SocketTools API.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csrshv10.lib`

CRshClient::GetLastError

```
DWORD GetLastError();  
  
DWORD GetLastError(  
    CString& strDescription  
);
```

Parameters

strDescription

A string which will contain a description of the last error code value when the method returns. If no error has been set, or the last error code has been cleared, this string will be empty.

Return Value

The return value is the last error code value for the current thread. Functions set this value by calling the **SetLastError** method. The Return Value section of each reference page notes the conditions under which the method sets the last error code.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. You should call the **GetLastError** method immediately when a method's return value indicates that an error has occurred. That is because some methods call **SetLastError(0)** when they succeed, clearing the error code set by the most recently failed method.

Most methods will set the last error code value when they fail; a few methods set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or RSH_ERROR. Those methods which call **SetLastError** when they succeed are noted on the method reference page.

The description of the error code is the same string that is returned by the **GetErrorString** method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csrshv10.lib

[GetErrorString](#), [SetLastError](#), [ShowError](#)

CRshClient::GetStatus

INT GetStatus();

The **GetStatus** method the current status of the client session.

Parameters

None.

Return Value

If the method succeeds, the return value is the client status code. If the method fails, the return value is RSH_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetStatus** method returns a numeric code which identifies the current state of the client session. The following values may be returned:

Value	Constant	Description
0	RSH_STATUS_UNUSED	No connection has been established.
1	RSH_STATUS_IDLE	The client is current idle and not sending or receiving data.
2	RSH_STATUS_CONNECT	The client is establishing a connection with the server.
3	RSH_STATUS_READ	The client is reading data from the server.
4	RSH_STATUS_WRITE	The client is writing data to the server.
5	RSH_STATUS_DISCONNECT	The client is disconnecting from the server.

In a multithreaded application, any thread in the current process may call this method to obtain status information for the specified client session.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csrshv10.lib

See Also

[IsBlocking](#), [IsConnected](#), [IsReadable](#)

CRshClient::GetTimeout

```
INT GetTimeout();
```

The **GetTimeout** method returns the number of seconds the client will wait for a response from the server. Once the specified number of seconds has elapsed, the method will fail and return to the caller.

Parameters

None.

Return Value

If the method succeeds, the return value is the timeout period in seconds. If the method fails, the return value is RSH_ERROR. To get extended error information, call **GetLastError**.

Remarks

The timeout value is only used with blocking client connections. A value of zero indicates that the default timeout period of 20 seconds should be used.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csrshv10.lib

See Also

[IsReadable](#), [IsWritable](#), [Read](#), [SetTimeout](#), [Write](#)

CRshClient::IsBlocking

BOOL IsBlocking();

The **IsBlocking** method is used to determine if the client is currently performing a blocking operation.

Parameters

None.

Return Value

If the client is performing a blocking operation, the method returns a non-zero value. If the client is not performing a blocking operation, or the client handle is invalid, the method returns zero.

Remarks

Because a blocking operation can allow the application to be re-entered (for example, by pressing a button while the operation is being performed), it is possible that another blocking method may be called while it is in progress. Since only one thread of execution may perform a blocking operation at any one time, an error would occur. The **IsBlocking** method can be used to determine if the client is already blocked, and if so, take some other action (such as warning the user that they must wait for the operation to complete).

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csrshv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

CRshClient::IsConnected

```
BOOL IsConnected();
```

The **IsConnected** method is used to determine if the client is currently connected to a server.

Parameters

None.

Return Value

If the client is connected to a server, the method returns a non-zero value. If the client is not connected, or the client handle is invalid, the method returns zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csrshv10.lib

See Also

[GetStatus](#), [IsBlocking](#), [IsInitialized](#), [IsReadable](#), [IsWritable](#)

CRshClient::IsInitialized

```
BOOL IsInitialized();
```

The **IsInitialized** method returns whether or not the class object has been successfully initialized.

Parameters

None.

Return Value

This method returns a non-zero value if the class object has been successfully initialized. A return value of zero indicates that the runtime license key could not be validated or the networking library could not be loaded by the current process.

Remarks

When an instance of the class is created, the class constructor will attempt to initialize the component with the runtime license key that was created when SocketTools was installed. If the constructor is unable to validate the license key or load the networking libraries, this initialization will fail.

If SocketTools was installed with an evaluation license, the application cannot be redistributed to another system. The class object will fail to initialize if the application is executed on another system, or if the evaluation period has expired. To redistribute your application, you must purchase a development license which will include the runtime key that is needed to redistribute your software to other systems. Refer to the Developer's Guide for more information.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csrshv10.lib

See Also

[CRshClient](#), [IsBlocking](#), [IsConnected](#)

CRshClient::IsReadable

```
BOOL IsReadable(  
    INT nTimeout,  
    LPDWORD lpdwAvail  
);
```

The **IsReadable** method is used to determine if data is available to be read from the server.

Parameters

nTimeout

Timeout for server response, in seconds. A value of zero specifies that the connection should be polled without blocking the current thread.

lpdwAvail

A pointer to an unsigned integer which will contain the number of bytes available to read. This parameter may be NULL if this information is not required.

Return Value

If the client can read data from the server within the specified timeout period, the method returns a non-zero value. If the client cannot read any data, the method returns zero.

Remarks

On some platforms, this value will not exceed the size of the receive buffer (typically 64K bytes). Because of differences between TCP/IP stack implementations, it is not recommended that your application exclusively depend on this value to determine the exact number of bytes available. Instead, it should be used as a general indicator that there is data available to be read.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csrshv10.lib

See Also

[GetStatus](#), [IsBlocking](#), [IsConnected](#), [IsInitialized](#), [IsWritable](#), [Write](#)

CRshClient::IsWritable

```
BOOL IsWritable(  
    INT nTimeout  
);
```

The **IsWritable** method is used to determine if data can be written to the server.

Parameters

nTimeout

Timeout for server response, in seconds. A value of zero specifies that the connection should be polled without blocking the current thread.

Return Value

If the client can write data to the server within the specified timeout period, the method returns a non-zero value. If the client cannot write any data, the method returns zero.

Remarks

Although this method can be used to determine if some amount of data can be sent to the remote process it does not indicate the amount of data that can be written without blocking the client. In most cases, it is recommended that large amounts of data be broken into smaller logical blocks, typically some multiple of 512 bytes in length.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csrshv10.lib

See Also

[GetStatus](#), [IsBlocking](#), [IsConnected](#), [IsInitialized](#), [IsReadable](#), [Write](#)

CRshClient::Login

```
BOOL Login(  
    LPCTSTR lpszRemoteHost,  
    LPCTSTR lpszUserName,  
    LPCTSTR lpszTerminal,  
    UINT nRemotePort,  
    UINT nTimeout,  
    HWND hEventWnd,  
    UINT uEventMsg  
);
```

The **Login** method is used to establish a terminal session with the server.

Parameters

lpszRemoteHost

A pointer to the name of the server to connect to; this may be a fully-qualified domain name or an IP address.

lpszUserName

A pointer to a string which specifies the username used to authenticate the client session.

lpszTerminal

A pointer to a string which specifies the terminal type which the client will be identified as using during the session. If no particular terminal emulation is required, this parameter may be NULL.

nRemotePort

The port number the server is listening on. A value of zero specifies that the default port of 513 should be used.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

hEventWnd

The handle to the event notification window. This window receives messages which notify the client of various asynchronous network events that occur. If this argument is NULL, then the client session will be blocking and no network events will be sent to the client.

uEventMsg

The message identifier that is used when an asynchronous network event occurs. This value should be greater than WM_USER as defined in the Windows header files. If the *hEventWnd* argument is NULL, this argument should be specified as WM_NULL.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The use of Windows event notification messages has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

To prevent this method from blocking the main user interface thread, the application should create a background worker thread and establish a connection by calling **Login** in that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each client session.

The **Login** method uses host equivalence, where the client is permitted to login without requiring a password. Host equivalence must be configured by the server administrator and it is typically restricted to specific users. Note that if configured improperly, host equivalence can introduce a significant security loophole. Refer to your UNIX system documentation for more information about host equivalence and the various remote command services.

On UNIX based systems, the terminal name specified by the *lpszTerminal* parameter corresponds to a termcap or terminfo entry as set in the TERM environment variable. On Windows based systems which implement the rlogin service, this parameter may be ignored and the server will assume that the client is capable of displaying ANSI escape sequences. On VMS systems, the terminal name should correspond to the terminal type used with the SET TERMINAL/DEVICE command.

If this parameter is passed as NULL pointer or an empty string, a default terminal type named "unknown" will be used. On most UNIX and VMS systems this defines a terminal which is not capable of cursor positioning using control or escape sequences. This terminal type may not be recognized and an error may be displayed when the user logs in indicating that the terminal type is invalid.

Refer to the documentation for the server system to determine what terminal type names are available to you. Remember that on UNIX systems, the terminal type is case-sensitive. Some of the more common terminal types are:

Terminal Type	Description
ansi	This terminal type is usually available on UNIX based servers. This specifies that the client is capable of displaying standard ANSI escape sequences for cursor control.
dumb	This terminal type typically specifies a terminal display which does not support control or escape sequences for cursor positioning. If you do not want escape sequences embedded in the data stream and the server returns an error if the terminal type is not specified, try using this terminal type.
pcansi	This terminal type is usually available on UNIX based servers. This specifies that the client is using a PC terminal emulator that supports basic ANSI escape sequences for cursor control. This may also enable escape sequences which can set the display colors.
vt100	This terminal type is usually available on UNIX and VMS based servers. On some VMS systems this string may need to be specified as DEC-VT100. This specifies that the client is capable of emulating a DEC VT100 terminal. The VT100 supports many of the same cursor control sequences as an ANSI terminal.
vt220	This terminal type is usually available on UNIX and VMS based servers. On some VMS systems this string may need to be specified as DEC-VT220. This specifies that the client is capable of emulating a DEC VT220 terminal, which is a later version of the VT100.

vt320	This terminal type is usually available on UNIX and VMS based servers. On some VMS systems this string may need to be specified as DEC-VT320. This specifies that the client is capable of emulating a DEC VT320 terminal, which is similar to the VT100 and VT220 and provides advanced features such as the ability to set display colors.
xterm	This terminal type is may be available on UNIX based servers which have X Windows installed. This specifies that the client is a using the X Windows xterm emulator which supports standard ANSI escape sequences for cursor control.

If you specify an event notification window, then the client session will be asynchronous. When a message is posted to the notification window, the low word of the *lParam* parameter contains the event identifier. The high word of *lParam* contains the low word of the error code, if an error has occurred. The *wParam* parameter contains the client handle. One or more of the following event identifiers may be sent:

Constant	Description
RSH_EVENT_CONNECT	The connection to the server has completed. The high word of the <i>lParam</i> parameter should be checked, since this notification message will be posted if an error has occurred.
RSH_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
RSH_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
RSH_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
RSH_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
RSH_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.

To cancel asynchronous notification and return the client to a blocking mode, use the **DisableEvents** method.

It is recommended that you only establish an asynchronous connection if you understand the implications of doing so. In most cases, it is preferable to create a synchronous connection and create threads for each additional session if more than one active client session is required.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csrshv10.lib

Unicode: Implemented as Unicode and ANSI versions.

CRshClient::Read

```
INT Read(  
    LPBYTE lpBuffer,  
    INT cbBuffer  
);  
  
INT Read(  
    CString& strBuffer,  
    INT cbBuffer  
);
```

The **Read** method reads the specified number of bytes from the client socket and copies them into the buffer. The data may be of any type, and is not terminated with a null character.

Parameters

lpBuffer

Pointer to the buffer in which the data will be copied. An alternate form of this method allows a **CString** variable to be passed and data read from the socket will be returned in that string.

cbBuffer

The maximum number of bytes to read and copy into the specified buffer. This value must be greater than zero.

Return Value

If the method succeeds, the return value is the number of bytes actually read. A return value of zero indicates that the server has closed the connection and there is no more data available to be read. If the method fails, the return value is RSH_ERROR. To get extended error information, call **GetLastError**.

Remarks

When **Read** is called and the client is in non-blocking mode, it is possible that the method will fail because there is no available data to read at that time. This should not be considered a fatal error. Instead, the application should simply wait to receive the next asynchronous notification that data is available.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csrshv10.lib

See Also

[EnableEvents](#), [IsBlocking](#), [IsReadable](#), [IsWritable](#), [RegisterEvent](#), [Write](#)

CRshClient::RegisterEvent

```
INT RegisterEvent(  
    UINT nEventId,  
    RSHEVENTPROC LpEventProc,  
    DWORD_PTR dwParam  
);
```

The **RegisterEvent** method registers an event handler for the specified event.

Parameters

nEventId

An unsigned integer which specifies which event should be registered with the specified callback function. One of the following values may be used:

Constant	Description
RSH_EVENT_CONNECT	The connection to the server has completed.
RSH_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
RSH_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
RSH_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
RSH_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
RSH_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **RshEventProc** callback function. If this parameter is NULL, the callback for the specified event is disabled.

dwParam

A user-defined integer value that is passed to the callback function. If the application targets the x86 (32-bit) platform, this parameter must be a 32-bit unsigned integer. If the application targets the x64 (64-bit) platform, this parameter must be a 64-bit unsigned integer.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is

RSH_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **RegisterEvent** method associates a callback function with a specific event. The event handler is an **RshEventProc** function that is invoked when the event occurs. Arguments are passed to the function to identify the client session, the event type and the user-defined value specified when the event handler is registered. If the event occurs because of an error condition, the error code will be provided to the handler.

The callback function specified by the *lpEventProc* parameter must be declared using the **__stdcall** calling convention. This ensures the arguments passed to the event handler are pushed on to the stack in the correct order. Failure to use the correct calling convention will corrupt the stack and cause the application to terminate abnormally.

The *dwParam* parameter is commonly used to identify the class instance which is associated with the event that has occurred. Applications will cast the **this** pointer to a **DWORD_PTR** value when calling this function, and then the event handler will cast it back to a pointer to the class instance. This gives the handler access to the class member variables and methods.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csrshv10.lib

See Also

[DisableEvents](#), [EnableEvents](#), [FreezeEvents](#), [RshEventProc](#)

CRshClient::Search

```
BOOL Search(  
    LPCTSTR lpszString  
);  
  
BOOL Search(  
    LPCTSTR lpszString,  
    LPVOID lpBuffer,  
    LPDWORD lpdwLength  
);  
  
BOOL Search(  
    LPCTSTR lpszString,  
    HGLOBAL* lpBuffer,  
    LPDWORD lpdwLength  
);  
  
BOOL Search(  
    LPCTSTR lpszString,  
    CString& strBuffer  
);
```

The **Search** method searches for a specific character sequence in the data stream and stops reading if the sequence is encountered.

Parameters

lpszString

A pointer to a string which specifies the sequence of characters to search for in the data stream. This parameter cannot be NULL or point to an empty string.

lpBuffer

A pointer to a byte buffer which will contain the output from the server, or a pointer to a global memory handle which will reference the output when the method returns. An alternate form of this method accepts a **CString** object which will contain the output when the method returns. If the output from the server is not required, this parameter may be NULL.

lpdwLength

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the *lpBuffer* parameter. If the *lpBuffer* parameter points to a global memory handle, the length value should be initialized to zero. When the method returns, this value will be updated with the actual number of bytes of output stored in the buffer. If the *lpBuffer* parameter is NULL, this parameter should also be NULL.

Return Value

If the method succeeds and the character sequences was found in the data stream, the return value is non-zero. If the method fails or a timeout occurs before the sequence is found, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **Search** method searches for a character sequence in the data stream and stops reading when it is found. This is useful when the client wants to automate responses to the server, such as executing a command and processing the output. The method collects the output from the server and stores it in the buffer specified by the *lpBuffer* parameter. When the method returns, the

buffer will contain everything sent by the server up to and including the search string.

The *lpBuffer* parameter may be specified in one of two ways, depending on the needs of the application. The first method is to pre-allocate a buffer large enough to store the a fixed amount of output. In this case, the *lpBuffer* parameter will point to the buffer that was allocated, the value that the *lpdwLength* parameter points to should be initialized to the size of that buffer. If the server sends more output than can be stored in the buffer, the remaining output will be discarded.

The second method that can be used is have the *lpBuffer* parameter point to a global memory handle which will contain the output when the method returns. In this case, the value that the *lpdwLength* parameter points to must be initialized to zero. It is important to note that the memory handle returned by the method must be freed by the application, otherwise a memory leak will occur. This method is preferred if the client application does not have a general idea of how much output will be generated until the search string is found.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csrshv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

CRshClient::SetLastError

```
VOID SetLastError(  
    DWORD dwErrorCode  
);
```

The **SetLastError** method sets the last error code for the current thread. This method is typically used to clear the last error by specifying a value of zero as the parameter.

Parameters

dwErrorCode

Specifies the last error code for the current thread.

Return Value

None.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. Most methods will set the last error code value when they fail; a few methods set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or RSH_ERROR. Those methods which call **SetLastError** when they succeed are noted on the method reference page.

Applications can retrieve the value saved by this method by using the **GetLastError** method. The use of **GetLastError** is optional; an application can call the method to determine the specific reason for a method failure.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csrshv10.lib

See Also

[GetErrorString](#), [GetLastError](#), [ShowError](#)

CRshClient::SetTimeout

```
INT SetTimeout(  
    UINT nTimeout  
);
```

The **SetTimeout** method sets the number of seconds the client will wait for a response from the server. Once the specified number of seconds has elapsed, the method will fail and return to the caller.

Parameters

nTimeout

The number of seconds to wait for a blocking operation to complete.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is RSH_ERROR. To get extended error information, call **GetLastError**.

Remarks

The timeout value is only used with blocking client connections.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csrshv10.lib

See Also

[Execute](#), [GetTimeout](#), [IsReadable](#), [IsWritable](#), [Login](#), [Read](#), [Write](#)

CRshClient::ShowError

```
INT ShowError(  
    LPCTSTR lpszAppTitle,  
    UINT uType,  
    DWORD dwErrorCode  
);
```

The **ShowError** method displays a message box which describes the specified error.

Parameters

lpszAppTitle

A pointer to a string which specifies the title of the message box that is displayed. If this argument is NULL or omitted, then the default title of "Error" will be displayed.

uType

An unsigned integer which specifies the type of message box that will be displayed. This is the same value that is used by the **MessageBox** method in the Windows API. If a value of zero is specified, then a message box with a single OK button will be displayed. Refer to that method for a complete list of options.

dwErrorCode

Specifies the error code that will be used when displaying the message box. If this argument is zero, then the last error that occurred in the current thread will be displayed.

Return Value

If the method is successful, the return value will be the return value from the **MessageBox** function. If the method fails, it will return a value of zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csrshv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[GetErrorString](#), [GetLastError](#), [SetLastError](#)

CRshClient::Write

```
INT Write(  
    LPBYTE lpBuffer,  
    INT cbBuffer  
);  
  
INT Write(  
    LPCTSTR lpszBuffer  
    INT cbBuffer  
);
```

The **Write** method sends the specified number of bytes to the server.

Parameters

lpBuffer

The pointer to the buffer which contains the data that is to be sent to the server. In an alternate form of the method, the pointer is to a string.

cbBuffer

The number of bytes to send from the specified buffer. This value must be greater than zero, unless a pointer to a string buffer is passed as the parameter. In that case, if the value is -1, all of the characters in the string, up to but not including the terminating null character, will be sent to the server.

Return Value

If the method succeeds, the return value is the number of bytes actually written. If the method fails, the return value is RSH_ERROR. To get extended error information, call **GetLastError**.

Remarks

The return value may be less than the number of bytes specified by the *cbBuffer* parameter. In this case, the data has been partially written and it is the responsibility of the client application to send the remaining data at some later point. For non-blocking clients, the client must wait for the next asynchronous notification message before it resumes sending data.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Secure Shell Protocol Class Library

Establish an interactive terminal session with an SSH server and execute remote commands.

Reference

- [Class Methods](#)
- [Data Structures](#)
- [Error Codes](#)

Library Information

Class Name	CSshClient
File Name	CSTSHV10.DLL
Version	10.0.1468.2518
LibID	4C76F231-8ED9-4850-B882-01B77485F43A
Import Library	CSTSHV10.LIB
Dependencies	None
Standards	RFC 4251

Overview

The Secure Shell (SSH) protocol is used to establish a secure connection with a server which provides a virtual terminal session for a user. Its functionality is similar to how character based consoles and serial terminals work, enabling a user to login to the server, execute commands and interact with applications running on the server. The SSH library provides an API for establishing the connection and handling the standard I/O functions needed by the program. The library also provides functions that enable a program to easily scan the data stream for specific sequences of characters, making it very simple to write light-weight client interfaces to applications running on the server. This library can be combined with the Terminal Emulation library to provide complete terminal emulation services for a standard ANSI or DEC-VT220 terminal.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). If you are using Visual C++ 6.0 it is required that you have Service Pack 6 (SP6) installed. You should install all updates for your development tools and have the current Windows SDK installed. The minimum recommended version of Visual Studio is Visual Studio 2010.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are using Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. It is recommended that you install the current service pack and all critical updates available for your version of the operating system.

This product includes both 32-bit and 64-bit libraries. Native 64-bit CPU support requires the 64-bit version of Windows 7 or later versions of the Windows operating system.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location

on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

SSH Protocol Class Methods

Class	Description
CSshClient	Constructor which initializes the current instance of the class
~CSshClient	Destructor which releases resources allocated by the class
Method	Description
AttachHandle	Attach the specified client handle to this instance of the class
AttachThread	Attach the specified client handle to another thread
Break	Send a break signal to the server
Cancel	Cancel the current blocking operation
Connect	Connect to the specified server
Control	Send a control message to the server
CreateSecurityCredentials	Create a new security credentials structure
DeleteSecurityCredentials	Delete a previously created security credentials structure
DetachHandle	Detach the handle for the current instance of this class
DisableEvents	Disable asynchronous event notification
DisableTrace	Disable logging of socket function calls to the trace log
Disconnect	Disconnect from the current server
EnableEvents	Enable asynchronous event notification
EnableTrace	Enable logging of socket function calls to a file
Execute	Execute a command on a server and return the output in the specified buffer
FreezeEvents	Suspend asynchronous event processing
GetErrorString	Return a description for the specified error code
GetExitCode	Return the exit code for the remote session
GetHandle	Return the client handle used by this instance of the class
GetLastError	Return the last error code
GetLineMode	Return the current mode used to send end-of-line character sequences
GetSecurityInformation	Return security information about the current client connection
GetStatus	Return the current client status
GetTimeout	Return the number of seconds until an operation times out
IsBlocking	Determine if the client is blocked, waiting for information
IsConnected	Determine if the client is connected to the server
IsInitialized	Determine if the class has been successfully initialized
IsReadable	Determine if data can be read from the server
IsWritable	Determine if data can be written to the server

Peek	Examine data in the receive buffer, but do not remove it
Read	Read data returned by the server
ReadLine	Read a line of data from the server and return it in a string buffer
RegisterEvent	Register an event callback function
Search	Search for a specific character sequence in the data stream
SetLastError	Set the last error code
SetLineMode	Change how end-of-line character sequences are sent to the server
SetTimeout	Set the number of seconds until an operation times out
ShowError	Display a message box with a description of the specified error
SshEventProc	Callback function that processes events generated by the client
Write	Write data to the server
WriteLine	Write a line of data to the server

CSshClient::CSshClient Method

`CSshClient();`

The **CSshClient** constructor initializes the class library and validates the license key at runtime.

Remarks

If the constructor fails to validate the runtime license, subsequent methods in this class will fail. If the product is installed with an evaluation license, then the application will only function on the development system and cannot be redistributed.

The constructor calls the **SshInitialize** function to initialize the library, which dynamically loads other system libraries and allocates thread local storage. If you are using this class within another DLL, it is important that you do not create or destroy an instance of the class from within the **DllMain** function because it can result in deadlocks or access violation errors. You should not declare static or global instances of this class within another DLL if it is linked with the C runtime library (CRT) because it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `cstshv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

See Also

[~CSshClient](#), [IsInitialized](#)

CSshClient::~CSshClient

`~CSshClient();`

The **CSshClient** destructor releases resources allocated by the current instance of the **CSshClient** object. It also uninitialized the library if there are no other concurrent uses of the class.

Remarks

When a **CSshClient** object goes out of scope, the destructor is automatically called to allow the library to free any resources allocated on behalf of the process. Any pending blocking or asynchronous calls in this process are canceled without posting any notification messages, and all handles that were created for the client session are destroyed.

The destructor is not called explicitly by the application.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstshv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[CSshClient](#)

CSshClient::AttachHandle Method

```
VOID AttachHandle(  
    HCLIENT hClient  
);
```

The **AttachHandle** method attaches the specified client handle to the current instance of the class.

Parameters

hClient

The handle to the client session that will be attached to the current instance of the class object.

Return Value

None.

Remarks

This method is used to attach a client handle created outside of the class using the SocketTools API. Once the client handle is attached to the class, the other class member functions may be used with that client session.

If a client handle already has been created for the class, that handle will be released when the new handle is attached to the class object. If you want to prevent the previous client session from being terminated, you must call the **DetachHandle** method. Failure to release the detached handle may result in a resource leak in your application.

Note that the *hClient* parameter is presumed to be a valid client handle and no checks are performed to ensure that the handle is valid. Specifying an invalid client handle will cause subsequent method calls to fail.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstshv10.lib

See Also

[AttachThread](#), [DetachHandle](#), [GetHandle](#)

CSshClient::AttachThread Method

```
DWORD AttachThread(  
    DWORD dwThreadId  
);
```

The **AttachThread** method attaches the specified client handle to another thread.

Parameters

dwThreadId

The ID of the thread that will become the new owner of the handle. A value of zero specifies that the current thread should become the owner of the client handle.

Return Value

If the method succeeds, the return value is the thread ID of the previous owner. If the method fails, the return value is SSH_ERROR. To get extended error information, call **GetLastError**.

Remarks

When a client handle is created, it is associated with the current thread that created it. Normally, if another thread attempts to perform an operation using that handle, an error is returned since it does not own the handle. This is used to ensure that other threads cannot interfere with an operation being performed by the owner thread. In some cases, it may be desirable for one thread in a client application to create the client handle, and then pass that handle to another worker thread. The **AttachThread** method can be used to change the ownership of the handle to the new worker thread. By preserving the return value from the method, the original owner of the handle can be restored before the worker thread terminates.

This method should be called by the new thread immediately after it has been created, and if the new thread does not release the handle itself, the ownership of the handle should be restored to the parent thread before it terminates. Under no circumstances should **AttachThread** be used to forcibly release a handle allocated by another thread while a blocking operation is in progress. To cancel an operation, use the **Cancel** method and then release the handle after the blocking method exits and control is returned to the current thread.

Note that the *dwThreadId* parameter is presumed to be a valid thread ID and no checks are performed to ensure that the thread actually exists. Specifying an invalid thread ID will orphan the client handle used by the class until the destructor is called.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstshv10.lib

See Also

[AttachHandle](#), [Cancel](#), [Connect](#), [DetachHandle](#), [Disconnect](#), [GetHandle](#)

CSshClient::Break Method

```
INT Break();
```

The **Break** method sends a signal to the server.

Parameters

None.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is SSH_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **Break** method sends a control message to the server which simulates a break signal on a physical terminal. This is used by some operating systems as an instruction to enter a privileged configuration mode. Note that this is not the same as sending an interrupt character such as Ctrl+C to the server. This control code is ignored for SSH 1.0 sessions.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstshv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[Cancel](#), [Control](#), [Read](#), [ReadLine](#), [Write](#), [WriteLine](#)

CSshClient::Cancel Method

```
INT Cancel();
```

The **Cancel** method cancels any outstanding blocking operation in the client, causing the blocking method to fail. The application may then retry the operation or terminate the client session.

Parameters

None.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is SSH_ERROR. To get extended error information, call **GetLastError**.

Remarks

When the **Cancel** method is called, the blocking method will not immediately fail. An internal flag is set which causes the blocking operation to exit with an error. This means that the application cannot cancel an operation and immediately perform some other operation. Instead it must allow the calling stack to unwind, returning back to the blocking operation before making any further function calls.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstshv10.lib

[Break](#), [IsBlocking](#)

CSshClient::Connect Method

```
BOOL Connect(  
    LPCTSTR lpszRemoteHost,  
    UINT nRemotePort,  
    LPCTSTR lpszUserName,  
    LPCTSTR lpszPassword,  
    UINT nTimeout,  
    DWORD dwOptions,  
    LPSSHOPTIONDATA lpOptions,  
    HWND hEventWnd,  
    UINT uEventMsg  
);
```

The **Connect** method establishes a connection with the specified server.

Parameters

lpszRemoteHost

A pointer to the name of the server to connect to; this may be a fully-qualified domain name or an IP address.

nRemotePort

The port number the server is listening on. A value of zero specifies that the default port number 22 should be used.

lpszUserName

A pointer to a string which specifies the user name which will be used to authenticate the client session. This parameter must specify a valid user name and cannot be NULL or an empty string.

lpszPassword

A pointer to a string which specifies the password which will be used to authenticate the client session. If the user does not have a password, this parameter can be NULL or an empty string.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
SSH_OPTION_NONE	No options specified. A standard terminal session will be established with the default terminal type.
SSH_OPTION_KEEPAIVE	This option specifies the library should attempt to maintain an idle client session for long periods of time. This option is only necessary if you expect that the connection will be held open for more than two hours.
SSH_OPTION_NOPTY	This option specifies that a pseudoterminal (PTY) should not be created for the client session. This option is automatically set if the SSH_OPTION_COMMAND option has been specified.

SSH_OPTION_NOSHELL	This option specifies that a command shell should not be used when executing a command on the server.
SSH_OPTION_NOAUTHRSA	This option specifies that RSA authentication should not be used with SSH-1 connections. This option is ignored with SSH-2 connections and should only be specified if required by the server.
SSH_OPTION_NOPWDNULL	This option specifies the user password cannot be terminated with a null character. This option is ignored with SSH-2 connections and should only be specified if required by the server.
SSH_OPTION_NOREKEY	This option specifies the client should never attempt a repeat key exchange with the server. Some SSH servers do not support rekeying the session, and this can cause the client to become non-responsive or abort the connection after being connected for an hour.
SSH_OPTION_COMPATSID	This compatibility option changes how the session ID is handled during public key authentication with older SSH servers. This option should only be specified when connecting to servers that use OpenSSH 2.2.0 or earlier versions.
SSH_OPTION_COMPATHMAC	This compatibility option changes how the HMAC authentication codes are generated. This option should only be specified when connecting to servers that use OpenSSH 2.2.0 or earlier versions.
SSH_OPTION_TERMINAL	This option specifies the client session will use terminal emulation and the SSHOPTIONDATA structure specifies the characteristics of the virtual terminal. This enables the caller to specify the dimensions of the virtual display (in columns and rows) and the type of terminal that will be emulated. If this option is omitted, the session will default to a virtual display that is 80 columns, 25 rows.
SSH_OPTION_COMMAND	This option specifies the client session will be used to issue a command that is executed on the server, and the output will be returned to the caller. If this option is specified, the session will not be interactive and no pseudoterminal is created for the client. The szCommandLine member of the SSHOPTIONDATA structure specifies the command string that will be sent to the server.
SSH_OPTION_PROXYSERVER	This option specifies the client should establish a connection through a proxy server. The two protocols that are supported are SSH_PROXY_HTTP and SSH_PROXY_TELNET, which specifies the protocol that the proxy connection is created through. The proxy-

	related members of the <code>SSH_OPTIONDATA</code> structure should be set to the appropriate values.
<code>SSH_OPTION_PREFER_IPV6</code>	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
<code>SSH_OPTION_FREETHREAD</code>	This option specifies the handle returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the handle is synchronized across multiple threads.

lpOptions

A pointer to a `SSH_OPTIONDATA` structure which specifies additional information for one or more options. If no optional data is required, a NULL pointer may be specified.

hEventWnd

The handle to the event notification window. This window receives messages which notify the client of various asynchronous network events that occur. If this argument is NULL, then the client session will be blocking and no network events will be sent to the client.

uEventMsg

The message identifier that is used when an asynchronous network event occurs. This value should be greater than `WM_USER` as defined in the Windows header files. If the *hEventWnd* argument is NULL, this argument should be specified as `WM_NULL`.

Return Value

If the method succeeds, the return value is a non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The use of Windows event notification messages has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

To prevent this method from blocking the main user interface thread, the application should create a background worker thread and establish a connection by calling **Connect** in that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each client session.

If you specify an event notification window, then the client session will be asynchronous. When a message is posted to the notification window, the low word of the *lParam* parameter contains the event identifier. The high word of *lParam* contains the low word of the error code, if an error has occurred. The *wParam* parameter contains the client handle. One or more of the following event identifiers may be sent:

Constant	Description
SSH_EVENT_CONNECT	The connection to the server has completed. The high word of the <i>lParam</i> parameter should be checked, since this notification message will be posted if an error has occurred.
SSH_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
SSH_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
SSH_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
SSH_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
SSH_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.

To cancel asynchronous notification and return the client to a blocking mode, use the **DisableEvents** methods.

It is recommended that you only establish an asynchronous connection if you understand the implications of doing so. In most cases, it is preferable to create a synchronous connection and create threads for each additional session if more than one active client session is required.

The *dwOptions* argument can be used to specify the threading model that is used by the library when a connection is established. By default, the class instance is initially attached to the thread that created it. From that point on, until the it is released, only the owner may call methods using that instance of the class. The ownership of the class instance may be transferred from one thread to another using the **AttachThread** method.

Specifying the SSH_OPTION_FREETHREAD option enables any thread to call any method in that instance of the class, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the class instance is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same instance.

Example

```
CSshClient sshClient;
SSHOPTIONDATA sshOptions;
BOOL bConnected;
```

```
// Initialize the SSHOPTIONDATA structure and specify the
```

```
// command that should be executed on the server
ZeroMemory(&sshOptions, sizeof(sshOptions));
lstrcpyn(sshOptions.szCommandLine, strCommand, SSH_MAXCOMMANDLEN);

// Establish a connection with the SSH server

bConnected = sshClient.Connect(strHostName,
                               SSH_PORT_DEFAULT,
                               strUserName,
                               strPassword,
                               SSH_TIMEOUT,
                               SSH_OPTION_COMMAND,
                               &sshOptions);

// If the connection attempt fails, then get a description of
// the error and display it in a message box

if (!bConnected)
{
    sshClient.ShowError();
    return;
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

SshClient::Control Method

```
INT Control(  
    DWORD dwControlCode  
);
```

The **SshControl** function sends a control message to the server.

Parameters

dwControlCode

A numeric control code which specifies the control message which should be sent to the server. This may be one of the following values:

Constant	Description
SSH_CONTROL_BREAK	Sends a control message to the server which simulates a break signal on a physical terminal. This is used by some operating systems as an instruction to enter a privileged configuration mode. Note that this is not the same as sending an interrupt character such as Ctrl+C to the server. This control code is ignored for SSH 1.0 sessions.
SSH_CONTROL_NOOP	Sends a control message to the server, but it does not perform any operation. This is typically used by clients to prevent the server from automatically closing a session that has been idle for a long period of time.
SSH_CONTROL_EOF	Sends a control message to the server indicating that the client has finished sending data. Note that this option is normally not used with interactive terminal sessions, and should only be used when required by the server.
SSH_CONTROL_PING	Sends a control message to the server which is used to test whether or not the server is responsive to the client. This is typically used by clients to attempt to detect if the connection to the server is still active.
SSH_CONTROL_REKEY	Sends a control message to the server requesting that the key exchange be performed again. This control code is ignored for SSH 1.0 sessions.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is SSH_ERROR. To get extended error information, call the **GetLastError** method.

Remarks

The **Control** method enables an application to send control messages to the server, which can cause it to take specific actions such as simulate a terminal break or request that the key exchanged be performed again. Some control messages are not supported by the SSH 1.0 protocol, in which case the control message is ignored.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstshv10.lib

CSshClient::CreateSecurityCredentials Method

```
BOOL CreateSecurityCredentials(  
    DWORD dwProtocol,  
    DWORD dwOptions,  
    LPCTSTR LpszKeyFile,  
    LPCTSTR LpszPassword  
);
```

```
BOOL CreateSecurityCredentials(  
    LPCTSTR LpszKeyFile,  
    LPCTSTR LpszPassword  
);
```

```
BOOL CreateSecurityCredentials(  
    LPCTSTR LpszKeyFile  
);
```

The **CreateSecurityCredentials** method establishes the security credentials for the client session.

Parameters

dwProtocol

A bitmask of supported security protocols. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
SECURITY_PROTOCOL_SSH	Select either version 1.0 or 2.0 of the Secure Shell protocol. The actual protocol version that is selected is determined automatically. This is the recommended value.
SECURITY_PROTOCOL_SSH1	Version 1.0 of the Secure Shell protocol. This protocol has been deprecated and its use widely used. It is not recommended that this protocol be used when establishing secure connections.
SECURITY_PROTOCOL_SSH2	Version 2.0 of the Secure Shell protocol. This is currently the most commonly used version of the protocol, and most servers will require this version when establishing a connection.

dwOptions

Credentials options. This argument is reserved for future use. Set it to zero when using this method.

lpszKeyFile

A pointer to a string which specifies the name of a private key file that used when authenticating the client connection. If a private key is not required, value of NULL should be specified.

lpszPassword

A pointer to a string which specifies the password for the private key file. A value of NULL specifies that no password is required.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Example

```
pClient->CreateSecurityCredentials(  
    SECURITY_PROTOCOL_SSH,  
    0,  
    lpszKeyFile,  
    lpszPassword);  
  
bConnected = pClient->Connect(lpszHostName,  
    SSH_PORT_DEFAULT,  
    lpszUserName,  
    lpszPassword,  
    SSH_TIMEOUT,  
    SSH_OPTION_KEEPAIVE);
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstshv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[Connect](#), [DeleteSecurityCredentials](#), [GetSecurityInformation](#), [SECURITYCREDENTIALS](#)

CSshClient::DeleteSecurityCredentials Method

```
VOID DeleteSecurityCredentials();
```

The **DeleteSecurityCredentials** method releases the security credentials for the current session.

Parameters

None.

Return Value

None.

Remarks

This method can be used to release the memory allocated to the client or server credentials after a secure connection has been terminated. The security credentials are released when the class destructor is called, so it is normally not required that the application explicitly call this method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstshv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[CreateSecurityCredentials](#)

CSshClient::DetachHandle Method

```
HCLIENT DetachHandle();
```

The **DetachHandle** method detaches the client handle associated with the current instance of the class.

Parameters

None.

Return Value

This method returns the client handle associated with the current instance of the class object. If there is no active client session, the value `INVALID_CLIENT` will be returned.

Remarks

This method is used to detach a client handle created by the class for use with the SocketTools API. Once the client handle is detached from the class, no other class member functions may be called. Note that the handle must be explicitly released at some later point by the process or a resource leak will occur.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `cstshv10.lib`

[AttachHandle](#), [GetHandle](#)

CSshClient::DisableEvents Method

```
INT DisableEvents();
```

The **DisableEvents** method disables the event notification mechanism, preventing subsequent event notification messages from being posted to the application's message queue.

This method has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Parameters

None.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is SSH_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **DisableEvents** method is used to disable event message posting for the specified client session. Although this will immediately prevent any new events from being generated, it is possible that messages could be waiting in the message queue. Therefore, an application must be prepared to handle client event messages after this method has been called.

This method is automatically called if the client has event notification enabled, and the **Disconnect** method is called. The same issues regarding outstanding event messages also applies in this situation, requiring that the application handle event messages that may reference a client handle that is no longer valid.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstshv10.lib

See Also

[EnableEvents](#), [RegisterEvent](#)

CSshClient::DisableTrace Method

```
BOOL DisableTrace();
```

The **DisableTrace** method disables the logging of socket function calls to the trace log.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, a value of zero is returned.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstshv10.lib

[Connect](#), [IsConnected](#)

CSshClient::EnableEvents Method

```
INT EnableEvents(  
    HWND hEventWnd,  
    UINT uEventMsg  
);
```

The **EnableEvents** method enables event notifications using Windows messages.

This method has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Applications should use the **RegisterEvent** method to register an event handler which is invoked when an event occurs.

Parameters

hEventWnd

Handle to the window which will receive the client notification messages. This parameter must specify a valid window handle. If a NULL handle is specified, event notification will be disabled.

uEventMsg

The message that is received when a client event occurs. This value must be greater than 1024.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is SSH_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **EnableEvents** method is used to request that notification messages be posted to the specified window whenever a client event occurs. This allows an application to monitor the status of different client operations, such as a file transfer.

The *wParam* argument will contain the client handle, the low word of the *lParam* argument will contain the event ID, and the high word will contain any error code. If no error has occurred, the high word will always have a value of zero. The following events may be generated:

Constant	Description
SSH_EVENT_CONNECT	The connection to the server has completed. The high word of the <i>lParam</i> parameter should be checked, since this notification message will be posted if an error has occurred.
SSH_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
SSH_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
SSH_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking

	operation. This event is only generated if the client is in asynchronous mode.
SSH_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
SSH_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and reconnect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.

To disable event notification, call the **DisableEvents** method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstshv10.lib

See Also

[DisableEvents](#), [RegisterEvent](#)

CSshClient::EnableTrace Method

```
BOOL EnableTrace(  
    LPCTSTR lpszTraceFile,  
    DWORD dwTraceFlags  
);
```

The **EnableTrace** method enables the logging of socket function calls to a file.

Parameters

lpszTraceFile

A pointer to a string which specifies the name of the trace log file. If this parameter is NULL or an empty string, the default file name **cstrace.log** is used. The file is stored in the directory specified by the TEMP environment variable, if it is defined; otherwise, the current working directory is used.

dwTraceFlags

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
TRACE_INFO	All function calls are written to the trace file. This is the default value.
TRACE_ERROR	Only those function calls which fail are recorded in the trace file.
TRACE_WARNING	Only those function calls which fail or return values which indicate a warning are recorded in the trace file.
TRACE_HEXDUMP	All functions calls are written to the trace file, plus all the data that is sent or received is displayed, in both ASCII and hexadecimal format.
TRACE_PROCESS	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for multithreaded applications that are using worker threads.

Return Value

If the method succeeds, the return value is non-zero. A return value of zero indicates an error. Failure typically indicates that the tracing library **cstrcv10.dll** cannot be loaded on the local system.

Remarks

When trace logging is enabled, the file is opened, appended to and closed for each socket function call. This makes it possible for an application to append its own logging information, however care should be taken to ensure that the file is closed before the next network operation is performed. To limit the size of the log files, enable and disable logging only around those sections of code that you wish to trace.

Note that the TRACE_HEXDUMP trace level generates very large log files since it includes all of the data exchanged between your application and the server.

Trace method logging is managed on a per-thread basis, not for each client handle. This means that all SocketTools libraries and components share the same settings in the current thread. If you

are using multiple SocketTools libraries or components in your application, you only need to enable logging once.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstshv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[DisableTrace](#)

CSshClient::Execute Method

```
INT Execute(  
    LPCTSTR lpszRemoteHost,  
    UINT nRemotePort,  
    LPCTSTR lpszUserName,  
    LPCTSTR lpszPassword,  
    LPCTSTR lpszCommandLine,  
    UINT nTimeout,  
    DWORD dwOptions,  
    HGLOBAL* lphgblBuffer,  
    LPDWORD lpdwLength  
);
```

```
INT Execute(  
    LPCTSTR lpszRemoteHost,  
    UINT nRemotePort,  
    LPCTSTR lpszUserName,  
    LPCTSTR lpszPassword,  
    LPCTSTR lpszCommandLine,  
    UINT nTimeout,  
    DWORD dwOptions,  
    LPBYTE lpBuffer,  
    LPDWORD lpdwLength  
);
```

```
INT Execute(  
    LPCTSTR lpszRemoteHost,  
    UINT nRemotePort,  
    LPCTSTR lpszUserName,  
    LPCTSTR lpszPassword,  
    LPCTSTR lpszCommandLine,  
    UINT nTimeout,  
    DWORD dwOptions,  
    CString& strBuffer  
);
```

The **Execute** method executes a command on the server and returns the output in the specified buffer.

Parameters

lpszRemoteHost

A pointer to a string which specifies the name of the server. This may either be a fully-qualified domain name, or an IP address. This parameter cannot be NULL.

nRemotePort

The port number the server is listening on. A value of zero specifies that the default port number 22 should be used.

lpszUserName

A pointer to a string which specifies the user name which will be used to authenticate the client session.

lpszPassword

A pointer to a string which specifies the password which will be used to authenticate the client

session.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
SSH_OPTION_NONE	No options specified. A standard terminal session will be established with the default terminal type.
SSH_OPTION_KEEPAIVE	This option specifies the library should attempt to maintain an idle client session for long periods of time. This option is only necessary if you expect that the connection will be held open for more than two hours.
SSH_OPTION_NOPTY	This option specifies that a pseudoterminal (PTY) should not be created for the client session. This option is automatically set if the SSH_OPTION_COMMAND option has been specified.
SSH_OPTION_NOSHELL	This option specifies that a command shell should not be used when executing a command on the server.
SSH_OPTION_NOAUTHRSA	This option specifies that RSA authentication should not be used with SSH-1 connections. This option is ignored with SSH-2 connections and should only be specified if required by the server.
SSH_OPTION_NOPWDNULL	This option specifies the user password cannot be terminated with a null character. This option is ignored with SSH-2 connections and should only be specified if required by the server.
SSH_OPTION_NOREKEY	This option specifies the client should never attempt a repeat key exchange with the server. Some SSH servers do not support rekeying the session, and this can cause the client to become non-responsive or abort the connection after being connected for an hour.
SSH_OPTION_COMPATSID	This compatibility option changes how the session ID is handled during public key authentication with older SSH servers. This option should only be specified when connecting to servers that use OpenSSH 2.2.0 or earlier versions.
SSH_OPTION_COMPATHMAC	This compatibility option changes how the HMAC authentication codes are generated. This option should only be specified when connecting to servers that use OpenSSH 2.2.0 or earlier versions.

lpBuffer, *lphgblBuffer* or *strBuffer*

A pointer to a byte buffer which will contain the data transferred from the server, or a pointer to a global memory handle which will reference the data when the function returns. If the application is using MFC, then a CString variable may also be specified, in which case the data is returned in the string

lpdwLength

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the *lpvBuffer* parameter. If the *lpvBuffer* parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the actual length of the file that was downloaded.

lpCredentials

A pointer to a [SECURITYCREDENTIALS](#) structure which specifies additional security-related information required to establish the connection. This parameter may be NULL, in which case default values will be used. Note that the *dwSize* member must be initialized to the size of the **SECURITYCREDENTIALS** structure that is being passed to the function.

Return Value

If the function succeeds, the return value is the exit code from the program that was executed on the server. If the function fails, the return value is SSH_ERROR. To get extended error information, call **SshGetLastError**.

Remarks

The **Execute** method is used to execute a command on a server, read the output from that command and copy it into a local buffer. This method cannot be used if the connection to the server must be established through a proxy server; if a proxy server must be used, then you should use the **Connect** method to establish the connection, and then use either the **Read** or **ReadLine** methods to read the output.

This method may be used in one of two ways, depending on the needs of the application. The first method is to pre-allocate a buffer large enough to store the command output. In this case, the *lpvBuffer* parameter will point to the buffer that was allocated, the value that the *lpdwLength* parameter points to should be initialized to the size of that buffer.

The second method that can be used is have the *lphgblBuffer* parameter point to a global memory handle which will contain the output when the function returns. In this case, the value that the *lpdwLength* parameter points to must be initialized to zero. It is important to note that the memory handle returned by the function must be freed by the application, otherwise a memory leak will occur. See the example code below.

When the command output is being read from the server, this method will automatically convert the data to match the end-of-line convention used on the Windows platform. This is useful when executing a command on a UNIX based system where the end-of-line is indicated by a single linefeed, while on Windows it is a carriage-return and linefeed pair. If the output contains embedded nulls or escape sequences, then this conversion will not be performed.

This method will cause the current thread to block until the command completes or a timeout occurs.

Example

```
HGLOBAL hgblBuffer = (HGLOBAL)NULL;  
LPBYTE lpBuffer = (LPBYTE)NULL;  
DWORD cbBuffer = 0;
```

```
// Execute a command on the server and return the data into block
// of global memory allocated by the GlobalAlloc function; the handle
// to this memory will be returned in the hgblBuffer parameter
nResult = sshClient.Execute(strHostName,
                            SSH_PORT_DEFAULT,
                            strUserName,
                            strPassword,
                            strCommandLine,
                            SSH_TIMEOUT,
                            SSH_OPTION_NONE,
                            &hgblBuffer,
                            &cbBuffer);

if (nResult != SSH_ERROR)
{
    // Lock the global memory handle, returning a pointer to the
    // resource data
    lpBuffer = (LPBYTE)::GlobalLock(hgblBuffer);

    // After the data has been used, the handle must be unlocked
    // and freed, otherwise a memory leak will occur
    ::GlobalUnlock(hgblBuffer);
    ::GlobalFree(hgblBuffer);
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Server: Requires Windows Server 2003 or Windows 2000 Server.

Header File: cstools10.h

Import Library: cstshv10.lib

Unicode: Implemented as Unicode and ANSI versions.

CSshClient::FreezeEvents Method

```
INT FreezeEvents(  
    BOOL bFreeze  
);
```

The **FreezeEvents** method is used to suspend and resume event handling by the client.

Parameters

bFreeze

A non-zero value specifies that event handling should be suspended by the client. A zero value specifies that event handling should be resumed.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is SSH_ERROR. To get extended error information, call **GetLastError**.

Remarks

This method should be used when the application does not want to process events, such as when a modal dialog is being displayed. When events are suspended, all client events are queued. If events are re-enabled at a later point, those queued events will be sent to the application for processing. Note that only one of each event will be generated. For example, if the client has suspended event handling, and four read events occur, once event handling is resumed only one of those read events will be posted to the client. This prevents the application from being flooded by a potentially large number of queued events.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstshv10.lib

Unicode: Implemented as Unicode and ANSI versions.

CSshClient::GetErrorString Method

```
INT GetErrorString(  
    DWORD dwErrorCode,  
    LPTSTR lpszDescription,  
    INT cbDescription  
);  
  
INT GetErrorString(  
    DWORD dwErrorCode,  
    CString& strDescription  
);
```

The **GetErrorString** method is used to return a description of a specific error code. Typically this is used in conjunction with the **GetLastError** method for use with warning dialogs or as diagnostic messages.

Parameters

dwErrorCode

The error code for which a description is returned.

lpszDescription

A pointer to the buffer that will contain a description of the specified error code. This buffer should be at least 128 characters in length. An alternate form of the method accepts a **CString** variable which will contain the error description.

cbDescription

The maximum number of characters that may be copied into the description buffer.

Return Value

If the method succeeds, the return value is the length of the description string. If the method fails, the return value is zero, meaning that no description exists for the specified error code. Typically this indicates that the error code passed to the method is invalid.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

CSshClient::GetExitCode Method

```
INT GetExitCode();
```

The **GetExitCode** function returns the exit code for the remote session.

Parameters

None.

Return Value

If the method succeeds, the return value is the numeric exit code. If the function fails, the return value is SSH_ERROR. To get extended error information, call the **GetLastError** method.

Remarks

This method should only be called after the command has completed and the **Read** method has returned a value of zero. In most cases, an exit code value of zero indicates success, while any other value indicates an error condition.

Note that the actual value is application dependent and is only meaningful in the context of that particular program. A program may choose or use exit codes in a non-standard way, such as having certain non-zero values indicate success.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstshv10.lib

[GetStatus](#)

CSshClient::GetHandle Method

```
HCLIENT GetHandle();
```

The **GetHandle** method returns the client handle associated with the current instance of the class.

Parameters

None.

Return Value

This method returns the client handle associated with the current instance of the class object. If there is no active client session, the value `INVALID_CLIENT` will be returned.

Remarks

This method is used to obtain the client handle created by the class for use with the SocketTools API.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `cstshv10.lib`

CSshClient::GetLastError Method

```
DWORD GetLastError();  
  
DWORD GetLastError(  
    CString& strDescription  
);
```

Parameters

strDescription

A string which will contain a description of the last error code value when the method returns. If no error has been set, or the last error code has been cleared, this string will be empty.

Return Value

The return value is the last error code value for the current thread. Functions set this value by calling the **SetLastError** method. The Return Value section of each reference page notes the conditions under which the method sets the last error code.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. You should call the **GetLastError** method immediately when a method's return value indicates that an error has occurred. That is because some methods call **SetLastError(0)** when they succeed, clearing the error code set by the most recently failed method.

Most methods will set the last error code value when they fail; a few methods set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or SSH_ERROR. Those methods which call **SetLastError** when they succeed are noted on the method reference page.

The description of the error code is the same string that is returned by the **GetErrorString** method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstshv10.lib

[GetErrorString](#), [SetLastError](#), [ShowError](#)

CSshClient::GetLineMode Method

```
INT GetLineMode();
```

The **GetLineMode** method returns the current line mode.

Parameters

None.

Return Value

If the method succeeds, the return value is the current line mode. If the method fails, the return value is SSH_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetLineMode** method returns an integer value that specifies how end-of-line character sequences are sent to the server. For more information about how newlines are processed by the class and the available options, refer to the **SetLineMode** method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstshv10.lib

See Also

CSshClient::GetSecurityInformation Method

```
BOOL GetSecurityInformation(  
    LPSECURITYINFO LpSecurityInfo  
);
```

The **GetSecurityInformation** method returns security protocol, encryption and certificate information about the current client connection.

Parameters

LpSecurityInfo

A pointer to a [SECURITYINFO](#) structure which contains information about the current client connection. The *dwSize* member of this structure must be initialized to the size of the structure before passing the address of the structure to this method.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

This method is used to obtain security related information about the current client connection to the server. It can be used to determine if a secure connection has been established, what security protocol was selected, and information about the server certificate. Note that a secure connection has not been established, the *dwProtocol* structure member will contain the value `SECURITY_PROTOCOL_NONE`.

Example

The following example demonstrates how to obtain the fingerprint for the server:

```
SECURITYINFO securityInfo;  
  
ZeroMemory(&securityInfo, sizeof(SECURITYINFO));  
securityInfo.dwSize = sizeof(SECURITYINFO);  
  
if (sshClient.GetSecurityInformation(&securityInfo))  
{  
    if (securityInfo.lpszFingerprint != NULL)  
    {  
        TCHAR szMessage[256];  
        wsprintf(szMessage, _T("The fingerprint is %s",  
securityInfo.lpszFingerprint);  
        MessageBox(NULL, szMessage, "Connection", MB_OK);  
    }  
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstshv10.lib

Unicode: Implemented as Unicode and ANSI versions.

CSshClient::GetStatus Method

INT GetStatus();

The **GetStatus** method the current status of the client session.

Parameters

None.

Return Value

If the method succeeds, the return value is the client status code. If the method fails, the return value is SSH_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetStatus** method returns a numeric code which identifies the current state of the client session. The following values may be returned:

Value	Constant	Description
0	SSH_STATUS_UNUSED	No connection has been established.
1	SSH_STATUS_IDLE	The client is current idle and not sending or receiving data.
2	SSH_STATUS_CONNECT	The client is establishing a connection with the server.
3	SSH_STATUS_AUTHENTICATE	The client is authenticating the session with the server.
4	SSH_STATUS_READ	The client is reading data from the server.
5	SSH_STATUS_WRITE	The client is writing data to the server.
6	SSH_STATUS_DISCONNECT	The client is disconnecting from the server.

In a multithreaded application, any thread in the current process may call this method to obtain status information for the specified client session.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstshv10.lib

See Also

[IsBlocking](#), [IsConnected](#), [IsReadable](#), [IsWritable](#)

CSshClient::GetTimeout Method

```
INT GetTimeout();
```

The **GetTimeout** method returns the number of seconds the client will wait for a response from the server. Once the specified number of seconds has elapsed, the method will fail and return to the caller.

Parameters

None.

Return Value

If the method succeeds, the return value is the timeout period in seconds. If the method fails, the return value is SSH_ERROR. To get extended error information, call **GetLastError**.

Remarks

The timeout value is only used with blocking client connections. A value of zero indicates that the default timeout period of 20 seconds should be used.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstshv10.lib

See Also

[Connect](#), [IsReadable](#), [IsWritable](#), [Read](#), [SetTimeout](#), [Write](#)

CSshClient::IsBlocking Method

BOOL IsBlocking();

The **IsBlocking** method is used to determine if the client is currently performing a blocking operation.

Parameters

None.

Return Value

If the client is performing a blocking operation, the method returns a non-zero value. If the client is not performing a blocking operation, or the client handle is invalid, the method returns zero.

Remarks

Because a blocking operation can allow the application to be re-entered (for example, by pressing a button while the operation is being performed), it is possible that another blocking method may be called while it is in progress. Since only one thread of execution may perform a blocking operation at any one time, an error would occur. The **IsBlocking** method can be used to determine if the client is already blocked, and if so, take some other action (such as warning the user that they must wait for the operation to complete).

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstshv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[Cancel](#), [GetStatus](#), [IsConnected](#), [IsInitialized](#), [IsReadable](#), [IsWritable](#), [Read](#), [Write](#)

CSshClient::IsConnected Method

```
BOOL IsConnected();
```

The **IsConnected** method is used to determine if the client is currently connected to a server.

Parameters

None.

Return Value

If the client is connected to a server, the method returns a non-zero value. If the client is not connected, or the client handle is invalid, the method returns zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstshv10.lib

See Also

[GetStatus](#), [IsBlocking](#), [IsInitialized](#), [IsReadable](#), [IsWritable](#)

CSshClient::IsInitialized Method

```
BOOL IsInitialized();
```

The **IsInitialized** method returns whether or not the class object has been successfully initialized.

Parameters

None.

Return Value

This method returns a non-zero value if the class object has been successfully initialized. A return value of zero indicates that the runtime license key could not be validated or the networking library could not be loaded by the current process.

Remarks

When an instance of the class is created, the class constructor will attempt to initialize the component with the runtime license key that was created when SocketTools was installed. If the constructor is unable to validate the license key or load the networking libraries, this initialization will fail.

If SocketTools was installed with an evaluation license, the application cannot be redistributed to another system. The class object will fail to initialize if the application is executed on another system, or if the evaluation period has expired. To redistribute your application, you must purchase a development license which will include the runtime key that is needed to redistribute your software to other systems. Refer to the Developer's Guide for more information.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstshv10.lib

[CSshClient](#), [IsBlocking](#), [IsConnected](#)

CSshClient::IsReadable Method

```
BOOL IsReadable(  
    INT nTimeout,  
    LPDWORD lpdwAvail  
);
```

The **IsReadable** method is used to determine if data is available to be read from the server.

Parameters

nTimeout

Timeout for server response, in seconds. A value of zero specifies that the connection should be polled without blocking the current thread.

lpdwAvail

A pointer to an unsigned integer which will contain the number of bytes available to read. This parameter may be NULL if this information is not required.

Return Value

If the client can read data from the server within the specified timeout period, the method returns a non-zero value. If the client cannot read any data, the method returns zero.

Remarks

On some platforms, this value will not exceed the size of the receive buffer (typically 8192 bytes). Because of differences between TCP/IP stack implementations, it is not recommended that your application exclusively depend on this value to determine the exact number of bytes available. Instead, it should be used as a general indicator that there is data available to be read.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstshv10.lib

See Also

[GetStatus](#), [IsBlocking](#), [IsConnected](#), [IsInitialized](#), [IsWritable](#), [Write](#)

CSshClient::IsWritable Method

```
BOOL IsWritable(  
    INT nTimeout  
);
```

The **IsWritable** method is used to determine if data can be written to the server.

Parameters

nTimeout

Timeout for server response, in seconds. A value of zero specifies that the connection should be polled without blocking the current thread.

Return Value

If the client can write data to the server within the specified timeout period, the method returns a non-zero value. If the client cannot write any data, the method returns zero.

Remarks

Although this method can be used to determine if some amount of data can be sent to the remote process it does not indicate the amount of data that can be written without blocking the client. In most cases, it is recommended that large amounts of data be broken into smaller logical blocks, typically some multiple of 512 bytes in length.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstshv10.lib

See Also

[GetStatus](#), [IsBlocking](#), [IsConnected](#), [IsInitialized](#), [IsReadable](#), [Write](#)

CSshClient::Peek Method

```
INT Peek(  
    LPBYTE lpBuffer,  
    INT cbBuffer  
);  
  
INT Peek(  
    CString& strBuffer,  
    INT cbBuffer  
);
```

The **Peek** method reads the specified number of bytes from the server and copies them into the buffer, but it does not remove the data from the internal receive buffer. The data may be of any type, and is not terminated with a null character.

Parameters

lpBuffer

Pointer to the buffer in which the data will be copied. An alternate form of this method allows a **CString** variable to be passed and data read from the socket will be returned in that string.

cbBuffer

The maximum number of bytes to read and copy into the specified buffer. This value must be greater than zero.

Return Value

If the method succeeds, the return value is the number of bytes actually read. A return value of zero indicates that the server has closed the connection and there is no more data available to be read. If the method fails, the return value is `SSH_ERROR`. To get extended error information, call **GetLastError**.

Remarks

The **Peek** method can be used to examine the data that is available to be read from the internal receive buffer. If there is no data in the receive buffer at that time, a value of zero is returned. It should be noted that this differs from the **Read** method, where a return value of zero indicates that there is no more data available to be read and the connection has been closed. The **Peek** method will never cause the client to block, and so may be safely used with asynchronous connections.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `cstshv10.lib`

See Also

[IsBlocking](#), [IsReadable](#), [Read](#), [ReadLine](#), [Write](#), [WriteLine](#)

CSshClient::Read Method

```
INT Read(  
    LPBYTE lpBuffer,  
    INT cbBuffer  
);  
  
INT Read(  
    CString& strBuffer,  
    INT cbBuffer  
);
```

The **Read** method reads the specified number of bytes from the client socket and copies them into the buffer. The data may be of any type, and is not terminated with a null character.

Parameters

lpBuffer

Pointer to the buffer in which the data will be copied. An alternate form of this method allows a **CString** variable to be passed and data read from the socket will be returned in that string.

cbBuffer

The maximum number of bytes to read and copy into the specified buffer. This value must be greater than zero.

Return Value

If the method succeeds, the return value is the number of bytes actually read. A return value of zero indicates that the server has closed the connection and there is no more data available to be read. If the method fails, the return value is SSH_ERROR. To get extended error information, call **GetLastError**.

Remarks

When **Read** is called and the client is in non-blocking mode, it is possible that the method will fail because there is no available data to read at that time. This should not be considered a fatal error. Instead, the application should simply wait to receive the next asynchronous notification that data is available.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstshv10.lib

See Also

[IsBlocking](#), [IsReadable](#), [Peek](#), [ReadLine](#), [Write](#), [WriteLine](#)

CSshClient::ReadLine Method

```
BOOL ReadLine(  
    LPTSTR lpszBuffer,  
    LPINT lpnLength  
);  
  
BOOL ReadLine(  
    LPTSTR lpszBuffer,  
    INT nMaxLength  
);  
  
BOOL ReadLine(  
    CString& strBuffer,  
    INT nMaxLength  
);
```

The **ReadLine** method reads up to a line of data from the server and returns it in a string buffer.

Parameters

lpszBuffer

Pointer to the string buffer that will contain the data when the method returns. The string will be terminated with a null character, and will not contain the end-of-line characters. An alternate form of the method accepts a **CString** argument which will contain the line of text returned by the server.

lpnLength

A pointer to an integer value which specifies the length of the buffer. The value should be initialized to the maximum number of characters that can be copied into the string buffer, including the terminating null character. When the method returns, its value will updated with the actual length of the string.

nMaxLength

An integer value which specifies the maximum length of the buffer.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **ReadLine** method reads data from the server and copies into a specified string buffer. Unlike the **Read** method which reads arbitrary bytes of data, this method is specifically designed to return a single line of text data in a string. When an end-of-line character sequence is encountered, the method will stop and return the data up to that point. The string buffer is guaranteed to be null-terminated and will not contain the end-of-line characters.

There are some limitations when using **ReadLine**. The method should only be used to read text, never binary data. In particular, the method will discard nulls, linefeed and carriage return control characters. The Unicode version of this method will return a Unicode string, however it does not support reading raw Unicode data from the socket. Any data read from the socket is internally buffered as octets (eight-bit bytes) and converted to Unicode using the **MultiByteToWideChar** function.

This method will force the thread to block until an end-of-line character sequence is processed, the read operation times out or the server closes its end of the socket connection. If this method is

called with asynchronous events enabled, it will automatically switch the socket into a blocking mode, read the data and then restore the socket to asynchronous operation. If another socket operation is attempted while **ReadLine** is blocked waiting for data from the server, an error will occur. It is recommended that this method only be used with blocking (synchronous) socket connections; if the application needs to establish multiple simultaneous connections, it should create worker threads to manage each connection.

The **Read** and **ReadLine** method calls can be intermixed, however be aware that **Read** will consume any data that has already been buffered by the **ReadLine** method and this may have unexpected results.

Unlike the **Read** method, it is possible for data to be returned in the string buffer even if the return value is zero. Applications should check the length of the string to determine if any data was copied into the buffer. For example, if a timeout occurs while the method is waiting for more data to arrive on the socket, it will return zero; however, data may have already been copied into the string buffer prior to the error condition. It is the responsibility of the application to process that data, regardless of the return value.

Example

```
CString strBuffer;
BOOL bResult;

do
{
    bResult = pClient->ReadLine(strBuffer);

    if (strBuffer.GetLength() > 0)
    {
        // Process the line of data returned in the string
        // buffer; the string is always null-terminated
    }
} while (bResult);

DWORD dwError = pClient->GetLastError();

if (dwError == ST_ERROR_CONNECTION_CLOSED)
{
    // The server has closed its side of the connection and
    // there is no more data available to be read
}
else if (dwError != 0)
{
    // An error has occurred while reading a line of data
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstshv10.lib

Unicode: Implemented as Unicode and ANSI versions.

CSshClient::RegisterEvent Method

```
INT RegisterEvent(  
    UINT nEventId,  
    SSHEVENTPROC lpEventProc,  
    DWORD_PTR dwParam  
);
```

The **RegisterEvent** method registers an event handler for the specified event.

Parameters

nEventId

An unsigned integer which specifies which event should be registered with the specified callback function. One of the following values may be used:

Constant	Description
SSH_EVENT_CONNECT	The connection to the server has completed.
SSH_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
SSH_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
SSH_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
SSH_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
SSH_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **SshEventProc** callback function. If this parameter is NULL, the callback for the specified event is disabled.

dwParam

A user-defined integer value that is passed to the callback function. If the application targets the x86 (32-bit) platform, this parameter must be a 32-bit unsigned integer. If the application targets the x64 (64-bit) platform, this parameter must be a 64-bit unsigned integer.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is

SSH_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **RegisterEvent** method associates a callback function with a specific event. The event handler is an **SshEventProc** function that is invoked when the event occurs. Arguments are passed to the function to identify the client session, the event type and the user-defined value specified when the event handler is registered. If the event occurs because of an error condition, the error code will be provided to the handler.

The callback function specified by the *lpEventProc* parameter must be declared using the **__stdcall** calling convention. This ensures the arguments passed to the event handler are pushed on to the stack in the correct order. Failure to use the correct calling convention will corrupt the stack and cause the application to terminate abnormally.

The *dwParam* parameter is commonly used to identify the class instance which is associated with the event that has occurred. Applications will cast the **this** pointer to a DWORD_PTR value when calling this function, and then the event handler will cast it back to a pointer to the class instance. This gives the handler access to the class member variables and methods.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstshv10.lib

CSshClient::Search Method

```
BOOL Search(  
    LPCTSTR lpszString  
);
```

```
BOOL Search(  
    LPCTSTR lpszString,  
    LPBYTE lpBuffer,  
    LPDWORD lpdwLength  
);
```

```
BOOL Search(  
    LPCTSTR lpszString,  
    HGLOBAL* lpBuffer,  
    LPDWORD lpdwLength  
);
```

```
BOOL Search(  
    LPCTSTR lpszString,  
    CString& strBuffer  
);
```

The **Search** method searches for a specific character sequence in the data stream and stops reading if the sequence is encountered.

Parameters

lpszString

A pointer to a string which specifies the sequence of characters to search for in the data stream. This parameter cannot be NULL or point to an empty string.

lpBuffer

A pointer to a byte buffer which will contain the output from the server, or a pointer to a global memory handle which will reference the output when the method returns. If the output from the server is not required, this parameter may be NULL.

lpdwLength

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the *lpBuffer* parameter. If the *lpBuffer* parameter points to a global memory handle, the length value should be initialized to zero. When the method returns, this value will be updated with the actual number of bytes of output stored in the buffer. If the *lpBuffer* parameter is NULL, this parameter should also be NULL.

Return Value

If the method succeeds and the character sequences was found in the data stream, the return value is non-zero. If the method fails or a timeout occurs before the sequence is found, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **Search** method searches for a character sequence in the data stream and stops reading when it is found. This is useful when the client wants to automate responses to the server, such as logging in a user and executing a command. The method collects the output from the server and stores it in the buffer specified by the *lpBuffer* parameter. When the method returns, the buffer will contain everything sent by the server up to and including the search string.

The *lpBuffer* parameter may be specified in one of two ways, depending on the needs of the application. The first method is to pre-allocate a buffer large enough to store the a fixed amount of output. In this case, the *lpBuffer* parameter will point to the buffer that was allocated, the value that the *lpdwLength* parameter points to should be initialized to the size of that buffer. If the server sends more output than can be stored in the buffer, the remaining output will be discarded.

The second method that can be used is have the *lpBuffer* parameter point to a global memory handle which will contain the output when the method returns. In this case, the value that the *lpdwLength* parameter points to must be initialized to zero. It is important to note that the memory handle returned by the method must be freed by the application, otherwise a memory leak will occur. This method is preferred if the client application does not have a general idea of how much output will be generated until the search string is found.

Example

```
LPCTSTR lpszCommand = _T("/bin/ls -l\r\n");
LPCTSTR lpszPrompt = _T("$ ");
HGLOBAL hglbOutput = NULL;
DWORD cbOutput = 0;
BOOL bResult;

// Search for a command prompt issued by the server

bResult = pClient->Search(lpszPrompt, NULL, NULL, 0);

// If the shell prompt was found, issue the command
// and capture the output into the hglbBuffer global
// memory buffer; the cbBuffer variable will contain
// the actual number of bytes in the buffer when the
// function returns

if (bResult)
{
    pClient->Write((LPBYTE)lpszCommand, lstrlen(lpszCommand));

    bResult = pClient->Search(lpszPrompt,
                             &hglbOutput,
                             &cbOutput,
                             0);
}

// Write the contents of the output buffer to the
// standard output stream

if (bResult)
{
    LPBYTE lpBuffer = (LPBYTE)GlobalLock(hglbBuffer);

    if (lpBuffer)
        fwrite(lpBuffer, 1, cbBuffer, stdout);

    GlobalUnlock(hglbBuffer);
    GlobalFree(hglbBuffer);
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstshv10.lib

Unicode: Implemented as Unicode and ANSI versions.

CSshClient::SetLastError Method

```
VOID SetLastError(  
    DWORD dwErrorCode  
);
```

The **SetLastError** method sets the last error code for the current thread. This method is typically used to clear the last error by specifying a value of zero as the parameter.

Parameters

dwErrorCode

Specifies the last error code for the current thread.

Return Value

None.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. Most methods will set the last error code value when they fail; a few methods set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or SSH_ERROR. Those methods which call **SetLastError** when they succeed are noted on the method reference page.

Applications can retrieve the value saved by this method by using the **GetLastError** method. The use of **GetLastError** is optional; an application can call the method to determine the specific reason for a method failure.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cstshv10.lib

See Also

[GetErrorString](#), [GetLastError](#), [ShowError](#)

CSshClient::SetLineMode Method

```
INT SetLineMode(  
    INT nLineMode  
);
```

The **SetLineMode** method changes the current line mode for the client session.

Parameters

nLineMode

An integer value which specifies how the newlines are sent by the class. It must be one of the following values:

Value	Constant	Description
0	SSH_NEWLINE_DEFAULT	There are no changes to how data is sent to the server. Any carriage return or linefeed characters that are sent using the Write method will be sent as-is. The WriteLine method will terminate each line of text with a carriage return and linefeed (CRLF) sequence. This is the default line mode that is set when a new connection is established.
1	SSH_NEWLINE_CR	A carriage return is used as the end-of-line character. Any data sent using the Write method that contains only a linefeed (LF) character or a carriage return and linefeed (CRLF) sequence to indicate the end-of-line will be replaced by a carriage return (CR) character. The WriteLine method will terminate each line of text with a single carriage return character.
2	SSH_NEWLINE_LF	A linefeed is used as the end-of-line character. Any data sent using the Write method that contains only a carriage return (CR) character or a carriage return and linefeed (CRLF) sequence to indicate the end-of-line will be replaced by a linefeed (LF) character. The WriteLine method will terminate each line of text with a single linefeed character.
3	SSH_NEWLINE_CRLF	A carriage return and linefeed (CRLF) character sequence is used to indicate the end-of-line. Any data sent using the Write method that contains only a carriage return (CR) or linefeed (LF) will be replaced by a carriage return and linefeed. The WriteLine method will terminate each line of text with a carriage return and linefeed sequence.

Return Value

If the method succeeds, the return value is the previous line mode for the client session. If the method fails, the return value is SSH_ERROR. To get extended error information, call **GetLastError**.

Remarks

When a connection is initially established with the server, it determines what characters are used to indicate the end-of-line and how they are displayed. On UNIX based systems, this is controlled by the settings for the pseudo-terminal that is allocated for the client session, and can be changed using the **stty** command. In most cases, the client line mode can be left at the default. However, in some cases you may need to change the line mode, particularly if you intend to send data from a Windows text file or copied from the clipboard.

Windows uses a carriage return and linefeed (CRLF) sequence to indicate the end-of-line and a UNIX based server may interpret that as multiple newlines. To prevent this, use the **SetLineMode** method to change the current line mode to **SSH_NEWLINE_CR** and the CRLF sequence in the text will be replaced by a single carriage return.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstshv10.lib

See Also

[GetLineMode](#), [Write](#), [WriteLine](#)

CSshClient::SetTimeout Method

```
INT SetTimeout(  
    UINT nTimeout  
);
```

The **SetTimeout** method sets the number of seconds the client will wait for a response from the server. Once the specified number of seconds has elapsed, the method will fail and return to the caller.

Parameters

nTimeout

The number of seconds to wait for a blocking operation to complete.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is `SSH_ERROR`. To get extended error information, call **GetLastError**.

Remarks

The timeout value is only used with blocking client connections.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `cstshv10.lib`

CSshClient::ShowError Method

```
INT ShowError(  
    LPCTSTR lpszAppTitle,  
    UINT uType,  
    DWORD dwErrorCode  
);
```

The **ShowError** method displays a message box which describes the specified error.

Parameters

lpszAppTitle

A pointer to a string which specifies the title of the message box that is displayed. If this argument is NULL or omitted, then the default title of "Error" will be displayed.

uType

An unsigned integer which specifies the type of message box that will be displayed. This is the same value that is used by the **MessageBox** method in the Windows API. If a value of zero is specified, then a message box with a single OK button will be displayed. Refer to that method for a complete list of options.

dwErrorCode

Specifies the error code that will be used when displaying the message box. If this argument is zero, then the last error that occurred in the current thread will be displayed.

Return Value

If the method is successful, the return value will be the return value from the **MessageBox** function. If the method fails, it will return a value of zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cstshv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[GetErrorString](#), [GetLastError](#), [SetLastError](#)

CSshClient::Write Method

```
INT Write(  
    LPBYTE lpBuffer,  
    INT cbBuffer  
);  
  
INT Write(  
    LPCTSTR lpszBuffer  
    INT cbBuffer  
);
```

The **Write** method sends the specified number of bytes to the server.

Parameters

lpBuffer

The pointer to the buffer which contains the data that is to be sent to the server. In an alternate form of the method, the pointer is to a string.

cbBuffer

The number of bytes to send from the specified buffer. This value must be greater than zero, unless a pointer to a string buffer is passed as the parameter. In that case, if the value is -1, all of the characters in the string, up to but not including the terminating null character, will be sent to the server.

Return Value

If the method succeeds, the return value is the number of bytes actually written. If the method fails, the return value is SSH_ERROR. To get extended error information, call **GetLastError**.

Remarks

The return value may be less than the number of bytes specified by the *cbBuffer* parameter. In this case, the data has been partially written and it is the responsibility of the client application to send the remaining data at some later point. For non-blocking clients, the client must wait for the next asynchronous notification message before it resumes sending data.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstshv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[IsBlocking](#), [IsWritable](#), [Peek](#), [Read](#), [ReadLine](#), [SetLineMode](#), [WriteLine](#)

CSshClient::WriteLine Method

```
BOOL WriteLine(  
    LPCTSTR lpszBuffer,  
    LPINT lpnLength  
);
```

The **WriteLine** function sends a line of text to the server, terminated by a carriage-return and linefeed.

Parameters

lpszBuffer

The pointer to a string buffer which contains the data that will be sent to the server. All characters up to, but not including, the terminating null character will be written to the socket. The data will always be terminated with a carriage-return and linefeed control character sequence. If this parameter points to an empty string or NULL pointer, then a only a carriage-return and linefeed are written to the socket.

lpnLength

A pointer to an integer value which will contain the number of characters written to the socket, including the carriage-return and linefeed sequence. If this information is not required, a NULL pointer may be specified.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **WriteLine** method writes a line of text to the server and terminates the line with a carriage-return and linefeed control character sequence. Unlike the **Write** method which writes arbitrary bytes of data to the socket, this method is specifically designed to write a single line of text data from a string.

If the *lpszBuffer* string is terminated with a linefeed (LF) or carriage return (CR) character, it will be automatically converted to a standard CRLF end-of-line sequence. Because the string will be sent with a terminating CRLF sequence, the value returned in the *lpnLength* parameter will typically be larger than the original string length (reflecting the additional CR and LF characters), unless the string was already terminated with CRLF.

There are some limitations when using **WriteLine**. This method should only be used to send text, never binary data. In particular, it will discard nulls and append linefeed and carriage return control characters to the data stream. The Unicode version of this method will accept a Unicode string, however it does not support writing raw Unicode data to the socket. Unicode strings will be automatically converted to UTF-8 encoding using the **WideCharToMultiByte** function and then written to the socket as a stream of bytes.

This method will force the thread to block until the complete line of text has been written, the write operation times out or the server aborts the connection. If this method is called with asynchronous events enabled, it will automatically switch the socket into a blocking mode, send the data and then restore the socket to asynchronous operation. If another socket operation is attempted while **WriteLine** is blocked sending data to the server, an error will occur. It is recommended that this method only be used with blocking (synchronous) socket connections; if the application needs to establish multiple simultaneous connections, it should create worker

threads to manage each connection.

The **Write** and **WriteLine** methods can be safely intermixed.

Unlike the **Write** function, it is possible for data to have been written to the socket if the return value is zero. For example, if a timeout occurs while the method is waiting to send more data to the server, it will return zero; however, some data may have already been written prior to the error condition. If this is the case, the *lpnLength* argument will specify the number of characters actually written up to that point.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstshv10.lib

Unicode: Implemented as Unicode and ANSI versions.

SSH Protocol Data Structures

- SECURITYCREDENTIALS
- SECURITYINFO
- SSOPTIONDATA

SECURITYCREDENTIALS Structure

The **SECURITYCREDENTIALS** structure specifies the information needed by the library to specify additional security credentials, such as a client certificate or private key, when establishing a secure connection.

```
typedef struct _SECURITYCREDENTIALS
{
    DWORD    dwSize;
    DWORD    dwProtocol;
    DWORD    dwOptions;
    DWORD    dwReserved;
    LPCTSTR  lpszHostName;
    LPCTSTR  lpszUserName;
    LPCTSTR  lpszPassword;
    LPCTSTR  lpszCertStore;
    LPCTSTR  lpszCertName;
    LPCTSTR  lpszKeyFile;
} SECURITYCREDENTIALS, *LPSECURITYCREDENTIALS;
```

Members

dwSize

Size of this structure. If the structure is being allocated dynamically, this member must be set to the size of the structure and all other unused structure members must be initialized to a value of zero or NULL.

dwProtocol

A value which specifies which security protocols are supported:

Constant	Description
SECURITY_PROTOCOL_SSH	Either version 1.0 or 2.0 of the Secure Shell protocol should be used when establishing the connection. The correct protocol is automatically selected based on the version of the protocol that is supported by the server.
SECURITY_PROTOCOL_SSH1	The Secure Shell 1.0 protocol should be used when establishing the connection. This is an older version of the protocol which should not be used unless explicitly required by the server. Most modern SSH server support version 2.0 of the protocol.
SECURITY_PROTOCOL_SSH2	The Secure Shell 2.0 protocol should be used when establishing the connection. This is the default version of the protocol that is supported by most SSH servers.

dwOptions

This structure member is reserved for use with SSL and TLS connections and should always be initialized to zero.

dwReserved

This structure member is reserved for future use and should always be initialized to zero.

lpszHostName

A pointer to a null terminated string which specifies the hostname that will be used when

validating a server certificate. This member should always be initialized as a NULL pointer for connections using the SSH protocol.

lpszUserName

A pointer to a null terminated string which identifies the owner of client certificate. Currently this member is not used by the library and should always be initialized as a NULL pointer.

lpszPassword

A pointer to a null terminated string which specifies the password needed to access the certificate. Currently this member is only used if a private key file has been specified. If there is no password associated with the certificate, then this member should be initialized as a NULL pointer.

lpszCertStore

A pointer to a null terminated string which specifies the name of the certificate store to open. This member should always be initialized as a NULL pointer for connections using the SSH protocol.

lpszCertName

A pointer to a null terminated string which specifies the name of the certificate to use. This member should always be initialized as a NULL pointer for connections using the SSH protocol.

lpszKeyFile

A pointer to a null terminated string which specifies the name of the file which contains the private key required to establish the connection. This member is only used with the SSH protocol. If the member is NULL, then no private key is used.

Remarks

A client application typically only needs to create this structure if the server requires that the client provide a private key as part of the process of negotiating the secure session.

Note that the *lpszUserName* and *lpszPassword* members are values which are used to access the private key file. They are not the credentials which are used when establishing the connection with the server or authenticating the client session.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Unicode: Implemented as Unicode and ANSI versions.

SECURITYINFO Structure

This structure contains information about a secure connection that has been established with a server.

```
typedef struct _SECURITYINFO
{
    DWORD        dwSize;
    DWORD        dwProtocol;
    DWORD        dwCipher;
    DWORD        dwCipherStrength;
    DWORD        dwHash;
    DWORD        dwHashStrength;
    DWORD        dwKeyExchange;
    DWORD        dwCertStatus;
    SYSTEMTIME   stCertIssued;
    SYSTEMTIME   stCertExpires;
    LPCTSTR      lpszCertIssuer;
    LPCTSTR      lpszCertSubject;
    LPCTSTR      lpszFingerprint;
} SECURITYINFO, *LPSECURITYINFO;
```

Members

dwSize

Specifies the size of the data structure. This member must always be initialized to **sizeof(SECURITYINFO)** prior to passing the address of this structure to the function. Note that if this member is not initialized, an error will be returned indicating that an invalid parameter has been passed to the function.

dwProtocol

A numeric value which specifies the protocol that was selected to establish the secure connection. One of the following values will be returned:

Constant	Description
SECURITY_PROTOCOL_NONE	No security protocol has been selected. A secure connection has not been established with the server. The remaining member values in this structure are not valid and should be ignored.
SECURITY_PROTOCOL_SSH1	The Secure Shell 1.0 protocol has been selected. This protocol has been deprecated and is no longer widely used. It is not recommended that this protocol be used when establishing secure connections. This protocol can only be specified when connecting to an SSH server and is not supported with any other application protocol.
SECURITY_PROTOCOL_SSH2	The Secure Shell 2.0 protocol has been selected. This is the most commonly used version of the protocol. It is recommended that this version of the protocol be used unless the server explicitly requires the client to use an earlier version. This protocol can only be specified when connecting to an SSH server and is not supported with any other application protocol.

dwCipher

A numeric value which specifies the cipher that was selected when establishing the secure connection. One of the following values will be returned:

Constant	Description
SECURITY_CIPHER_RC5	The RC5 block cipher was selected. This is a variable key length cipher which supports keys up to 2040 bits, in 8-bit increments.
SECURITY_CIPHER_DES	The DES (Data Encryption Standard) block cipher was selected. This is a fixed key length cipher, using 56-bit keys.
SECURITY_CIPHER_DES3	The Triple DES block cipher was selected. This cipher encrypts the data three times using different keys, effectively providing a 168-bit length key.
SECURITY_CIPHER_DESX	A variant of the DES block cipher which XORs an extra 64-bits of the key before and after the plaintext has been encrypted, increasing the key size to 184 bits.
SECURITY_CIPHER_AES	The Advanced Encryption Standard cipher (also known as the Rijndael cipher) is a fixed block size cipher which use a key size of 128, 192 or 256 bits. This cipher is supported on Windows XP SP3 and later versions of the operating system.

dwCipherStrength

A numeric value which specifies the strength (the length of the cipher key in bits) of the cipher that was selected. Typically this value will be 128 or 256. 40-bit and 56-bit key lengths are considered weak encryption, and subject to brute force attacks. 128-bit and 256-bit key lengths are considered to be secure and are the recommended key length for secure communications.

dwHash

A numeric value which specifies the hash algorithm which was selected. One of the following values will be returned:

Constant	Description
SECURITY_HASH_MD5	The MD5 algorithm was selected. Its use has been deprecated and is no longer considered to be cryptographically secure.
SECURITY_HASH_SHA1	The SHA-1 algorithm was selected. Its use has been deprecated and is no longer considered to be cryptographically secure.
SECURITY_HASH_SHA256	The SHA-256 algorithm was selected.

dwHashStrength

A numeric value which specifies the strength (the length in bits) of the message digest that was selected.

dwKeyExchange

A numeric value which specifies the key exchange algorithm which was selected. One of the following values will be returned:

--	--

Constant	Description
SECURITY_KEYEX_RSA	The RSA public key algorithm was selected.
SECURITY_KEYEX_KEA	The Key Exchange Algorithm (KEA) was selected. This is an improved version of the Diffie-Hellman public key algorithm.
SECURITY_KEYEX_DH	The Diffie-Hellman key exchange algorithm was selected.
SECURITY_KEYEX_ECDH	The Elliptic Curve Diffie-Hellman key exchange algorithm was selected. This is a variant of the Diffie-Hellman algorithm which uses elliptic curve cryptography. This key exchange algorithm is only supported on Windows XP SP3 and later versions of the operating system.

dwCertStatus

A numeric value which specifies the status of the certificate returned by the secure server. This member only has meaning for connections using the SSL or TLS protocols.

stCertIssued

A structure which contains the date and time that the certificate was issued by the certificate authority. If the issue date cannot be determined for the certificate, the SYSTEMTIME structure members will have zero values. This member only has meaning for connections using the SSL or TLS protocols.

stCertExpires

A structure which contains the date and time that the certificate expires. If the expiration date cannot be determined for the certificate, the SYSTEMTIME structure members will have zero values. This member only has meaning for connections using the SSL or TLS protocols.

lpszCertIssuer

A pointer to a string which contains information about the organization that issued the certificate. This string consists of one or more comma-separated tokens. Each token consists of an identifier, followed by an equal sign and a value. If the certificate issuer could not be determined, this member may be NULL. This member only has meaning for connections using the SSL or TLS protocols.

lpszCertSubject

A pointer to a string which contains information about the organization that the certificate was issued to. This string consists of one or more comma-separated tokens. Each token consists of an identifier, followed by an equal sign and a value. If the certificate subject could not be determined, this member may be NULL. This member only has meaning for connections using the SSL or TLS protocols.

lpszFingerprint

A pointer to a string which contains a sequence of hexadecimal values that uniquely identify the server. This member is only used when a connection has been established using the Secure Shell (SSH) protocol.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Unicode: Implemented as Unicode and ANSI versions.

SSHOPTIONDATA Structure

This structure specifies additional option information for the client session. A pointer to this structure can be passed to the [Connect](#) method.

```
#define SSH_MAXTERMNAMELEN    32
#define SSH_MAXHOSTNAMELEN   128
#define SSH_MAXUSERNAMELEN   128
#define SSH_MAXPASSWORDLEN   128
#define SSH_MAXCOMMANDLEN    512

typedef struct _SSHOPTIONDATA
{
    DWORD dwSize;
    DWORD dwReserved;
    UINT nProxyType;
    UINT nProxyPort;
    TCHAR szProxyHost[SSH_MAXHOSTNAMELEN];
    TCHAR szProxyUser[SSH_MAXUSERNAMELEN];
    TCHAR szProxyPassword[SSH_MAXPASSWORDLEN];
    UINT nTermCols;
    UINT nTermRows;
    TCHAR szTermName[SSH_MAXTERMNAMELEN];
    TCHAR szCommandLine[SSH_MAXCOMMANDLEN];
} SSHOPTIONDATA, *LPSSHOPTIONDATA;
```

Members

dwSize

An unsigned integer value which specifies the size of the SSHOPTIONDATA structure. This member must be initialized prior to passing the structure to the Connect method.

dwReserved

An unsigned integer value that is reserved for internal use, and should always be initialized to a value of zero.

nProxyType

An unsigned integer value that specifies the type of proxy that the client should connect through. This structure member is only used if the option SSH_OPTION_PROXYSERVER has been specified. Possible values are:

Constant	Description
SSH_PROXY_NONE	No proxy server should be used when establishing the connection.
SSH_PROXY_HTTP	The connection should be established on port 80 using HTTP. An alternate port number can be specified by setting the <i>nProxyPort</i> structure member to the desired value.
SSH_PROXY_TELNET	The connection should be established on port 23 using TELNET. An alternate port number can be specified by setting the <i>nProxyPort</i> structure member to the desired value.

nProxyPort

An unsigned integer value that specifies the port number which should be used to establish the proxy connection. A value of zero specifies that the default port number appropriate for the

selected protocol should be used. This structure member is only used if the option SSH_OPTION_PROXYSERVER has been specified.

szProxyHost

A null terminated string which specifies the host name or IP address of the proxy server. This structure member is only used if the option SSH_OPTION_PROXYSERVER has been specified.

szProxyUser

A null terminated string which specifies the user name which is used to authenticate the connection through the proxy server. This structure member is only used if the option SSH_OPTION_PROXYSERVER has been specified.

szProxyPassword

A null terminated string which specifies the password which is used to authenticate the connection through the proxy server. This structure member is only used if the option SSH_OPTION_PROXYSERVER has been specified.

nTermCols

An unsigned integer value which specifies the number of columns for the virtual terminal allocated for the client session. The default number of columns is 80. This structure member is only used if the option SSH_OPTION_TERMINAL has been specified.

nTermRows

An unsigned integer value which specifies the number of rows for the virtual terminal allocated for the client session. The default number of rows is 25. This structure member is only used if the option SSH_OPTION_TERMINAL has been specified.

szTermName

A null terminated string which specifies the name of the terminal emulation type. On UNIX based systems, this name typically corresponds to an entry in the terminal capability database (either termcap or terminfo). If the name is not specified, then the default name terminal name of "unknown" will be used. This structure member is only used if the option SSH_OPTION_TERMINAL has been specified.

szCommandLine

A null terminated string which specifies the command that should be executed on the server. The output from the command is returned to the client, and the session is terminated. This structure member is only used if the option SSH_OPTION_COMMAND has been specified.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Unicode: Implemented as Unicode and ANSI versions.

Simple Mail Transfer Protocol Class Library

Submit email messages for delivery to one or more recipients.

Reference

- [Class Methods](#)
- [Data Structures](#)
- [Error Codes](#)

Library Information

Class Name	CSmtpClient
File Name	CSMTPV10.DLL
Version	10.0.1468.2518
LibID	D74CB488-F2C1-4F78-858A-201AEA7483FE
Import Library	CSMTPV10.LIB
Dependencies	None
Standards	RFC 821, RFC 1425, RFC 1869, RFC 2821

Overview

The Simple Mail Transfer Protocol (SMTP) enables applications to deliver email messages to one or more recipients. The class library provides an interface for addressing and delivering messages, and extended features such as user authentication and delivery status notification. Unlike Microsoft's Messaging API (MAPI) or Collaboration Data Objects (CDO), there is no requirement to have certain third-party email applications installed or specific types of servers installed on the local system. The CSmtpClient class can be used to deliver mail through a wide variety of systems, from standard UNIX based mail servers to Windows systems running Microsoft Exchange.

Using this class library, messages can be delivered directly to the recipient, or they can be routed through a relay server, such as an Internet service provider's mail system. The SocketTools CMailMessage class can be integrated with this class in order to provide an extremely simple, yet flexible interface for composing and delivering messages.

This class library supports secure connections using the standard SSL and TLS protocols. Both implicit and explicit SSL connections are supported, as well as client certificates used for authentication.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). If you are using Visual C++ 6.0 it is required that you have Service Pack 6 (SP6) installed. You should install all updates for your development tools and have the current Windows SDK installed. The minimum recommended version of Visual Studio is Visual Studio 2010.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are using Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. It is recommended that you install the current service pack and all critical updates available for your version of the operating system.

This product includes both 32-bit and 64-bit libraries. Native 64-bit CPU support requires the 64-bit version of Windows 7 or later versions of the Windows operating system.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

Simple Mail Transfer Protocol Class Methods

Class	Description
CSmtpClient	Constructor which initializes the current instance of the class
~CSmtpClient	Destructor which releases resources allocated by the class
Method	Description
AddRecipient	Add an address to the recipient list
AppendMessage	Append contents of specified file to the current message
AttachHandle	Attach the specified client handle to this instance of the class
AttachThread	Attach the specified client handle to another thread
Authenticate	Authenticate the client session with a user name and password
Cancel	Cancel the current blocking operation
CloseMessage	Close the message being composed and submit for delivery
Command	Send a command to the server
Connect	Establish a connection with a server
CreateMessage	Create a new message
CreateSecurityCredentials	Allocate a structure to establish client security credentials
DeleteSecurityCredentials	Delete the specified client security credentials
DetachHandle	Detach the handle for the current instance of this class
DisableEvents	Disable all event notification, including event callbacks
DisableTrace	Disable logging of socket function calls to the trace log
Disconnect	Disconnect from the current server
EnableEvents	Enable event handling by the library
EnableTrace	Enable logging of socket function calls to a file
ExpandAddress	Expand the specified address
FreezeEvents	Suspend and resume event handling by the client
GetCurrentDate	Return the current date and time
GetDeliveryOptions	Return the delivery options for the current session
GetErrorString	Return a description for the specified error code
GetExtendedOptions	Return the extended options supported by the server
GetHandle	Return the client handle used by this instance of the class
GetLastError	Return the last error code
GetLocalName	Return the local host name assigned for the client session
GetResultCode	Return the result code from the previous command

GetResultString	Return the result string from the previous command
GetSecurityInformation	Return security information about the current client connection
GetStatus	Return the current status of the client
GetTimeout	Return the number of seconds until an operation times out
GetTransferStatus	Return data transfer statistics
IsBlocking	Determine if the client is blocked, waiting for information
IsConnected	Determine if the client is connected to the server
IsInitialized	Determine if the class has been successfully initialized
IsReadable	Determine if data can be read from the server
IsWritable	Determine if data can be written to the server
RegisterEvent	Register an event handler for the specified event
Reset	Reset the client and return to a command state
SendMessage	Send message to the specified recipient
SetDeliveryOptions	Set the delivery options for the current session
SetLastError	Set the last error code
SetLocalName	Set the local host name to be used for the client session
SetTimeout	Set the number of seconds until an operation times out
ShowError	Display a message box with a description of the specified error
SmtpeventProc	Process events generated by the client
SubmitMessage	Compose and submit a message for delivery to the specified mail server
VerifyAddress	Verify that the specified address is valid
Write	Write data to the server

CSmtpClient::CSmtpClient Method

`CSmtpClient();`

The **CSmtpClient** constructor initializes the class library and validates the license key at runtime.

Remarks

If the constructor fails to validate the runtime license, subsequent methods in this class will fail. If the product is installed with an evaluation license, then the application will only function on the development system and cannot be redistributed.

The constructor calls the **SmtplibInitialize** function to initialize the library, which dynamically loads other system libraries and allocates thread local storage. If you are using this class within another DLL, it is important that you do not create or destroy an instance of the class from within the **DllMain** function because it can result in deadlocks or access violation errors. You should not declare static or global instances of this class within another DLL if it is linked with the C runtime library (CRT) because it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csmtpv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

See Also

[~CSmtpClient](#), [IsInitialized](#)

CSmtpClient::~CSmtpClient

`~CSmtpClient();`

The **CSmtpClient** destructor releases resources allocated by the current instance of the **CSmtpClient** object. It also uninitializes the library if there are no other concurrent uses of the class.

Remarks

When a **CSmtpClient** object goes out of scope, the destructor is automatically called to allow the library to free any resources allocated on behalf of the process. Any pending blocking or asynchronous calls in this process are canceled without posting any notification messages, and all handles that were created for the client session are destroyed.

The destructor is not called explicitly by the application.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csmtpv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

See Also

[CSmtpClient](#)

CSmtpClient::AddRecipient Method

```
INT AddRecipient(  
    LPCTSTR lpszAddress  
);
```

The **AddRecipient** method adds the specified address to the recipient list for the current message. This method should be called once for each recipient.

Parameters

lpszAddress

Points to a string which specifies the address to be added to the recipient list.

Return Value

If the method succeeds, the return value is the server result code. If the method fails, the return value is SMTP_ERROR. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmtpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[CloseMessage](#), [CreateMessage](#), [ExpandAddress](#), [VerifyAddress](#)

CSmtpClient::AppendMessage Method

```
INT AppendMessage(  
    LPCTSTR lpszFileName  
);  
  
INT AppendMessage(  
    LPBYTE lpMessage,  
    DWORD dwMessageSize  
);  
  
INT AppendMessage(  
    HGLOBAL hgblMessage,  
    DWORD dwMessageSize  
);
```

The **AppendMessage** method writes the contents of a specified file or buffer to the data stream, appending it to the current message contents.

Parameters

lpszFileName

A pointer to a string which specifies the name of a file. The contents of the file are appended to the current message being submitted to the mail server for delivery.

lpMessage

Pointer to a buffer which contains the message data to be appended to the current message.

hgblMessage

A global memory handle which references data that is to be appended to the current message.

dwMessageSize

An unsigned integer which specifies the length of the message in bytes.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is SMTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **AppendMessage** method is used to append the contents of a file, memory buffer, or global memory handle to the current message that is being composed for delivery. To send a complete RFC 822 formatted message, refer to the **SendMessage** method.

This method will cause the current thread to block until the complete message has been written, a timeout occurs or the operation is canceled. During the transfer, the SMTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **EnableEvents**, or by registering a callback function using the **RegisterEvent** method.

To determine the current status of a transfer while it is in progress, use the **GetTransferStatus** method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmtpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[CloseMessage](#), [CreateMessage](#), [SendMessage](#)

CSmtpClient::AttachHandle Method

```
VOID AttachHandle(  
    HCLIENT hClient  
);
```

The **AttachHandle** method attaches the specified client handle to the current instance of the class.

Parameters

hClient

The handle to the client session that will be attached to the current instance of the class object.

Return Value

None.

Remarks

This method is used to attach a client handle created outside of the class using the SocketTools API. Once the client handle is attached to the class, the other class member functions may be used with that client session.

If a client handle already has been created for the class, that handle will be released when the new handle is attached to the class object. If you want to prevent the previous client session from being terminated, you must call the **DetachHandle** method. Failure to release the detached handle may result in a resource leak in your application.

Note that the *hClient* parameter is presumed to be a valid client handle and no checks are performed to ensure that the handle is valid. Specifying an invalid client handle will cause subsequent method calls to fail.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmtpv10.lib

See Also

[AttachThread](#), [DetachHandle](#), [GetHandle](#)

CSmtpClient::AttachThread Method

```
DWORD AttachThread(  
    DWORD dwThreadId  
);
```

The **AttachThread** method attaches the specified client handle to another thread.

Parameters

dwThreadId

The ID of the thread that will become the new owner of the handle. A value of zero specifies that the current thread should become the owner of the client handle.

Return Value

If the method succeeds, the return value is the thread ID of the previous owner. If the method fails, the return value is SMTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

When a client handle is created, it is associated with the current thread that created it. Normally, if another thread attempts to perform an operation using that handle, an error is returned since it does not own the handle. This is used to ensure that other threads cannot interfere with an operation being performed by the owner thread. In some cases, it may be desirable for one thread in a client application to create the client handle, and then pass that handle to another worker thread. The **AttachThread** method can be used to change the ownership of the handle to the new worker thread. By preserving the return value from the method, the original owner of the handle can be restored before the worker thread terminates.

This method should be called by the new thread immediately after it has been created, and if the new thread does not release the handle itself, the ownership of the handle should be restored to the parent thread before it terminates. Under no circumstances should **AttachThread** be used to forcibly release a handle allocated by another thread while a blocking operation is in progress. To cancel an operation, use the **Cancel** method and then release the handle after the blocking method exits and control is returned to the current thread.

Note that the *dwThreadId* parameter is presumed to be a valid thread ID and no checks are performed to ensure that the thread actually exists. Specifying an invalid thread ID will orphan the client handle used by the class until the destructor is called.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmtpv10.lib

CSmtpClient::Authenticate Method

```
INT Authenticate(  
    LPCTSTR lpszUserName,  
    LPCTSTR lpszPassword,  
    UINT nAuthType  
);
```

The **Authenticate** method provides client authentication information to the server.

Parameters

lpszUserName

A null terminated string which specifies the account name for the user authorized to send mail through the server.

lpszPassword

A null terminated string which specifies the password to be used when authenticating the current client session. If you are using the SMTP_AUTH_XOAUTH2 or SMTP_AUTH_BEARER authentication methods, this parameter is not a password, instead it specifies the bearer token provided by the mail service.

nAuthType

An integer value which specifies which method the library should use to authenticate the client session. This parameter should be set to one of the following values:

Constant	Description
SMTP_AUTH_LOGIN	The client will authenticate using the AUTH LOGIN command. This encodes the username and password, however the credentials are not encrypted and it is recommended you use a secure connection. This is the default method accepted by most mail servers and is the preferred authentication type for most clients.
SMTP_AUTH_PLAIN	The client will authenticate using the AUTH PLAIN command. This encodes the username and password, however the credentials are not encrypted and it is recommended you use a secure connection. The server must support the PLAIN Simple Authentication and Security Layer (SASL) mechanism as defined in RFC 4616.
SMTP_AUTH_XOAUTH2	The client will authenticate using the AUTH XOAUTH2 command. This authentication method does not require the user password, instead the <i>lpszPassword</i> parameter must specify the bearer token issued by the service provider. The application must provide a valid access token which has not expired, or this method will fail.
SMTP_AUTH_BEARER	The client will authenticate using the AUTH OAUTHBEARER command as defined in RFC 7628. This authentication method does not require the user password, instead the <i>lpszPassword</i> parameter must specify the bearer token issued by the service provider. The application must provide a valid access token which has not expired, or this method

will fail.

Return Value

If the method succeeds, the return value is the command result code. If the method fails, the return value is SMTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

To submit a mail message for delivery, virtually all public mail servers require clients to authenticate and will only accept messages from authorized users. In some cases, they may also require the sender email address match the account being used to authenticate the session. It is also typical for most public mail servers to reject authentication attempts over a standard (non-secure) connection. You should always use a secure connection whenever possible.

All authentication methods require the mail server to support the standard service extensions for authentication as specified in the RFC 4954. The server must support the ESMTP protocol extensions and the AUTH command. A user name and password are required for authentication. If you wish to authenticate without a user password, you must use one of the OAuth 2.0 authentication methods.

If the *nAuthType* parameter is omitted, it will default to using SMTP_AUTH_LOGIN and this is accepted by most mail servers. It is common for mail servers to allow the SMTP_AUTH_PLAIN method as well, however it is recommended you explicitly check whether the server supports the desired authentication method by calling the **GetExtendedOptions** method. If you attempt to use an authentication type which is not supported by the server, this method will fail and the last error code will be set to ST_ERROR_INVALID_AUTHENTICATION_TYPE.

You should only use an OAuth 2.0 authentication method if you understand the process of how to request the access token. Obtaining an access token requires registering your application with the mail service provider (e.g.: Microsoft or Google), getting a unique client ID associated with your application and then requesting the access token using the appropriate scope for the service. Obtaining the initial token will typically involve interactive confirmation on the part of the user, requiring they grant permission to your application to access their mail account.

The SMTP_AUTH_XOAUTH2 and SMTP_AUTH_BEARER authentication methods are similar, but they are not interchangeable. Both use an OAuth 2.0 bearer token to authenticate the client session, but they differ in how the token is presented to the server. It is currently preferable to use the XOAUTH2 method because it is more widely available and some service providers do not yet support the OAUTHBEARER method.

Your application should not store an OAuth 2.0 bearer token for later use. They have a relatively short lifespan, typically about an hour, and are designed to be used with that session. You should specify offline access as part of the OAuth 2.0 scope if necessary and store the refresh token provided by the service. The refresh token has a much longer validity period and can be used to obtain a new bearer token when needed.

Example

```
DWORD dwOptions = 0;

// Determine which extended options and authentication methods
// are supported by this server

BOOL bExtended = pClient->GetExtendedOptions(&dwOptions);

if (bUseBearerToken)
{
```

```

    if (bExtended && (dwOptions & SMTP_EXTOPT_XOAUTH2))
    {
        INT nResult = pClient->Authenticate(lpszUserName, lpszBearerToken,
SMTP_AUTH_XOAUTH2);

        if (nResult == SMTP_ERROR)
        {
            // An error occurred during authentication; when using an
            // OAuth 2.0 bearer token, this typically means that the token
            // has expired and must be refreshed
            return;
        }
    }
    else
    {
        // The server does not support XOAUTH2
        return;
    }
}
else
{
    if (bExtended && (dwOptions & SMTP_EXTOPT_AUTHLOGIN))
    {
        INT nResult = pClient->Authenticate(lpszUserName, lpszPassword);

        if (nResult == SMTP_ERROR)
        {
            // An error occurred during authentication
            return;
        }
    }
    else
    {
        // The server does not support AUTH LOGIN
        return;
    }
}
}

```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmtpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

CSmtpClient::Cancel Method

```
INT Cancel();
```

The **Cancel** method cancels any outstanding blocking operation in the client, causing the blocking method to fail. The application may then retry the operation or terminate the client session.

Parameters

None.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is SMTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

When the **Cancel** method is called, the blocking method will not immediately fail. An internal flag is set which causes the blocking operation to exit with an error. This means that the application cannot cancel an operation and immediately perform some other operation. Instead it must allow the calling stack to unwind, returning back to the blocking operation before making any further function calls.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmtpv10.lib

See Also

[IsBlocking](#)

CSmtpClient::CloseMessage Method

```
INT CloseMessage();
```

The **CloseMessage** method ends the composition of the current message. The server then queues the message for delivery to each recipient specified by the client.

Parameters

None.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is SMTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **CloseMessage** method should be called after all of the message data has been written to the data stream.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmtpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

CSmtpClient::Command Method

```
INT Command(  
    LPCTSTR LpszCommand,  
    LPCTSTR LpszParameter  
);
```

The **Command** method sends a command to the server, and returns the result code back to the caller. This method is typically used for site-specific commands not directly supported by the API.

Parameters

LpszCommand

The command which will be executed by the server.

LpszParameter

An optional command parameter. If the command requires more than one parameter, then they should be combined into a single string, with a space separating each parameter. If the command does not accept any parameters, this value may be NULL.

Return Value

If the command was successful, the method returns the result code. If the command failed, the method returns SMTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

A list of valid commands can be found in the technical specification for the protocol. Many servers will list supported commands when the HELP command is used.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmtpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

CSmtpClient::Connect Method

```
BOOL Connect(  
    LPCTSTR lpszRemoteHost,  
    UINT nRemotePort,  
    UINT nTimeout,  
    DWORD dwOptions,  
    HWND hEventWnd,  
    UINT uEventMsg  
);
```

The **Connect** method is used to establish a connection with the server.

Parameters

lpszRemoteHost

A pointer to the name of the server to connect to; this may be a fully-qualified domain name or an IP address.

nRemotePort

The port number the server is listening on. A value of zero specifies that the default port number should be used. For standard connections, the default port number is 25. An alternative port is 587, which is commonly used by authenticated clients to submit messages for delivery. For implicit SSL connections, the default port number is 465.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
SMTP_OPTION_NONE	No additional options are specified when establishing a connection with the server. A standard, non-secure connection will be used and the client will not attempt to use extended (ESMTP) features of the protocol. Note that if the mail server requires authentication, the SMTP_OPTION_EXTENDED option must be specified.
SMTP_OPTION_EXTENDED	Extended SMTP commands should be used if possible. This option enables features such as authentication and delivery status notification. If this option is not specified, the library will not attempt to use any extended features. This option is automatically enabled if the connection is established on port 587 because submitting messages for delivery using this port typically requires client authentication.
SMTP_OPTION_TUNNEL	This option specifies that a tunneled TCP

	connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established.
SMTP_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using either the SSL or TLS protocols.
SMTP_OPTION_SECURE	This option specifies that a secure connection should be established with the server and requires that the server support either the SSL or TLS protocol. The client will initiate the secure session using the STARTTLS command.
SMTP_OPTION_SECURE_IMPLICIT	This option specifies the client should attempt to establish a secure connection with the server. The server must support secure connections using either the SSL or TLS protocol, and the secure session must be negotiated immediately after the connection has been established.
SMTP_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
SMTP_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
SMTP_OPTION_FREETHREAD	This option specifies that this instance of the class may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the class instance is synchronized across multiple threads.

hEventWnd

The handle to the event notification window. This window receives messages which notify the client of various asynchronous socket events that occur. If this argument is NULL, then the client session will be blocking and no network events will be sent to the client.

uEventMsg

The message identifier that is used when an asynchronous socket event occurs. This value should be greater than WM_USER as defined in the Windows header files. If the *hEventWnd* argument is NULL, this argument should be specified as WM_NULL.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The use of Windows event notification messages has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

To prevent this method from blocking the main user interface thread, the application should create a background worker thread and establish a connection by calling **Connect** in that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each client session.

If you specify an event notification window, then the client session will be asynchronous. When a message is posted to the notification window, the low word of the *lParam* parameter contains the event identifier. The high word of *lParam* contains the low word of the error code, if an error has occurred. The *wParam* parameter contains the client handle. One or more of the following event identifiers may be sent:

Constant	Description
SMTP_EVENT_CONNECT	The connection to the server has completed. The high word of the <i>lParam</i> parameter should be checked, since this notification message will be posted if an error has occurred.
SMTP_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
SMTP_EVENT_READ	Data is available to read by the client. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the calling process is in asynchronous mode.
SMTP_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
SMTP_EVENT_TIMEOUT	The client has timed out while waiting for a response from the server. Note that under some circumstances this event can be generated for a non-blocking connection, such as when the client is establishing a secure connection.
SMTP_EVENT_CANCEL	The client has canceled the current operation.
SMTP_EVENT_COMMAND	The client has processed a command that was sent to the server. The result code and result string can be used to determine if the

	response to the command. The high word of the IParam parameter should be checked, since this notification message will also be posed if the command cannot be executed.
SMTP_EVENT_PROGRESS	This event notification is sent periodically during lengthy blocking operations, such as retrieving a complete message from the server.

To cancel asynchronous notification and return the client to a blocking mode, use the **DisableEvents** method.

It is recommended that you only establish an asynchronous connection if you understand the implications of doing so. In most cases, it is preferable to create a synchronous connection and create threads for each additional session if more than one active client session is required.

The *dwOptions* argument can be used to specify the threading model that is used by the library when a connection is established. By default, the class instance is initially attached to the thread that created it. From that point on, until the it is released, only the owner may call methods using that instance of the class. The ownership of the class instance may be transferred from one thread to another using the **AttachThread** method.

Specifying the SMTP_OPTION_FREETHREAD option enables any thread to call any method in that instance of the class, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the class instance is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same instance.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmtpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[Authenticate](#), [Disconnect](#), [GetExtendedOptions](#)

CSmtpClient::CreateMessage Method

```
INT CreateMessage(  
    LPCTSTR lpszSender,  
    DWORD dwMessageSize  
);
```

The **CreateMessage** method creates a new message for delivery.

Parameters

lpszSender

A pointer to a string which specifies the email address of the user sending the message. This typically corresponds to the address in the From header of the message, but it is not required that they be the same.

dwMessageSize

An unsigned integer which specifies the size of the message in bytes. If the size of the message is unknown, this value should be zero. This parameter is ignored if the server does not support extended features. If the message size is larger than what the server will accept, this method will fail. Most Internet Service Providers impose a limit on the size of an email message, typically between 5 and 10 megabytes.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is SMTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **CreateMessage** method begins the composition of a new message to be submitted to the mail server for delivery. There are several steps that must be followed when dynamically composing a message for delivery:

1. Call the **CreateMessage** method to begin the message composition. The sender email address should generally be the same address as the one used in the "From" header field in the message.
2. Call the **AddRecipient** method for each recipient of the message. These addresses are typically specified in the "To" and "Cc" header fields in the message. Additional addresses may also be provided which are not specified in the email message itself. This is how one or more blind carbon copies of a message is delivered. Most servers have a limit on the total number of recipients that may be specified for a single message. This limit is usually around 100 addresses.
3. Call the **Write** method to write the contents of the message to the data stream. The application may also choose to use the **AppendMessage** method to write out a large amount of message data, or write the contents of a file to the data stream.
4. Call the **CloseMessage** method to close the message and submit it to the mail server for delivery.

For applications that do not need to dynamically compose the message and already have the message contents stored in a file or memory buffer, the **SendMessage** method is the preferred method of submitting a message for delivery.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmtpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[AddRecipient](#), [AppendMessage](#), [CloseMessage](#), [SendMessage](#), [Write](#)

CSmtpClient::CreateSecurityCredentials Method

```
BOOL CreateSecurityCredentials(  
    DWORD dwProtocol,  
    DWORD dwOptions,  
    LPCTSTR lpszUserName,  
    LPCTSTR lpszPassword,  
    LPCTSTR lpszCertStore,  
    LPCTSTR lpszCertName  
);  
  
BOOL CreateSecurityCredentials(  
    LPCTSTR lpszCertStore,  
    LPCTSTR lpszCertName  
);  
  
BOOL CreateSecurityCredentials(  
    LPCTSTR lpszCertName  
);
```

The **CreateSecurityCredentials** method establishes the security credentials for the client session.

Parameters

dwProtocol

A bitmask of supported security protocols. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_SSL	Either SSL 2.0 or SSL 3.0 should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, TLS will be excluded from the list of supported protocols. Both SSL 2.0 and 3.0 have been deprecated and will never be used unless explicitly specified. It is not recommended that you enable either of these protocols for secure connections because it will cause most servers to reject your connection request, even if a version of TLS is also specified.
SECURITY_PROTOCOL_TLS	Either the TLS 1.0, 1.1 or 1.2 protocol should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols.

	This may be necessary for some servers that reject any attempt to use the older SSL protocol and require that only TLS be used.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This is the recommended version of TLS to use with secure connections.

dwOptions

A value which specifies one or options. This member is constructed by using a bitwise operator with any of the following values:

Constant	Description
CREDENTIAL_STORE_CURRENT_USER	The library will attempt to open a store for the current user using the certificate store name provided in this structure. If no options are specified, then this is the default behavior.
CREDENTIAL_STORE_LOCAL_MACHINE	The library will attempt to open a local machine store using the certificate store name provided in this structure. If this option is specified, the library will always search for a local machine store before searching for the store by that name for the current user.
CREDENTIAL_STORE_FILENAME	The certificate store name is a file that contains the certificate and private key that will be used.

lpzUserName

A pointer to a string which specifies the certificate owner's username. A value of NULL specifies that no username is required. Currently this parameter is not used and any value specified will be ignored.

lpszPassword

A pointer to a string which specifies the certificate owner's password. A value of NULL specifies that no password is required. This parameter is only used if a PKCS12 (PFX) certificate file is specified and that certificate has been secured with a password. This value will be ignored the current user or local machine certificate store is specified.

lpszCertStore

A pointer to a string which specifies the name of the certificate store to open. A certificate store is a collection of certificates and their private keys, typically organized by how they are used. If this value is NULL or points to an empty string, the default certificate store "MY" will be used.

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as VeriSign and Thawte act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. This corresponds to the "Personal" store that is displayed by the certificate manager utility and is the default store used by the library.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as VeriSign and Thawte are installed as part of the operating system and periodically updated by Microsoft.

lpszCertName

A pointer to a null terminated string which specifies the name of the certificate to use. The function will first search the certificate store for a certificate with a matching "friendly name"; this is a name for the certificate that is assigned by the user. Note that the name must match completely, but the comparison is not case sensitive. If no matching certificate is found, the function will then attempt to find a certificate that has a matching common name (also called the certificate subject). This comparison is less stringent, and the first partial match will be returned. If this second search fails, the function will return an error indicating that the certificate could not be found.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Example

```
pClient->CreateSecurityCredentials(  
    SECURITY_PROTOCOL_DEFAULT,  
    0,  
    NULL,  
    NULL,  
    lpszCertStore,  
    lpszCertName);
```

```
bConnected = pClient->Connect(lpszHostName,  
                               SMTP_PORT_SECURE,  
                               SMTP_TIMEOUT,  
                               SMTP_OPTION_SECURE);
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmtpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[Connect](#), [DeleteSecurityCredentials](#), [GetSecurityInformation](#), [SECURITYCREDENTIALS](#)

CSmtpClient::DeleteSecurityCredentials Method

```
VOID DeleteSecurityCredentials();
```

The **DeleteSecurityCredentials** method releases the security credentials for the current session.

Parameters

None.

Return Value

None.

Remarks

This method can be used to release the memory allocated to the client or server credentials after a secure connection has been terminated. The security credentials are released when the class destructor is called, so it is normally not required that the application explicitly call this method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmtpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[CreateSecurityCredentials](#)

CSmtpClient::DetachHandle Method

```
HCLIENT DetachHandle();
```

The **DetachHandle** method detaches the client handle associated with the current instance of the class.

Parameters

None.

Return Value

This method returns the client handle associated with the current instance of the class object. If there is no active client session, the value `INVALID_CLIENT` will be returned.

Remarks

This method is used to detach a client handle created by the class for use with the SocketTools API. Once the client handle is detached from the class, no other class member functions may be called. Note that the handle must be explicitly released at some later point by the process or a resource leak will occur.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csmtpv10.lib`

See Also

[AttachHandle](#), [GetHandle](#)

CSmtpClient::DisableEvents Method

```
INT DisableEvents();
```

The **DisableEvents** method disables the event notification mechanism, preventing subsequent event notification messages from being posted to the application's message queue.

This method has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Parameters

None.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is SMTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **DisableEvents** method is used to disable event message posting for the specified client session. Although this will immediately prevent any new events from being generated, it is possible that messages could be waiting in the message queue. Therefore, an application must be prepared to handle client event messages after this method has been called.

This method is automatically called if the client has event notification enabled, and the **Disconnect** method is called. The same issues regarding outstanding event messages also applies in this situation, requiring that the application handle event messages that may reference a client handle that is no longer valid.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmtpv10.lib

See Also

[EnableEvents](#), [RegisterEvent](#)

CSmtpClient::DisableTrace Method

```
BOOL DisableTrace();
```

The **DisableTrace** method disables the logging of socket function calls to the trace log.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, a value of zero is returned.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmtpv10.lib

See Also

[EnableTrace](#)

CSmtpClient::Disconnect Method

VOID Disconnect();

The **Disconnect** method terminates the connection with the server, closing the socket and releasing the memory allocated for the client session.

Parameters

None.

Return Value

None.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmtpv10.lib

[Connect](#), [IsConnected](#)

CSmtpClient::EnableEvents Method

```
INT EnableEvents(  
    HWND hEventWnd,  
    UINT uEventMsg  
);
```

The **EnableEvents** method enables event notifications using Windows messages.

This method has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Applications should use the **RegisterEvent** method to register an event handler which is invoked when an event occurs.

Parameters

hEventWnd

Handle to the window which will receive the client notification messages. This parameter must specify a valid window handle. If a NULL handle is specified, event notification will be disabled.

uEventMsg

The message that is received when a client event occurs. This value must be greater than 1024.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is SMTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **EnableEvents** method is used to request that notification messages be posted to the specified window whenever a client event occurs. This allows an application to monitor the status of different client operations, such as a file transfer.

The *wParam* argument will contain the client handle, the low word of the *lParam* argument will contain the event ID, and the high word will contain any error code. If no error has occurred, the high word will always have a value of zero. The following events may be generated:

Constant	Description
SMTP_EVENT_CONNECT	The connection to the server has completed. The high word of the <i>lParam</i> parameter should be checked, since this notification message will be posted if an error has occurred.
SMTP_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
SMTP_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
SMTP_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking

	operation. This event is only generated if the client is in asynchronous mode.
SMTP_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
SMTP_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.
SMTP_EVENT_COMMAND	A command has been issued by the client and the server response has been received and processed. This event can be used to log the result codes and messages returned by the server in response to actions taken by the client.
SMTP_EVENT_PROGRESS	The client is in the process of sending or receiving a file on the data channel. This event is called periodically during a transfer so that the client can update any user interface components such as a status control or progress bar.

It is not required that the client be placed in asynchronous mode in order to receive command and progress event notifications. To disable event notification, call the **DisableEvents** method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmtpv10.lib

See Also

[DisableEvents](#), [RegisterEvent](#)

CSmtpClient::EnableTrace Method

```
BOOL EnableTrace(  
    LPCTSTR lpszTraceFile,  
    DWORD dwTraceFlags  
);
```

The **EnableTrace** method enables the logging of socket function calls to a file.

Parameters

lpszTraceFile

A pointer to a string which specifies the name of the trace log file. If this parameter is NULL or an empty string, the default file name **cstrace.log** is used. The file is stored in the directory specified by the TEMP environment variable, if it is defined; otherwise, the current working directory is used.

dwTraceFlags

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
TRACE_INFO	All function calls are written to the trace file. This is the default value.
TRACE_ERROR	Only those function calls which fail are recorded in the trace file.
TRACE_WARNING	Only those function calls which fail or return values which indicate a warning are recorded in the trace file.
TRACE_HEXDUMP	All functions calls are written to the trace file, plus all the data that is sent or received is displayed, in both ASCII and hexadecimal format.
TRACE_PROCESS	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for multithreaded applications that are using worker threads.

Return Value

If the method succeeds, the return value is non-zero. A return value of zero indicates an error. Failure typically indicates that the tracing library **cstrcv10.dll** cannot be loaded on the local system.

Remarks

When trace logging is enabled, the file is opened, appended to and closed for each socket function call. This makes it possible for an application to append its own logging information, however care should be taken to ensure that the file is closed before the next network operation is performed. To limit the size of the log files, enable and disable logging only around those sections of code that you wish to trace.

Note that the TRACE_HEXDUMP trace level generates very large log files since it includes all of the data exchanged between your application and the server.

Trace method logging is managed on a per-thread basis, not for each client handle. This means that all SocketTools libraries and components share the same settings in the current thread. If you

are using multiple SocketTools libraries or components in your application, you only need to enable logging once.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmtpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[DisableTrace](#)

CSmtpClient::ExpandAddress Method

```
INT ExpandAddress(  
    LPCTSTR lpszMailingList,  
    LPTSTR lpszAddresses,  
    INT nMaxLength  
);
```

```
INT ExpandAddress(  
    LPCTSTR lpszMailingList,  
    CString& strAddresses  
);
```

The **ExpandAddress** method expands the specified mailing list, returning the membership of that list.

Parameters

lpszMailingList

Points to a string which specifies the mailing list that the server should expand into full addresses.

lpszAddresses

Points to a buffer that the expanded addresses will be copied into. This argument may also be a **CString** object which will contain the expanded addresses when the method returns.

nMaxLength

Maximum number of characters that may be copied into the buffer, including the terminating null character.

Return Value

If the method succeeds, the return value is the server result code. If the method fails, the return value is SMTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **ExpandAddress** method requests that the server expand the specified email address. Typically this is used to expand aliases which refer to a mailing list, returning all of the members of that list. A server may not support this command, or may restrict its usage. An application should not depend on the ability to expand addresses.

This method cannot be called while a mail message is being composed.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmtpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[AddRecipient](#), [VerifyAddress](#)

CSmtpClient::FreezeEvents Method

```
INT FreezeEvents(  
    BOOL bFreeze  
);
```

The **FreezeEvents** method is used to suspend and resume event handling by the client.

Parameters

bFreeze

A non-zero value specifies that event handling should be suspended by the client. A zero value specifies that event handling should be resumed.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is SMTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

This method should be used when the application does not want to process events, such as when a modal dialog is being displayed. When events are suspended, all client events are queued. If events are re-enabled at a later point, those queued events will be sent to the application for processing. Note that only one of each event will be generated. For example, if the client has suspended event handling, and four read events occur, once event handling is resumed only one of those read events will be posted to the client. This prevents the application from being flooded by a potentially large number of queued events.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmtpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

CSmtpClient::GetCurrentDate Method

```
INT GetCurrentDate(  
    LPTSTR lpszDateString,  
    INT nMaxLength  
);  
  
INT GetCurrentDate(  
    CString& strDateString  
);
```

The **GetCurrentDate** method copies the current date and time to the specified buffer in a format that is commonly used in mail messages. This date format should be used in all date-related fields in the message header.

Parameters

lpszDateString

Pointer to a string buffer that will contain the current date and time when the method returns. This argument may also be a **CString** object.

nMaxLength

The maximum number of characters that can be copied into the string buffer.

Return Values

If the method succeeds, the return value is the number of characters copied into the buffer, not including the null-terminator. If the method fails, the return value is SMTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The date value that is returned is adjusted for the local timezone.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmtpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

CSmtpClient::GetDeliveryOptions Method

```
BOOL GetDeliveryOptions(  
    LPDWORD LpdwOptions  
);
```

The **GetDeliveryOptions** method returns the delivery status notification options for the current session.

Parameters

LpdwOptions

Address of a variable that will be set to the current delivery options. This bitmask is created by combining one or more of the following values with a bitwise Or operator:

Constant	Description
SMTP_NOTIFY_NEVER	Never return information about the success or failure of the message delivery process.
SMTP_NOTIFY_SUCCESS	Return a message to the sender if the message has been successfully delivered to the recipient's mail server.
SMTP_NOTIFY_FAILURE	Return a message to the sender if the message could not be delivered to the recipient's mail server.
SMTP_NOTIFY_DELAY	Return a message to the sender if delivery of the message was delayed.
SMTP_RETURN_HEADERS	Return only the message headers to the sender.
SMTP_RETURN_MESSAGE	Return the complete message headers and body to the sender.

Return Values

If the method succeeds, the return value is a non-zero value. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **GetDeliveryOptions** method returns the current delivery options for the client session. Note that delivery options are only available on those mail servers which support delivery status notification (DSN) using the extended SMTP protocol. The client must connect specifying SMTP_OPTION_EXTENDED in order to use extended server options.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmtpv10.lib

CSmtpClient::GetErrorString Method

```
INT GetErrorString(  
    DWORD dwErrorCode,  
    LPTSTR lpszDescription,  
    INT cbDescription  
);
```

```
INT GetErrorString(  
    DWORD dwErrorCode,  
    CString& strDescription  
);
```

The **GetErrorString** method is used to return a description of a specific error code. Typically this is used in conjunction with the **GetLastError** method for use with warning dialogs or as diagnostic messages.

Parameters

dwErrorCode

The error code for which a description is returned.

lpszDescription

A pointer to the buffer that will contain a description of the specified error code. This buffer should be at least 128 characters in length. An alternate form of the method accepts a **CString** variable which will contain the error description.

cbDescription

The maximum number of characters that may be copied into the description buffer.

Return Value

If the method succeeds, the return value is the length of the description string. If the method fails, the return value is zero, meaning that no description exists for the specified error code. Typically this indicates that the error code passed to the method is invalid.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmtpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[GetLastError](#), [SetLastError](#), [ShowError](#)

CSmtpClient::GetExtendedOptions Method

```
BOOL GetExtendedOptions(  
    LPDWORD LpdwOptions  
);
```

The **GetExtendedOptions** method returns the extended server options for the current session.

Parameters

LpdwOptions

Address of a variable that will be set to the current server options. This bitmask is created by combining one or more of the following values with a bitwise Or operator:

Constant	Description
SMTP_EXTOPT_EXPN	The server supports address expansion using the EXPN command. The ExpandAddress method can be used to expand addresses, which typically returns the email addresses associated with a mailing list. Most public mail servers restrict or disable this functionality because it can present a security risk. If a server does permit the use of the command, it is often limited to specific authorized users.
SMTP_EXTOPT_VRFY	The server supports verification of addresses using the VRFY command. The VerifyAddress method can be used to verify addresses. Most public mail servers restrict the ability for clients to verify email addresses to prevent potential abuse. If a server does permit the use of the command, it is often limited to specific authorized users.
SMTP_EXTOPT_DSN	The server supports delivery status notification (DSN) which allows the sender to be notified when a message has been delivered, or when an error occurs during the delivery process. The SetDeliveryOptions method can be used to specify the delivery options to be used in the current session.
SMTP_EXTOPT_SIZE	The server supports the use of the SIZE parameter, which enables the client to determine the maximum message size that may be delivered through the server. Most public mail servers impose a limit of on the total size of a message, including any encoded attachments.
SMTP_EXTOPT_ETRN	The server supports the use of the ETRN command, instructing the server to start processing its message queues for a specific host. Most public mail servers do not support this capability and its use has been deprecated.
SMTP_EXTOPT_8BITMIME	The server supports the delivery of messages that contain characters with the high bit set. Most servers support this option, however it is recommended that you encode any message text which contains non-ASCII characters to ensure the broadest compatibility with other servers and clients.

SMTP_EXTOPT_STARTTLS	The server supports explicit TLS sessions. This extended option is used internally to determine how secure connections should be established, and if a secure connection can be made using the standard submission port.
SMTP_EXTOPT_UTF8	The server supports UTF-8 encoding in email addresses and the message envelope. Not all mail servers will have this extended capability enabled, and applications should not depend on being able to provide internationalized user and domain names unless this option bitflag has been set.

In addition, there are extended options which specify the authentication methods supported by the server. A server will typically support multiple authentication methods and may be one or more of the following values:

Constant	Description
SMTP_EXTOPT_AUTHLOGIN	The server supports client authentication using the AUTH LOGIN command. This is the default authentication method and is supported by most mail servers. The user name and password are encoded in a specific format, but are not encrypted. The client should use a secure connection whenever possible.
SMTP_EXTOPT_AUTHPLAIN	The server supports client authentication using the AUTH PLAIN command. The use name and password are encoded in a specific format, but are not encrypted. If a server supports this authentication method, it is very likely it also supports AUTH LOGIN. It is recommended you use only use AUTH PLAIN authentication if the server does not support AUTH LOGIN.
SMTP_EXTOPT_XOAUTH2	The server supports client authentication using AUTH XOAUTH2 command. Instead of a password, an OAuth 2.0 bearer token is used to authenticate the user which previously authorized access to the mail server using their account information. The connection must be secure to use this authentication method.
SMTP_EXTOPT_BEARER	The server supports client authentication using AUTH OAUTHBEARER command as specified in RFC 7628. Instead of a password, an OAuth 2.0 bearer token is used to authenticate the user which previously authorized access to the mail server using their account information. The connection must be secure to use this authentication method. The connection must be secure to use this authentication method.

Return Value

If the method succeeds, the return value is a non-zero value. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **GetExtendedOptions** method returns the extended options supported by the server. The use of extended options requires that the server support the ESMTP protocol, and that the client connect using the SMTP_OPTION_EXTENDED option.

You should check these options prior to calling **Authenticate** to determine which authentication methods are acceptable to the server. If you wish to use an OAuth 2.0 bearer token, always check to make sure either the SMTP_EXTOPT_XOAUTH2 or SMTP_EXTOPT_BEARER bitflags are set in the options value returned by this method.

Example

```
BOOL bExtended = FALSE;
DWORD dwOptions = 0;

// Determine which extended options and authentication methods
// are supported by this server

bExtended = pClient->GetExtendedOptions(&dwOptions);

if (bExtended && (dwOptions & SMTP_EXTOPT_XOAUTH2))
{
    INT nResult = pClient->Authenticate(lpszUserName, lpszBearerToken,
SMTP_AUTH_XOAUTH2);

    if (nResult == SMTP_ERROR)
    {
        // An error occurred during authentication; when using an
        // OAuth 2.0 bearer token, this typically means that the token
        // has expired and must be refreshed
        return;
    }
}
else
{
    // The server does not support XOAUTH2
    return;
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

CSmtpClient::GetHandle Method

```
HCLIENT GetHandle();
```

The **GetHandle** method returns the client handle associated with the current instance of the class.

Parameters

None.

Return Value

This method returns the client handle associated with the current instance of the class object. If there is no active client session, the value `INVALID_CLIENT` will be returned.

Remarks

This method is used to obtain the client handle created by the class for use with the SocketTools API.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

CSmtpClient::GetLastError Method

```
DWORD GetLastError();  
  
DWORD GetLastError(  
    CString& strDescription  
);
```

Parameters

strDescription

A string which will contain a description of the last error code value when the method returns. If no error has been set, or the last error code has been cleared, this string will be empty.

Return Value

The return value is the last error code value for the current thread. Functions set this value by calling the **SetLastError** method. The Return Value section of each reference page notes the conditions under which the method sets the last error code.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. You should call the **GetLastError** method immediately when a method's return value indicates that an error has occurred. That is because some methods call **SetLastError(0)** when they succeed, clearing the error code set by the most recently failed method.

Most methods will set the last error code value when they fail; a few methods set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or SMTP_ERROR. Those methods which call **SetLastError** when they succeed are noted on the method reference page.

The description of the error code is the same string that is returned by the **GetErrorString** method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

);  
  
INT GetLocalName(  
    CString& strLocalName  
);
```

The **GetLocalName** method returns the local domain name used to identify the client to the mail server.

Parameters

lpszLocalName

A pointer to the buffer that will contain the local domain name as a string. This may also be a **CString** object which will contain the domain name when the method returns.

cbDescription

The maximum number of characters that may be copied into the string buffer.

Return Value

If the method succeeds, the return value is the length of the domain name string. If the method fails, the return value is zero, meaning that no local domain name has been specified for this client session.

Remarks

If no local domain name has been explicitly set, then the client will use the default domain name for the local host as configured in the operating system. Note that this is not a general purpose method which can be used to determine the domain name that has been assigned to the local host. It will only return the local domain name set by a previous call to the **SetLocalName** method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmtpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[Connect](#), [SetLocalName](#)

CSmtpClient::GetResultCode Method

INT GetResultCode();

The **GetResultCode** method reads the result code returned by the server in response to a command. The result code is a three-digit numeric code, and indicates if the operation succeeded, failed or requires additional action by the client.

Parameters

None.

Return Value

If the method succeeds, the return value is the result code. If the method fails, the return value is SMTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

Result codes are three-digit numeric values returned by the server. They may be broken down into the following ranges:

Value	Description
100-199	Positive preliminary result. This indicates that the requested action is being initiated, and the client should expect another reply from the server before proceeding.
200-299	Positive completion result. This indicates that the server has successfully completed the requested action.
300-399	Positive intermediate result. This indicates that the requested action cannot complete until additional information is provided to the server.
400-499	Transient negative completion result. This indicates that the requested action did not take place, but the error condition is temporary and may be attempted again.
500-599	Permanent negative completion result. This indicates that the requested action did not take place.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmtpv10.lib

See Also

[Command](#), [GetResultString](#)

CSmtpClient::GetResultString Method

```
INT GetResultString(  
    LPTSTR lpszResult,  
    INT cbResult  
);
```

```
INT GetResultString(  
    CString& strResult  
);
```

The **GetResultString** method returns the last message sent by the server along with the result code.

Parameters

lpszResult

A pointer to the buffer that will contain the result string returned by the server. An alternate form of the method accepts a **CString** argument which will contain the result string returned by the server.

cbResult

The maximum number of characters that may be copied into the result string buffer, including the terminating null character.

Return Value

If the method succeeds, the return value is the length of the result string. If a value of zero is returned, this means that no result string was sent by the server. If the method fails, the return value is SMTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetResultString** method is most useful when an error occurs because the server will typically include a brief description of the cause of the error. This can then be parsed by the application or displayed to the user. The result string is updated each time the client sends a command to the server and then calls **GetResultCode** to obtain the result code for the operation.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmtpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[Command](#), [GetResultCode](#)

CSmtpClient::GetSecurityInformation Method

```
BOOL GetSecurityInformation(  
    LPSECURITYINFO LpSecurityInfo  
);
```

The **GetSecurityInformation** method returns security protocol, encryption and certificate information about the current client connection.

Parameters

LpSecurityInfo

A pointer to a [SECURITYINFO](#) structure which contains information about the current client connection. The *dwSize* member of this structure must be initialized to the size of the structure before passing the address of the structure to this method.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

This method is used to obtain security related information about the current client connection to the server. It can be used to determine if a secure connection has been established, what security protocol was selected, and information about the server certificate. Note that a secure connection has not been established, the *dwProtocol* structure member will contain the value SECURITY_PROTOCOL_NONE.

Example

The following example notifies the user if the connection is secure or not:

```
SECURITYINFO securityInfo;  
securityInfo.dwSize = sizeof(SECURITYINFO);  
  
if (pClient->GetSecurityInformation(&securityInfo))  
{  
    if (securityInfo.dwProtocol == SECURITY_PROTOCOL_NONE)  
    {  
        MessageBox(NULL, _T("The connection is not secure"),  
                    _T("Connection"), MB_OK);  
    }  
    else  
    {  
        if (securityInfo.dwCertStatus == SECURITY_CERTIFICATE_VALID)  
        {  
            MessageBox(NULL, _T("The connection is secure"),  
                        _T("Connection"), MB_OK);  
        }  
        else  
        {  
            MessageBox(NULL, _T("The server certificate not valid"),  
                        _T("Connection"), MB_OK);  
        }  
    }  
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmtpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[Connect](#), [CreateSecurityCredentials](#), [SECURITYINFO](#)

CSmtpClient::GetStatus Method

INT GetStatus();

The **GetStatus** method the current status of the client session.

Parameters

None.

Return Value

If the method succeeds, the return value is the client status code. If the method fails, the return value is SMTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetStatus** method returns a numeric code which identifies the current state of the client session. The following values may be returned:

Value	Constant	Description
0	SMTP_STATUS_UNUSED	No connection has been established.
1	SMTP_STATUS_IDLE	The client is current idle and not sending or receiving data.
2	SMTP_STATUS_CONNECT	The client is establishing a connection with the server.
3	SMTP_STATUS_READ	The client is reading data from the server.
4	SMTP_STATUS_WRITE	The client is writing data to the server.
5	SMTP_STATUS_DISCONNECT	The client is disconnecting from the server.

In a multithreaded application, any thread in the current process may call this method to obtain status information for the specified client session.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmtpv10.lib

See Also

[IsBlocking](#), [IsConnected](#), [IsInitialized](#), [IsReadable](#), [IsWritable](#)

CSmtpClient::GetTimeout Method

```
INT GetTimeout();
```

The **GetTimeout** method returns the number of seconds the client will wait for a response from the server. Once the specified number of seconds has elapsed, the method will fail and return to the caller.

Parameters

None.

Return Value

If the method succeeds, the return value is the timeout period in seconds. If the method fails, the return value is SMTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The timeout value is only used with blocking client connections. A value of zero indicates that the default timeout period of 20 seconds should be used.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmtpv10.lib

See Also

[Connect](#), [IsReadable](#), [IsWritable](#), [Read](#), [SetTimeout](#), [Write](#)

CSmtpClient::GetTransferStatus Method

```
INT GetTransferStatus(  
    HCLIENT hClient,  
    LPSMTPTRANSFERSTATUS lpStatus  
);
```

The **GetTransferStatus** method returns information about the message being submitted to the mail server.

Parameters

hClient

Handle to the client session.

lpStatus

A pointer to an [SMTPTRANSFERSTATUS](#) structure which contains information about the status of the message being submitted for delivery.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is SMTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetTransferStatus** method returns information about the current message being submitted, including the average number of bytes transferred per second and the estimated amount of time until the transfer completes. If there is no message currently being submitted, this method will return the status of the last successful submission made by the client.

In a multithreaded application, any thread in the current process may call this method to obtain the status of a submission for the specified client session.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmtpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[EnableEvents](#), [GetStatus](#), [RegisterEvent](#)

CSmtpClient::IsBlocking Method

BOOL IsBlocking();

The **IsBlocking** method is used to determine if the client is currently performing a blocking operation.

Parameters

None.

Return Value

If the client is performing a blocking operation, the method returns a non-zero value. If the client is not performing a blocking operation, or the client handle is invalid, the method returns zero.

Remarks

Because a blocking operation can allow the application to be re-entered (for example, by pressing a button while the operation is being performed), it is possible that another blocking method may be called while it is in progress. Since only one thread of execution may perform a blocking operation at any one time, an error would occur. The **IsBlocking** method can be used to determine if the client is already blocked, and if so, take some other action (such as warning the user that they must wait for the operation to complete).

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmtpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[Cancel](#), [GetStatus](#), [IsConnected](#), [IsInitialized](#), [IsReadable](#), [IsWritable](#), [Read](#), [Write](#)

CSmtpClient::IsConnected Method

```
BOOL IsConnected();
```

The **IsConnected** method is used to determine if the client is currently connected to a server.

Parameters

None.

Return Value

If the client is connected to a server, the method returns a non-zero value. If the client is not connected, or the client handle is invalid, the method returns zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmtpv10.lib

See Also

[GetStatus](#), [IsBlocking](#), [IsInitialized](#), [IsReadable](#), [IsWritable](#)

CSmtpClient::IsInitialized Method

```
BOOL IsInitialized();
```

The **IsInitialized** method returns whether or not the class object has been successfully initialized.

Parameters

None.

Return Value

This method returns a non-zero value if the class object has been successfully initialized. A return value of zero indicates that the runtime license key could not be validated or the networking library could not be loaded by the current process.

Remarks

When an instance of the class is created, the class constructor will attempt to initialize the component with the runtime license key that was created when SocketTools was installed. If the constructor is unable to validate the license key or load the networking libraries, this initialization will fail.

If SocketTools was installed with an evaluation license, the application cannot be redistributed to another system. The class object will fail to initialize if the application is executed on another system, or if the evaluation period has expired. To redistribute your application, you must purchase a development license which will include the runtime key that is needed to redistribute your software to other systems. Refer to the Developer's Guide for more information.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmtpv10.lib

See Also

[CSmtpClient](#), [IsBlocking](#), [IsConnected](#)

CSmtpClient::IsReadable Method

```
BOOL IsReadable(  
    INT nTimeout,  
    LPDWORD lpdwAvail  
);
```

The **IsReadable** method is used to determine if data is available to be read from the server.

Parameters

nTimeout

Timeout for server response, in seconds. A value of zero specifies that the connection should be polled without blocking the current thread.

lpdwAvail

A pointer to an unsigned integer which will contain the number of bytes available to read. This parameter may be NULL if this information is not required.

Return Value

If the client can read data from the server within the specified timeout period, the method returns a non-zero value. If the client cannot read any data, the method returns zero.

Remarks

On some platforms, this value will not exceed the size of the receive buffer (typically 64K bytes). Because of differences between TCP/IP stack implementations, it is not recommended that your application exclusively depend on this value to determine the exact number of bytes available. Instead, it should be used as a general indicator that there is data available to be read.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmtpv10.lib

See Also

[GetStatus](#), [IsBlocking](#), [IsConnected](#), [IsInitialized](#), [IsWritable](#), [Write](#)

CSmtpClient::IsWritable Method

```
BOOL IsWritable(  
    INT nTimeout  
);
```

The **IsWritable** method is used to determine if data can be written to the server.

Parameters

nTimeout

Timeout for server response, in seconds. A value of zero specifies that the connection should be polled without blocking the current thread.

Return Value

If the client can write data to the server within the specified timeout period, the method returns a non-zero value. If the client cannot write any data, the method returns zero.

Remarks

Although this method can be used to determine if some amount of data can be sent to the remote process it does not indicate the amount of data that can be written without blocking the client. In most cases, it is recommended that large amounts of data be broken into smaller logical blocks, typically some multiple of 512 bytes in length.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmtpv10.lib

See Also

[GetStatus](#), [IsBlocking](#), [IsConnected](#), [IsInitialized](#), [IsReadable](#), [Write](#)

CSmtpClient::Read Method

```
INT Read(  
    LPBYTE lpBuffer,  
    INT cbBuffer  
);  
  
INT Read(  
    CString& strBuffer,  
    INT cbBuffer  
);
```

The **Read** method reads the specified number of bytes from the client socket and copies them into the buffer. The data may be of any type, and is not terminated with a null character.

Parameters

lpBuffer

Pointer to the buffer in which the data will be copied. An alternate form of this method allows a **CString** variable to be passed and data read from the socket will be returned in that string.

cbBuffer

The maximum number of bytes to read and copy into the specified buffer. This value must be greater than zero.

Return Value

If the method succeeds, the return value is the number of bytes actually read. A return value of zero indicates that the server has closed the connection and there is no more data available to be read. If the method fails, the return value is SMTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

When **Read** is called and the client is in non-blocking mode, it is possible that the method will fail because there is no available data to read at that time. This should not be considered a fatal error. Instead, the application should simply wait to receive the next asynchronous notification that data is available.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmtpv10.lib

See Also

[EnableEvents](#), [IsBlocking](#), [IsReadable](#), [IsWritable](#), [RegisterEvent](#), [Write](#)

CSmtpClient::RegisterEvent Method

```
INT RegisterEvent(  
    UINT nEventId,  
    SMTPEVENTPROC lpEventProc,  
    DWORD_PTR dwParam  
);
```

The **RegisterEvent** method registers an event handler for the specified event.

Parameters

nEventId

An unsigned integer which specifies which event should be registered with the specified callback function. One of the following values may be used:

Constant	Description
SMTP_EVENT_CONNECT	The connection to the server has completed.
SMTP_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
SMTP_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
SMTP_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
SMTP_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
SMTP_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.
SMTP_EVENT_COMMAND	A command has been issued by the client and the server response has been received and processed. This event can be used to log the result codes and messages returned by the server in response to actions taken by the client.
SMTP_EVENT_PROGRESS	The client is in the process of sending or receiving a file on the data channel. This event is called periodically during a transfer so that the client can update any user interface components such as a status control or progress bar.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **SmtplibEventProc** callback function. If this parameter is NULL, the callback for the specified event is disabled.

dwParam

A user-defined integer value that is passed to the callback function. If the application targets the x86 (32-bit) platform, this parameter must be a 32-bit unsigned integer. If the application targets the x64 (64-bit) platform, this parameter must be a 64-bit unsigned integer.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is SMTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **RegisterEvent** method associates a callback function with a specific event. The event handler is an **SmtplibEventProc** function that is invoked when the event occurs. Arguments are passed to the function to identify the client session, the event type and the user-defined value specified when the event handler is registered. If the event occurs because of an error condition, the error code will be provided to the handler.

This method is typically used to register an event handler that is invoked while a message is being submitted to the server for delivery. The SMTP_EVENT_PROGRESS event will only be generated periodically during the transfer to ensure the application is not flooded with event notifications. It is guaranteed that at least one SMTP_EVENT_PROGRESS notification will occur at the beginning of the transfer, and one at the end of the transfer when it has completed.

The callback function specified by the *lpEventProc* parameter must be declared using the **__stdcall** calling convention. This ensures the arguments passed to the event handler are pushed on to the stack in the correct order. Failure to use the correct calling convention will corrupt the stack and cause the application to terminate abnormally.

The *dwParam* parameter is commonly used to identify the class instance which is associated with the event that has occurred. Applications will cast the **this** pointer to a DWORD_PTR value when calling this function, and then the event handler will cast it back to a pointer to the class instance. This gives the handler access to the class member variables and methods.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmtplib10.lib

See Also

[DisableEvents](#), [EnableEvents](#), [FreezeEvents](#), [SmtplibEventProc](#)

CSmtpClient::Reset Method

```
INT Reset();
```

The **Reset** method resets the client state and resynchronizes with the server. This method is typically called after an unexpected error has occurred, or an operation has been canceled.

Parameters

None.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is SMTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The client cannot be reset while in a blocked state.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmtpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[Cancel](#), [CloseMessage](#), [CreateMessage](#), [IsBlocking](#)

CSmtpClient::SendMessage Method

```
INT SendMessage(  
    LPCTSTR lpszFrom,  
    LPCTSTR lpszRecipient,  
    LPCTSTR lpszFileName  
);
```

```
INT SendMessage(  
    LPCTSTR lpszFrom,  
    LPCTSTR lpszRecipient,  
    LPBYTE lpMessage,  
    DWORD dwMessageSize  
);
```

```
INT SendMessage(  
    LPCTSTR lpszFrom,  
    LPCTSTR lpszRecipient,  
    HGLOBAL hglbMessage,  
    DWORD dwMessageSize  
);
```

The **SendMessage** method sends the contents of a file or buffer to the specified recipients.

Parameters

lpszFrom

Pointer to a string which specifies the email address of the sender.

lpszRecipient

Pointer to a string which specifies the recipient of the message. Multiple recipients may be specified by separating each address with a comma.

lpszFileName

Pointer to a string which specifies a file that contains the message to be delivered.

lpMessage

Pointer to a buffer which contains the message to be delivered. This may also be a global memory handle which references the message data.

dwMessageSize

An unsigned integer which specifies the length of the message in bytes.

Return Value

If the method succeeds, the return value is the result code from the server. If the method fails, the return value is SMTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **SendMessage** method is used to send the contents of a file, buffer or global memory handle to the specified recipients. The message must be in the standard format as described in RFC 822. The **CMailMessage** class can be used to compose and export a message in the correct format.

This protocol is only concerned with the delivery of a message and not its contents. Header fields in the message are not parsed to determine the recipients. This recipient parameter should be a concatenation of all recipients, including carbon copies and blind carbon copies, with each address separated with a comma.

This method will cause the current thread to block until the complete message has been delivered, a timeout occurs or the operation is canceled. During the transfer, the SMTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **EnableEvents**, or by registering a callback function using the **RegisterEvent** method.

To determine the current status of the transaction while it is in progress, use the **GetTransferStatus** method.

An alternative approach to creating a message without using the **CMailMessage** class is the **SubmitMessage** method. It accepts two structure parameters which define the message contents and the connection information for the mail server. This enables the application to compose the message and submit it for delivery in a single method call.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csmtpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[AppendMessage](#), [CloseMessage](#), [GetTransferStatus](#), [SubmitMessage](#)

CSmtpClient::SetDeliveryOptions Method

```
BOOL SetDeliveryOptions(  
    DWORD dwOptions  
);
```

The **SetDeliveryOptions** method sets the delivery status notification options for the current session.

Parameters

dwOptions

A bitmask that defines the current delivery options. This value is created by combining one or more of the following constants with a bitwise Or operator:

Constant	Description
SMTP_NOTIFY_NEVER	Never return information about the success or failure of the message delivery process.
SMTP_NOTIFY_SUCCESS	Return a message to the sender if the message has been successfully delivered to the recipient's mail server.
SMTP_NOTIFY_FAILURE	Return a message to the sender if the message could not be delivered to the recipient's mail server.
SMTP_NOTIFY_DELAY	Return a message to the sender if delivery of the message was delayed.
SMTP_RETURN_HEADERS	Return only the message headers to the sender.
SMTP_RETURN_MESSAGE	Return the complete message headers and body to the sender.

Return Value

If the method succeeds, the return value is a non-zero value. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **SetDeliveryOptions** method sets the current delivery options for the client session. Note that delivery options are only available on those mail servers which support delivery status notification (DSN) using the extended SMTP protocol. The client must connect specifying SMTP_OPTION_EXTENDED in order to use extended server options.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmtpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[GetDeliveryOptions](#), [GetExtendedOptions](#)

CSmtpClient::SetLastError Method

```
VOID SetLastError(  
    DWORD dwErrorCode  
);
```

The **SetLastError** method sets the last error code for the current thread. This method is typically used to clear the last error by specifying a value of zero as the parameter.

Parameters

dwErrorCode

Specifies the last error code for the current thread.

Return Value

None.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. Most methods will set the last error code value when they fail; a few methods set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or SMTP_ERROR. Those methods which call **SetLastError** when they succeed are noted on the method reference page.

Applications can retrieve the value saved by this method by using the **GetLastError** method. The use of **GetLastError** is optional; an application can call the method to determine the specific reason for a method failure.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmtpv10.lib

See Also

[GetErrorString](#), [GetLastError](#), [ShowError](#)

CSmtpClient::SetLocalName Method

```
BOOL SetLocalName(  
    LPCTSTR lpszLocalName  
);
```

The **SetLocalName** method sets the local domain name used to identify the client to the mail server.

Parameters

lpszLocalName

A pointer to a string which specifies the local domain name to be used by the client when establishing a connection with the mail server. A value of NULL or an empty string clears the domain name.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **SetLocalName** method should only be used to specify a domain name if it is absolutely necessary. In most cases, it is preferable to allow the library to automatically determine the correct domain name to use. Providing an invalid domain name may cause the mail server to reject the connection.

This method may only be called prior to establishing a connection with the mail server using the **Connect** method. After the connection has been made, this method will fail. To change the local domain name used by the client, you must first terminate the current session.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmtpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[Connect](#), [GetLocalName](#)

CSmtpClient::SetTimeout Method

```
INT SetTimeout(  
    UINT nTimeout  
);
```

The **SetTimeout** method sets the number of seconds the client will wait for a response from the server. Once the specified number of seconds has elapsed, the method will fail and return to the caller.

Parameters

nTimeout

The number of seconds to wait for a blocking operation to complete.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is SMTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The timeout value is only used with blocking client connections.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmtpv10.lib

CSmtpClient::ShowError Method

```
INT ShowError(  
    LPCTSTR lpszAppTitle,  
    UINT uType,  
    DWORD dwErrorCode  
);
```

The **ShowError** method displays a message box which describes the specified error.

Parameters

lpszAppTitle

A pointer to a string which specifies the title of the message box that is displayed. If this argument is NULL or omitted, then the default title of "Error" will be displayed.

uType

An unsigned integer which specifies the type of message box that will be displayed. This is the same value that is used by the **MessageBox** method in the Windows API. If a value of zero is specified, then a message box with a single OK button will be displayed. Refer to that method for a complete list of options.

dwErrorCode

Specifies the error code that will be used when displaying the message box. If this argument is zero, then the last error that occurred in the current thread will be displayed.

Return Value

If the method is successful, the return value will be the return value from the **MessageBox** function. If the method fails, it will return a value of zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmtpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

CSmtpClient::SubmitMessage Method

```
BOOL SubmitMessage(  
    LPSMTPSERVER LpServer,  
    LPSMTPMESSAGE LpMessage,  
    SMTPEVENTPROC LpEventProc,  
    DWORD_PTR dwParam  
);
```

```
BOOL SubmitMessage(  
    LPSMTPSERVER LpServer,  
    LPSMTPMESSAGEEX LpMessage,  
    SMTPEVENTPROC LpEventProc,  
    DWORD_PTR dwParam  
);
```

The **SubmitMessage** method composes and submits a message for delivery to the specified mail server.

Parameters

lpServer

A pointer to an **SMTPSERVER** structure that contains information about the mail server that the message will be submitted to for delivery. This parameter cannot be NULL and the structure members must be properly initialized prior to calling this function.

lpMessage

A pointer to an **SMTPMESSAGE** or **SMTPMESSAGEEX** structure that contains information about the message, including the sender, recipients and the body of the message. This parameter cannot be NULL and the structure members must be properly initialized prior to calling this function.

lpEventProc

An optional pointer to the procedure-instance address of an application defined callback function. For more information about event handling and the callback function, see the description of the **SmtplibEventProc** callback function. If this parameter is NULL or is omitted, event notification is disabled.

dwParam

An optional user-defined integer value that is passed to the callback function. If the *lpEventProc* parameter is NULL, this value should be zero.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **SmtplibGetLastError**.

Remarks

The **SubmitMessage** method provides a high-level interface that enables an application to send an email message with a single function call. The **SMTPSERVER** and **SMTPMESSAGE** structures are used to provide the function with information about the mail server that will accept the message and the contents of the message itself. Note that this method does not require you to call the **Connect** method prior to calling this function.

If you need to specify additional custom headers in the message that is submitted for delivery, you should use the **SMTPMESSAGEEX** structure. It is an extended version of the message structure

which will allow you to define custom headers to be included in the message.

This method will cause the calling thread to block until the message has been submitted for delivery, an error occurs or the connection to the mail server times out. If an event handler is specified, then the callback function will be periodically invoked as the message is being sent. For large messages, the SMTP_EVENT_PROGRESS event can be used to monitor the submission process and update the user interface. The **GetTransferStatus** method can be used within the callback function to obtain information about the current status of the submission.

Example

```
CSmtpClient smtpClient;

SMTPSERVER mailServer;
ZeroMemory(&mailServer, sizeof(mailServer));
mailServer.lpszHostName = _T("smtp.gmail.com");
mailServer.nHostPort = SMTP_PORT_SUBMIT;
mailServer.lpszUserName = m_strSender;
mailServer.lpszPassword = m_strPassword;
mailServer.dwOptions = SMTP_OPTION_SECURE;

SMTPMESSAGE mailMessage;
ZeroMemory(&mailMessage, sizeof(mailMessage));
mailMessage.lpszFrom = m_strSender;
mailMessage.lpszTo = m_strRecipients;
mailMessage.lpszSubject = m_strSubject;
mailMessage.lpszText = m_strMessage;

if (smtpClient.SubmitMessage(&mailServer, &mailMessage))
    _tprintf(_T("SubmitMessage was successful\n"));
else
{
    CString strError;
    smtpClient.GetErrorString(strError);
    _tprintf(_T("SubmitMessage failed: %s\n"), strError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csmtpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

CSmtpClient::VerifyAddress Method

```
INT VerifyAddress(  
    LPCTSTR lpszAddress,  
    LPTSTR lpszBuffer,  
    INT nMaxLength  
);
```

```
INT VerifyAddress(  
    LPCTSTR lpszAddress,  
    CString& strBuffer  
);
```

The **VerifyAddress** method verifies the specified address is valid.

Parameters

lpszAddress

Points to a string which specifies the address that the server should verify.

lpszBuffer

Points to a buffer that the verified address will be copied into. This argument may also be a **CString** object which will contain the verified address when the method returns.

nMaxLength

Maximum number of characters that may be copied into the buffer, including the terminating null character.

Return Value

If the method succeeds, the return value is the server result code. If the method fails, the return value is SMTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **VerifyAddress** method requests that the server verify the specified email address. Typically this is used to verify that a recipient address is valid, and return a fully qualified email address for that recipient. A server may not support this command, or may restrict its usage. An application should not depend on the ability to verify addresses.

This method cannot be called while a mail message is being composed.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csmtpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[AddRecipient](#), [ExpandAddress](#)

CSmtpClient::Write Method

```
INT Write(  
    LPBYTE lpBuffer,  
    INT cbBuffer  
);  
  
INT Write(  
    LPCTSTR lpszBuffer  
    INT cbBuffer  
);
```

The **Write** method sends the specified number of bytes to the server.

Parameters

lpBuffer

The pointer to the buffer which contains the data that is to be sent to the server. In an alternate form of the method, the pointer is to a string.

cbBuffer

The number of bytes to send from the specified buffer. This value must be greater than zero, unless a pointer to a string buffer is passed as the parameter. In that case, if the value is -1, all of the characters in the string, up to but not including the terminating null character, will be sent to the server.

Return Value

If the method succeeds, the return value is the number of bytes actually written. If the method fails, the return value is SMTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

The return value may be less than the number of bytes specified by the *cbBuffer* parameter. In this case, the data has been partially written and it is the responsibility of the client application to send the remaining data at some later point. For non-blocking clients, the client must wait for the next asynchronous notification message before it resumes sending data.

If the **Write** method is used to send the message contents to the server, the application must first call the **CreateMessage** method to specify the sender and the length of the message, followed by one or more calls to the **AddRecipient** method to specify each recipient of the message. When all of the message text has been submitted to the server, the application must call the **CloseMessage** method.

The message text is filtered by the **Write** method, and it will automatically normalize end-of-line character sequences to ensure the message meets the protocol requirements. The message itself must be in a standard RFC 822 or multi-part MIME message format, or the server may reject the message. Binary data, such as file attachments, should always be encoded. The **CMailMessage** class can be used to compose and export a message in the correct format, which can then be submitted to the server.

It is recommended that most applications use the **SendMessage** method to submit the message for delivery.

An alternative approach to creating a message without using the **CMailMessage** class is the **SubmitMessage** method. It accepts two structure parameters which define the message contents and the connection information for the mail server. This enables the application to compose the

message and submit it for delivery in a single method call.

Requirements

- SMTPSERVER
- SMTPTRANSFERSTATUS
- SYSTEMTIME

SECURITYCREDENTIALS Structure

The **SECURITYCREDENTIALS** structure specifies the information needed by the library to specify additional security credentials, such as a client certificate or private key, when establishing a secure connection.

```
typedef struct _SECURITYCREDENTIALS
{
    DWORD    dwSize;
    DWORD    dwProtocol;
    DWORD    dwOptions;
    DWORD    dwReserved;
    LPCTSTR  lpszHostName;
    LPCTSTR  lpszUserName;
    LPCTSTR  lpszPassword;
    LPCTSTR  lpszCertStore;
    LPCTSTR  lpszCertName;
    LPCTSTR  lpszKeyFile;
} SECURITYCREDENTIALS, *LPSECURITYCREDENTIALS;
```

Members

dwSize

Size of this structure. If the structure is being allocated dynamically, this member must be set to the size of the structure and all other unused structure members must be initialized to a value of zero or NULL.

dwProtocol

A bitmask of supported security protocols. The value of this structure member is constructed by using a bitwise operator with any of the following values:

Constant	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_SSL	Either SSL 2.0 or SSL 3.0 should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, TLS will be excluded from the list of supported protocols. Both SSL 2.0 and 3.0 have been deprecated and will never be used unless explicitly specified. It is not recommended that you enable either of these protocols for secure connections because it will cause most servers to reject your connection request, even if a version of TLS is also specified.
SECURITY_PROTOCOL_TLS	Either the TLS 1.0, 1.1 or 1.2 protocol should be used when establishing a secure connection. The correct protocol is automatically selected, based on

	what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers that reject any attempt to use the older SSL protocol and require that only TLS be used.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This is the recommended version of TLS to use with secure connections.

dwOptions

A value which specifies one or options. This member is constructed by using a bitwise operator with any of the following values:

Constant	Description
CREDENTIAL_STORE_CURRENT_USER	The library will attempt to open a store for the current user using the certificate store name provided in this structure. If no options are specified, then this is the default behavior.
CREDENTIAL_STORE_LOCAL_MACHINE	The library will attempt to open a local machine store using the certificate store name provided in this structure. If this option is specified, the library will always search for a local machine store before searching for the store by that name for the current user.
CREDENTIAL_STORE_FILENAME	The certificate store name is a file that contains the certificate and private key that

will be used.

dwReserved

This structure member is reserved for future use and should always be initialized to zero.

lpszHostName

A pointer to a null terminated string which specifies the hostname that will be used when validating the server certificate. If this member is NULL, then the server certificate will be validated against the hostname used to establish the connection.

lpszUserName

A pointer to a null terminated string which identifies the owner of client certificate. Currently this member is not used by the library and should always be initialized as a NULL pointer.

lpszPassword

A pointer to a null terminated string which specifies the password needed to access the certificate. Currently this member is only used if the CREDENTIAL_STORE_FILENAME option has been specified. If there is no password associated with the certificate, then this member should be initialized as a NULL pointer.

lpszCertStore

A pointer to a null terminated string which specifies the name of the certificate store to open. A certificate store is a collection of certificates and their private keys, typically organized by how they are used. If this value is NULL or points to an empty string, the default certificate store "MY" will be used.

Store Name	Description
------------	-------------

CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as VeriSign and Thawte act as certification authorities.
----	---

MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. This corresponds to the "Personal" store that is displayed by the certificate manager utility and is the default store used by the library.
----	--

ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as VeriSign and Thawte are installed as part of the operating system and periodically updated by Microsoft.
------	--

lpszCertName

A pointer to a null terminated string which specifies the name of the certificate to use. The library will first search the certificate store for a certificate with a matching "friendly name"; this is a name for the certificate that is assigned by the user. Note that the name must match completely, but the comparison is not case sensitive. If no matching certificate is found, the library will then attempt to find a certificate that has a matching common name (also called the certificate subject). This comparison is less stringent, and the first partial match will be returned. If this second search fails, the library will return an error indicating that the certificate could not be found. If the SECURITY_PROTOCOL_SSH protocol has been specified, this member should be NULL.

lpszKeyFile

A pointer to a null terminated string which specifies the name of the file which contains the private key required to establish the connection. This member is only used for SSH connections

and should always be NULL when establishing a secure connection using SSL or TLS.

Remarks

A client application only needs to create this structure if the server requires that the client provide a certificate as part of the process of negotiating the secure session. If a certificate is required, note that it must have a private key associated with it. Attempting to use a certificate that does not have a private key will result in an error during the connection process indicating that the client credentials could not be established.

If you are using a local certificate store, with the certificate and private key stored in the registry, you can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU:" for the current user, or "HKLM:" for the local machine. For example, a certificate store name of "HKLM:MY" would specify the personal certificate store for the local machine, rather than the current user. If neither prefix is specified, then it will default to the certificate store for the current user. You can manage these certificates using the CertMgr.msc Microsoft Management Console (MMC) snap-in.

It is possible to load the certificate from a file rather than from current user's certificate store. The *dwOptions* member should be set to CREDENTIAL_STORE_FILENAME and the *lpzCertStore* member should specify the name of the file that contains the certificate and its private key. The file must be in Private Information Exchange (PFX) format, also known as PKCS#12. These certificate files typically have an extension of .pfx or .p12. Note that if a password was specified when the certificate file was created, it must be provided in the *lpzPassword* member or the library will be unable to access the certificate.

Note that the *lpzUserName* and *lpzPassword* members are values which are used to access the certificate store or private key file. They are not the credentials which are used when establishing the connection with the remote host or authenticating the client session.

The TLS 1.1 and TLS 1.2 protocols are only supported on Windows 7, Windows Server 2008 R2 and later versions of the platform. If these options are specified and the application is running on Windows XP or Windows Vista, the protocol version will be downgraded to TLS 1.0 for backwards compatibility with those platforms.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include ctools10.h

Unicode: Implemented as Unicode and ANSI versions.

SECURITYINFO Structure

This structure contains information about a secure connection that has been established.

```
typedef struct _SECURITYINFO
{
    DWORD        dwSize;
    DWORD        dwProtocol;
    DWORD        dwCipher;
    DWORD        dwCipherStrength;
    DWORD        dwHash;
    DWORD        dwHashStrength;
    DWORD        dwKeyExchange;
    DWORD        dwCertStatus;
    SYSTEMTIME   stCertIssued;
    SYSTEMTIME   stCertExpires;
    LPCTSTR      lpszCertIssuer;
    LPCTSTR      lpszCertSubject;
    LPCTSTR      lpszFingerprint;
} SECURITYINFO, *LPSECURITYINFO;
```

Members

dwSize

Specifies the size of the data structure. This member must always be initialized to **sizeof(SECURITYINFO)** prior to passing the address of this structure to the function. Note that if this member is not initialized, an error will be returned indicating that an invalid parameter has been passed to the function.

dwProtocol

A numeric value which specifies the protocol that was selected to establish the secure connection. One of the following values will be returned:

Constant	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_SSL	Either SSL 2.0 or SSL 3.0 should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, TLS will be excluded from the list of supported protocols. Both SSL 2.0 and 3.0 have been deprecated and will never be used unless explicitly specified. It is not recommended that you enable either of these protocols for secure connections because it will cause most servers to reject your connection request, even if a version of TLS is also specified.
SECURITY_PROTOCOL_TLS	Either the TLS 1.0, 1.1 or 1.2 protocol should be used when establishing a secure connection. The

	<p>correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers that reject any attempt to use the older SSL protocol and require that only TLS be used.</p>
SECURITY_PROTOCOL_TLS10	<p>The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.</p>
SECURITY_PROTOCOL_TLS11	<p>The TLS 1.1 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.</p>
SECURITY_PROTOCOL_TLS12	<p>The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This is the recommended version of TLS to use with secure connections.</p>

dwCipher

A numeric value which specifies the cipher that was selected when establishing the secure connection. One of the following values will be returned:

Constant	Description
SECURITY_CIPHER_RC2	The RC2 block cipher was selected. This is a variable key length cipher which supports keys between 40 and 128 bits, in 8-bit increments.
SECURITY_CIPHER_RC4	The RC4 stream cipher was selected. This is a variable key length cipher which supports keys between 40 and 128 bits, in 8-bit increments.
SECURITY_CIPHER_RC5	The RC5 block cipher was selected. This is a variable key length cipher which supports keys up to 2040 bits, in 8-bit increments.
SECURITY_CIPHER_DES	The DES (Data Encryption Standard) block cipher was selected. This is a fixed key length cipher, using 56-bit

	keys.
SECURITY_CIPHER_DES3	The Triple DES block cipher was selected. This cipher encrypts the data three times using different keys, effectively providing a 168-bit length key.
SECURITY_CIPHER_DESX	A variant of the DES block cipher which XORs an extra 64-bits of the key before and after the plaintext has been encrypted, increasing the key size to 184 bits.
SECURITY_CIPHER_AES	The Advanced Encryption Standard cipher (also known as the Rijndael cipher) is a fixed block size cipher which use a key size of 128, 192 or 256 bits. This cipher is supported on Windows XP SP3 and later versions of the operating system.
SECURITY_CIPHER_SKIPJACK	The Skipjack block cipher was selected. This is a fixed key length cipher, using 80-bit keys.
SECURITY_CIPHER_BLOWFISH	The Blowfish block cipher was selected. This is a variable key length cipher up to 448 bits, using a 64-bit block size.

dwCipherStrength

A numeric value which specifies the strength (the length of the cipher key in bits) of the cipher that was selected. Typically this value will be 128 or 256. 40-bit and 56-bit key lengths are considered weak encryption, and subject to brute force attacks. 128-bit and 256-bit key lengths are considered to be secure, and are the recommended key length for secure communications.

dwHash

A numeric value which specifies the hash algorithm which was selected. One of the following values will be returned:

Constant	Description
SECURITY_HASH_MD5	The MD5 algorithm was selected. Its use has been deprecated and is no longer considered to be cryptographically secure.
SECURITY_HASH_SHA1	The SHA-1 algorithm was selected. Its use has been deprecated and is no longer considered to be cryptographically secure.
SECURITY_HASH_SHA256	The SHA-256 algorithm was selected.
SECURITY_HASH_SHA384	The SHA-384 algorithm was selected.
SECURITY_HASH_SHA512	The SHA-512 algorithm was selected.

dwHashStrength

A numeric value which specifies the strength (the length in bits) of the message digest that was selected.

dwKeyExchange

A numeric value which specifies the key exchange algorithm which was selected. One of the following values will be returned:

--	--

Constant	Description
SECURITY_KEYEX_RSA	The RSA public key algorithm was selected.
SECURITY_KEYEX_KEA	The Key Exchange Algorithm (KEA) was selected. This is an improved version of the Diffie-Hellman public key algorithm.
SECURITY_KEYEX_DH	The Diffie-Hellman key exchange algorithm was selected.
SECURITY_KEYEX_ECDH	The Elliptic Curve Diffie-Hellman key exchange algorithm was selected. This is a variant of the Diffie-Hellman algorithm which uses elliptic curve cryptography. This key exchange algorithm is only supported on Windows XP SP3 and later versions of the operating system.

dwCertStatus

A numeric value which specifies the status of the certificate returned by the secure server. This member only has meaning for connections using the SSL or TLS protocols. One of the following values will be returned:

Constant	Description
SECURITY_CERTIFICATE_VALID	The certificate is valid.
SECURITY_CERTIFICATE_NOMATCH	The certificate is valid, but the domain name does not match the common name in the certificate.
SECURITY_CERTIFICATE_EXPIRED	The certificate is valid, but has expired.
SECURITY_CERTIFICATE_REVOKED	The certificate has been revoked and is no longer valid.
SECURITY_CERTIFICATE_UNTRUSTED	The certificate or certificate authority is not trusted on the local system.
SECURITY_CERTIFICATE_INVALID	The certificate is invalid. This typically indicates that the internal structure of the certificate has been damaged.

stCertIssued

A structure which contains the date and time that the certificate was issued by the certificate authority. If the issue date cannot be determined for the certificate, the SYSTEMTIME structure members will have zero values. This member only has meaning for connections using the SSL or TLS protocols.

stCertExpires

A structure which contains the date and time that the certificate expires. If the expiration date cannot be determined for the certificate, the SYSTEMTIME structure members will have zero values. This member only has meaning for connections using the SSL or TLS protocols.

lpszCertIssuer

A pointer to a string which contains information about the organization that issued the certificate. This string consists of one or more comma-separated tokens. Each token consists of an identifier, followed by an equal sign and a value. If the certificate issuer could not be determined, this member may be NULL. This member only has meaning for connections using the SSL or TLS protocols.

lpszCertSubject

A pointer to a string which contains information about the organization that the certificate was issued to. This string consists of one or more comma-separated tokens. Each token consists of an identifier, followed by an equal sign and a value. If the certificate subject could not be determined, this member may be NULL. This member only has meaning for connections using the SSL or TLS protocols.

lpszFingerprint

A pointer to a string which contains a sequence of hexadecimal values that uniquely identify the server. This member is only used when a connection has been established using the Secure Shell (SSH) protocol.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Unicode: Implemented as Unicode and ANSI versions.

SMTPMESSAGE Structure

This structure provides information about the contents of a message and is used by the [SubmitMessage](#) method.

```
typedef struct _SMTPMESSAGE
{
    LPCTSTR lpszFrom;
    LPCTSTR lpszTo;
    LPCTSTR lpszCc;
    LPCTSTR lpszBcc;
    LPCTSTR lpszSubject;
    LPCTSTR lpszText;
    LPCTSTR lpszHTML;
    LPCTSTR lpszAttach;
    UINT nCharSet;
    UINT nEncType;
    DWORD dwReserved;
} SMTPMESSAGE, *LPSMTPMESSAGE;
```

Members

lpszFrom

A pointer to a string that specifies the email address of the person sending the message. This structure member must point to a valid address and cannot be NULL.

lpszTo

A pointer to a string that specifies the email addresses of one or more recipients. If multiple addresses are provided, they must be separated by commas or semi-colons. This structure member must point to at least one valid address and cannot be NULL.

lpszCc

A pointer to a string that specifies the email addresses of one or more recipients that will receive copies of the message. If multiple addresses are provided, they must be separated by commas or semi-colons. This structure member may be NULL or point to an empty string.

lpszBcc

A pointer to a string that specifies the email addresses of one or more recipients that will receive blind copies of the message. If multiple addresses are provided, they must be separated by commas or semi-colons. This structure member may be NULL or point to an empty string. Unlike the recipients specified by the *lpszTo* and *lpszCc* members, any addresses specified by this member will not be included in the header of the email message.

lpszSubject

A pointer to a string that specifies the subject of the message. This structure member may be NULL, in which case no subject will be included in the message.

lpszText

A pointer to a string which contains the body of the message as plain text. Each line of text contained in the string should be terminated with a carriage-return and linefeed (CRLF) pair, which is recognized as the end-of-line. If this structure member is NULL or points to an empty string, then the *lpszHTML* member must specify the body of the message.

lpszHTML

A pointer to a string which contains the message using HTML formatting. If the *lpszText* member is not NULL, then a multipart message will be created with both plain text and HTML

text as the alternative. This allows mail clients to select which message body they wish to display. If the *lpszText* member is NULL or points to an empty string, then the message will only contain HTML. Although this is supported, it is not recommended because older mail clients may be unable to display the message correctly.

lpszAttach

A pointer to a string which specifies one or more file attachments for the message. If multiple files are to be attached to the message, each file name must be separated by a semi-colon. It is recommended that you provide the complete path to the file. If this structure member is NULL or points to an empty string, the message will be created without attachments.

nCharSet

A integer value which specifies the character set to use when composing the message. A value of zero specifies that the default USASCII character set should be used. The following values may also be used:

Constant	Description
MIME_CHARSET_USASCII	Each character is encoded in one or more bytes, with each byte being 8 bits long, with the first bit cleared. This encoding is most commonly used with plain text using the US-ASCII character set, where each character is represented by a single byte in the range of 20h to 7Eh.
MIME_CHARSET_ISO8859_1	An 8-bit character set for most western European languages such as English, French, Spanish and German. This character set is also commonly referred to as Latin1.
MIME_CHARSET_ISO8859_2	An 8-bit character set for most central and eastern European languages such as Czech, Hungarian, Polish and Romanian. This character set is also commonly referred to as Latin2.
MIME_CHARSET_ISO8859_5	An 8-bit character set for Cyrillic languages such as Russian, Bulgarian and Serbian.
MIME_CHARSET_ISO8859_6	An 8-bit character set for Arabic languages. Note that the application is responsible for displaying text that uses this character set. In particular, any display engine needs to be able to handle the reverse writing direction and analyze the context of the message to correctly combine the glyphs.
MIME_CHARSET_ISO8859_7	An 8-bit character set for the Greek language.
MIME_CHARSET_ISO8859_8	An 8-bit character set for the Hebrew language. Note that similar to Arabic, Hebrew uses a reverse writing direction. An application which displays this character should be capable of processing bi-directional text where a single message may include both right-to-left and left-to-right languages, such as Hebrew and English.
MIME_CHARSET_ISO8859_9	An 8-bit character set for the Turkish language. This character set is also commonly referred to as Latin5.

nEncType

A numeric identifier which specifies the encoding type to use when composing the message. A value of zero specifies that default 7bit encoding should be used. The following values may also be used:

Constant	Description
MIME_ENCODING_7BIT	Each character is encoded in one or more bytes, with each byte being 8 bits long, with the most significant bit cleared. This encoding is most commonly used with plain text using the US-ASCII character set, where each character is represented by a single byte in the range of 20h to 7Eh.
MIME_ENCODING_8BIT	Each character is encoded in one or more bytes, with each byte being 8 bits long and all bits are used. 8-bit encoding is typically used with multibyte character sets and is the default encoding used with Unicode text.
MIME_ENCODING_QUOTED	Quoted-printable encoding is designed for textual messages where most of the characters are represented by the ASCII character set and is generally human-readable. Non-printable characters or 8-bit characters with the high bit set are encoded as hexadecimal values and represented as 7-bit text. Quoted-printable encoding is typically used for messages which use character sets such as ISO-8859-1, as well as those which use HTML.

dwReserved

An unsigned integer value reserved for future use. This structure member should always have a value of zero.

Remarks

This structure is used to define the contents of a message that will be submitted for delivery using the **SmtplibSubmitMessage** function. It is required that you specify a sender, at least one recipient and a message body. All other structure members may be NULL or have a value of zero to indicate that either the value is not required, or that a default should be used. It is recommended that you initialize all of the structure members to a value of zero using the **ZeroMemory** function prior to populating the structure.

email addresses may be specified as simple addresses, or as commented addresses that include the sender's name or other information. For example, any one of these address formats are acceptable:

```
user@domain.tld
User Name <user@domain.tld>
user@domain.tld (User Name)
```

To specify multiple addresses, you should separate each address by a comma or semi-colon. Note that the *lpszFrom* member cannot specify multiple addresses, however it is permitted with the *lpszTo*, *lpszCc* and *lpszBcc* structure members. Each message must have at least one valid recipient, or the message cannot be submitted for delivery.

To send a message that contains HTML, it is recommended that you provide both a plain text version of the message body and an HTML formatted version. While it is permitted to send a

message that only contains HTML, some older mail clients may not be capable of displaying the message correctly. In some cases, anti-spam software will increase the spam score of messages that do not contain a plain text message body. This can result in your message being rejected or quarantined by the mail server.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Unicode: Implemented as Unicode and ANSI versions.

See Also

[SMTPSERVER](#)

SMTPMESSAGEEX Structure

This structure provides information about the contents of a message and is used by the [SubmitMessage](#) method.

```
typedef struct _SMTPMESSAGEEX
{
    DWORD    dwSize
    LPCTSTR  lpszFrom;
    LPCTSTR  lpszTo;
    LPCTSTR  lpszCc;
    LPCTSTR  lpszBcc;
    LPCTSTR  lpszDate;
    LPCTSTR  lpszSubject;
    LPCTSTR  lpszHeaders;
    LPCTSTR  lpszText;
    LPCTSTR  lpszHTML;
    LPCTSTR  lpszAttach;
    UINT     nCharSet;
    UINT     nEncType;
    DWORD    dwReserved;
} SMTPMESSAGEEX, *LPSMTPMESSAGEEX;
```

Members

dwSize

An integer value that specifies the size of the **SMTPMESSAGEEX** data structure. This must always be explicitly defined, and if the value is incorrect, an error will be returned. This structure member is used to ensure that the correct version of the structure is being passed to the method.

lpszFrom

A pointer to a string that specifies the email address of the person sending the message. This structure member must point to a valid address and cannot be NULL.

lpszTo

A pointer to a string that specifies the email addresses of one or more recipients. If multiple addresses are provided, they must be separated by commas or semi-colons. This structure member must point to at least one valid address and cannot be NULL.

lpszCc

A pointer to a string that specifies the email addresses of one or more recipients that will receive copies of the message. If multiple addresses are provided, they must be separated by commas or semi-colons. This structure member may be NULL or point to an empty string.

lpszBcc

A pointer to a string that specifies the email addresses of one or more recipients that will receive blind copies of the message. If multiple addresses are provided, they must be separated by commas or semi-colons. This structure member may be NULL or point to an empty string. Unlike the recipients specified by the *lpszTo* and *lpszCc* members, any addresses specified by this member will not be included in the header of the email message.

lpszDate

A pointer to a string that specifies the date and time for the message. This structure member may be NULL or point to an empty string. If the date is not specified, then the current date and time will be used by default. If a date is specified, it should be in the standard format as defined

by RFC822.

lpzSubject

A pointer to a string that specifies the subject of the message. This structure member may be NULL, in which case no subject will be included in the message.

lpzHeaders

A pointer to a string that specifies additional headers that should be included in the message. Header names should be separated from values by a colon, and multiple headers may be defined by separating them with a newline character. This structure member may be NULL, in which case no additional headers will be included in the message.

lpzText

A pointer to a string which contains the body of the message as plain text. Each line of text contained in the string should be terminated with a carriage-return and linefeed (CRLF) pair, which is recognized as the end-of-line. If this structure member is NULL or points to an empty string, then the *lpzHTML* member must specify the body of the message.

lpzHTML

A pointer to a string which contains the message using HTML formatting. If the *lpzText* member is not NULL, then a multipart message will be created with both plain text and HTML text as the alternative. This allows mail clients to select which message body they wish to display. If the *lpzText* member is NULL or points to an empty string, then the message will only contain HTML. Although this is supported, it is not recommended because older mail clients may be unable to display the message correctly.

lpzAttach

A pointer to a string which specifies one or more file attachments for the message. If multiple files are to be attached to the message, each file name must be separated by a semi-colon. It is recommended that you provide the complete path to the file. If this structure member is NULL or points to an empty string, the message will be created without attachments.

nCharSet

A integer value which specifies the character set to use when composing the message. A value of zero specifies that the default USASCII character set should be used. The following values may also be used:

Constant	Description
MIME_CHARSET_USASCII	Each character is encoded in one or more bytes, with each byte being 8 bits long, with the first bit cleared. This encoding is most commonly used with plain text using the US-ASCII character set, where each character is represented by a single byte in the range of 20h to 7Eh.
MIME_CHARSET_ISO8859_1	An 8-bit character set for most western European languages such as English, French, Spanish and German. This character set is also commonly referred to as Latin1.
MIME_CHARSET_ISO8859_2	An 8-bit character set for most central and eastern European languages such as Czech, Hungarian, Polish and Romanian. This character set is also commonly referred to as Latin2.
MIME_CHARSET_ISO8859_5	An 8-bit character set for Cyrillic languages such as Russian, Bulgarian and Serbian.

MIME_CHARSET_ISO8859_6	An 8-bit character set for Arabic languages. Note that the application is responsible for displaying text that uses this character set. In particular, any display engine needs to be able to handle the reverse writing direction and analyze the context of the message to correctly combine the glyphs.
MIME_CHARSET_ISO8859_7	An 8-bit character set for the Greek language.
MIME_CHARSET_ISO8859_8	An 8-bit character set for the Hebrew language. Note that similar to Arabic, Hebrew uses a reverse writing direction. An application which displays this character should be capable of processing bi-directional text where a single message may include both right-to-left and left-to-right languages, such as Hebrew and English.
MIME_CHARSET_ISO8859_9	An 8-bit character set for the Turkish language. This character set is also commonly referred to as Latin5.

nEncType

A numeric identifier which specifies the encoding type to use when composing the message. A value of zero specifies that default 7bit encoding should be used. The following values may also be used:

Constant	Description
MIME_ENCODING_7BIT	Each character is encoded in one or more bytes, with each byte being 8 bits long, with the most significant bit cleared. This encoding is most commonly used with plain text using the US-ASCII character set, where each character is represented by a single byte in the range of 20h to 7Eh.
MIME_ENCODING_8BIT	Each character is encoded in one or more bytes, with each byte being 8 bits long and all bits are used. 8-bit encoding is typically used with multibyte character sets and is the default encoding used with Unicode text.
MIME_ENCODING_QUOTED	Quoted-printable encoding is designed for textual messages where most of the characters are represented by the ASCII character set and is generally human-readable. Non-printable characters or 8-bit characters with the high bit set are encoded as hexadecimal values and represented as 7-bit text. Quoted-printable encoding is typically used for messages which use character sets such as ISO-8859-1, as well as those which use HTML.

dwReserved

An unsigned integer value reserved for future use. This structure member should always have a value of zero.

Remarks

This structure is used to define the contents of a message that will be submitted for delivery using

the **SubmitMessage** method. It is required that you specify a sender, at least one recipient and a message body. Other structure members may be NULL or have a value of zero to indicate that either the value is not required, or that a default should be used. It is recommended that you initialize all of the structure members to a value of zero using the **ZeroMemory** function prior to populating the structure.

Note that you must explicitly define the size of the structure by setting the value of the **dwSize** member variable. This ensures that the correct version of the structure is being passed to the method.

Email addresses may be specified as simple addresses, or as commented addresses that include the sender's name or other information. For example, any one of these address formats are acceptable:

```
user@domain.tld
User Name <user@domain.tld>
user@domain.tld (User Name)
```

To specify multiple addresses, you should separate each address by a comma or semi-colon. Note that the **lpzFrom** member cannot specify multiple addresses, however it is permitted with the **lpzTo**, **lpzCc** and **lpzBcc** structure members. Each message must have at least one valid recipient, or the message cannot be submitted for delivery.

If you specify a message date by assigning a value to the **lpzDate** member, and it does not include any timezone information, Coordinated Universal Time (UTC) will be used by default. This is an important consideration if you provide input from a user, because in most cases they will not include the timezone and will assume the date and time they enter is for their current timezone.

If you wish to include additional headers in the message, you can specify them in a string. Each header consists of a name and value, separated by a colon (":") character. If you wish to define multiple headers, then you can separate them with a newline (e.g.: a linefeed character or combination of a carriage-return and linefeed). Extraneous leading and trailing whitespace are trimmed from header names and values. Invalid names or values will be ignored and will not generate an error.

To send a message that contains HTML, it is recommended that you provide both a plain text version of the message body and an HTML formatted version. While it is permitted to send a message that only contains HTML, some older mail clients may not be capable of displaying the message correctly. In some cases, anti-spam software will increase the spam score of messages that do not contain a plain text message body. This can result in your message being rejected or quarantined by the mail server.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Unicode: Implemented as Unicode and ANSI versions.

[SMTPSERVER](#)

SMTPSERVER Structure

This structure provides connection information for a mail server and is used by the [SubmitMessage](#) method.

```
typedef struct _SMTPSERVER
{
    LPCTSTR lpszHostName;
    LPCTSTR lpszUserName;
    LPCTSTR lpszPassword;
    UINT nHostPort;
    UINT nTimeout;
    DWORD dwOptions;
    DWORD dwReserved;
} SMTPSERVER, *LPSMTPSERVER;
```

Members

lpszHostName

A pointer to a string that specifies the host name or IP address of the mail server. This structure member cannot be NULL.

lpszUserName

A pointer to a string that specifies the username that will be used to authenticate the client session. If the mail server does not require authentication, this structure member can be NULL or point to an empty string.

lpszPassword

A pointer to a string that specifies the password that will be used to authenticate the client session. If the mail server does not require authentication, this structure member can be NULL or point to an empty string.

nHostPort

An integer value that specifies the port number used to establish the connection. A value of zero specifies that the default port number should be used. For standard connections, the default port number is 25. An alternative port is 587, which is commonly used by authenticated clients to submit messages for delivery. For implicit SSL connections, the default port number is 465.

nTimeout

An integer value that specifies the number of seconds that the client will wait for a response from the server before failing the operation. A value of zero specifies the default timeout period of 20 seconds.

dwOptions

An unsigned integer that specifies one or more options. The value of this structure member is constructed by using a bitwise operator with any of the following values:

Constant	Description
SMTP_OPTION_NONE	No additional options are specified when establishing a connection with the server. A standard, non-secure connection will be used.
SMTP_OPTION_EXTENDED	Extended SMTP commands should be used if possible. This option enables features such as

	authentication and delivery status notification. If this option is not specified, the library will not attempt to use any extended features. This option is automatically enabled if a username and password are specified, or if the connection is established on port 587, because submitting messages for delivery using this port typically requires client authentication.
SMTP_OPTION_TUNNEL	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established.
SMTP_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using either the SSL or TLS protocols.
SMTP_OPTION_SECURE	This option specifies that a secure connection should be established with the server and requires that the server support either the SSL or TLS protocol. The client will initiate the secure session using the STARTTLS command.
SMTP_OPTION_SECURE_IMPLICIT	This option specifies the client should attempt to establish a secure connection with the server. The server must support secure connections using either the SSL or TLS protocol, and the secure session must be negotiated immediately after the connection has been established.

dwReserved

An unsigned integer value reserved for future use. This structure member should always have a value of zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Unicode: Implemented as Unicode and ANSI versions.

See Also

[SMTPMESSAGE](#)

SMTPTTRANSFERSTATUS Structure

This structure is used by the [GetTransferStatus](#) method to return information about a message being submitted for delivery.

```
typedef struct _SMTPTTRANSFERSTATUS
{
    DWORD    dwBytesTotal;
    DWORD    dwBytesCopied;
    DWORD    dwBytesPerSecond;
    DWORD    dwTimeElapsed;
    DWORD    dwTimeEstimated;
} SMTPTTRANSFERSTATUS, *LPSMTPTTRANSFERSTATUS;
```

Members

dwBytesTotal

The total number of bytes that will be transferred. If the size of the message cannot be determined, this value will be zero.

dwBytesCopied

The total number of bytes that have been copied.

dwBytesPerSecond

The average number of bytes that have been copied per second.

dwTimeElapsed

The number of seconds that have elapsed since the file transfer started.

dwTimeEstimated

The estimated number of seconds until the transfer is completed. This is based on the average number of bytes transferred per second.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

SYSTEMTIME Structure

The **SYSTEMTIME** structure represents a date and time using individual members for the month, day, year, weekday, hour, minute, second, and millisecond.

```
typedef struct _SYSTEMTIME
{
    WORD wYear;
    WORD wMonth;
    WORD wDayOfWeek;
    WORD wDay;
    WORD wHour;
    WORD wMinute;
    WORD wSecond;
    WORD wMilliseconds;
} SYSTEMTIME, *LPSYSTEMTIME;
```

Members

wYear

Specifies the current year. The year value must be greater than 1601.

wMonth

Specifies the current month. January is 1, February is 2 and so on.

wDayOfWeek

Specifies the current day of the week. Sunday is 0, Monday is 1 and so on.

wDay

Specifies the current day of the month

wHour

Specifies the current hour.

wMinute

Specifies the current minute

wSecond

Specifies the current second.

wMilliseconds

Specifies the current millisecond.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include windows.h.

SocketWrench Class Library

A general purpose TCP/IP networking library for developing client and server applications.

Reference

- [Class Methods](#)
- [Data Structures](#)
- [Error Codes](#)

Library Information

Class Name	CSocketWrench
File Name	CSWSKV10.DLL
Version	10.0.1468.2518
LibID	1437629B-0693-44DE-93ED-1482DBEFE8DC
Import Library	CSWSKV10.LIB
Dependencies	None
Standards	RFC 768, RFC 791, RFC 793

Overview

At the core of all of the SocketTools networking libraries is the Windows Sockets API. This provides a low level interface for sending and receiving data over the Internet or a local intranet using the Transmission Control Protocol (TCP) and/or User Datagram Protocol (UDP). The SocketWrench class library provides a simpler interface to the Windows Sockets API, without sacrificing features or functionality. Using SocketWrench, you can easily create client and server applications while avoiding many of the mundane tasks and common problems that developers face when building Internet applications.

This class library supports secure connections using the TLS 1.2 protocol and can also be used to create secure, customized server applications. Both implicit and explicit SSL connections are supported, enabling the class to work with a wide variety of client and server applications without requiring that you use third-party libraries or Microsoft's CryptoAPI.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). If you are using Visual C++ 6.0 it is required that you have Service Pack 6 (SP6) installed. You should install all updates for your development tools and have the current Windows SDK installed. The minimum recommended version of Visual Studio is Visual Studio 2010.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are using Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. It is recommended that you install the current service pack and all critical updates available for your version of the operating system.

This class provides an implementation of a multithreaded server which should only be used with languages that support the creation of multithreaded applications. It is important that you do not link against static libraries which were not built with support for threading.

This product includes both 32-bit and 64-bit libraries. Native 64-bit CPU support requires the 64-bit version of Windows 7 or later versions of the Windows operating system.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

SocketWrench Class Methods

Class	Description
CSocketWrench	Constructor which initializes the current instance of the class
~CSocketWrench	Destructor which releases resources allocated by the class
Method	Description
Abort	Abort the connection and immediately close the socket
Accept	Accept a connection request from a remote host
AttachHandle	Attach the specified client handle to this instance of the class
AttachThread	Attach the specified socket to another thread
Cancel	Cancel a blocking operation
CompareAddress	Compare two IP addresses to determine if they are identical
Connect	Connect to the specified server
CreateSecurityCredentials	Create a new security credentials structure
DeleteSecurityCredentials	Delete a previously created security credentials structure
DetachHandle	Detach the handle for the current instance of this class
DisableEvents	Disable asynchronous event notification
DisableSecurity	Disable secure communication with the remote host
DisableTrace	Disable logging of socket function calls to the trace log
Disconnect	Disconnect from the current server
EnableEvents	Enable asynchronous event notification
EnableSecurity	Enable secure communication with the remote host
EnableTrace	Enable logging of socket function calls to a file
EnumNetworkAddresses	Return the list of network addresses that are configured for the local host
Flush	Flush the send and receive buffers
FormatAddress	Convert an IP address in binary format into a printable string
FreezeEvents	Suspend or resume event handling by the application
GetAdapterAddress	Return the IP or MAC assigned to the specified network adapter
GetAddress	Convert an IP address string to a binary format
GetAddressFamily	Return the address family for the specified IP address
GetDefaultHostFile	Return the fully qualified path name of the host file on the local system
GetErrorString	Return a description for the specified error code
GetExternalAddress	Return the external IP address assigned to the local system
GetFirstAlias	Return the first alias for the specified host name
GetHandle	Return the client handle used by this instance of the class

GetHostAddress	Return the IP address assigned to the specified hostname
GetHostFile	Return the name of the host file
GetHostName	Return the hostname assigned to the specified IP address
GetLastError	Return the last error code
GetLocalAddress	Return the local IP address and port number for a socket
GetLocalName	Return the hostname assigned to the local system
GetNextAlias	Return the next alias for the specified host name
GetOption	Return the current socket options
GetPeerAddress	Return the IP address of the peer that the socket is connected to
GetPeerPort	Returns the remote port number used by the client to establish the connection
GetPhysicalAddress	Return the media access control (MAC) address for the primary network adapter
GetSecurityInformation	Return information about the security characteristics of a connection
GetServiceName	Return the service name associated with a specified port number
GetServicePort	Return the port number associated with a service name
GetStatus	Report what sort of socket operation is in progress
GetStreamInfo	Return information about the current stream read or write operation
GetTimeout	Return the timeout interval for blocking operations, in seconds
HostNameToUnicode	Converts the canonical form of a host name to its Unicode version
InetEventProc	Callback method that processes events generated on the socket
IsAddressNull	Determine if the specified IP address is a null address
IsAddressRoutable	Determine if the specified IP address is routable over the Internet
IsBlocking	Determine if the socket is performing a blocking operation
IsClosed	Determine if the remote host has closed its socket
IsConnected	Determine if the socket is connected to a remote host
IsInitialized	Determine if the class has been successfully initialized
IsListening	Determine if the socket is listening for a connection
IsProtocolAvailable	Determine if the specified protocol and address family are supported
IsReadable	Determine if data can read from the socket without blocking
IsUrgent	Determine if there is any out-of-band data available to be read
IsWritable	Determine if data can be written to to the socket without blocking
Listen	Listen for client connections on the specified socket
MatchHostName	Match a host name against of list of addresses including wildcards
NormalizeHostName	Return the canonical form of a host name
Peek	Read data from the socket without removing it from the socket buffer
Read	Read data from the socket
ReadLine	Read a line of data from the socket, storing it in a string buffer

ReadStream	Read a stream of data from the socket
RegisterEvent	Register an event callback function
Reject	Reject a pending client connection
SetHostFile	Specify the name of an alternate host table
SetLastError	Set the last error code
SetOption	Set one or more options for the current socket
SetTimeout	Set the interval used when waiting for a blocking operation to complete
ShowError	Display a message box with a description of the specified error
Shutdown	Disable reception or transmission of data
StoreStream	Read a stream of data from the socket and store it in a file
Write	Write data to the socket
WriteLine	Write a line of data to the socket, terminated with a carriage-return and linefeed
WriteStream	Write a stream of data to the socket

CSocketWrench::CSocketWrench Method

`CSocketWrench()`;

The **CSocketWrench** constructor initializes the class library and validates the license key at runtime.

Remarks

If the constructor fails to validate the runtime license, subsequent methods in this class will fail. If the product is installed with an evaluation license, then the application will only function on the development system and cannot be redistributed.

The constructor calls the **InetInitialize** function to initialize the library, which dynamically loads other system libraries and allocates thread local storage. If you are using this class within another DLL, it is important that you do not create or destroy an instance of the class from within the **DllMain** function because it can result in deadlocks or access violation errors. You should not declare static or global instances of this class within another DLL if it is linked with the C runtime library (CRT) because it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cswsock10.h`

Import Library: `cswskv10.lib`

See Also

[~CSocketWrench](#), [IsInitialized](#)

CSocketWrench::~CSocketWrench

`~CSocketWrench();`

The **CSocketWrench** destructor releases resources allocated by the current instance of the **CSocketWrench** object. It also uninitialized the library if there are no other concurrent uses of the class.

Remarks

When a **CSocketWrench** object goes out of scope, the destructor is automatically called to allow the library to free any resources allocated on behalf of the process. Any pending blocking or asynchronous calls in this process are canceled without posting any notification messages, and all handles that were created for the connection are destroyed.

The destructor is not called explicitly by the application.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cssock10.h`

Import Library: `cswskv10.lib`

See Also

[CSocketWrench](#)

CSocketWrench::Abort Method

```
BOOL Abort();
```

Immediately close the socket without waiting for any remaining data to be written out.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **Abort** method should only be used when the connection must be closed immediately before the application terminates. This method should only be used to abort client connections and should not be used with passive (listening) sockets. Server applications that need to abort an incoming client connection should use the **Reject** method.

In most cases, the application should call the **Disconnect** method to gracefully close the connection to the remote host. Aborting the connection will discard any buffered data and may cause errors or result in unpredictable behavior.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

See Also

[Cancel](#), [Disconnect](#), [Reject](#)

CSocketWrench::Accept Method

```
BOOL Accept(  
    SOCKET hServer,  
    UINT nTimeout,  
    DWORD dwOptions,  
    HWND hEventWnd,  
    UINT uEventMsg  
);  
  
BOOL Accept(  
    CSocketWrench& swServer,  
    UINT nTimeout,  
    DWORD dwOptions,  
    HWND hEventWnd,  
    UINT uEventMsg  
);
```

The **Accept** method is used to accept a connection on a listening socket.

This method is included for backwards compatibility with legacy applications. New projects should use the **CInternetServer** class to create a server application.

Parameters

hServer

Handle to the listening socket. This argument may also reference a **CSocketWrench** object which is listening for connections. In either case, the server socket must have been created by calling the **Listen** method.

nTimeout

The number of seconds that the server will wait for a client connection before failing the operation. This value is used only for blocking connections.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
INET_OPTION_KEEPALIVE	This option specifies that packets are to be sent to the remote system when no data is being exchanged to keep the connection active. This is only valid for stream sockets.
INET_OPTION_REUSEADDRESS	This option specifies the local address can be reused. This option is commonly used by server applications.
INET_OPTION_NODELAY	This option disables the Nagle algorithm, which buffers unacknowledged data and insures that a full-size packet can be sent to the remote host.
INET_OPTION_INLINE	This option controls how urgent (out-of-band) data is handled when reading data from the socket. If set, urgent data is placed in the data stream along with non-urgent data.

INET_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using either the SSL or TLS protocols.
INET_OPTION_SECURE	This option determines if a secure connection is established with the remote host.
INET_OPTION_SECURE_FALLBACK	This option specifies the server should permit the use of less secure cipher suites for compatibility with legacy clients. If this option is specified, the server will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
INET_OPTION_FREETHREAD	This option specifies that this instance of the class may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the class instance is synchronized across multiple threads.

hEventWnd

The handle to the event notification window. This window receives messages which notify the application of various asynchronous socket events that occur. If this argument is NULL, then the connection will be blocking and no network events will be sent to the client.

uEventMsg

The message identifier that is used when an asynchronous socket event occurs. This value should be greater than WM_USER as defined in the Windows header files. If the *hEventWnd* argument is NULL, this argument should be specified as WM_NULL.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The use of Windows event notification messages has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

To prevent this method from blocking the main user interface thread, the application should create a background worker thread and establish a connection by calling **Accept** in that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread to accept each client session.

When a connection is accepted by the server, the original listening socket continues to listen for more connections. If no event notification window is specified, then **Accept** will block until a client attempts to connect to the server or the timeout period expires.

If you specify an event notification window, then the connection will be asynchronous. When a message is posted to the notification window, the low word of the *lParam* parameter contains the event identifier. The high word of *lParam* contains the low word of the error code, if an error has

occurred. The *wParam* parameter contains the socket handle. One or more of the following event identifiers may be sent:

Constant	Description
INET_EVENT_DISCONNECT	The remote host has closed the connection. The process should read any remaining data and disconnect.
INET_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the process has read at least some of the data from the socket. This event is only generated if the socket is in asynchronous mode.
INET_EVENT_WRITE	The process can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the socket is in asynchronous mode.

It is recommended that you only establish an asynchronous connection if you understand the implications of doing so. In most cases, it is preferable to create a synchronous connection and create threads for each additional connection if more than one active connection is required.

The *dwOptions* argument can be used to specify the threading model that is used by the library when a connection is established. By default, the class instance is initially attached to the thread that created it. From that point on, until the it is released, only the owner may call methods using that instance of the class. The ownership of the class instance may be transferred from one thread to another using the **AttachThread** method.

Specifying the INET_OPTION_FREETHREAD option enables any thread to call any method in that instance of the class, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the class instance is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same instance.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cswskv10.lib

Unicode: Implemented as Unicode and ANSI versions.

CSocketWrench::AttachHandle Method

```
VOID AttachHandle(  
    SOCKET hSocket  
);  
  
VOID AttachHandle(  
    SOCKET hSocket,  
    DWORD dwProcessId  
);
```

The **AttachHandle** method attaches the specified socket handle to the current instance of the class.

Parameters

hSocket

The socket handle that will be attached to the current instance of the class object.

dwProcessId

The process ID for the process that currently owns the socket handle. This value may be zero to specify the current process.

Return Value

None.

Remarks

This method is used to attach a socket handle created outside of the class using the SocketWrench API. Once the socket handle is attached to the class, the other class member functions may be used with that socket. If the socket was created by a third-party library or the Windows Sockets API, then the handle will be automatically inherited by the library.

If a socket handle already has been created for the class, that handle will be released when the new handle is attached to the class object. If you want to prevent the previous socket connection from being terminated, you must call the **DetachHandle** method. Failure to release the detached handle may result in a resource leak in your application.

If the *dwProcessId* parameter specifies another process, the socket will be duplicated into the current process, attached to the current thread and the original socket handle will be closed in the other process. This enables an application to effectively take control of a connection created by another process. The original socket handle must be inheritable by the by the current process and must be an actual Windows socket handle, not a pseudo-handle. This functionality is only supported on Windows NT 4.0 and later versions of the operating system with the Microsoft TCP/IP stack. Note that Layered Service Providers (LSPs) may interfere with the ability to inherit handles across processes.

If the socket was created by another process, it is initialized by the library in a blocking state, even if was originally using asynchronous socket events. If the application requires that the socket use events, it must explicitly call **EnableEvents**. A program should never try to attach to a secure connection created by another process because the attached socket will not have the security context required to encrypt and decrypt the data exchanged with the remote host.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cswsock10.h

Import Library: cswskv10.lib

See Also

[AttachThread](#), [DetachHandle](#), [GetHandle](#)

CSocketWrench::AttachThread Method

```
DWORD AttachThread(  
    DWORD dwThreadId  
);
```

The **AttachThread** method attaches the specified client handle to another thread.

Parameters

dwThreadId

The ID of the thread that will become the new owner of the handle. A value of zero specifies that the current thread should become the owner of the client handle.

Return Value

If the method succeeds, the return value is the thread ID of the previous owner. If the method fails, the return value is `INET_ERROR`. To get extended error information, call **GetLastError**.

Remarks

When a client handle is created, it is associated with the current thread that created it. Normally, if another thread attempts to perform an operation using that handle, an error is returned since it does not own the handle. This is used to ensure that other threads cannot interfere with an operation being performed by the owner thread. In some cases, it may be desirable for one thread in a client application to create the client handle, and then pass that handle to another worker thread. The **AttachThread** method can be used to change the ownership of the handle to the new worker thread. By preserving the return value from the method, the original owner of the handle can be restored before the worker thread terminates.

This method should be called by the new thread immediately after it has been created, and if the new thread does not release the handle itself, the ownership of the handle should be restored to the parent thread before it terminates. Under no circumstances should **AttachThread** be used to forcibly release a handle allocated by another thread while a blocking operation is in progress. To cancel an operation, use the **Cancel** method and then release the handle after the blocking method exits and control is returned to the current thread.

Note that the *dwThreadId* parameter is presumed to be a valid thread ID and no checks are performed to ensure that the thread actually exists. Specifying an invalid thread ID will orphan the client handle used by the class until the destructor is called.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cswsock10.h`

Import Library: `cswskv10.lib`

See Also

[AttachHandle](#), [Cancel](#), [Connect](#), [DetachHandle](#), [Disconnect](#), [GetHandle](#)

CSocketWrench::Cancel Method

```
BOOL Cancel(  
    SOCKET hSocket  
);  
BOOL Cancel();
```

The **Cancel** method cancels any outstanding blocking socket operation, causing the blocking method to fail. The application may then retry the operation or terminate the connection.

Parameters

hSocket

An optional parameter that specifies the handle to the socket. If this parameter is omitted, the socket handle for the current class instance will be used.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

When the **Cancel** method is called, the blocking method will not immediately fail. An internal flag is set which causes the blocking operation to exit with an error. This means that the application cannot cancel an operation and immediately perform some other operation. Instead it must allow the calling stack to unwind, returning back to the blocking operation before making any further function calls.

This method is typically called from within an event handler to signal that the current blocking operation should stop. It may also be used to cancel a blocking operation that is occurring on another thread.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

CSocketWrench::CompareAddress Method

```
BOOL CompareAddress(  
    LPINTERNET_ADDRESS lpAddress1,  
    LPINTERNET_ADDRESS lpAddress2  
);  
  
BOOL CompareAddress(  
    LPCTSTR lpszAddress1,  
    LPCTSTR lpszAddress2  
);
```

Compare two IP addresses to determine if they are identical.

Parameters

lpAddress1

A pointer to an INTERNET_ADDRESS structure that contains the first IP address to be compared. An alternate version of this method accepts a string that specifies the IP address to be compared.

lpAddress2

A pointer to an INTERNET_ADDRESS structure that contains the second IP address to be compared. An alternate version of this method accepts a string that specifies the IP address to be compared.

Return Value

If the method succeeds and the two addresses are identical, the return value is non-zero. If the method fails or the two addresses are not identical, the return value is zero. If either parameter is NULL, or the address family for the two addresses are not the same, the last error code will be updated. If the addresses are valid and in the same address family, but are not identical, the last error code will be set to NO_ERROR.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cswskv10.lib

See Also

[GetHostAddress](#), [GetLocalAddress](#), [GetPeerAddress](#), [INTERNET_ADDRESS](#)

CSocketWrench::Connect Method

```
BOOL Connect(  
    LPCTSTR lpszRemoteHost,  
    UINT nRemotePort,  
    UINT nProtocol,  
    UINT nTimeout,  
    DWORD dwOptions,  
    LPCTSTR lpszLocalAddress,  
    UINT nLocalPort,  
    HWND hEventWnd,  
    UINT uEventMsg  
);
```

The **Connect** method is used to establish a connection with a server.

Parameters

lpszRemoteHost

A pointer to the name of the server to connect to; this may be a fully-qualified domain name or an IP address.

nRemotePort

The port number the server is listening on; a value of zero specifies that the default port number should be used.

nProtocol

The protocol to be used when establishing the connection. This may be one of the following values:

Constant	Description
INET_PROTOCOL_TCP	Specifies the Transmission Control Protocol. This protocol provides a reliable, bi-directional byte stream. This is the default protocol.
INET_PROTOCOL_UDP	Specifies the User Datagram Protocol. This protocol is message oriented, sending data in discrete packets. Note that UDP is unreliable in that there is no way for the sender to know that the receiver has actually received the datagram.

nTimeout

The number of seconds to wait for a response before failing the current operation.

dwOptions

An unsigned integer used to specify one or more socket options. This parameter is constructed by using the bitwise Or operator with any of the following values:

Constant	Description
INET_OPTION_BROADCAST	This option specifies that broadcasting should be enabled for datagrams. This option is invalid for stream sockets.
INET_OPTION_DONTROUTE	This option specifies default routing should not be used. This option should not be specified unless

	absolutely necessary.
INET_OPTION_KEEPALIVE	This option specifies that packets are to be sent to the remote system when no data is being exchanged to keep the connection active. This is only valid for stream sockets.
INET_OPTION_NODELAY	This option disables the Nagle algorithm. By default, small amounts of data written to the socket are buffered, increasing efficiency and reducing network congestion. However, this buffering can negatively impact the responsiveness of certain applications. This option disables this buffering and immediately sends data packets as they are written to the socket.
INET_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using either the SSL or TLS protocols.
INET_OPTION_SECURE	This option specifies that a secure connection should be established with the remote host. The specific version of TLS and other security related options are provided in the <i>lpCredentials</i> parameter. If the <i>lpCredentials</i> parameter is NULL, the connection will default to using TLS 1.2 and the strongest cipher suites available. Older versions of Windows prior to Windows 7 and Windows Server 2008 R2 only support TLS 1.0 and secure connections will automatically downgrade on those platforms.
INET_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
INET_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
INET_OPTION_FREETHREAD	This option specifies that this instance of the class may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the class

instance is synchronized across multiple threads.

lpszLocalAddress

A pointer to a null terminated string that specifies the local IP address that the socket should be bound to. If this parameter is NULL, then an appropriate address will automatically be used. A specific address should only be used if it is required by the application.

nLocalPort

The local port number that the socket should be bound to. If this parameter is set to zero, then an appropriate port number will automatically be used. A specific port number should only be used if it is required by the application.

hEventWnd

The handle to the event notification window. This window receives messages which notify the application of various asynchronous socket events that occur. If this argument is NULL, then the connection will be blocking and no network events will be sent to the client.

uEventMsg

The message identifier that is used when an asynchronous socket event occurs. This value should be greater than WM_USER as defined in the Windows header files. If the *hEventWnd* argument is NULL, this argument should be specified as WM_NULL.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The use of Windows event notification messages has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

To prevent this method from blocking the main user interface thread, the application should create a background worker thread and establish a connection by calling **Connect** in that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each client session.

If you specify an event notification window, then the connection will be asynchronous. When a message is posted to the notification window, the low word of the *lParam* parameter contains the event identifier. The high word of *lParam* contains the low word of the error code, if an error has occurred. The *wParam* parameter contains the socket handle. One or more of the following event identifiers may be sent:

Constant	Description
INET_EVENT_CONNECT	The connection to the remote host has completed. The high word of the <i>lParam</i> parameter should be checked, since this notification message will be posted if an error has occurred.
INET_EVENT_DISCONNECT	The remote host has closed the connection. The process should read any remaining data and disconnect.
INET_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the process has read at least some

	of the data from the socket. This event is only generated if the socket is in asynchronous mode.
INET_EVENT_WRITE	The process can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the socket is in asynchronous mode.

To cancel asynchronous notification and return the socket to a blocking mode, use the **DisableEvents** method.

It is not recommended that you disable the Nagle algorithm by specifying the INET_OPTION_NODELAY flag unless it is absolutely required. Doing so can have a significant, negative impact on the performance of the application and network.

The *dwOptions* argument can be used to specify the threading model that is used by the library when a connection is established. By default, the class instance is initially attached to the thread that created it. From that point on, until the it is released, only the owner may call methods using that instance of the class. The ownership of the class instance may be transferred from one thread to another using the **AttachThread** method.

Specifying the INET_OPTION_FREETHREAD option enables any thread to call any method in that instance of the class, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the class instance is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same instance.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

CSocketWrench::CreateSecurityCredentials Method

```
BOOL CreateSecurityCredentials(  
    DWORD dwProtocol,  
    DWORD dwOptions,  
    LPCTSTR lpszUserName,  
    LPCTSTR lpszPassword,  
    LPCTSTR lpszCertStore,  
    LPCTSTR lpszCertName  
);
```

```
BOOL CreateSecurityCredentials(  
    LPCTSTR lpszCertStore,  
    LPCTSTR lpszCertName  
);
```

```
BOOL CreateSecurityCredentials(  
    LPCTSTR lpszCertName  
);
```

The **CreateSecurityCredentials** method establishes the security credentials for the connection.

Parameters

dwProtocol

A bitmask of supported security protocols. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_SSL	Either SSL 2.0 or SSL 3.0 should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, TLS will be excluded from the list of supported protocols. Both SSL 2.0 and 3.0 have been deprecated and will never be used unless explicitly specified. It is not recommended that you enable either of these protocols for secure connections because it will cause most servers to reject your connection request, even if a version of TLS is also specified.
SECURITY_PROTOCOL_TLS	Either the TLS 1.0, 1.1 or 1.2 protocol should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols.

	This may be necessary for some servers that reject any attempt to use the older SSL protocol and require that only TLS be used.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This is the recommended version of TLS to use with secure connections.

dwOptions

A value which specifies one or options. This member is constructed by using a bitwise operator with any of the following values:

Constant	Description
CREDENTIAL_STORE_CURRENT_USER	The library will attempt to open a store for the current user using the certificate store name provided in this structure. If no options are specified, then this is the default behavior.
CREDENTIAL_STORE_LOCAL_MACHINE	The library will attempt to open a local machine store using the certificate store name provided in this structure. If this option is specified, the library will always search for a local machine store before searching for the store by that name for the current user.
CREDENTIAL_STORE_FILENAME	The certificate store name is a file that contains the certificate and private key that will be used.

lpzUserName

A pointer to a string which specifies the certificate owner's username. A value of NULL specifies that no username is required. Currently this parameter is not used and any value specified will be ignored.

lpzPassword

A pointer to a string which specifies the certificate owner's password. A value of NULL specifies that no password is required. This parameter is only used if a PKCS12 (PFX) certificate file is specified and that certificate has been secured with a password. This value will be ignored the current user or local machine certificate store is specified.

lpzCertStore

A pointer to a string which specifies the name of the certificate store to open. A certificate store is a collection of certificates and their private keys, typically organized by how they are used. If this value is NULL or points to an empty string, the default certificate store "MY" will be used.

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as VeriSign and Thawte act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. This corresponds to the "Personal" store that is displayed by the certificate manager utility and is the default store used by the library.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as VeriSign and Thawte are installed as part of the operating system and periodically updated by Microsoft.

lpzCertName

A pointer to a null terminated string which specifies the name of the certificate to use. The function will first search the certificate store for a certificate with a matching "friendly name"; this is a name for the certificate that is assigned by the user. Note that the name must match completely, but the comparison is not case sensitive. If no matching certificate is found, the function will then attempt to find a certificate that has a matching common name (also called the certificate subject). This comparison is less stringent, and the first partial match will be returned. If this second search fails, the function will return an error indicating that the certificate could not be found.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Example

```
pSocket->CreateSecurityCredentials(lpzCertName);  
  
bConnected = pSocket->Connect(lpzHostName,  
                              INET_PORT_HTTP,  
                              INET_PROTOCOL_TCP,  
                              INET_TIMEOUT,  
                              INET_OPTION_SECURE);
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cswsock10.h

Import Library: cswskv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

CSocketWrench::DeleteSecurityCredentials Method

```
VOID DeleteSecurityCredentials();
```

The **DeleteSecurityCredentials** method releases the security credentials for the current connection.

Parameters

None.

Return Value

None.

Remarks

This method can be used to release the memory allocated to the client or server credentials after a secure connection has been terminated. The security credentials are released when the class destructor is called, so it is normally not required that the application explicitly call this method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[CreateSecurityCredentials](#)

CSocketWrench::DetachHandle Method

```
SOCKET DetachHandle();
```

The **DetachHandle** method detaches the socket handle associated with the current instance of the class.

Parameters

None.

Return Value

This method returns the client handle associated with the current instance of the class object. If there is no active connection, the value `INVALID_SOCKET` will be returned.

Remarks

This method is used to detach a socket handle created by the class for use with the SocketWrench API. Once the socket handle is detached from the class, no other class member functions may be called. Note that the handle must be explicitly closed at some later point by the process or a resource leak will occur.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cssock10.h`

Import Library: `cswskv10.lib`

See Also

[AttachHandle](#), [GetHandle](#)

CSocketWrench::DisableEvents Method

BOOL DisableEvents();

Disables event notifications, preventing messages from being posted to the application's message queue.

This method has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **DisableEvents** method is used to disable event message posting for the specified socket handle. Although this will immediately prevent any new events from being generated, it is possible that messages could be waiting in the message queue. Therefore, an application must be prepared to handle client event messages after this method has been called.

This method is automatically called if the socket has event notification enabled, and the **Disconnect** method is called. The same issues regarding outstanding event messages also applies in this situation, requiring that the application handle event messages that may reference a socket handle that is no longer valid.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

[EnableEvents](#), [RegisterEvent](#)

CSocketWrench::DisableSecurity Method

```
INT DisableSecurity();
```

The **DisableSecurity** method disables a secure session with the remote host.

Parameters

None.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is INET_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **DisableSecurity** method disables a secure session, with subsequent calls to **Read** and **Write** sending and receiving unencrypted data. It is important to note that because this method sends a shutdown message to terminate the secure session, this may cause connection to be closed by the remote host.

This method does not close the socket. Use the **Disconnect** method to close the socket and release the resources allocated for the current session.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

See Also

[CreateSecurityCredentials](#), [DeleteSecurityCredentials](#), [EnableSecurity](#)

CSocketWrench::DisableTrace Method

```
BOOL DisableTrace();
```

The **DisableTrace** method disables the logging of socket function calls to the trace log.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, a value of zero is returned.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

See Also

[EnableTrace](#)

CSocketWrench::Disconnect Method

BOOL Disconnect();

Terminate the connection, closing the socket and releasing the memory allocated for the session.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

Once the connection has been terminated, the class instance socket handle is no longer valid and should no longer be used. Note that it is possible that the actual handle value may be re-used at a later point when a new connection is established. An application should always consider the socket handle to be opaque and never depend on it being a specific value.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cswskv10.lib

See Also

[Abort](#), [Accept](#), [Connect](#), [DisableEvents](#), [EnableEvents](#), [Listen](#)

CSocketWrench::EnableEvents Method

```
BOOL EnableEvents(  
    HWND hEventWnd,  
    UINT uEventMsg  
);
```

The **EnableEvents** method enables event notifications using Windows messages.

This method has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Applications should use the **RegisterEvent** method to register an event handler which is invoked when an event occurs.

Parameters

hEventWnd

Handle to the window which will receive the socket notification messages. This parameter must specify a valid window handle. If a NULL handle is specified, event notification will be disabled.

uEventMsg

The message that is received when a network event occurs. This value must be greater than 1024.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **EnableEvents** method is used to request that notification messages be posted to the specified window whenever a network event occurs. This allows an application to monitor the status of different socket operations.

The *wParam* argument will contain the client handle, the low word of the *lParam* argument will contain the event ID, and the high word will contain any error code. If no error has occurred, the high word will always have a value of zero. The following events may be generated:

Constant	Description
INET_EVENT_CONNECT	The connection to the remote host has completed. The high word of the <i>lParam</i> parameter should be checked, since this notification message will be posted if an error has occurred.
INET_EVENT_DISCONNECT	The remote host has closed the connection to the client. The client should read any remaining data and disconnect.
INET_EVENT_READ	Data is available to be read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
INET_EVENT_WRITE	The application can now send data to the remote host. This notification is sent after a connection has been established, or

	after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
INET_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The application may attempt to retry the operation, or may disconnect from the remote host and report an error to the user.
INET_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.

To disable event notification, call the **DisableEvents** method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cswskv10.lib

See Also

[DisableEvents](#), [RegisterEvent](#)

CSocketWrench::EnableSecurity Method

```
BOOL EnableSecurity();  
BOOL EnableSecurity(  
    LPCTSTR lpszCertName  
);  
BOOL EnableSecurity(  
    LPCTSTR lpszCertStore,  
    LPCTSTR lpszCertName  
);
```

The **EnableSecurity** method enables a secure session with the remote host.

Parameters

lpszCertStore

A pointer to a string which specifies the name of certificate store.

lpszCertName

A pointer to a string which specifies the common name for the certificate that will be used.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **EnableSecurity** method enables a secure communications session with the remote host, automatically negotiating the encryption algorithm and validating the certificate. If the socket was created using the **Connect** method to establish a client connection, then **EnableSecurity** will initiate the handshake with the remote host to establish a secure session. If the **Accept** method was used to accept a connection from a client, then the method will block and wait for the remote host to initiate the handshake.

This method is useful if the application needs to establish an initial, non-secure connection to the remote host and then negotiate a secure connection at a later point. If the method succeeds, all subsequent calls to **Read** and **Write** to receive and send data will be encrypted.

If no arguments are specified, then the security credentials established with a previous call to **CreateSecurityCredentials** will be used. If a certificate name is specified, then the current security credentials will be updated to use that certificate.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cswsock10.h`

Import Library: `cswskv10.lib`

See Also

[CreateSecurityCredentials](#), [DeleteSecurityCredentials](#), [DisableSecurity](#)

CSocketWrench::EnableTrace Method

```
BOOL EnableTrace(  
    LPCTSTR lpszTraceFile,  
    DWORD dwTraceFlags  
);
```

The **EnableTrace** method enables the logging of socket function calls to a file.

Parameters

lpszTraceFile

A pointer to a string which specifies the name of the trace log file. If this parameter is NULL or an empty string, the default file name **cstrace.log** is used. The file is stored in the directory specified by the TEMP environment variable, if it is defined; otherwise, the current working directory is used.

dwTraceFlags

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
TRACE_INFO	All function calls are written to the trace file. This is the default value.
TRACE_ERROR	Only those function calls which fail are recorded in the trace file.
TRACE_WARNING	Only those function calls which fail or return values which indicate a warning are recorded in the trace file.
TRACE_HEXDUMP	All functions calls are written to the trace file, plus all the data that is sent or received is displayed, in both ASCII and hexadecimal format.
TRACE_PROCESS	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for multithreaded applications that are using worker threads.

Return Value

If the method succeeds, the return value is non-zero. A return value of zero indicates an error. Failure typically indicates that the tracing library **cstrcv10.dll** cannot be loaded on the local system.

Remarks

When trace logging is enabled, the file is opened, appended to and closed for each socket function call. This makes it possible for an application to append its own logging information, however care should be taken to ensure that the file is closed before the next network operation is performed. To limit the size of the log files, enable and disable logging only around those sections of code that you wish to trace.

Note that the TRACE_HEXDUMP trace level generates very large log files since it includes all of the data exchanged between your application and the remote host.

Trace method logging is managed on a per-thread basis, not for each client handle. This means that all SocketTools libraries and components share the same settings in the current thread. If you

are using multiple SocketTools libraries or components in your application, you only need to enable logging once.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[DisableTrace](#)

CSocketWrench::EnumNetworkAddresses Method

```
INT EnumNetworkAddresses(  
    INT nAddressFamily,  
    LPINTERNET_ADDRESS lpAddressList,  
    INT nMaxAddresses  
);  
  
INT EnumNetworkAddresses(  
    LPINTERNET_ADDRESS lpAddressList,  
    INT nMaxAddresses  
);
```

The **EnumNetworkAddresses** method returns the list of network addresses that are configured for the local host.

Parameters

nAddressFamily

An integer which identifies the type of IP address that should be returned by this method. It may be one of the following values:

Constant	Description
INET_ADDRESS_ANY	Return both IPv4 or IPv6 addresses assigned to the local host, depending on how the system is configured and which network interfaces are enabled. This option is only recommended for applications that require support for IPv6 connections.
INET_ADDRESS_IPV4	Return only the IPv4 addresses assigned to the local host. The first four bytes of the <i>ipNumber</i> array are significant and contains the IP address. The remaining bytes are not significant and an application should not depend on them having any particular value, including zero.
INET_ADDRESS_IPV6	Return only the IPv6 addresses assigned to the local host. All bytes in the <i>ipNumber</i> array are significant. This option is only recommended for those applications that require support for IPv6 connections.

lpAddressList

A pointer to an array of [INTERNET_ADDRESS](#) structures that will contain the IP address of each local network interface. This parameter may be NULL, in which case the method will only return the number of available addresses.

nMaxAddresses

Maximum number of addresses to be returned. If the *lpAddressList* parameter is NULL, this value must be zero.

Return Value

If the method succeeds, the return value is the number of network addresses that are configured for the local host. If the method fails, the return value is INET_ERROR. To get extended error information, call the **GetLastError** method.

Remarks

If the *nAddressFamily* parameter is specified as INET_ADDRESS_ANY, the application must be prepared to accept IPv6 addresses returned by this method. On Windows Vista and later versions of the operating system, IPv6 support is enabled and the local network adapter will have IPv6 addresses assigned to them by default. For legacy applications that only recognize IPv4 addresses, the *nAddressFamily* parameter should always be specified as INET_ADDRESS_IPV4 to ensure that only IPv4 addresses are returned.

This method will ignore addresses that are bound to a disabled interface, as well as those addresses bound to a virtual loopback interface. For example, although the loopback address 127.0.0.1 is a valid network address, it will not be included in list of addresses returned by this method.

The first IPv4 or IPv6 address returned by this method is typically the address assigned to the primary network adapter on the local system. However, your application should not depend on addresses being returned in any particular order. If the system has virtualization software installed, this method may also include the IP addresses assigned to any virtualized network adapters installed by that software.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

See Also

[GetAdapterAddress](#), [GetHostAddress](#), [GetLocalAddress](#)

CSocketWrench::Flush Method

```
BOOL Flush();
```

The **Flush** method flushes the internal send and receive buffers used by the socket.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **Flush** method will flush any data waiting to be read or written to the remote host . It is important to note that this method is not similar to flushing data to a disk file; it does not ensure that a specific block of data has been written to the socket. For example, you should never call this function immediately after calling the **Write** method or prior to calling the **Disconnect** method.

An application never needs to use the **Flush** method under normal circumstances. This method is only to be used when the application needs to immediately return the socket to an inactive state with no pending data to be read or written. Calling this function may result in data loss and should only be used if you understand the implications of discarding any data which has been sent by the remote host.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cswskv10.lib

See Also

[IsReadable](#), [IsWritable](#), [Read](#), [Write](#)

CSocketWrench::FormatAddress Method

```
INT FormatAddress(  
    LPINTERNET_ADDRESS lpAddress,  
    LPTSTR lpszAddress,  
    INT cchAddress  
);  
  
INT FormatAddress(  
    LPINTERNET_ADDRESS lpAddress,  
    CString& strAddress  
);
```

The **FormatAddress** method converts a numeric IP address to a printable string. The format of the string depends on whether an IPv4 or IPv6 address is specified.

Parameters

lpAddress

A pointer to an [INTERNET_ADDRESS](#) structure which specifies the numeric IP address that should be converted to a string.

lpszAddress

A pointer to the buffer that will contain the formatted IP address. This buffer should be at least 46 characters in length. This may also reference a **CString** object which will contain the formatted address when the method returns.

cchAddress

The maximum number of characters that can be copied into the address buffer.

Return Value

If the method succeeds, the return value is the length of the IP address string. If the method fails, the return value is `INET_ERROR`, meaning that the IP address could not be converted into a string. Typically this indicates that the pointer to the `INTERNET_ADDRESS` structure is invalid, or the data does not specify a valid IP address family.

Remarks

The format and length of IPv4 and IPv6 address strings are very different. An IPv4 address string looks like "192.168.0.20", while an IPv6 address string can look something like "fd7c:2f6a:4f4f:ba34::a32". If your application checks for the format of these address strings, it needs to be aware of the differences. You also need to make sure that you're providing enough space to display or store an address to avoid buffer overruns.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cssock10.h`

Import Library: `cswskv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

See Also

[GetHostAddress](#), [GetLocalAddress](#), [GetPeerAddress](#), [INTERNET_ADDRESS](#)

CSocketWrench::FreezeEvents Method

```
INT FreezeEvents(  
    BOOL bFreeze  
);
```

The **FreezeEvents** method is used to suspend and resume event handling by the application.

Parameters

bFreeze

A non-zero value specifies that event handling should be suspended by the client. A zero value specifies that event handling should be resumed.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is `INET_ERROR`. To get extended error information, call **GetLastError**.

Remarks

This method should be used when the application does not want to process events, such as when a modal dialog is being displayed. When events are suspended, all socket events are queued. If events are re-enabled at a later point, those queued events will be sent to the application for processing. Note that only one of each event will be generated. For example, if the program has suspended event handling, and four read events occur, once event handling is resumed only one of those read events will be posted to the client. This prevents the application from being flooded by a potentially large number of queued events.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cswsock10.h`

Import Library: `cswskv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

See Also

[DisableEvents](#), [EnableEvents](#), [RegisterEvent](#)

CSocketWrench::GetAdapterAddress Method

```
INT GetAdapterAddress(  
    INT nAdapterIndex,  
    INT nAddressType,  
    LPTSTR lpszAddress,  
    INT nMaxLength  
);
```

```
INT GetAdapterAddress(  
    INT nAdapterIndex,  
    INT nAddressType,  
    CString& strAddress  
);
```

Return the IP or MAC assigned to the specified network adapter.

Parameters

nAdapterIndex

An integer value that identifies the network adapter.

nAddressType

An integer value which specifies the type of address that should be returned:

Constant	Description
INET_ADAPTER_IPV4	The address string will contain the primary IPv4 unicast address assigned to the network adapter.
INET_ADAPTER_IPV6	The address string will contain the primary IPv6 unicast address assigned to the network adapter.
INET_ADAPTER_MAC	The address string will contain the media access control (MAC) address assigned to the network adapter.

lpszAddress

A string buffer that will contain the IP or MAC address assigned to the adapter. This parameter cannot be NULL and it is recommended that it be at least 64 characters in length to provide enough space for any address type. An alternate form of the method accepts a **CString** argument which will contain the hostname.

nMaxLength

The maximum number of characters that can be copied into the string buffer, including the terminating null character. If the buffer is too small to store the complete address, this method will fail.

Return Value

If the method succeeds, the return value is the number of characters copied to the string buffer, not including the terminating null character. A return value of zero indicates that the requested address type has not been assigned to the adapter. If the method fails, the return value is `INET_ERROR` and this typically indicates that either the adapter index is invalid or the string buffer is not large enough to store the complete address. To get extended error information, call **GetLastError**.

Remarks

The **GetAdapterAddress** method will return the IPv4, IPv6 or MAC address assigned to a specific network adapter. The primary network adapter has an index value of zero, and it increments for each adapter that is configured on the local system.

The media access control (MAC) address is a 48 bit or 64 bit value that is assigned to each network interface and is used for identification and access control. All network devices on the same subnet must be assigned their own unique MAC address. Unlike IP addresses which may be assigned dynamically and can be frequently changed, MAC addresses are considered to be more permanent because they are usually assigned by the device manufacturer and stored in firmware. Note that in some cases it is possible to change the address assigned to a device, and virtual network interfaces may have configurable MAC addresses.

This method returns the MAC address string as sequence of hexadecimal values separated by a colon. An example of a 48 bit MAC address would be "01:23:45:67:89:AB". Note that some virtual network adapters may not have a MAC address assigned to them, in which case this method would return zero.

This method will ignore network adapters that have been disabled, as well as those that are bound to a virtual loopback interface. If the system has dial-up networking or virtualization software installed, this method may also return IP addresses assigned to a virtualized network adapters installed by that software.

Example

```
// Display the IPv4 address assigned to each network adapter
for (INT nIndex = 0;; nIndex++)
{
    CString strAddress;

    if (pSocket->GetAdapterAddress(nIndex, INET_ADAPTER_IPV4, strAddress) ==
INET_ERROR)
        break;

    _tprintf(_T("Adapter %d: %s\n"), nIndex, szAddress);
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

See Also

[EnumNetworkAddresses](#), [GetLocalAddress](#), [GetLocalName](#)

CSocketWrench::GetAddress Method

```
INT GetAddress(  
    LPCTSTR lpszAddress,  
    INT nAddressFamily,  
    LPINTERNET_ADDRESS lpAddress  
);
```

```
INT GetAddress(  
    LPCTSTR lpszAddress,  
    LPINTERNET_ADDRESS lpAddress  
);
```

The **GetAddress** method converts an IP address string to binary format.

Parameters

lpszAddress

A pointer to a null terminated string which specifies an IP address. This method recognizes the format for both IPv4 and IPv6 format addresses.

nAddressFamily

An integer which identifies the type of IP address specified by the *lpszAddress* parameter. It may be one of the following values:

Constant	Description
INET_ADDRESS_UNKNOWN	Return the IP address for the specified host in either IPv4 or IPv6 format, depending on the value of the <i>lpszAddress</i> parameter.
INET_ADDRESS_IPV4	Specifies that the address should be in IPv4 format. The first four bytes of the <i>ipNumber</i> array are significant and contains the IP address. The remaining bytes are not significant and an application should not depend on them having any particular value, including zero. If the <i>lpszAddress</i> parameter does not specify a valid IPv4 address string, this method will fail.
INET_ADDRESS_IPV6	Specifies that the address should be in IPv6 format. All bytes in the <i>ipNumber</i> array are significant. If the <i>lpszAddress</i> parameter does not specify a valid IPv6 address string, this method will fail.

lpAddress

A pointer to an [INTERNET_ADDRESS](#) structure that will contain the IP address.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is INET_ERROR. To get extended error information, call **GetLastError**.

Remarks

If the *nAddressFamily* parameter is specified as INET_ADDRESS_UNKNOWN, the application must be prepared to handle IPv6 addresses because it is possible that an IPv6 address string has been specified. For legacy applications that only recognize IPv4 addresses, the *nAddressFamily* member

should always be specified as `INET_ADDRESS_IPV4` to ensure that only IPv4 addresses are returned and any attempt to specify an IPv6 address string would result in an error.

To determine if the local system has an IPv6 TCP/IP stack installed and configured on the local system, use the **IsProtocolAvailable** method. If an IPv6 stack is not installed, this method will fail if the *lpszAddress* parameter specifies an IPv6 address, even if the address itself is valid.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cssock10.h`

Import Library: `cswskv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

See Also

[FormatAddress](#), [IsAddressNull](#), [IsAddressRoutable](#), [IsProtocolAvailable](#), [INTERNET_ADDRESS](#)

CSocketWrench::GetAddressFamily Method

```
INT GetAddressFamily(  
    LPCTSTR lpszAddress,  
);
```

Return the address family for the specified IP address.

Parameters

lpszAddress

A pointer to a string which specifies an IP address. This method recognizes the format for both IPv4 and IPv6 format addresses.

Return Value

If the method succeeds, the return value is the address family for the specified IP address and may be one of the values listed below. If the method fails, the return value is INET_ADDRESS_UNKNOWN. To get extended error information, call the **GetLastError** method.

Constant	Description
INET_ADDRESS_IPV4	The address passed to the method is a valid IPv4 address.
INET_ADDRESS_IPV6	The address passed to the method is a valid IPv6 address.

Remarks

The **GetAddressFamily** method returns the address family associated with the specified IP address string. This can be used to determine if a string specifies a valid IPv4 or IPv6 address that can be passed to other methods such as **Connect**. Note that this method will not attempt to resolve hostnames, it will only accept IP addresses.

To determine if the local system has an IPv6 TCP/IP stack installed and configured on the local system, use the **IsProtocolAvailable** method. If an IPv6 stack is not installed, this method will fail if the *lpszAddress* parameter specifies an IPv6 address, even if the address itself is valid.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[IsAddressNull](#), [IsAddressRoutable](#), [IsProtocolAvailable](#), [INTERNET_ADDRESS](#)

CSocketWrench::GetDefaultHostFile Method

```
INT GetDefaultHostFile(  
    LPTSTR lpszFileName,  
    INT nMaxLength  
);  
  
INT GetDefaultHostFile(  
    CString& lpszFileName  
);
```

The **GetDefaultHostFile** method returns the fully qualified path name of the host file on the local system. The host file is used as a database that maps an IP address to one or more hostnames, and is used by the **GetHostAddress** and **GetHostNames** method. The file is a plain text file, with each line in the file specifying a record, and each field separated by spaces or tabs. The format of the file must be as follows:

```
ipaddress hostname [hostalias ...]
```

For example, one typical entry maps the name "localhost" to the local loopback IP address. This would be entered as:

```
127.0.0.1 localhost
```

The hash character (#) may be used to specify a comment in the file, and all characters after it are ignored up to the end of the line. Blank lines are ignored, as are any lines which do not follow the required format.

The location of the default host file depends on the operating system. For Windows 95/98 and Windows Me the file is stored in C:\Windows\hosts and for Windows NT and later versions the file is stored in C:\Windows\system32\drivers\etc\hosts. Regardless of platform, there is no filename extension and this file may or may not exist on a given system.

Parameters

lpszFileName

Pointer to a string buffer that will contain the fully qualified file name to the default host file. It is recommended that this buffer be at least MAX_PATH characters in size. This parameter may be NULL, in which case the method will return the length of the string, not including the terminating null byte.

nMaxLength

The maximum number of characters that may be copied to the string buffer.

Return Value

If the method succeeds, the return value is length of the string. A return value of zero indicates that the default host file could not be determined for the current platform. To get extended error information, call **GetLastError**.

Remarks

This method only returns the default location of the host file and does not determine if the file actually exists. It is not required that a host file be present on the system.

The default host file is processed before performing a nameserver lookup when resolving a hostname into an IP address, or an IP address into a hostname.

To specify an alternate local host file, use the **SetHostFile** method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cswsock10.h

Import Library: csWSKV10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

CSocketWrench::GetErrorString Method

```
INT GetErrorString(  
    DWORD dwErrorCode,  
    LPTSTR lpszDescription,  
    INT cbDescription  
);  
  
INT GetErrorString(  
    DWORD dwErrorCode,  
    CString& strDescription  
);
```

The **GetErrorString** method is used to return a description of a specific error code. Typically this is used in conjunction with the **GetLastError** method for use with warning dialogs or as diagnostic messages.

Parameters

dwErrorCode

The error code for which a description is returned.

lpszDescription

A pointer to the buffer that will contain a description of the specified error code. This buffer should be at least 128 characters in length. An alternate form of the method accepts a **CString** variable which will contain the error description.

cbDescription

The maximum number of characters that may be copied into the description buffer.

Return Value

If the method succeeds, the return value is the length of the description string. If the method fails, the return value is zero, meaning that no description exists for the specified error code. Typically this indicates that the error code passed to the method is invalid.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cswsock10.h`

Import Library: `cswskv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

CSocketWrench::GetExternalAddress Method

```
INT GetExternalAddress(  
    INT nAddressFamily,  
    LPINTERNET_ADDRESS lpAddress,  
    INT nMaxLength  
);  
  
INT GetExternalAddress(  
    INT nAddressFamily,  
    LPTSTR lpszAddress,  
    INT nMaxLength  
);  
  
INT GetExternalAddress(  
    INT nAddressFamily,  
    CString& strAddress  
);
```

The **GetExternalAddress** method returns the external IP address for the local system.

Parameters

nAddressFamily

An integer which identifies the type of IP address that should be returned by this function. It may be one of the following values:

Constant	Description
INET_ADDRESS_IPV4	Specifies that the address should be in IPv4 format. The method will attempt to determine the external IP address using an IPv4 network connection.
INET_ADDRESS_IPV6	Specifies that the address should be in IPv6 format. The method will attempt to determine the external IP address using an IPv6 network connection and requires that the local host have an IPv6 network interface installed and enabled.

lpAddress

A pointer to an [INTERNET_ADDRESS](#) structure that will contain the external IP address of the local host in binary form.

lpszAddress

A pointer to a string buffer that will contain the external IP address of the local host.

nMaxLength

The maximum length of the string that will contain the IP address when the method returns.

Return Value

In the first form of the method, if it succeeds, the return value is the IP address of the local system in numeric form. If the method fails, the return value is INET_ADDRESS_NONE. In the second form, the return value is the length of the IP address string and an error is indicated by the return value INET_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetExternalAddress** method returns the IP address assigned to the router that connects the

local host to the Internet. This is typically used by an application executing on a system in a local network that uses a router which performs Network Address Translation (NAT). In that network configuration, the **GetLocalAddress** method will only return the IP address for the local system on the LAN side of the network unless a connection has already been established to a remote host. The **GetExternalAddress** function can be used to determine the IP address assigned to the router on the Internet side of the connection and can be particularly useful for servers running on a system behind a NAT router.

This method requires that you have an active connection to the Internet and calling this function on a system that uses dial-up networking may cause the operating system to automatically connect to the Internet service provider. An application should always check the return value in case there is an error; never assume that the return value is always a valid address. The function may be unable to determine the external IP address for the local host for a number of reasons, particularly if the system is behind a firewall or uses a proxy server that restricts access to external sites on the Internet. If the function is able to obtain a valid external address for the local host, that address will be cached by the library for sixty minutes. Because dial-up connections typically have different IP addresses assigned to them each time the system is connected to the Internet, it is recommended that this function only be used with broadband connections where a NAT router is being used.

Calling this function may cause the current thread to block until the external IP address can be resolved and should never be used in conjunction with asynchronous socket connections. If you need to call this function in an application which uses asynchronous sockets, it is recommended that you create a new thread and call this function from within that thread.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cswsock10.h`

Import Library: `cswskv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

CSocketWrench::GetFirstAlias Method

```
BOOL GetFirstAlias(  
    LPCTSTR lpszHostName,  
    LPTSTR lpszHostAlias,  
    INT nMaxLength  
);
```

```
BOOL GetFirstAlias(  
    LPCTSTR lpszHostName,  
    CString& strHostAlias  
);
```

The **GetFirstAlias** method returns the first alias for the specified host name.

Parameters

lpszHostName

A pointer to a string which specifies the host name that you wish to return aliases for. This should be complete domain name.

lpszHostAlias

A string buffer which will contain the first alias for the specified host name. This string should be at least 64 bytes in length. This argument may also reference a **CString** object which will contain the host alias when the method returns.

nMaxLength

Maximum number of characters that can be copied into the *lpszHostAlias* string buffer, including the terminating null byte.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Example

```
CSocketWrench sockClient;  
CString strHostAlias;  
BOOL bResult;  
  
m_ctlListBox.ResetContent();  
  
bResult = sockClient.GetFirstAlias(m_strHostName, strHostAlias);  
if (bResult == FALSE)  
{  
    sockClient.ShowError();  
    return;  
}  
  
while (bResult)  
{  
    m_ctlListBox.AddString(strHostAlias);  
    bResult = sockClient.GetNextAlias(strHostAlias);  
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

Unicode: Implemented as Unicode and ANSI versions.

CSocketWrench::GetHandle Method

```
SOCKET GetHandle();
```

The **GetHandle** method returns the socket handle associated with the current instance of the class.

Parameters

None.

Return Value

This method returns the socket handle associated with the current instance of the class object. If there is no active connection, the value `INVALID_SOCKET` will be returned.

Remarks

This method is used to obtain the client handle created by the class for use with the SocketTools API.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cswsock10.h`

Import Library: `cswskv10.lib`

CSocketWrench::GetHostAddress Method

```
INT GetHostAddress(  
    LPCTSTR lpszHostName,  
    INT nAddressFamily,  
    LPINTERNET_ADDRESS lpAddress  
);
```

```
INT GetHostAddress(  
    LPCTSTR lpszHostName,  
    LPINTERNET_ADDRESS lpAddress  
);
```

The **InetGetHostAddress** method resolves the specified host name into an IP address in binary format.

Parameters

lpszHostName

A pointer to the name of the host to resolve; this may be a fully-qualified domain name or an IP address. This method recognizes the format for both IPv4 and IPv6 format addresses.

nAddressFamily

An integer which identifies the type of IP address to return. It may be one of the following values:

Constant	Description
INET_ADDRESS_UNKNOWN	Return the IP address for the specified host in either IPv4 or IPv6 format, depending on how the host name can be resolved. By default, a preference will be given for returning an IPv4 address. However, if the host only has an IPv6 address, that value will be returned.
INET_ADDRESS_IPV4	Specifies that the address should be returned in IPv4 format. The first four bytes of the <i>ipNumber</i> array are significant and contains the IP address. The remaining bytes are not significant and an application should not depend on them having any particular value, including zero.
INET_ADDRESS_IPV6	Specifies that the address should be returned in IPv6 format. All bytes in the <i>ipNumber</i> array are significant. Note that it is possible for an IPv6 address to actually represent an IPv4 address. This is indicated by the first 10 bytes of the address being zero.

lpAddress

A pointer to an [INTERNET_ADDRESS](#) structure that will contain the IP address of the specified host.

Return Value

If the method succeeds, the return value is zero. If the function fails, the return value is INET_ERROR. To get extended error information, call **InetGetLastError**.

Remarks

This method can also be used to convert an address in dot notation to a binary format. If the method must perform a DNS lookup to resolve the hostname, the calling thread will block. To ensure future compatibility with IPv6 networks, it is important that the application does not make any assumptions about the format of the address. If the function returns successfully, the *ipFamily* member of the **INTERNET_ADDRESS** structure should always be checked to determine the type of address.

The *nAddressFamily* parameter is used to specify a preference for the type of address returned, however it is possible that a host may not have an IPv4 or IPv6 address record, in which case this function will fail. Although IPv4 is still the most common address used at this time, an application should not assume that because a given host name does not have an IPv4 address, that the host name is invalid.

If the *nAddressFamily* parameter is specified as `INET_ADDRESS_UNKNOWN`, the application must be prepared to handle IPv6 addresses because it is possible for a host name to have an IPv6 address assigned to it and no IPv4 address. For legacy applications that only recognize IPv4 addresses, the *nAddressFamily* member should always be specified as `INET_ADDRESS_IPV4` to ensure that only IPv4 addresses are returned.

To determine if the local system has an IPv6 TCP/IP stack installed and configured on the local system, use the **IsProtocolAvailable** method. If an IPv6 stack is not installed, this method will fail if the *lpszHostName* parameter specifies a host that only has an IPv6 (AAAA) DNS record.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cswsock10.h`

Import Library: `cswskv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

See Also

[GetHostName](#), [GetLocalAddress](#), [GetLocalName](#), [GetPeerAddress](#), [IsProtocolAvailable](#), [INTERNET_ADDRESS](#)

CSocketWrench::GetHostFile Method

```
INT GetHostFile(  
    LPTSTR lpszFileName,  
    INT nMaxLength  
);  
  
INT GetHostFile(  
    CString& strFileName  
);
```

The **GetHostFile** method returns the name of the host file previously set using the **SetHostFile** method. The host file is used as a database that maps an IP address to one or more hostnames, and is used by the **GetHostAddress** and **GetHostNames** method.

Parameters

lpszFileName

Pointer to a string buffer that will contain the host file name. It is recommended that this buffer be at least MAX_PATH characters in size. This parameter may be NULL, in which case the method will return the length of the string, not including the terminating null character.

nMaxLength

The maximum number of characters that may be copied to the string buffer.

Return Value

If the method succeeds, the return value is length of the string. A return value of zero indicates that no host file has been specified or the method was unable to determine the file name. To get extended error information, call **GetLastError**. If the last error is zero, this indicates that no host file name has been specified for the current thread. If the last error is non-zero, this indicates the reason that the method failed.

Remarks

This method only returns the name of the host file that is cached in memory for the current thread. The contents of the file on the disk may have changed after the file was loaded into memory. To reload the host file or clear the cache, call the **SetHostFile** method.

If a host file has been specified, it is processed before the default host file when resolving a hostname into an IP address, or an IP address into a hostname. If the host name or address is not found, or no host file has been specified, a nameserver lookup is performed.

The host file returned by this method may be different than the default host file for the local system. To determine the file name for the default host file, use the **GetDefaultHostFile** method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[GetDefaultHostFile](#), [GetHostAddress](#), [GetHostName](#), [SetHostFile](#)

CSocketWrench::GetHostName Method

```
INT GetHostName(  
    LPINTERNET_ADDRESS LpAddress,  
    LPTSTR LpszHostName,  
    INT cchHostName  
);
```

```
INT GetHostName(  
    LPINTERNET_ADDRESS LpAddress,  
    CString& strHostName  
);
```

The **GetHostName** method performs a reverse lookup, returning the host name associated with a given IP address.

Parameters

LpAddress

A pointer to an [INTERNET_ADDRESS](#) structure which specifies the IP address that should be resolved into a host name.

LpszHostName

A pointer to the buffer that will contain the host name. It is recommended that this buffer be at least 256 characters in length to accommodate the longest possible fully qualified domain name.

cchHostName

The maximum number of characters that can be copied into the buffer.

Return Value

If the method succeeds, the return value is the length of the hostname. If the method fails, the return value is `INET_ERROR`. To get extended error information, call **InetGetLastError**.

Remarks

If the method must perform a reverse DNS lookup to resolve the IP address into a host name, the calling thread will block. This method requires that the host have a PTR record, otherwise it will fail. Because many hosts do not have a PTR record, calling this method frequently may have a negative impact on the overall performance of the application.

To determine if the local system has an IPv6 TCP/IP stack installed and configured on the local system, use the **IsProtocolAvailable** method. If an IPv6 stack is not installed, this method will fail if the *LpAddress* parameter specifies an IPv6 address, even if the address itself is valid.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cssock10.h`

Import Library: `cswskv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

CSocketWrench::GetLastError Method

```
DWORD GetLastError();  
  
DWORD GetLastError(  
    CString& strDescription  
);
```

Parameters

strDescription

A string which will contain a description of the last error code value when the method returns. If no error has been set, or the last error code has been cleared, this string will be empty.

Return Value

The return value is the last error code value for the current thread. Functions set this value by calling the **SetLastError** method. The Return Value section of each reference page notes the conditions under which the method sets the last error code.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. You should call the **GetLastError** method immediately when a method's return value indicates that an error has occurred. That is because some methods call **SetLastError(0)** when they succeed, clearing the error code set by the most recently failed method.

Most methods will set the last error code value when they fail; a few methods set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_SOCKET or INET_ERROR. Those methods which call **SetLastError** when they succeed are noted on the method reference page.

The description of the error code is the same string that is returned by the **GetErrorString** method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cswskv10.lib

See Also

[GetErrorString](#), [SetLastError](#), [ShowError](#)

CSocketWrench::GetLocalAddress Method

```
INT GetLocalAddress(  
    INT nAddressFamily,  
    LPINTERNET_ADDRESS lpAddress,  
    UINT * lpnPort  
);
```

```
INT GetLocalAddress(  
    LPTSTR lpszAddress,  
    INT nMaxLength  
);
```

```
INT GetLocalAddress(  
    CString& strAddress,  
    UINT * lpnPort  
);
```

The **GetLocalAddress** method returns the local IP address and port number for the current socket.

Parameters

nAddressFamily

An integer which identifies the type of IP address to return. It may be one of the following values:

Constant	Description
INET_ADDRESS_UNKNOWN	Return the IP address for the specified host in either IPv4 or IPv6 format, depending on the type of connection that was established. If the <i>hSocket</i> parameter is INVALID_SOCKET, a preference will be given for returning an IPv4 address. However, if the local host only has an IPv6 address, that value will be returned.
INET_ADDRESS_IPV4	Specifies that the address should be returned in IPv4 format. The first four bytes of the <i>ipNumber</i> array are significant and contains the IP address. The remaining bytes are not significant and an application should not depend on them having any particular value, including zero.
INET_ADDRESS_IPV6	Specifies that the address should be returned in IPv6 format. All bytes in the <i>ipNumber</i> array are significant. Note that it is possible for an IPv6 address to actually represent an IPv4 address. This is indicated by the first 10 bytes of the address being zero.

lpAddress

A pointer to an [INTERNET_ADDRESS](#) structure that will contain the IP address of the local host. If there is no active connection, this function will attempt to determine the IP address of the local host assigned by the system. If the address is not required, this parameter may be NULL.

lpszAddress

A pointer to a null terminated string that will contain the IP address of the local host. If this

version of the method is used, the IP address is converted to a string format using the **FormatAddress** method. The string should be able to store at least 46 characters to ensure that both IPv4 and IPv6 formatted addresses can be returned without the possibility of a buffer overrun. An alternate form of the method accepts a **CString** argument which will contain the local address.

lpnPort

A pointer to an unsigned integer that will contain the local port number. If there is an active connection, this parameter will be set to the local port that the socket is bound to. If there is no active connection, this parameter is ignored. If the local port number is not required, this parameter may be NULL.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is `INET_ERROR`. To get extended error information, call **GetLastError**.

Remarks

To ensure future compatibility with IPv6 networks, it is important that the application does not make any assumptions about the format of the address. If the function returns successfully, the *ipFamily* member of the **INTERNET_ADDRESS** structure should always be checked to determine the type of address.

If the *nAddressFamily* parameter is specified as `INET_ADDRESS_UNKNOWN`, the application must be prepared to handle IPv6 addresses because it is possible for the local host to have an IPv6 address assigned to it and no IPv4 address. For legacy applications that only recognize IPv4 addresses, the *nAddressFamily* member should always be specified as `INET_ADDRESS_IPV4` to ensure that only IPv4 addresses are returned.

If the system is connected to the Internet through a local network and/or uses a router that performs Network Address Translation (NAT), the **GetLocalAddress** method will return the local, non-routable IP address assigned to the local system. To determine the public IP address has been assigned to the system, you should use the **GetExternalAddress** method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cswsock10.h`

Import Library: `cswskv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

CSocketWrench::GetLocalName Method

```
INT GetLocalName(  
    LPTSTR lpszHostName,  
    INT cchHostName  
);  
  
INT GetLocalName(  
    CString& strHostName  
);
```

The **GetLocalName** method returns the hostname assigned to the local system.

Parameters

lpszHostName

A pointer to the buffer that will contain the hostname. This parameter cannot be NULL. An alternate form of the method accepts a **CString** argument which will contain the local hostname.

cchHostName

The maximum number of characters that can be copied into the address buffer.

Return Value

If the method succeeds, the return value is the length of the hostname. If the method fails, the return value is INET_ERROR. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

Unicode: Implemented as Unicode and ANSI versions.

CSocketWrench::GetNextAlias Method

```
BOOL GetNextAlias(  
    LPTSTR lpszHostAlias,  
    INT nMaxLength  
);  
  
BOOL GetNextAlias(  
    CString& strHostAlias  
);
```

The **GetNextAlias** method returns the next alias for the host name specified in the call to **GetFirstAlias**.

Parameters

lpszHostAlias

A string buffer which will contain the next alias for the specified host name. This string should be at least 64 bytes in length. This argument may also reference a **CString** object which will contain the host alias when the method returns.

nMaxLength

Maximum number of characters that can be copied into the *lpszHostAlias* string buffer, including the terminating null byte.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Example

```
CSocketWrench sockClient;  
CString strHostAlias;  
BOOL bResult;  
  
m_ctlListBox.ResetContent();  
  
bResult = sockClient.GetFirstAlias(m_strHostName, strHostAlias);  
if (bResult == FALSE)  
{  
    sockClient.ShowError();  
    return;  
}  
  
while (bResult)  
{  
    m_ctlListBox.AddString(strHostAlias);  
    bResult = sockClient.GetNextAlias(strHostAlias);  
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cswsock10.h

Import Library: cswskv10.lib

Unicode: Implemented as Unicode and ANSI versions.

CSocketWrench::GetOption Method

```
INT GetOption(  
    DWORD dwOption,  
    LPBOOL lpbEnabled  
);
```

The **GetOption** method is used to determine if a specific socket option has been enabled.

Parameters

dwOption

An unsigned integer used to specify one of the socket options. These options cannot be combined. The following values are recognized:

Constant	Description
INET_OPTION_BROADCAST	This option specifies that broadcasting should be enabled for datagrams. This option is invalid for stream sockets.
INET_OPTION_KEEPAIVE	This option specifies that packets are to be sent to the remote system when no data is being exchanged to keep the connection active. This is only valid for stream sockets.
INET_OPTION_REUSEADDRESS	This option specifies the local address can be reused. This option is commonly used by server applications.
INET_OPTION_NODELAY	This option disables the Nagle algorithm, which buffers unacknowledged data and insures that a full-size packet can be sent to the remote host.

lpbEnabled

A pointer to a boolean flag. If the option is enabled, the flag is set to a non-zero value, otherwise it is set to a value of zero.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is INET_ERROR. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cswskv10.lib

See Also

CSocketWrench::GetPeerAddress Method

```
INT GetPeerAddress(  
    LPINTERNET_ADDRESS LpAddress,  
    UINT * LpnRemotePort  
);  
  
INT GetPeerAddress(  
    LPTSTR LpszAddress,  
    INT nMaxLength  
);  
  
INT GetPeerAddress(  
    CString& strAddress  
);
```

The **GetPeerAddress** method returns the peer IP address and remote port number for the specified socket.

Parameters

lpAddress

A pointer to an [INTERNET_ADDRESS](#) structure that will contain the IP address of the remote host that is connected to the socket.

lpnRemotePort

A pointer to an unsigned integer that will contain the port number of the remote host that is connected to the socket.

lpszAddress

A pointer to a string buffer that will contain the formatted IP address, terminated with a null character. To accommodate both IPv4 and IPv6 addresses, this buffer should be at least 46 characters in length.

nMaxLength

The maximum number of characters that can be copied into the address buffer.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is `INET_ERROR`. To get extended error information, call **GetLastError**.

Remarks

If this method is called by a server application in response to a `INET_EVENT_ACCEPT` event, it will return the IP address and port number for the client that is attempting to establish the connection. If the peer address is unavailable, the *ipFamily* member of the `INTERNET_ADDRESS` structure will be zero.

The format and length of IPv4 and IPv6 address strings are very different. An IPv4 address string looks like "192.168.0.20", while an IPv6 address string can look something like "fd7c:2f6a:4f4f:ba34::a32". If your application checks for the format of these address strings, it needs to be aware of the differences. You also need to make sure that you're providing enough space to display or store an address to avoid buffer overruns.

It is not recommended that you use the port number for anything other than informational and logging purposes. Server applications should not make any assumptions about the specific port number or range of port numbers that a client is using when establishing a connection to the

server. The ephemeral port number that a client is bound to can vary based on the client operating system.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

See Also

[GetHostAddress](#), [GetHostName](#), [GetLocalAddress](#), [GetLocalName](#), [GetPeerPort](#), [INTERNET_ADDRESS](#)

CSocketWrench::GetPhysicalAddress Method

```
BOOL GetPhysicalAddress(  
    LPTSTR lpszAddress,  
    UINT cchAddress  
);  
  
BOOL GetPhysicalAddress(  
    CString& strAddress  
);
```

Return the media access control (MAC) address for the primary network adapter.

Parameters

lpszAddress

A string buffer that will contain the address in a printable format when the function returns. This parameter cannot be NULL. An alternate form of the method accepts a **CString** argument which will contain the address.

cchAddress

The maximum number of characters that can be copied into the buffer, including the terminating null character.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **GetPhysicalAddress** method returns the media access control (MAC) address for the primary network adapter. This is a 48 bit or 64 bit address that is assigned to each network interface and is used for identification and access control. All network devices on the same subnet must be assigned their own unique MAC address. Unlike IP addresses which may be assigned dynamically and can be frequently changed, MAC addresses are considered to be more permanent because they are usually assigned by the device manufacturer and stored in firmware. Note that in some cases it is possible to change the address assigned to a device, and virtual network interfaces may have configurable MAC addresses.

This method returns the MAC address as a printable string, with each byte of the address as a two-digit hexadecimal value separated by a colon. The string buffer passed to the method should be at least 20 characters long to accommodate the address and terminating null character. An example of a 48 bit address would be "01:23:45:67:89:AB". If the local system is multi-homed (having more than one network adapter) then this method will return the MAC address for the primary network adapter.

This method is provided for backwards compatibility with previous versions of the library and it is recommended that new applications use the **GetAdapterAddress** method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cswsock10.h`

Import Library: `cswskv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

See Also

[EnumNetworkAddresses](#), [GetAdapterAddress](#), [GetLocalName](#), [GetHostAddress](#)

CSocketWrench::GetSecurityInformation Method

```
BOOL GetSecurityInformation(  
    LPSECURITYINFO LpSecurityInfo  
);
```

The **GetSecurityInformation** method returns security protocol, encryption and certificate information about the current client connection.

Parameters

LpSecurityInfo

A pointer to a [SECURITYINFO](#) structure which contains information about the current client connection. The *dwSize* member of this structure must be initialized to the size of the structure before passing the address of the structure to this method.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

This method is used to obtain security related information about the current client connection to the server. It can be used to determine if a secure connection has been established, what security protocol was selected, and information about the server certificate. Note that a secure connection has not been established, the *dwProtocol* structure member will contain the value SECURITY_PROTOCOL_NONE.

Example

The following example notifies the user if the connection is secure or not:

```
SECURITYINFO securityInfo;  
securityInfo.dwSize = sizeof(SECURITYINFO);  
  
if (pSocket->GetSecurityInformation(&securityInfo))  
{  
    if (securityInfo.dwProtocol == SECURITY_PROTOCOL_NONE)  
    {  
        MessageBox(NULL, _T("The connection is not secure"),  
                    _T("Connection"), MB_OK);  
    }  
    else  
    {  
        if (securityInfo.dwCertStatus == SECURITY_CERTIFICATE_VALID)  
        {  
            MessageBox(NULL, _T("The connection is secure"),  
                        _T("Connection"), MB_OK);  
        }  
        else  
        {  
            MessageBox(NULL, _T("The server certificate not valid"),  
                        _T("Connection"), MB_OK);  
        }  
    }  
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: csuskv10.lib

Unicode: Implemented as Unicode and ANSI versions.

CSocketWrench::GetServiceName Method

```
BOOL GetServiceName(  
    UINT nServicePort,  
    LPTSTR lpszServiceName,  
    INT nMaxLength  
);  
  
BOOL GetServiceName(  
    UINT nServicePort,  
    CString& strServiceName  
);
```

The **GetServiceName** method returns the service name associated with a specified port number.

Parameters

nServicePort

Port number associated with some network service.

lpszServiceName

A pointer to a string buffer that will contain the service name when the method returns. This may also reference a **CString** object that will contain the service name.

nMaxLength

An integer value which specifies the maximum number of characters that can be copied into the string buffer.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[GetServicePort](#)

CSocketWrench::GetServicePort Method

```
UINT GetServicePort(  
    LPCTSTR lpszServiceName  
);
```

The **GetServicePort** method returns the port number associated with a service name.

Parameters

lpszServiceName

A pointer to a string which specifies the name of the service to return the port number for.

Return Value

If the method succeeds, the return value is the port number associated with a service name. If the method fails, the return value is INET_ERROR. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cswskv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[GetServiceName](#)

CSocketWrench::GetStatus Method

```
INT GetStatus();
```

The **GetStatus** method returns the current status of the socket.

Parameters

None.

Return Value

If the method succeeds, the return value is the client status code. If the method fails, the return value is `INET_ERROR`. To get extended error information, call **GetLastError**.

Remarks

The return value is one of the following values:

Value	Constant	Description
0	<code>INET_STATUS_UNUSED</code>	No connection has been established.
1	<code>INET_STATUS_IDLE</code>	The socket is idle and not in a blocked state
2	<code>INET_STATUS_LISTEN</code>	The socket is listening for inbound connections from a client
3	<code>INET_STATUS_CONNECT</code>	The socket is establishing a connection with a server
4	<code>INET_STATUS_ACCEPT</code>	The socket is accepting a connection from a client
5	<code>INET_STATUS_READ</code>	Data is being read from the socket
6	<code>INET_STATUS_WRITE</code>	Data is being written to the socket
7	<code>INET_STATUS_FLUSH</code>	The socket is being flushed; all data in the receive buffers is being discarded
8	<code>INET_STATUS_DISCONNECT</code>	The socket is disconnecting from the remote host

In a multithreaded application, any thread in the current process may call this method to obtain status information for the specified socket.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cswsock10.h`

Import Library: `cswskv10.lib`

CSocketWrench::GetStreamInfo Method

```
BOOL GetStreamInfo(  
    LPINETSTREAMINFO LpStreamInfo  
);
```

The **GetStreamInfo** function fills a structure with information about the current stream I/O operation.

Parameters

lpSecurityInfo

A pointer to an **INETSTREAMINFO** structure which contains information about the status of the current operation.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **GetStreamInfo** method returns information about the current streaming socket operation, including the average number of bytes transferred per second and the estimated amount of time until the operation completes. If there is no operation currently in progress, this method will return the status of the last successful streaming read or write performed by the client.

In a multithreaded application, any thread in the current process may call this method to obtain status information for the specified socket.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cswsock10.h`

Import Library: `cswskv10.lib`

See Also

[ReadStream](#), [StoreStream](#), [WriteStream](#), [INETSTREAMINFO](#)

CSocketWrench::GetTimeout Method

```
INT GetTimeout();
```

The **GetTimeout** method returns the number of seconds the client will wait for a response from the remote host. Once the specified number of seconds has elapsed, the method will fail and return to the caller.

Parameters

None.

Return Value

If the method succeeds, the return value is the timeout period in seconds. If the method fails, the return value is `INET_ERROR`. To get extended error information, call **GetLastError**.

Remarks

The timeout value is only used with blocking client connections. A value of zero indicates that the default timeout period of 20 seconds should be used.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cssock10.h`

Import Library: `cswskv10.lib`

See Also

[Connect](#), [IsReadable](#), [IsWritable](#), [Read](#), [SetTimeout](#), [Write](#)

CSocketWrench::HostNameToUnicode Method

```
INT HostNameToUnicode(  
    LPCTSTR lpszHostName,  
    LPTSTR lpszUnicodeName,  
    INT nMaxLength  
);  
  
INT HostNameToUnicode(  
    LPCTSTR lpszHostName,  
    CString& strUnicodeName  
);
```

The **HostNameToUnicode** method converts the canonical form of a host name to its Unicode version.

Parameters

lpszHostName

Pointer to the host name as a null-terminated string. This parameter cannot be a NULL pointer or a zero length string.

lpszUnicodeName

Pointer to the string buffer that will contain the original Unicode version of the host name, including the terminating null character. It is recommended that this buffer be at least 256 characters in size. This parameter cannot be a NULL pointer. An alternate version of this method accepts a reference to a CString object.

nMaxLength

The maximum number of characters that can be copied to the *lpszUnicodeName* string buffer. This parameter cannot be zero, and must include the terminating null character.

Return Value

If the method succeeds, the return value is the number of characters copied into the string buffer. If the method fails, the return value is INET_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **HostNameToUnicode** method will convert the encoded ASCII version of a host name to its Unicode version. Although any valid host name is accepted by this method, it is intended to convert a Punycode encoded host name to its original Unicode character encoding.

If the application is compiled using the Unicode character set, the value returned in *lpszUnicodeName* will be a Unicode string using UTF-16 encoding. If the ANSI character set is used, the value returned will be a Unicode string using UTF-8 encoding. To display a UTF-8 encoded host name, your application will need to convert it to UTF-16 using the **MultiByteToWideChar** function.

Although this method performs checks to ensure that the *lpszHostName* parameter is in the correct format and does not contain any illegal characters or malformed encoding, it does not validate the existence of the domain name. To check if the host name exists and has a valid IP address, use the [GetHostAddress](#) method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cswsock10.h

Import Library: cswskv10.lib

Unicode: Implemented as Unicode and ANSI versions.

CSocketWrench::IsAddressNull Method

```
BOOL IsAddressNull(  
    LPCTSTR lpszAddress  
);  
  
BOOL IsAddressNull(  
    LPINTERNET_ADDRESS lpAddress  
);
```

The **IsAddressNull** method determines if the IP address is null.

Parameters

lpszAddress

A string that specifies the IP address.

lpAddress

A pointer to an INTERNET_ADDRESS structure that specifies the IP address.

Return Value

If the method succeeds and the IP address is null, or the parameter is a NULL pointer, the return value is non-zero. If the method fails or the address is not null, the return value is zero. If the address family is not supported, the last error code will be updated. If the address is valid but not null, the last error code will be set to NO_ERROR.

Remarks

A null IP address is one where all bits for the address (32 bits for IPv4 or 128 bits for IPv6) are zero. This is a special address that is typically used when creating a passive socket that should listen for connections on all available network interfaces.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: csuskv10.lib

See Also

[GetAddress](#), [IsAddressRoutable](#), [INTERNET_ADDRESS](#)

CSocketWrench::IsAddressRoutable Method

```
BOOL IsAddressRoutable(  
    LPCTSTR lpszAddress  
);  
  
BOOL IsAddressRoutable(  
    LPINTERNET_ADDRESS lpAddress  
);
```

The **IsAddressRoutable** method determines if the IP address is routable over the Internet.

Parameters

lpszAddress

A string that specifies the IP address.

lpAddress

A pointer to an INTERNET_ADDRESS structure that specifies the IP address.

Return Value

If the method succeeds and the IP address is routable over the Internet, the return value is non-zero. If the method fails or the address is not routable, the return value is zero. If the parameter is NULL, or the address family is not supported, the last error code will be updated. If the address is valid but not routable, the last error code will be set to NO_ERROR.

Remarks

A routable IP address is one that can be reached by anyone over the public Internet. These are also commonly referred to as "public addresses" which are typically assigned to networks and individual hosts by an Internet service provider. There are also certain addresses that are not routable over the Internet, and used to address systems over a local network or private intranet. This function can be used to determine if a given IP address is public (routable) or private.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cswskv10.lib

CSocketWrench::IsBlocking Method

```
BOOL IsBlocking();
```

The **IsBlocking** method is used to determine if the socket is performing a blocking operation.

Parameters

None.

Return Value

If the socket is currently performing a blocking operation, the method returns a non-zero value. If the socket is not performing a blocking operation, or the socket handle is invalid, the method returns zero.

Remarks

This method is typically used to determine if a socket that is being used by another thread is currently blocked. A socket may block when waiting to receive data from a remote host or while data is actively being exchanged. Because there can only be one blocking socket operation per thread, this method can be used to determine if a method such as **Read** or **Write** would fail because another thread is currently sending or receiving data on that socket.

It is important to note that if this method returns a non-zero value, it does not guarantee that a subsequent read or write on the socket will succeed. The application should always check the return value from methods such as **Read** and **Write** to ensure they were successful.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cswskv10.lib

CSocketWrench::IsClosed Method

```
BOOL IsClosed();
```

The **IsClosed** method is used to determine if the remote host has closed its socket.

Parameters

None.

Return Value

If the remote host has closed its socket, the method returns a non-zero value. If the remote host has not closed its connection, or the socket handle is invalid, the method returns zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

See Also

[IsConnected](#), [IsListening](#), [IsReadable](#), [IsWritable](#)

CSocketWrench::IsConnected Method

BOOL IsConnected();

The **IsConnected** method is used to determine if the socket is currently connected to a remote host.

Parameters

None.

Return Value

If the client is connected to a remote host, the method returns a non-zero value. If the client is not connected, or the client handle is invalid, the method returns zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

See Also

[GetStatus](#), [IsBlocking](#), [IsInitialized](#), [IsReadable](#), [IsWritable](#)

CSocketWrench::IsInitialized Method

```
BOOL IsInitialized();
```

The **IsInitialized** method returns whether or not the class object has been successfully initialized.

Parameters

None.

Return Value

This method returns a non-zero value if the class object has been successfully initialized. A return value of zero indicates that the runtime license key could not be validated or the networking library could not be loaded by the current process.

Remarks

When an instance of the class is created, the class constructor will attempt to initialize the component with the runtime license key that was created when SocketTools was installed. If the constructor is unable to validate the license key or load the networking libraries, this initialization will fail.

If SocketTools was installed with an evaluation license, the application cannot be redistributed to another system. The class object will fail to initialize if the application is executed on another system, or if the evaluation period has expired. To redistribute your application, you must purchase a development license which will include the runtime key that is needed to redistribute your software to other systems. Refer to the Developer's Guide for more information.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cswskv10.lib

See Also

[CSocketWrench](#), [IsBlocking](#), [IsConnected](#)

CSocketWrench::IsListening Method

```
BOOL IsListening();
```

The **IsListening** method determines if the socket is listening for connection requests.

Parameters

None.

Return Value

If the socket is being used to listen for connection requests, the method returns a non-zero value. If the socket is not listening or the socket handle is invalid, the method returns zero.

Remarks

The **IsListening** method determines if the socket is being used in a server application to actively listen for incoming connection requests from client applications. A listening socket can be created using the **Listen** method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cswskv10.lib

See Also

CSocketWrench::IsProtocolAvailable Method

```
BOOL IsProtocolAvailable(  
    INT nAddressFamily,  
    INT nProtocol  
);
```

The **IsProtocolAvailable** method determines if the operating system supports creating a socket for the specified address family and protocol.

Parameters

nAddressFamily

An integer which identifies the address family that should be checked. It should be one of the following values:

Constant	Description
INET_ADDRESS_IPV4	Specifies that the function should determine if it can create an Internet Protocol version 4 (IPv4) socket. This requires that the system have an IPv4 TCP/IP stack bound to at least one network adapter on the local system. All Windows systems include support for IPv4 by default.
INET_ADDRESS_IPV6	Specifies that the function should determine if it can create an Internet Protocol version 6 (IPv6) socket. This requires that the system have an IPv6 TCP/IP stack bound to at least one network adapter on the local system. Windows XP and Windows Server 2003 includes support for IPv6, however it is not installed by default. Windows Vista and later versions include support for IPv6 and enable it by default.

nProtocol

An integer which identifies the protocol that should be checked. It should be one of the following values:

Constant	Description
INET_PROTOCOL_TCP	Specifies the Transmission Control Protocol. This protocol provides a reliable, bi-directional byte stream. This requires that the system be capable of creating a stream socket using the specified address family.
INET_PROTOCOL_UDP	Specifies the User Datagram Protocol. This protocol is message oriented, sending data in discrete packets. This requires that the system be capable of creating a datagram socket using the specified address family.

Return Value

If the the system is capable of creating a socket using the specified address family and protocol, this method will return a non-zero value. If the combination of address family and protocol is not supported, this method will return a value of zero.

Remarks

The **IsProtocolAvailable** method is used to determine if the operating system supports creating a particular type of socket. Typically it is used by an application to determine if the system has an IPv6 TCP/IP stack installed and configured. By default, all Windows systems will have an IPv4 stack installed if the system has a network adapter. However, not all systems may have an IPv6 stack installed, particularly older Windows XP and Windows Server 2003 systems. Note that if an IPv6 stack is not installed, the library will not recognize IPv6 addresses and cannot resolve host names that only have an IPv6 (AAAA) record, even if the address or host name is valid.

Example

```
if (!pSocket->IsProtocolAvailable(INET_ADDRESS_IPV6, INET_PROTOCOL_TCP))
{
    AfxMessageBox(_T("This system does not support IPv6"), MB_ICONEXCLAMATION);
    return;
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

See Also

[GetAddress](#), [GetHostAddress](#), [GetHostName](#)

CSocketWrench::IsReadable Method

```
BOOL IsReadable(  
    INT nTimeout,  
    LPDWORD lpdwAvail  
);
```

The **IsReadable** method is used to determine if data is available to be read from the remote host.

Parameters

nTimeout

Timeout for remote host response, in seconds. A value of zero specifies that the connection should be polled without blocking the current thread.

lpdwAvail

A pointer to an unsigned integer which will contain the number of bytes available to read. This parameter may be NULL if this information is not required.

Return Value

If the current thread can read data from the socket without blocking, the method returns a non-zero value. If the current thread cannot read any data without blocking, the function returns zero.

Remarks

On some platforms, this value will not exceed the size of the receive buffer (typically 64K bytes). Because of differences between TCP/IP stack implementations, it is not recommended that your application exclusively depend on this value to determine the exact number of bytes available. Instead, it should be used as a general indicator that there is data available to be read.

If the connection is secure, the value returned in *lpdwAvail* will reflect the number of bytes available in the encrypted data stream. The actual amount of data available to the application after it has been decrypted will vary.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cssock10.h`

Import Library: `cswskv10.lib`

See Also

[IsWritable](#), [Peek](#), [Read](#), [ReadLine](#), [ReadStream](#)

CSocketWrench::IsUrgent Method

BOOL IsUrgent();

The **IsUrgent** method determines if there is any out-of-band (OOB) data available to be read.

Parameters

None.

Return Value

If there is out-of-band data, the return value is non-zero. If there is no out-of-band data, or an error occurs the return value is zero. To determine if an error has occurred, use the **GetLastError** method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: csuskv10.lib

See Also

[SetOption \(INET_OPTION_INLINE\)](#)

CSocketWrench::IsWritable Method

```
BOOL IsWritable(  
    INT nTimeout  
);
```

The **IsWritable** method is used to determine if data can be written to the remote host.

Parameters

nTimeout

Timeout for remote host response, in seconds. A value of zero specifies that the connection should be polled without blocking the current thread.

Return Value

If data can be written to the socket within the specified timeout period, the method returns a non-zero value. The method will return zero if the socket send buffer is full.

Remarks

The **IsWritable** method cannot be used to determine the amount of data that can be sent to the remote host without blocking the current thread. A non-zero return value only indicates that the send buffer is not full and can accept some data. In most cases, it is recommended that larger blocks of data be broken into smaller logical blocks rather than attempting to send it all of the data at once. For very large streams of data, it is recommended that you use the **WriteStream** method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cswskv10.lib

See Also

[IsReadable](#), [Write](#), [WriteLine](#), [WriteStream](#)

CSocketWrench::Listen Method

```
SOCKET Listen(  
    LPCTSTR lpszLocalAddress,  
    UINT nLocalPort,  
    UINT nBackLog,  
    DWORD dwOptions,  
    HWND hEventWnd,  
    UINT uEventMsg  
);
```

The **Listen** method creates a listening socket and specifies the maximum number of connection requests that will be queued.

This method is included for backwards compatibility with legacy applications. New projects should use the **CInternetServer** class to create a server application.

Parameters

lpszLocalAddress

A pointer to a string which specifies the local IP address that the socket should be bound to. If this parameter is NULL or points to an empty string, a client may establish a connection using any valid network interface configured on the local system. If an address is specified, then a client may only establish a connection with the system using that address.

nLocalPort

The local port number that the socket should be bound to. This value must be greater than zero. Port numbers less than 1024 are considered reserved ports and may require that the process execute with administrative privileges and/or require changes to the default firewall rules to permit inbound connections.

nBacklog

The maximum length of queue of pending connections. On Windows workstations, the maximum backlog value is 5. On Windows servers, the maximum value is 200.

dwOptions

An unsigned integer used to specify one or more socket options. The following values are recognized:

Constant	Description
INET_OPTION_NONE	No option specified. If the address and port number are in use by another application or a closed socket which was listening on this port is still in the TIME_WAIT state, the function will fail.
INET_OPTION_REUSEADDRESS	This option enables a server application to listen for connections using the specified address and port number even if they were in use recently. This is typically used to enable an application to close the listening socket and immediately reopen it without getting an error that the address is in use.
INET_OPTION_EXCLUSIVE	This option specifies the local address and port number is for the exclusive use by the current process, preventing another application from forcibly

	binding to the same address. If another process has already bound a socket to the address provided by the caller, this function will fail.
--	--

hEventWnd

The handle to the event notification window. This window receives messages which notify the application of various asynchronous socket events that occur.

uEventMsg

The message identifier that is used when an asynchronous socket event occurs. This value should be greater than WM_USER as defined in the Windows header files.

Return Value

If the method succeeds, the return value is a handle to the socket. If the method fails, the return value is INVALID_SOCKET. To get extended error information, call **GetLastError**.

Remarks

To listen for connections on any suitable IPv4 interface, specify the special dotted-quad address "0.0.0.0". You can accept connections from clients using either IPv4 or IPv6 on the same socket by specifying the special IPv6 address "::0", however this is only supported on Windows 7 and Windows Server 2008 R2 or later platforms. If no local address is specified, then the server will only listen for connections from clients using IPv4. This behavior is by design for backwards compatibility with systems that do not have an IPv6 TCP/IP stack installed.

If the INET_OPTION_REUSEADDRESS option is not specified, an error may be returned if a listening socket was recently created for the same local address and port number. By default, once a listening socket is closed there is a period of time that all applications must wait before the address can be reused (this is called the TIME_WAIT state). The actual amount of time depends on the operating system and configuration parameters, but is typically two to four minutes. Specifying this option enables an application to immediately re-use a local address and port number that was previously in use. Note that this does not permit more than one server to bind to the same address.

If the INET_OPTION_EXCLUSIVE option is specified, the local address and port number cannot be used by another process until the listening socket is closed. This can prevent another application from forcibly binding to the same listening address as your server. This option can be useful in determining whether or not another process is already bound to the address you wish to use, but it may also prevent your server application from restarting immediately, regardless if the INET_OPTION_REUSEADDRESS option has also been specified.

If an IPv6 address is specified as the local address, the system must have an IPv6 stack installed and configured, otherwise the method will fail.

The use of Windows event notification messages has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

To prevent this method from blocking the main user interface thread, the application should create a background worker thread and establish a connection by calling **Listen** in that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread to accept each client session.

When a message is posted to the notification window, the low word of the *lParam* parameter

contains the event identifier. The high word of *lParam* contains the low word of the error code, if an error has occurred. The *wParam* parameter contains the socket handle. One or more of the following event identifiers may be sent:

Constant	Description
INET_EVENT_ACCEPT	An incoming client connection is pending. The connection will be assigned to a new socket. This event is only generated if the socket is in asynchronous mode.

To cancel asynchronous notification and return the socket to a blocking mode, use the **DisableEvents** method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cswsock10.h

Import Library: cswskv10.lib

Unicode: Implemented as Unicode and ANSI versions.

CSocketWrench::MatchHostName Method

```
BOOL MatchHostName(  
    LPCTSTR lpszHostName,  
    LPCTSTR lpszHostMask  
    BOOL bResolve  
);
```

The **MatchHostName** method matches a host name against one or more strings that may contain wildcards.

Parameters

lpszHostName

A pointer to a string which specifies the host name or IP address to match.

lpszHostMask

A pointer to a string which specifies one or more values to match against the host name. The asterisk character can be used to match any number of characters in the host name, and the question mark can be used to match any single character. Multiple values may be specified by separating them with a semicolon.

bResolve

A boolean value which specifies if the host name or IP address should be resolved when matching the host against the mask string. If this parameter is non-zero, two checks against the host mask string will be performed; once for the host name specified and once for its IP address. If this parameter is zero, then the match is made only against the host name string provided.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **MatchHostName** method provides a convenient way for an application to determine if a given host name matches one or more mask strings which may contain wildcard characters. For example, the host name could be "www.microsoft.com" and the host mask string could be "*.microsoft.com". In this example, the method would return a non-zero value indicating the host name matched the mask. However, if the mask string was "*.net" then the method would return zero, indicating that there was no match. Multiple mask values can be combined by separating them with a semicolon; for example, the mask "*.com;*.org" would match any host name in either the .com or .org top-level domains.

If an internationalized domain name (IDN) is specified, it will be converted internally to an ASCII string using Punycode encoding. The host mask will be matched against this encoded version of the host name, not its Unicode version.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

Unicode: Implemented as Unicode and ANSI versions.

Copyright © 2023 Catalyst Development Corporation. All rights reserved.

CSocketWrench::NormalizeHostName Method

```
INT NormalizeHostName(  
    LPCTSTR lpszHostName,  
    LPTSTR lpszNormalized,  
    INT nMaxLength  
);  
  
INT NormalizeHostName(  
    LPCTSTR lpszHostName,  
    CString& strNormalized  
);
```

The **NormalizeHostName** method returns the canonical form of a host name in the specified buffer.

Parameters

lpszHostName

Pointer to the host name as a null-terminated string. This parameter cannot be a NULL pointer or a zero length string.

lpszNormalized

Pointer to the string buffer that will contain the canonical form of the host name, including the terminating null character. It is recommended that this buffer be at least 256 characters in size. This parameter cannot be a NULL pointer. An alternate version of this method accepts a reference to a CString object.

nMaxLength

The maximum number of characters that can be copied to the *lpszNormalized* string buffer. This parameter cannot be zero, and must include the terminating null character.

Return Value

If the method succeeds, the return value is the number of characters copied into the string buffer. If the method fails, the return value is `INET_ERROR`. To get extended error information, call **GetLastError**.

Remarks

The **NormalizeHostName** method will remove all leading and trailing whitespace characters from the host name and fold all upper-case characters to lower-case. If an internationalized domain name (IDN) containing Unicode characters is passed to this method, it will be converted to an ASCII compatible format for domain names.

If the application is compiled using the Unicode character set, the host name will be converted from UTF-16 to UTF-8 and then processed. If you are unsure if an internationalized domain name will be specified as the host name, it is recommended that you use Unicode.

Although this method performs checks to ensure that the *lpszHostName* parameter is in the correct format and does not contain any illegal characters or malformed encoding, it does not validate the existence of the domain name. To check if the host name exists and has a valid IP address, use the [GetHostAddress](#) method.

It is recommended that you use this method if your application needs to store the host name, and if accepts a host name as user input. It is not necessary to call this method prior to calling the other methods that accept a host name as a parameter. They already normalize the host name

and perform checks to ensure it is in the correct format.

If the *lpzHostName* parameter specifies a valid IPv4 or IPv6 address string instead of a host name, this method will return a copy of that IP address in the buffer provided by the caller. This allows the method to be used in cases where a user may input either a host name or IP address. To determine if the IP address has a corresponding host name, use the [GetHostName](#) method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cswsock10.h

Import Library: cswskv10.lib

Unicode: Implemented as Unicode and ANSI versions.

CSocketWrench::Peek Method

```
INT Peek(  
    LPBYTE lpBuffer,  
    INT cbBuffer  
);
```

The **Peek** method reads the specified number of bytes from the socket and copies them into the buffer, but it does not remove the data from the internal socket buffer. The data may be of any type, and is not terminated with a null character.

Parameters

lpBuffer

Pointer to the buffer in which the data will be stored. This argument may be NULL, in which case no data is copied from the socket buffers, however the function will return the number of bytes available to read.

cbBuffer

The maximum number of bytes to read and copy into the specified buffer. If the *lpBuffer* parameter is not NULL, this value must be greater than zero.

Return Value

If the function succeeds, the return value is the number of bytes available to read from the socket. A return value of zero indicates that there is no data available to read at that time. If the function fails, the return value is INET_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **Peek** method returns data that is available to read from the socket, up to the number of bytes specified. The data returned by this method is not removed from the socket buffers. It must be consumed by a subsequent call to the **Read** method. The return value indicates the number of bytes that can be read in a single operation, up to the specified buffer size. However, it is important to note that it may not indicate the total amount of data available to be read from the socket at that time.

If no data is available to be read, the method will return a value of zero. Using this method in a loop to poll a non-blocking socket may cause the application to become non-responsive. To determine if there is data available to be read, use the **IsReadable** method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cswskv10.lib

See Also

[EnableEvents](#), [IsBlocking](#), [IsReadable](#), [IsWritable](#), [Read](#), [ReadLine](#), [RegisterEvent](#), [Write](#), [WriteLine](#)

CSocketWrench::Read Method

```
INT Read(  
    LPBYTE lpBuffer,  
    INT cbBuffer  
);  
  
INT Read(  
    LPBYTE lpBuffer,  
    INT cbBuffer,  
    LPINTERNET_ADDRESS lpAddress,  
    UINT* lpnRemotePort  
);
```

The **Read** method reads the specified number of bytes from the socket and copies them into the buffer. The data may be of any type, and is not terminated with a null character.

Parameters

lpBuffer

Pointer to the buffer in which the data will be stored.

cbBuffer

The maximum number of bytes to read and copy into the specified buffer. This value must be greater than zero.

lpAddress

Pointer to an [INTERNET_ADDRESS](#) structure that which will contain the IP address of the remote host that sent the data being read. If this information is not required, the parameter may be specified as NULL.

lpnRemotePort

Pointer to an unsigned integer which will contain the remote port number. If this information is not required, the parameter may be specified as NULL.

Return Value

If the method succeeds, the return value is the number of bytes actually read. A return value of zero indicates that the remote host has closed the connection and there is no more data available to be read. If the method fails, the return value is `INET_ERROR`. To get extended error information, call **GetLastError**.

Remarks

The **Read** method will read up to the specified number of bytes and store the data in the buffer provided by the caller. If there is no data available to be read at the time this method is invoked, the session thread will block until at least one byte of data becomes available, the timeout period elapses or an error occurs. This method will return if any amount of data is sent by the remote host, and will not block until the entire buffer has been filled. To avoid blocking the current thread, either create an asynchronous socket or use the **IsReadable** method to determine if there is data available to be read prior to calling this function.

The application should never make an assumption about the amount of data that will be available to read. TCP considers all data to be an arbitrary stream of bytes and does not impose any structure on the data itself. For example, if the remote host is sending data to the server in fixed 512 byte blocks of data, it is possible that a single call to the **Read** method will return only a partial block of data, or it may return multiple blocks combined together. It is the responsibility of the

application to buffer and process this data appropriately.

For applications that are built using the Unicode character set, it is important to note that the buffer is an array of bytes, not characters. If the remote host is sending string data to the server, it must be read as a stream of bytes and converted using the **MultiByteToWideChar** function. If the remote host is sending lines of text terminated with a linefeed or carriage return and linefeed pair, the **ReadLine** method will return a line of text at a time and perform this conversion for you.

When **Read** is called and the socket is in non-blocking mode, it is possible that the method will fail because there is no available data to read at that time. This should not be considered a fatal error. Instead, the application should simply wait to receive the next asynchronous notification that data is available.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cswsock10.h

Import Library: csWSKV10.lib

See Also

[EnableEvents](#), [IsBlocking](#), [IsReadable](#), [IsWritable](#), [Peek](#), [ReadLine](#), [RegisterEvent](#), [Write](#), [WriteLine](#)

CSocketWrench::ReadLine Method

```
BOOL ReadLine(  
    LPTSTR lpszBuffer,  
    LPINT lpnLength  
);  
  
BOOL ReadLine(  
    LPTSTR lpszBuffer,  
    INT nMaxLength  
);  
  
BOOL ReadLine(  
    CString& strBuffer,  
    INT nMaxLength  
);
```

The **ReadLine** method reads up to a line of data from the socket and returns it in a string buffer.

Parameters

lpszBuffer

Pointer to the string buffer that will contain the data when the method returns. The string will be terminated with a null character, and will not contain the end-of-line characters. An alternate form of the method accepts a **CString** argument which will contain the line of text returned by the server.

lpnLength

A pointer to an integer value which specifies the length of the buffer. The value should be initialized to the maximum number of characters that can be copied into the string buffer, including the terminating null character. When the method returns, its value will updated with the actual length of the string.

nMaxLength

An integer value which specifies the maximum length of the buffer.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **ReadLine** method reads data from the socket and copies into a specified string buffer. Unlike the **Read** method which reads arbitrary bytes of data, this method is specifically designed to return a single line of text data in a string. When an end-of-line character sequence is encountered, the method will stop and return the data up to that point. The string buffer is guaranteed to be null-terminated and will not contain the end-of-line characters.

There are some limitations when using **ReadLine**. The method should only be used to read text, never binary data. In particular, the method will discard nulls, linefeed and carriage return control characters. The Unicode version of this method will return a Unicode string, however it does not support reading raw Unicode data from the socket. Any data read from the socket is internally buffered as octets (eight-bit bytes) and converted to Unicode using the **MultiByteToWideChar** function.

This method will force the thread to block until an end-of-line character sequence is processed, the read operation times out or the remote host closes its end of the socket connection. If this

method is called with asynchronous events enabled, it will automatically switch the socket into a blocking mode, read the data and then restore the socket to asynchronous operation. If another socket operation is attempted while **ReadLine** is blocked waiting for data from the remote host, an error will occur. It is recommended that this method only be used with blocking (synchronous) socket connections; if the application needs to establish multiple simultaneous connections, it should create worker threads to manage each connection.

The **Read** and **ReadLine** method calls can be intermixed, however be aware that **Read** will consume any data that has already been buffered by the **ReadLine** method and this may have unexpected results.

Unlike the **Read** method, it is possible for data to be returned in the string buffer even if the return value is zero. Applications should check the length of the string to determine if any data was copied into the buffer. For example, if a timeout occurs while the method is waiting for more data to arrive on the socket, it will return zero; however, data may have already been copied into the string buffer prior to the error condition. It is the responsibility of the application to process that data, regardless of the return value.

Example

```
CString strBuffer;
BOOL bResult;

do
{
    bResult = pSocket->ReadLine(strBuffer);

    if (strBuffer.GetLength() > 0)
    {
        // Process the line of data returned in the string
        // buffer; the string is always null-terminated
    }
} while (bResult);

DWORD dwError = pSocket->GetLastError();

if (dwError == ST_ERROR_CONNECTION_CLOSED)
{
    // The remote host has closed its side of the connection and
    // there is no more data available to be read
}
else if (dwError != 0)
{
    // An error has occurred while reading a line of data
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[IsReadable](#), [Peek](#), [Read](#), [ReadStream](#), [Write](#), [WriteLine](#), [WriteStream](#)

CSocketWrench::ReadStream Method

```
BOOL ReadStream(  
    LPVOID lpvBuffer,  
    LPDWORD lpdwLength,  
    DWORD dwOptions,  
    LPBYTE lpMarker,  
    DWORD cbMarker  
);
```

The **ReadStream** method reads the socket data stream and stores the contents in the specified buffer.

Parameters

lpvBuffer

Pointer to the buffer that will contain or reference the data when the method returns. The actual argument depends on the value of the *dwOptions* parameter which specifies how the data stream will be stored.

lpdwLength

A pointer to an unsigned integer value which specifies the maximum length of the buffer and contains the number of bytes read when the method returns. This argument should always point to an initialized value. If the *lpvBuffer* argument specifies a memory buffer, then this argument cannot point to an initialized value of zero; if any other type of stream buffer is used and the initialized value is zero, that indicates that all available data from the socket should be returned until the end-of-stream marker is encountered or the remote host disconnects.

dwOptions

An unsigned integer value which specifies both the stream buffer type and any options to be used when reading the data stream. One of the following stream types may be specified:

Constant	Description
INET_STREAM_DEFAULT	The default stream buffer type is determined by the value passed as the <i>lpvBuffer</i> parameter. If the argument specifies a pointer to a global memory handle initialized to NULL, then the method will return a handle which references the data; otherwise, the method will consider the parameter a pointer to a block of pre-allocated memory which will contain the stream data when the method returns. In most cases, it is recommended that an application explicitly specify the stream buffer type rather than using the default value.
INET_STREAM_MEMORY	The <i>lpvBuffer</i> argument specifies a pointer to a pre-allocated block of memory which will contain the data read from the socket when the method returns. If this stream buffer type is used, the <i>lpdwLength</i> argument must point to an unsigned integer which has been initialized with the maximum length of the buffer.

INET_STREAM_HGLOBAL	The <i>lpvBuffer</i> argument specifies a pointer to a global memory handle. When the method returns, the handle will reference a block of memory that contains the stream data. The application should take care to make sure that the handle passed to the method does not currently reference a valid block of memory; it is recommended that the handle be initialized to NULL prior to calling this method.
INET_STREAM_HANDLE	The <i>lpvBuffer</i> argument specifies a Windows handle to an open file, console or pipe. This should be the same handle value returned by the CreateFile function in the Windows API. The data read from the socket will be written to this handle using the WriteFile function.
INET_STREAM_SOCKET	The <i>lpvBuffer</i> argument specifies a socket handle. The data read from the socket specified by the <i>hSocket</i> argument will be written to this socket. The socket handle passed to this method must have been created by this library; if it is a socket created by an third-party library or directly by the Windows Sockets API, you should either create another instance of the class and attach the socket using the AttachHandle method or use the INET_STREAM_HANDLE stream buffer type instead.

In addition to the stream buffer types listed above, the *dwOptions* parameter may also have one or more of the following bit flags set. Programs should use a bitwise operator to combine values.

Constant	Description
INET_STREAM_CONVERT	The data stream is considered to be textual and will be modified so that end-of-line character sequences are converted to follow standard Windows conventions. This will ensure that all lines of text are terminated with a carriage-return and linefeed sequence. Because this option modifies the data stream, it should never be used with binary data. Using this option may result in the amount of data returned in the buffer to be larger than the source data. For example, if the source data only terminates a line of text with a single linefeed, this option will have the effect of inserting a carriage-return character before each linefeed.
INET_STREAM_UNICODE	The data stream should be converted to Unicode. This option should only be used with text data, and will result in the stream data being returned as 16-bit wide characters rather than 8-bit bytes. The amount of data returned will be twice the amount

read from the source data stream; if the application is using a pre-allocated memory buffer, this must be considered before calling this method.
--

lpMarker

A pointer to an array of bytes which marks the end of the data stream. When this byte sequence is encountered by the method, it will stop reading and return to the caller. The buffer will contain all of the data read from the socket up to and including the end-of-stream marker. If this argument is NULL, then the method will continue to read from the socket until the maximum buffer size is reached, the remote host closes its socket or an error is encountered.

cbMarker

An unsigned integer value which specifies the length of the end-of-stream marker in bytes. If the *lpMarker* parameter is NULL, then this value must be zero.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **ReadStream** method enables an application to read an arbitrarily large stream of data and store it in memory, write it to a file or even another socket. Unlike the **Read** method, which will return immediately when any amount of data has been read, **ReadStream** will only return when the buffer is full as specified by the *lpdwLength* parameter, the logical end-of-stream marker has been read, the socket closed by the remote host or when an error occurs.

This method will force the thread to block until the operation completes. If this method is called with asynchronous events enabled, it will automatically switch the socket into a blocking mode, read the data stream and then restore the socket to asynchronous operation when it has finished. If another socket operation is attempted while **ReadStream** is blocked waiting for data from the remote host, an error will occur. It is recommended that this method only be used with blocking (synchronous) socket connections; if the application needs to establish multiple simultaneous connections, it should create worker threads to manage each connection.

It is possible for data to be returned in the buffer even if the method returns a value of zero. Applications should also check the value of the *lpdwLength* argument to determine if any data was copied into the buffer. For example, if a timeout occurs while the method is waiting for more data to arrive on the socket, it will return zero; however, data may have already been copied into the buffer prior to the error condition. It is the responsibility of the application to process that data, regardless of the method return value.

Because **ReadStream** can potentially cause the application to block for long periods of time as the data stream is being read, the method will periodically generate INET_EVENT_PROGRESS events. An application can register an event handler using the **RegisterEvent** method, and can obtain information about the current operation by calling the **GetStreamInfo** method.

Example

```
HGLOBAL hglbBuffer = NULL; // Return data in a global memory buffer
```

```
DWORD cbBuffer = 102400; // Read up to 100K bytes
BOOL bResult;

bResult = pSocket->ReadStream(&hgblBuffer, &cbBuffer,
                             INET_STREAM_HGLOBAL | INET_STREAM_CONVERT);

if (bResult && cbBuffer > 0)
{
    LPBYTE lpBuffer = (LPBYTE)GlobalLock(hgblBuffer);

    // Use data in the stream buffer

    GlobalUnlock(hgblBuffer);
    GlobalFree(hgblBuffer);
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cssock10.lib

CSocketWrench::RegisterEvent Method

```
INT RegisterEvent(  
    UINT nEventId,  
    INETEVENTPROC lpEventProc,  
    DWORD_PTR dwParam  
);
```

The **RegisterEvent** method registers an event handler for the specified event.

Parameters

nEventId

An unsigned integer which specifies which event should be registered with the specified callback function. One of the following values may be used:

Constant	Description
INET_EVENT_CONNECT	The connection to the remote host has completed.
INET_EVENT_DISCONNECT	The remote host has closed the connection to the client. The client should read any remaining data and disconnect.
INET_EVENT_READ	A network event which indicates data is available to read. No additional messages will be posted until the process has read at least some of the data from the socket. This event is only generated if the socket is in asynchronous mode.
INET_EVENT_WRITE	A network event which indicates the application can send data to the remote host. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the socket is in asynchronous mode.
INET_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The application may attempt to retry the operation, or may disconnect from the remote host and report an error to the user.
INET_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **InetEventProc** callback function. If this parameter is NULL, the callback for the specified event is disabled.

dwParam

A user-defined integer value that is passed to the callback function. If the application targets the x86 (32-bit) platform, this parameter must be a 32-bit unsigned integer. If the application targets the x64 (64-bit) platform, this parameter must be a 64-bit unsigned integer.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is

INET_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **RegisterEvent** method associates a callback function with a specific event. The event handler is an **InetEventProc** function that is invoked when the event occurs. Arguments are passed to the function to identify the client session, the event type and the user-defined value specified when the event handler is registered. If the event occurs because of an error condition, the error code will be provided to the handler.

The callback function specified by the *lpEventProc* parameter must be declared using the **__stdcall** calling convention. This ensures the arguments passed to the event handler are pushed on to the stack in the correct order. Failure to use the correct calling convention will corrupt the stack and cause the application to terminate abnormally.

The *dwParam* parameter is commonly used to identify the class instance which is associated with the event that has occurred. Applications will cast the **this** pointer to a DWORD_PTR value when calling this function, and then the event handler will cast it back to a pointer to the class instance. This gives the handler access to the class member variables and methods.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cswskv10.lib

[DisableEvents](#), [EnableEvents](#), [FreezeEvents](#), [InetEventProc](#)

CSocketWrench::Reject Method

```
BOOL Reject();
```

The **Reject** method is used to reject a client connection request.

Parameters

None.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **Reject** method rejects a pending client connection and the remote host will see this as the connection being aborted. If there are no pending client connections at the time, this method will immediately return with an error indicating that the operation would cause the thread to block.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cswskv10.lib

[Accept](#), [Listen](#)

CSocketWrench::SetHostFile Method

```
INT SetHostFile(  
    LPCTSTR lpszFileName  
);
```

The **SetHostFile** method specifies the name of an alternate file to use when resolving hostnames and IP addresses. The host file is used as a database that maps an IP address to one or more hostnames, and is used by the **GetHostAddress** and **GetHostNames** method. The file is a plain text file, with each line in the file specifying a record, and each field separated by spaces or tabs. The format of the file must be as follows:

```
ipaddress hostname [hostalias ...]
```

For example, one typical entry maps the name "localhost" to the local loopback IP address. This would be entered as:

```
127.0.0.1 localhost
```

The hash character (#) may be used to specify a comment in the file, and all characters after it are ignored up to the end of the line. Blank lines are ignored, as are any lines which do not follow the required format.

Parameters

lpszFileName

Pointer to a string that specifies the name of the file. If the parameter is NULL, then the current host file is cleared from the cache and only the default host file will be used to resolve hostnames and addresses.

Return Value

If the method succeeds, the return value is the number of entries in the host file. A return value of INET_ERROR indicates failure. To get extended error information, call **GetLastError**.

Remarks

This method loads the file into memory allocated for the current thread. If the contents of the file have changed after the method has been called, those changes will not be reflected when resolving hostnames or addresses. To reload the host file from disk, call this method again with the same file name. To remove the alternate host file from memory, specify a NULL pointer as the parameter.

If a host file has been specified, it is processed before the default host file when resolving a hostname into an IP address, or an IP address into a hostname. If the host name or address is not found, or no host file has been specified, a nameserver lookup is performed.

To determine if an alternate host file has been specified, use the **GetHostFile** method. A return value of zero indicates that no alternate host file has been cached for the current thread.

A system may have a default host file, which is used to resolve hostnames before performing a nameserver lookup. To determine the name of this file, use the **GetDefaultHostFile** method. It is not necessary to specify this default host file, since it is always used to resolve host names and addresses.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cswsock10.h

Import Library: csWSKV10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[GetDefaultHostFile](#), [GetHostAddress](#), [GetHostFile](#), [GetHostName](#)

CSocketWrench::SetLastError Method

```
VOID SetLastError(  
    DWORD dwErrorCode  
);
```

The **SetLastError** method sets the last error code for the current thread. This method is typically used to clear the last error by specifying a value of zero as the parameter.

Parameters

dwErrorCode

Specifies the last error code for the current thread.

Return Value

None.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. Most methods will set the last error code value when they fail; a few methods set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_SOCKET or INET_ERROR. Those methods which call **SetLastError** when they succeed are noted on the method reference page.

Applications can retrieve the value saved by this method by using the **GetLastError** method. The use of **GetLastError** is optional; an application can call the method to determine the specific reason for a method failure.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cswskv10.lib

CSocketWrench::SetOption Method

```
INT SetOption(  
    DWORD dwOption,  
    BOOL bEnabled  
);
```

The **SetOption** method is used to enable or disable a specific socket option.

Parameters

dwOption

An unsigned integer used to specify one of the socket options. These options cannot be combined. The following values are recognized:

Constant	Description
INET_OPTION_BROADCAST	This option specifies that broadcasting should be enabled for datagrams. This option is invalid for stream sockets.
INET_OPTION_KEEPAIVE	This option specifies that packets are to be sent to the remote system when no data is being exchanged to keep the connection active. This is only valid for stream sockets.
INET_OPTION_REUSEADDRESS	This option specifies the local address can be reused. This option is commonly used by server applications.
INET_OPTION_NODELAY	This option disables the Nagle algorithm, which buffers unacknowledged data and insures that a full-size packet can be sent to the remote host.

bEnabled

A boolean flag. If the flag is set to a non-zero value, the option is enabled. Otherwise the socket option is disabled.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is INET_ERROR. To get extended error information, call **GetLastError**.

Remarks

It is not recommend that you disable the Nagle algorithm by specifying the INET_OPTION_NODELAY flag unless it is absolutely required. Doing so can have a significant, negative impact on the performance of the application and network.

If if the INET_OPTION_KEEPAIVE option is enabled, keep-alive packets will start being generated five seconds after the socket has become idle with no data being sent or received. Enabling this option can be used by applications to detect when a physical network connection has been lost. However, it is recommended that most applications query the remote host directly to determine if the connection is still active. This is typically accomplished by sending specific commands to the server to query its status, or checking the elapsed time since the last response from the server.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cswsock10.h

Import Library: cswskv10.lib

See Also

[Connect](#), [GetOption](#)

CSocketWrench::SetTimeout Method

```
INT SetTimeout(  
    UINT nTimeout  
);
```

The **SetTimeout** method sets the number of seconds the client will wait for a response from the remote host. Once the specified number of seconds has elapsed, the method will fail and return to the caller.

Parameters

nTimeout

The number of seconds to wait for a blocking operation to complete.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is INET_ERROR. To get extended error information, call **GetLastError**.

Remarks

The timeout value is only used with blocking client connections.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cswskv10.lib

CSocketWrench::ShowError Method

```
INT ShowError(  
    LPCTSTR lpszAppTitle,  
    UINT uType,  
    DWORD dwErrorCode  
);
```

The **ShowError** method displays a message box which describes the specified error.

Parameters

lpszAppTitle

A pointer to a string which specifies the title of the message box that is displayed. If this argument is NULL or omitted, then the default title of "Error" will be displayed.

uType

An unsigned integer which specifies the type of message box that will be displayed. This is the same value that is used by the **MessageBox** method in the Windows API. If a value of zero is specified, then a message box with a single OK button will be displayed. Refer to that method for a complete list of options.

dwErrorCode

Specifies the error code that will be used when displaying the message box. If this argument is zero, then the last error that occurred in the current thread will be displayed.

Return Value

If the method is successful, the return value will be the return value from the **MessageBox** function. If the method fails, it will return a value of zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cswsock10.h`

Import Library: `cswskv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

[GetErrorString](#), [GetLastError](#), [SetLastError](#)

CSocketWrench::Shutdown Method

```
INT Shutdown(  
    DWORD dwOption  
);
```

The **Shutdown** method is used to disable reception or transmission of data, or both.

Parameters

dwOption

An unsigned integer used to specify one of the shutdown options. These options cannot be combined. The following values are recognized:

Value	Constant	Description
0	INET_SHUTDOWN_READ	Disable reception of data.
1	INET_SHUTDOWN_WRITE	Disable transmission of data.
2	INET_SHUTDOWN_BOTH	Disable both reception and transmission of data.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is INET_ERROR. To get extended error information, call **GetLastError**.

Remarks

This method is rarely needed. It is provided as an interface to the Windows Sockets **shutdown** method.

In some asynchronous applications, it may be desirable for a client to inform the server that no further communication is wanted, while allowing the client to read any residual data that may reside in internal buffers on the client side. **Shutdown** accomplishes this because the socket handle is still valid after it has been called, although some or all communication with the remote host has ceased.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Import Library: cswskv10.lib

CSocketWrench::StoreStream Method

```
BOOL StoreStream(  
    LPCTSTR lpszFileName,  
    DWORD dwLength,  
    LPDWORD lpdwCopied  
    DWORD dwOffset,  
    DWORD dwOptions  
);
```

The **StoreStream** method reads the socket data stream and stores the contents in the specified file.

Parameters

lpszFileName

Pointer to a string which specifies the name of the file to create or overwrite.

dwLength

An unsigned integer which specifies the maximum number of bytes to read from the socket and write to the file. If this value is zero, then the method will continue to read data from the socket until the remote host disconnects or an error occurs.

lpdwCopied

A pointer to an unsigned integer value which will contain the number of bytes written to the file when the method returns.

dwOffset

An unsigned integer which specifies the byte offset into the file where the method will start storing data read from the socket. Note that all data after this offset will be truncated. A value of zero specifies that the file should be completely overwritten if it already exists.

dwOptions

An unsigned integer value which specifies one or more options. Programs can use a bitwise operator to combine any of the following values:

Constant	Description
INET_STREAM_CONVERT	The data stream is considered to be textual and will be modified so that end-of-line character sequences are converted to follow standard Windows conventions. This will ensure that all lines of text are terminated with a carriage-return and linefeed sequence. Because this option modifies the data stream, it should never be used with binary data. Using this option may result in the amount of data written to the file to be larger than the source data. For example, if the source data only terminates a line of text with a single linefeed, this option will have the effect of inserting a carriage-return character before each linefeed.
INET_STREAM_UNICODE	The data stream should be converted to Unicode. This option should only be used with text data, and will result in the stream data being written as 16-bit

wide characters rather than 8-bit bytes. The amount of data returned will be twice the amount read from the source data stream. If the *dwOffset* parameter has a value of zero, the Unicode byte order mark (BOM) will be written to the beginning of the file.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **StoreStream** method enables an application to read an arbitrarily large stream of data and store it in a file. This method is essentially a simplified version of the **ReadStream** method, designed specifically to be used with files rather than memory buffers or handles.

This method will force the thread to block until the operation completes. If this method is called with asynchronous events enabled, it will automatically switch the socket into a blocking mode, read the data stream and then restore the socket to asynchronous operation when it has finished. If another socket operation is attempted while **StoreStream** is blocked waiting for data from the remote host, an error will occur. It is recommended that this method only be used with blocking (synchronous) socket connections; if the application needs to establish multiple simultaneous connections, it should create worker threads to manage each connection.

Because **StoreStream** can potentially cause the application to block for long periods of time as the data stream is being read, the method will periodically generate `INET_EVENT_PROGRESS` events. An application can register an event handler using the **RegisterEvent** method, and can obtain information about the current operation by calling the **GetStreamInfo** method.

Example

```
DWORD dwCopied;
BOOL bResult;

bResult = pSocket->StoreStream(lpszFileName, 0, &dwCopied, 0,
                               INET_STREAM_CONVERT);

if (bResult && dwCopied > 0)
{
    // The data has been written to the file
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cssock10.h`

Import Library: `cswskv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

See Also

[GetStreamInfo](#), [Read](#), [ReadLine](#), [ReadStream](#), [Write](#), [WriteLine](#), [WriteStream](#)

CSocketWrench::Write Method

```
INT Write(  
    LPBYTE lpBuffer,  
    INT cbBuffer  
);  
  
INT Write(  
    LPBYTE lpBuffer,  
    INT cbBuffer,  
    LPINTERNET_ADDRESS lpAddress,  
    UINT nRemotePort  
);
```

The **Write** method sends the specified number of bytes to the remote host.

Parameters

lpBuffer

The pointer to the buffer which contains the data that is to be sent to the remote host.

cbBuffer

The number of bytes to send from the specified buffer. This value must be greater than zero.

lpAddress

Pointer to an [INTERNET_ADDRESS](#) structure that specifies the address of the remote host that is to receive the data being written. For TCP stream sockets, this parameter must always be NULL or specify the same address that was used to establish the connection. For UDP datagram sockets, this may specify any valid IP address.

nRemotePort

The port number of the remote host that is to receive the data being written. For TCP stream sockets, this value must always be zero, or specify the same port number that was used to establish the connection. For UDP datagram sockets, this may specify any valid port number.

Return Value

If the method succeeds, the return value is the number of bytes actually written. If the method fails, the return value is `INET_ERROR`. To get extended error information, call **GetLastError**.

Remarks

The return value may be less than the number of bytes specified by the *cbBuffer* parameter. In this case, the data has been partially written and it is the responsibility of the client application to send the remaining data at some later point. For non-blocking sockets, the client must wait for the next asynchronous notification message before it resumes sending data.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cssock10.h`

Import Library: `cswskv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

[EnableEvents](#), [IsBlocking](#), [IsReadable](#), [IsWritable](#), [Read](#), [ReadLine](#), [RegisterEvent](#), [WriteLine](#)

CSocketWrench::WriteLine Method

```
BOOL WriteLine(  
    LPCTSTR lpszBuffer,  
    LPINT lpnLength  
);
```

The **WriteLine** function sends a line of text to the remote host, terminated by a carriage-return and linefeed.

Parameters

lpszBuffer

The pointer to a string buffer which contains the data that will be sent to the remote host. All characters up to, but not including, the terminating null character will be written to the socket. The data will always be terminated with a carriage-return and linefeed control character sequence. If this parameter points to an empty string or NULL pointer, then a only a carriage-return and linefeed are written to the socket.

lpnLength

A pointer to an integer value which will contain the number of characters written to the socket, including the carriage-return and linefeed sequence. If this information is not required, a NULL pointer may be specified.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **WriteLine** method writes a line of text to the remote host and terminates the line with a carriage-return and linefeed control character sequence. Unlike the **Write** method which writes arbitrary bytes of data to the socket, this method is specifically designed to write a single line of text data from a null-terminated string.

If the *lpszBuffer* string is terminated with a linefeed (LF) or carriage return (CR) character, it will be automatically converted to a standard CRLF end-of-line sequence. Because the string will be sent with a terminating CRLF sequence, the value returned in the *lpnLength* parameter will typically be larger than the original string length (reflecting the additional CR and LF characters), unless the string was already terminated with CRLF.

There are some limitations when using **WriteLine**. This method should only be used to send text, never binary data. In particular, it will discard nulls and append linefeed and carriage return control characters to the data stream. The Unicode version of this method will accept a Unicode string, however it does not support writing raw Unicode data to the socket. Unicode strings will be automatically converted to UTF-8 encoding using the **WideCharToMultiByte** function and then written to the socket as a stream of bytes.

This method will force the thread to block until the complete line of text has been written, the write operation times out or the remote host aborts the connection. If this method is called with asynchronous events enabled, it will automatically switch the socket into a blocking mode, send the data and then restore the socket to asynchronous operation. If another socket operation is attempted while **WriteLine** is blocked sending data to the remote host, an error will occur. It is recommended that this method only be used with blocking (synchronous) socket connections; if the application needs to establish multiple simultaneous connections, it should create worker

threads to manage each connection.

The **Write** and **WriteLine** methods can be safely intermixed.

Unlike the **Write** function, it is possible for data to have been written to the socket if the return value is zero. For example, if a timeout occurs while the method is waiting to send more data to the remote host, it will return zero; however, some data may have already been written prior to the error condition. If this is the case, the *lpnLength* argument will specify the number of characters actually written up to that point.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cssock10.h`

Import Library: `cswskv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

[IsWritable](#), [Read](#), [ReadLine](#), [ReadStream](#), [Write](#), [WriteStream](#)

CSocketWrench::WriteStream Method

```
BOOL WriteStream(  
    LPVOID lpvBuffer,  
    LPDWORD lpdwLength,  
    DWORD dwOptions  
);
```

The **WriteStream** method writes data from the stream buffer to the specified socket.

Parameters

lpvBuffer

Pointer to the buffer that contains or references the data to be written to the socket. The actual argument depends on the value of the *dwOptions* parameter which specifies how the data stream will be accessed.

lpdwLength

A pointer to an unsigned integer value which specifies the size of the buffer and contains the number of bytes written when the method returns. This argument should always point to an initialized value. If the *lpvBuffer* argument specifies a memory buffer or global memory handle, then this argument cannot point to an initialized value of zero.

dwOptions

An unsigned integer value which specifies the stream buffer type to be used when writing the data stream to the socket. One of the following stream types may be specified:

Constant	Description
INET_STREAM_DEFAULT	The default stream buffer type is determined by the value passed as the <i>lpvBuffer</i> parameter. If the argument specifies a global memory handle, then the method will write the data referenced by that handle; otherwise, the method will consider the parameter a pointer to a block of memory which contains data to be written. In most cases, it is recommended that an application explicitly specify the stream buffer type rather than using the default value.
INET_STREAM_MEMORY	The <i>lpvBuffer</i> argument specifies a pointer to a block of memory which contains the data to be written to the socket. If this stream buffer type is used, the <i>lpdwLength</i> argument must point to an unsigned integer which has been initialized with the size of the buffer.
INET_STREAM_HGLOBAL	The <i>lpvBuffer</i> argument specifies a global memory handle that references the data to be written to the socket. The handle must have been created by a call to the GlobalAlloc or GlobalReAlloc function. If this stream buffer type is used, the <i>lpdwLength</i> argument must point to an unsigned integer which has been initialized with the size of the buffer.

INET_STREAM_HANDLE	The <i>lpvBuffer</i> argument specifies a Windows handle to an open file, console or pipe. This should be the same handle value returned by the CreateFile function in the Windows API. The data read using the ReadFile function with this handle will be written to the socket.
INET_STREAM_SOCKET	The <i>lpvBuffer</i> argument specifies a socket handle. The data read from the socket specified by this handle will be written to the socket specified by the <i>hSocket</i> parameter. The socket handle passed to this method must have been created by this library; if it is a socket created by an third-party library or directly by the Windows Sockets API, you should either create another instance of the class and attach the socket using the AttachHandle method or use the INET_STREAM_HANDLE stream buffer type instead.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **InetGetLastError**.

Remarks

The **WriteStream** method enables an application to write an arbitrarily large stream of data from memory or a file to the specified socket. Unlike the **Write** method, which may not write all of the data in a single method call, **WriteStream** will only return when all of the data has been written or an error occurs.

This method will force the thread to block until the operation completes. If this method is called with asynchronous events enabled, it will automatically switch the socket into a blocking mode, write the data stream and then restore the socket to asynchronous operation when it has finished. If another socket operation is attempted while **WriteStream** is blocked sending data to the remote host, an error will occur. It is recommended that this method only be used with blocking (synchronous) socket connections; if the application needs to establish multiple simultaneous connections, it should create worker threads to manage each connection.

It is possible for some data to have been written even if the method returns a value of zero. Applications should also check the value of the *lpdwLength* argument to determine if any data was sent. For example, if a timeout occurs while the method is waiting to write more data, it will return zero; however, some data may have already been written to the socket prior to the error condition.

Because **WriteStream** can potentially cause the application to block for long periods of time as the data stream is being written, the method will periodically generate INET_EVENT_PROGRESS events. An application can register an event handler using the **RegisterEvent** method, and can obtain information about the current operation by calling the **GetStreamInfo** method.

Example

```
CFile *pFile = new CFile();
DWORD dwLength = 0;
```

```
if (!pFile->Open(strFileName, CFile::modeRead | CFile::shareDenyWrite))
    return;

dwLength = pFile->GetLength();

if (dwLength > 0)
{
    BOOL bResult = pSocket->WriteStream(
        pFile->m_hFile,
        &dwLength,
        INET_STREAM_HANDLE);
}

delete pFile;
```

Requirements

INETSTREAMINFO Structure

This structure contains information about the data stream being currently read or written.

```
typedef struct _INETSTREAMINFO
{
    DWORD    dwStreamThread;
    DWORD    dwStreamSize;
    DWORD    dwStreamCopied;
    DWORD    dwStreamMode;
    DWORD    dwStreamError;
    DWORD    dwBytesPerSecond;
    DWORD    dwTimeElapsed;
    DWORD    dwTimeEstimated;
} INETSTREAMINFO, *LPINETSTREAMINFO;
```

Members

dwStreamThread

Specifies the numeric ID for the thread that created the socket.

dwStreamSize

The maximum number of bytes that will be read or written. This is the same value as the buffer length specified by the caller, and may be zero which indicates that no maximum size was specified. Note that if this value is zero, the application will be unable to calculate a completion percentage or estimate the amount of time for the operation to complete.

dwStreamCopied

The total number of bytes that have been copied to or from the stream buffer.

dwStreamMode

A numeric value which specifies the stream operation that is current being performed. It may be one of the following values:

Constant	Description
INET_STREAM_READ	Data is being read from the socket and stored in the specified stream buffer.
INET_STREAM_WRITE	Data is being written from the specified stream buffer to the socket.

dwStreamError

The last error that occurred when reading or writing the data stream. If no error has occurred, this value will be zero.

dwBytesPerSecond

The average number of bytes that have been copied per second.

dwTimeElapsed

The number of seconds that have elapsed since the file transfer started.

dwTimeEstimated

The estimated number of seconds until the operation is completed. This is based on the average number of bytes transferred per second and requires that a maximum stream buffer size be specified by the caller.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

See Also

[ReadStream](#), [StoreStream](#), [WriteStream](#)

INTERNET_ADDRESS Structure

This structure represents a numeric IPv4 or IPv6 address in network byte order.

```
typedef struct _INTERNET_ADDRESS
{
    INT    ipFamily;
    BYTE   ipNumber[16];
} INTERNET_ADDRESS, *LPINTERNET_ADDRESS;
```

Members

ipFamily

An integer which identifies the type of IP address. It will be one of the following values:

Constant	Description
INET_ADDRESS_UNKNOWN	The address has not been specified or the bytes in the <i>ipNumber</i> array does not represent a valid address. Functions which populate this structure will use this value to indicate that the address cannot be determined.
INET_ADDRESS_IPV4	Specifies that the address is in IPv4 format. The first four bytes of the <i>ipNumber</i> array are significant and contains the IP address. The remaining bytes are not significant and an application should not depend on them having any particular value, including zero.
INET_ADDRESS_IPV6	Specifies that the address is in IPv6 format. All bytes in the <i>ipNumber</i> array are significant. Note that it is possible for an IPv6 address to actually represent an IPv4 address. This is indicated by the first 10 bytes of the address being zero.

ipNumber

A byte array which contains the numeric form of the IP address. This array is large enough to store both IPv4 (32 bit) and IPv6 (128 bit) addresses. The values are stored in network byte order.

Remarks

The **INTERNET_ADDRESS** structure is used by some functions to represent an Internet address in a binary format that is compatible with both IPv4 and IPv6 addresses. Applications that use this structure should consider it to be opaque, and should not modify the contents of the structure directly.

For compatibility with legacy applications that expect an IP address to be 32 bits and stored in an unsigned integer, you can copy the first four bytes of the *ipNumber* array using the **CopyMemory** function or equivalent. Note that if this is done, your application should always check the *ipFamily* member first to make sure that it is actually an IPv4 address.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

SECURITYCREDENTIALS Structure

The **SECURITYCREDENTIALS** structure specifies the information needed by the library to specify additional security credentials, such as a client certificate or private key, when establishing a secure connection.

```
typedef struct _SECURITYCREDENTIALS
{
    DWORD    dwSize;
    DWORD    dwProtocol;
    DWORD    dwOptions;
    DWORD    dwReserved;
    LPCTSTR  lpszHostName;
    LPCTSTR  lpszUserName;
    LPCTSTR  lpszPassword;
    LPCTSTR  lpszCertStore;
    LPCTSTR  lpszCertName;
    LPCTSTR  lpszKeyFile;
} SECURITYCREDENTIALS, *LPSECURITYCREDENTIALS;
```

Members

dwSize

Size of this structure. If the structure is being allocated dynamically, this member must be set to the size of the structure and all other unused structure members must be initialized to a value of zero or NULL.

dwProtocol

A bitmask of supported security protocols. The value of this structure member is constructed by using a bitwise operator with any of the following values:

Constant	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_SSL	Either SSL 2.0 or SSL 3.0 should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, TLS will be excluded from the list of supported protocols. Both SSL 2.0 and 3.0 have been deprecated and will never be used unless explicitly specified. It is not recommended that you enable either of these protocols for secure connections because it will cause most servers to reject your connection request, even if a version of TLS is also specified.
SECURITY_PROTOCOL_TLS	Either the TLS 1.0, 1.1 or 1.2 protocol should be used when establishing a secure connection. The correct protocol is automatically selected, based on

	what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers that reject any attempt to use the older SSL protocol and require that only TLS be used.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This is the recommended version of TLS to use with secure connections.

dwOptions

A value which specifies one or options. This member is constructed by using a bitwise operator with any of the following values:

Constant	Description
CREDENTIAL_STORE_CURRENT_USER	The library will attempt to open a store for the current user using the certificate store name provided in this structure. If no options are specified, then this is the default behavior.
CREDENTIAL_STORE_LOCAL_MACHINE	The library will attempt to open a local machine store using the certificate store name provided in this structure. If this option is specified, the library will always search for a local machine store before searching for the store by that name for the current user.
CREDENTIAL_STORE_FILENAME	The certificate store name is a file that contains the certificate and private key that

will be used.

dwReserved

This structure member is reserved for future use and should always be initialized to zero.

lpszHostName

A pointer to a null terminated string which specifies the hostname that will be used when validating the server certificate. If this member is NULL, then the server certificate will be validated against the hostname used to establish the connection.

lpszUserName

A pointer to a null terminated string which identifies the owner of client certificate. Currently this member is not used by the library and should always be initialized as a NULL pointer.

lpszPassword

A pointer to a null terminated string which specifies the password needed to access the certificate. Currently this member is only used if the CREDENTIAL_STORE_FILENAME option has been specified. If there is no password associated with the certificate, then this member should be initialized as a NULL pointer.

lpszCertStore

A pointer to a null terminated string which specifies the name of the certificate store to open. A certificate store is a collection of certificates and their private keys, typically organized by how they are used. If this value is NULL or points to an empty string, the default certificate store "MY" will be used.

Store Name	Description
------------	-------------

CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as VeriSign and Thawte act as certification authorities.
----	---

MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. This corresponds to the "Personal" store that is displayed by the certificate manager utility and is the default store used by the library.
----	--

ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as VeriSign and Thawte are installed as part of the operating system and periodically updated by Microsoft.
------	--

lpszCertName

A pointer to a null terminated string which specifies the name of the certificate to use. The library will first search the certificate store for a certificate with a matching "friendly name"; this is a name for the certificate that is assigned by the user. Note that the name must match completely, but the comparison is not case sensitive. If no matching certificate is found, the library will then attempt to find a certificate that has a matching common name (also called the certificate subject). This comparison is less stringent, and the first partial match will be returned. If this second search fails, the library will return an error indicating that the certificate could not be found. If the SECURITY_PROTOCOL_SSH protocol has been specified, this member should be NULL.

lpszKeyFile

A pointer to a null terminated string which specifies the name of the file which contains the private key required to establish the connection. This member is only used for SSH connections

and should always be NULL when establishing a secure connection using SSL or TLS.

Remarks

A client application only needs to create this structure if the server requires that the client provide a certificate as part of the process of negotiating the secure session. If a certificate is required, note that it must have a private key associated with it. Attempting to use a certificate that does not have a private key will result in an error during the connection process indicating that the client credentials could not be established.

If you are using a local certificate store, with the certificate and private key stored in the registry, you can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU:" for the current user, or "HKLM:" for the local machine. For example, a certificate store name of "HKLM:MY" would specify the personal certificate store for the local machine, rather than the current user. If neither prefix is specified, then it will default to the certificate store for the current user. You can manage these certificates using the CertMgr.msc Microsoft Management Console (MMC) snap-in.

It is possible to load the certificate from a file rather than from current user's certificate store. The *dwOptions* member should be set to CREDENTIAL_STORE_FILENAME and the *lpzCertStore* member should specify the name of the file that contains the certificate and its private key. The file must be in Private Information Exchange (PFX) format, also known as PKCS#12. These certificate files typically have an extension of .pfx or .p12. Note that if a password was specified when the certificate file was created, it must be provided in the *lpzPassword* member or the library will be unable to access the certificate.

Note that the *lpzUserName* and *lpzPassword* members are values which are used to access the certificate store or private key file. They are not the credentials which are used when establishing the connection with the remote host or authenticating the client session.

The TLS 1.1 and TLS 1.2 protocols are only supported on Windows 7, Windows Server 2008 R2 and later versions of the platform. If these options are specified and the application is running on Windows XP or Windows Vista, the protocol version will be downgraded to TLS 1.0 for backwards compatibility with those platforms.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cssock10.h

Unicode: Implemented as Unicode and ANSI versions.

SECURITYINFO Structure

This structure contains information about a secure connection that has been established.

```
typedef struct _SECURITYINFO
{
    DWORD        dwSize;
    DWORD        dwProtocol;
    DWORD        dwCipher;
    DWORD        dwCipherStrength;
    DWORD        dwHash;
    DWORD        dwHashStrength;
    DWORD        dwKeyExchange;
    DWORD        dwCertStatus;
    SYSTEMTIME   stCertIssued;
    SYSTEMTIME   stCertExpires;
    LPCTSTR      lpszCertIssuer;
    LPCTSTR      lpszCertSubject;
    LPCTSTR      lpszFingerprint;
} SECURITYINFO, *LPSECURITYINFO;
```

Members

dwSize

Specifies the size of the data structure. This member must always be initialized to **sizeof(SECURITYINFO)** prior to passing the address of this structure to the function. Note that if this member is not initialized, an error will be returned indicating that an invalid parameter has been passed to the function.

dwProtocol

A numeric value which specifies the protocol that was selected to establish the secure connection. One of the following values will be returned:

Constant	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_SSL	Either SSL 2.0 or SSL 3.0 should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, TLS will be excluded from the list of supported protocols. Both SSL 2.0 and 3.0 have been deprecated and will never be used unless explicitly specified. It is not recommended that you enable either of these protocols for secure connections because it will cause most servers to reject your connection request, even if a version of TLS is also specified.
SECURITY_PROTOCOL_TLS	Either the TLS 1.0, 1.1 or 1.2 protocol should be used when establishing a secure connection. The

	<p>correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers that reject any attempt to use the older SSL protocol and require that only TLS be used.</p>
SECURITY_PROTOCOL_TLS10	<p>The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.</p>
SECURITY_PROTOCOL_TLS11	<p>The TLS 1.1 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.</p>
SECURITY_PROTOCOL_TLS12	<p>The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This is the recommended version of TLS to use with secure connections.</p>

dwCipher

A numeric value which specifies the cipher that was selected when establishing the secure connection. One of the following values will be returned:

Constant	Description
SECURITY_CIPHER_RC2	The RC2 block cipher was selected. This is a variable key length cipher which supports keys between 40 and 128 bits, in 8-bit increments.
SECURITY_CIPHER_RC4	The RC4 stream cipher was selected. This is a variable key length cipher which supports keys between 40 and 128 bits, in 8-bit increments.
SECURITY_CIPHER_RC5	The RC5 block cipher was selected. This is a variable key length cipher which supports keys up to 2040 bits, in 8-bit increments.
SECURITY_CIPHER_DES	The DES (Data Encryption Standard) block cipher was selected. This is a fixed key length cipher, using 56-bit

	keys.
SECURITY_CIPHER_DES3	The Triple DES block cipher was selected. This cipher encrypts the data three times using different keys, effectively providing a 168-bit length key.
SECURITY_CIPHER_DESX	A variant of the DES block cipher which XORs an extra 64-bits of the key before and after the plaintext has been encrypted, increasing the key size to 184 bits.
SECURITY_CIPHER_AES	The Advanced Encryption Standard cipher (also known as the Rijndael cipher) is a fixed block size cipher which use a key size of 128, 192 or 256 bits. This cipher is supported on Windows XP SP3 and later versions of the operating system.
SECURITY_CIPHER_SKIPJACK	The Skipjack block cipher was selected. This is a fixed key length cipher, using 80-bit keys.
SECURITY_CIPHER_BLOWFISH	The Blowfish block cipher was selected. This is a variable key length cipher up to 448 bits, using a 64-bit block size.

dwCipherStrength

A numeric value which specifies the strength (the length of the cipher key in bits) of the cipher that was selected. Typically this value will be 128 or 256. 40-bit and 56-bit key lengths are considered weak encryption, and subject to brute force attacks. 128-bit and 256-bit key lengths are considered to be secure, and are the recommended key length for secure communications.

dwHash

A numeric value which specifies the hash algorithm which was selected. One of the following values will be returned:

Constant	Description
SECURITY_HASH_MD5	The MD5 algorithm was selected. Its use has been deprecated and is no longer considered to be cryptographically secure.
SECURITY_HASH_SHA1	The SHA-1 algorithm was selected. Its use has been deprecated and is no longer considered to be cryptographically secure.
SECURITY_HASH_SHA256	The SHA-256 algorithm was selected.
SECURITY_HASH_SHA384	The SHA-384 algorithm was selected.
SECURITY_HASH_SHA512	The SHA-512 algorithm was selected.

dwHashStrength

A numeric value which specifies the strength (the length in bits) of the message digest that was selected.

dwKeyExchange

A numeric value which specifies the key exchange algorithm which was selected. One of the following values will be returned:

--	--

Constant	Description
SECURITY_KEYEX_RSA	The RSA public key algorithm was selected.
SECURITY_KEYEX_KEA	The Key Exchange Algorithm (KEA) was selected. This is an improved version of the Diffie-Hellman public key algorithm.
SECURITY_KEYEX_DH	The Diffie-Hellman key exchange algorithm was selected.
SECURITY_KEYEX_ECDH	The Elliptic Curve Diffie-Hellman key exchange algorithm was selected. This is a variant of the Diffie-Hellman algorithm which uses elliptic curve cryptography. This key exchange algorithm is only supported on Windows XP SP3 and later versions of the operating system.

dwCertStatus

A numeric value which specifies the status of the certificate returned by the secure server. This member only has meaning for connections using the SSL or TLS protocols. One of the following values will be returned:

Constant	Description
SECURITY_CERTIFICATE_VALID	The certificate is valid.
SECURITY_CERTIFICATE_NOMATCH	The certificate is valid, but the domain name does not match the common name in the certificate.
SECURITY_CERTIFICATE_EXPIRED	The certificate is valid, but has expired.
SECURITY_CERTIFICATE_REVOKED	The certificate has been revoked and is no longer valid.
SECURITY_CERTIFICATE_UNTRUSTED	The certificate or certificate authority is not trusted on the local system.
SECURITY_CERTIFICATE_INVALID	The certificate is invalid. This typically indicates that the internal structure of the certificate has been damaged.

stCertIssued

A structure which contains the date and time that the certificate was issued by the certificate authority. If the issue date cannot be determined for the certificate, the SYSTEMTIME structure members will have zero values. This member only has meaning for connections using the SSL or TLS protocols.

stCertExpires

A structure which contains the date and time that the certificate expires. If the expiration date cannot be determined for the certificate, the SYSTEMTIME structure members will have zero values. This member only has meaning for connections using the SSL or TLS protocols.

lpszCertIssuer

A pointer to a string which contains information about the organization that issued the certificate. This string consists of one or more comma-separated tokens. Each token consists of an identifier, followed by an equal sign and a value. If the certificate issuer could not be determined, this member may be NULL. This member only has meaning for connections using the SSL or TLS protocols.

lpszCertSubject

A pointer to a string which contains information about the organization that the certificate was issued to. This string consists of one or more comma-separated tokens. Each token consists of an identifier, followed by an equal sign and a value. If the certificate subject could not be determined, this member may be NULL. This member only has meaning for connections using the SSL or TLS protocols.

lpszFingerprint

A pointer to a string which contains a sequence of hexadecimal values that uniquely identify the server. This member is only used when a connection has been established using the Secure Shell (SSH) protocol.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Unicode: Implemented as Unicode and ANSI versions.

SocketWrench Class Error Codes

Value	Constant	Description
0x80042711	ST_ERROR_NOT_HANDLE_OWNER	Handle not owned by the current thread
0x80042712	ST_ERROR_FILE_NOT_FOUND	The specified file or directory does not exist
0x80042713	ST_ERROR_FILE_NOT_CREATED	The specified file could not be created
0x80042714	ST_ERROR_OPERATION_CANCELED	The blocking operation has been canceled
0x80042715	ST_ERROR_INVALID_FILE_TYPE	The specified file is a block or character device, not a regular file
0x80042716	ST_ERROR_INVALID_DEVICE	The specified device or address does not exist
0x80042717	ST_ERROR_TOO_MANY_PARAMETERS	The maximum number of method parameters has been exceeded
0x80042718	ST_ERROR_INVALID_FILE_NAME	The specified file name contains invalid characters or is too long
0x80042719	ST_ERROR_INVALID_FILE_HANDLE	Invalid file handle passed to method
0x8004271A	ST_ERROR_FILE_READ_FAILED	Unable to read data from the specified file
0x8004271B	ST_ERROR_FILE_WRITE_FAILED	Unable to write data to the specified file
0x8004271C	ST_ERROR_OUT_OF_MEMORY	Out of memory
0x8004271D	ST_ERROR_ACCESS_DENIED	Access denied
0x8004271E	ST_ERROR_INVALID_PARAMETER	Invalid argument passed to method
0x8004271F	ST_ERROR_CLIPBOARD_UNAVAILABLE	The system clipboard is currently unavailable
0x80042720	ST_ERROR_CLIPBOARD_EMPTY	The system clipboard is empty or does not contain any text data
0x80042721	ST_ERROR_FILE_EMPTY	The specified file does not contain any data
0x80042722	ST_ERROR_FILE_EXISTS	The specified file already exists
0x80042723	ST_ERROR_END_OF_FILE	End of file
0x80042724	ST_ERROR_DEVICE_NOT_FOUND	The specified device could not be found
0x80042725	ST_ERROR_DIRECTORY_NOT_FOUND	The specified directory could not be found
0x80042726	ST_ERROR_INVALID_BUFFER	Invalid memory address passed to method
0x80042728	ST_ERROR_NO_HANDLES	No more handles available to this process
0x80042733	ST_ERROR_OPERATION_WOULD_BLOCK	The specified operation would block the current thread
0x80042734	ST_ERROR_OPERATION_IN_PROGRESS	A blocking operation is currently in progress
0x80042735	ST_ERROR_ALREADY_IN_PROGRESS	The specified operation is already in progress
0x80042736	ST_ERROR_INVALID_HANDLE	Invalid handle passed to method

0x80042737	ST_ERROR_INVALID_ADDRESS	Invalid network address specified
0x80042738	ST_ERROR_INVALID_SIZE	Datagram is too large to fit in specified buffer
0x80042739	ST_ERROR_INVALID_PROTOCOL	Invalid network protocol specified
0x8004273A	ST_ERROR_PROTOCOL_NOT_AVAILABLE	The specified network protocol is not available
0x8004273B	ST_ERROR_PROTOCOL_NOT_SUPPORTED	The specified protocol is not supported
0x8004273C	ST_ERROR_SOCKET_NOT_SUPPORTED	The specified socket type is not supported
0x8004273D	ST_ERROR_INVALID_OPTION	The specified option is invalid
0x8004273E	ST_ERROR_PROTOCOL_FAMILY	Specified protocol family is not supported
0x8004273F	ST_ERROR_PROTOCOL_ADDRESS	The specified address is invalid for this protocol family
0x80042740	ST_ERROR_ADDRESS_IN_USE	The specified address is in use by another process
0x80042741	ST_ERROR_ADDRESS_UNAVAILABLE	The specified address cannot be assigned
0x80042742	ST_ERROR_NETWORK_UNAVAILABLE	The networking subsystem is unavailable
0x80042743	ST_ERROR_NETWORK_UNREACHABLE	The specified network is unreachable
0x80042744	ST_ERROR_NETWORK_RESET	Network dropped connection on remote reset
0x80042745	ST_ERROR_CONNECTION_ABORTED	Connection was aborted due to timeout or other failure
0x80042746	ST_ERROR_CONNECTION_RESET	Connection was reset by remote network
0x80042747	ST_ERROR_OUT_OF_BUFFERS	No buffer space is available
0x80042748	ST_ERROR_ALREADY_CONNECTED	Connection already established with remote host
0x80042749	ST_ERROR_NOT_CONNECTED	No connection established with remote host
0x8004274A	ST_ERROR_CONNECTION_SHUTDOWN	Unable to send or receive data after connection shutdown
0x8004274C	ST_ERROR_OPERATION_TIMEOUT	The specified operation has timed out
0x8004274D	ST_ERROR_CONNECTION_REFUSED	The connection has been refused by the remote host
0x80042750	ST_ERROR_HOST_UNAVAILABLE	The specified host is unavailable
0x80042751	ST_ERROR_HOST_UNREACHABLE	Remote host is unreachable
0x80042753	ST_ERROR_TOO_MANY_PROCESSES	Too many processes are using the networking subsystem
0x8004276B	ST_ERROR_NETWORK_NOT_READY	Network subsystem is not ready for communication
0x8004276C	ST_ERROR_INVALID_VERSION	This version of the operating system is not supported

0x8004276D	ST_ERROR_NETWORK_NOT_INITIALIZED	The networking subsystem has not been initialized
0x80042775	ST_ERROR_REMOTE_SHUTDOWN	The remote host has initiated a graceful shutdown sequence
0x80042AF9	ST_ERROR_INVALID_HOSTNAME	The specified hostname is invalid or could not be resolved
0x80042AFA	ST_ERROR_HOSTNAME_NOT_FOUND	The specified hostname could not be found
0x80042AFB	ST_ERROR_HOSTNAME_REFUSED	Unable to resolve hostname, request refused
0x80042AFC	ST_ERROR_HOSTNAME_NOT_RESOLVED	Unable to resolve hostname, no address for specified host
0x80042EE1	ST_ERROR_INVALID_LICENSE	The license for this product is invalid
0x80042EE2	ST_ERROR_PRODUCT_NOT_LICENSED	This product is not licensed to perform this operation
0x80042EE3	ST_ERROR_NOT_IMPLEMENTED	This method has not been implemented on this platform
0x80042EE4	ST_ERROR_UNKNOWN_LOCALHOST	Unable to determine local host name
0x80042EE5	ST_ERROR_INVALID_HOSTADDRESS	Invalid host address specified
0x80042EE6	ST_ERROR_INVALID_SERVICE_PORT	Invalid service port number specified
0x80042EE7	ST_ERROR_INVALID_SERVICE_NAME	Invalid or unknown service name specified
0x80042EE8	ST_ERROR_INVALID_EVENTID	Invalid event identifier specified
0x80042EE9	ST_ERROR_OPERATION_NOT_BLOCKING	No blocking operation in progress on this socket
0x80042F45	ST_ERROR_SECURITY_NOT_INITIALIZED	Unable to initialize security interface for this process
0x80042F46	ST_ERROR_SECURITY_CONTEXT	Unable to establish security context for this session
0x80042F47	ST_ERROR_SECURITY_CREDENTIALS	Unable to open client certificate store or establish client credentials
0x80042F48	ST_ERROR_SECURITY_CERTIFICATE	Unable to validate the certificate chain for this session
0x80042F49	ST_ERROR_SECURITY_DECRYPTION	Unable to decrypt data stream
0x80042F4A	ST_ERROR_SECURITY_ENCRYPTION	Unable to encrypt data stream
0x80043031	ST_ERROR_MAXIMUM_CONNECTIONS	The maximum number of client connections exceeded
0x80043032	ST_ERROR_THREAD_CREATION_FAILED	Unable to create a new thread for the current process
0x80043033	ST_ERROR_INVALID_THREAD_HANDLE	The specified thread handle is no longer valid
0x80043034	ST_ERROR_THREAD_TERMINATED	The specified thread has been terminated
0x80043035	ST_ERROR_THREAD_DEADLOCK	The operation would result in the current

		thread becoming deadlocked
0x80043036	ST_ERROR_INVALID_CLIENT_MONIKER	The specified moniker is not associated with any client session
0x80043037	ST_ERROR_CLIENT_MONIKER_EXISTS	The specified moniker has been assigned to another client session
0x80043038	ST_ERROR_SERVER_INACTIVE	The specified server is not listening for client connections
0x80043039	ST_ERROR_SERVER_SUSPENDED	The specified server is suspended and not accepting client connections

Telnet Protocol Class Library

Establish an interactive terminal session with a server.

Reference

- [Class Methods](#)
- [Data Structures](#)
- [Error Codes](#)

Library Information

Class Name	CTelnetClient
File Name	CSTNTV10.DLL
Version	10.0.1468.2518
LibID	A081335C-B907-4179-949F-FCE154F7C456
Import Library	CSTNTV10.LIB
Dependencies	None
Standards	RFC 854

Overview

The Telnet protocol is used to establish a connection with a server which provides a virtual terminal session for a user. Its functionality is similar to how character based consoles and serial terminals work, enabling a user to login to the server, execute commands and interact with applications running on the server. The class provides an interface for establishing the connection, negotiating certain options (such as whether characters will be echoed back to the client) and handling the standard I/O functions needed by the program.

The class also provides methods that enable a program to easily scan the data stream for specific sequences of characters, making it very simple to write light-weight client interfaces to applications running on the server. The CTelnetClient class can be combined with the CTerminalEmulator class to provide complete terminal emulation services for a standard ANSI or DEC-VT220 terminal.

This class supports secure connections using the standard SSL and TLS protocols. To establish a secure connection to the server using the Secure Shell (SSH) protocol, use the SocketTools CSshClient class.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). If you are using Visual C++ 6.0 it is required that you have Service Pack 6 (SP6) installed. You should install all updates for your development tools and have the current Windows SDK installed. The minimum recommended version of Visual Studio is Visual Studio 2010.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are using Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. It is recommended that you install the current service pack and all critical updates available for your version of the operating system.

This product includes both 32-bit and 64-bit libraries. Native 64-bit CPU support requires the 64-

bit version of Windows 7 or later versions of the Windows operating system.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

Telnet Protocol Class Methods

Class	Description
CTelnetClient	Constructor which initializes the current instance of the class
~CTelnetClient	Destructor which releases resources allocated by the class
Method	Description
Abort	Abort the current session and close the connection with the server
AttachHandle	Attach the specified client handle to this instance of the class
AttachThread	Attach the specified client handle to another thread
Break	Send a break signal to the server
Cancel	Cancel the current blocking operation
Connect	Connect to the specified server
CreateSecurityCredentials	Create a new security credentials structure
DeleteSecurityCredentials	Delete a previously created security credentials structure
DetachHandle	Detach the handle for the current instance of this class
DisableEvents	Disable asynchronous event notification
DisableTrace	Disable logging of socket function calls to the trace log
Disconnect	Disconnect from the current server
EnableEvents	Enable asynchronous event notification
EnableTrace	Enable logging of socket function calls to a file
FreezeEvents	Suspend asynchronous event processing
GetErrorString	Return a description for the specified error code
GetHandle	Return the client handle used by this instance of the class
GetLastError	Return the last error code
GetMode	Return the current client mode
GetSecurityInformation	Return security information about the current client connection
GetStatus	Return the current client status
GetTerminalType	Return the current terminal type
GetTimeout	Return the number of seconds until an operation times out
IsBlocking	Determine if the client is blocked, waiting for information
IsConnected	Determine if the client is connected to the server
IsInitialized	Determine if the class has been successfully initialized
IsReadable	Determine if data can be read from the server
IsThere	Determine if the server is available
IsWritable	Determine if data can be written to the server

Login	Login to the server using the specified username and password
Read	Read data returned by the server
ReadLine	Read a line of text from the server and return it in a string buffer
RegisterEvent	Register an event callback function
Search	Search for a specific character sequence in the data stream
SetLastError	Set the last error code
SetMode	Set the current client mode
SetTerminalType	Set the current terminal type
SetTimeout	Set the number of seconds until an operation times out
ShowError	Display a message box with a description of the specified error
TelnetEventProc	Callback function that processes events generated by the client
Write	Write data to the server
WriteLine	Write a line of text to the server

CTelnetClient::CTelnetClient Method

`CTelnetClient();`

The **CTelnetClient** constructor initializes the class library and validates the license key at runtime.

Remarks

If the constructor fails to validate the runtime license, subsequent methods in this class will fail. If the product is installed with an evaluation license, then the application will only function on the development system and cannot be redistributed.

The constructor calls the **TelnetInitialize** function to initialize the library, which dynamically loads other system libraries and allocates thread local storage. If you are using this class within another DLL, it is important that you do not create or destroy an instance of the class from within the **DllMain** function because it can result in deadlocks or access violation errors. You should not declare static or global instances of this class within another DLL if it is linked with the C runtime library (CRT) because it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `cstntv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

See Also

[~CTelnetClient](#), [IsInitialized](#)

CTelnetClient::~CTelnetClient

`~CTelnetClient();`

The **CTelnetClient** destructor releases resources allocated by the current instance of the **CTelnetClient** object. It also uninitialized the library if there are no other concurrent uses of the class.

Remarks

When a **CTelnetClient** object goes out of scope, the destructor is automatically called to allow the library to free any resources allocated on behalf of the process. Any pending blocking or asynchronous calls in this process are canceled without posting any notification messages, and all handles that were created for the client session are destroyed.

The destructor is not called explicitly by the application.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `cstntv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

See Also

[CTelnetClient](#)

CTelnetClient::Abort Method

```
INT Abort();
```

The **Abort** method aborts the current session and terminates the connection.

Parameters

None.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is TELNET_ERROR. To get extended error information, call **GetLastError**.

Remarks

When the **Abort** method is called, the abort sequence is sent to the server and the connection to the server is terminated. Once this method returns, the client handle is no longer valid. If a program is currently executing on the server at the time this method is called, that program may be terminated as a result of the session being aborted. Applications should normally call **Disconnect** to gracefully disconnect from the server and should only use this method when the connection must be aborted immediately.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstntv10.lib

See Also

[Break](#), [Cancel](#), [IsBlocking](#)

CTelnetClient::AttachHandle Method

```
VOID AttachHandle(  
    HCLIENT hClient  
);
```

The **AttachHandle** method attaches the specified client handle to the current instance of the class.

Parameters

hClient

The handle to the client session that will be attached to the current instance of the class object.

Return Value

None.

Remarks

This method is used to attach a client handle created outside of the class using the SocketTools API. Once the client handle is attached to the class, the other class member functions may be used with that client session.

If a client handle already has been created for the class, that handle will be released when the new handle is attached to the class object. If you want to prevent the previous client session from being terminated, you must call the **DetachHandle** method. Failure to release the detached handle may result in a resource leak in your application.

Note that the *hClient* parameter is presumed to be a valid client handle and no checks are performed to ensure that the handle is valid. Specifying an invalid client handle will cause subsequent method calls to fail.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstntv10.lib

[AttachThread](#), [DetachHandle](#), [GetHandle](#)

CTelnetClient::AttachThread Method

```
DWORD AttachThread(  
    DWORD dwThreadId  
);
```

The **AttachThread** method attaches the specified client handle to another thread.

Parameters

dwThreadId

The ID of the thread that will become the new owner of the handle. A value of zero specifies that the current thread should become the owner of the client handle.

Return Value

If the method succeeds, the return value is the thread ID of the previous owner. If the method fails, the return value is TELNET_ERROR. To get extended error information, call **GetLastError**.

Remarks

When a client handle is created, it is associated with the current thread that created it. Normally, if another thread attempts to perform an operation using that handle, an error is returned since it does not own the handle. This is used to ensure that other threads cannot interfere with an operation being performed by the owner thread. In some cases, it may be desirable for one thread in a client application to create the client handle, and then pass that handle to another worker thread. The **AttachThread** method can be used to change the ownership of the handle to the new worker thread. By preserving the return value from the method, the original owner of the handle can be restored before the worker thread terminates.

This method should be called by the new thread immediately after it has been created, and if the new thread does not release the handle itself, the ownership of the handle should be restored to the parent thread before it terminates. Under no circumstances should **AttachThread** be used to forcibly release a handle allocated by another thread while a blocking operation is in progress. To cancel an operation, use the **Cancel** method and then release the handle after the blocking method exits and control is returned to the current thread.

Note that the *dwThreadId* parameter is presumed to be a valid thread ID and no checks are performed to ensure that the thread actually exists. Specifying an invalid thread ID will orphan the client handle used by the class until the destructor is called.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cstntv10.lib

See Also

[AttachHandle](#), [Cancel](#), [Connect](#), [DetachHandle](#), [Disconnect](#), [GetHandle](#)

CTelnetClient::Break Method

INT Break();

The **Break** method sends a signal to the server which may terminate an application that is currently running. The actual response to the break signal depends on the application.

Parameters

None.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is TELNET_ERROR. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstntv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[Abort](#), [Cancel](#), [Read](#), [Write](#)

CTelnetClient::Cancel Method

```
INT Cancel();
```

The **Cancel** method cancels any outstanding blocking operation in the client, causing the blocking method to fail. The application may then retry the operation or terminate the client session.

Parameters

None.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is TELNET_ERROR. To get extended error information, call **GetLastError**.

Remarks

When the **Cancel** method is called, the blocking method will not immediately fail. An internal flag is set which causes the blocking operation to exit with an error. This means that the application cannot cancel an operation and immediately perform some other operation. Instead it must allow the calling stack to unwind, returning back to the blocking operation before making any further function calls.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstntv10.lib

See Also

CTelnetClient::Connect Method

```
BOOL Connect(  
    LPCTSTR lpszRemoteHost,  
    UINT nRemotePort,  
    UINT nTimeout,  
    DWORD dwOptions,  
    HWND hEventWnd,  
    UINT uEventMsg  
);
```

The **Connect** method establishes a connection with the specified server.

Parameters

lpszRemoteHost

A pointer to the name of the server to connect to; this may be a fully-qualified domain name or an IP address.

nRemotePort

The port number the server is listening on; a value of zero specifies that the default port number should be used. For standard connections, the default port number is 23. For secure connections, the default port number is 992.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
TELNET_OPTION_NONE	No connection options specified. A standard connection to the server will be established using the specified host name and port number.
TELNET_OPTION_TUNNEL	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established.
TELNET_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using either the SSL or TLS protocols.
TELNET_OPTION_SECURE	This option specifies the client should attempt to establish a secure connection with the server.

	Note that the server must support secure connections using either the SSL or TLS protocol.
TELNET_OPTION_SECURE_EXPLICIT	This option specifies the client should attempt to establish a secure connection with the server using the START_TLS option. The client initiates a standard connection with the server, then requests a secure connection during the option negotiation process.
TELNET_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
TELNET_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
TELNET_OPTION_FREETHREAD	This option specifies the handle returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the handle is synchronized across multiple threads.

hEventWnd

The handle to the event notification window. This window receives messages which notify the client of various asynchronous network events that occur. If this argument is NULL, then the client session will be blocking and no network events will be sent to the client.

uEventMsg

The message identifier that is used when an asynchronous network event occurs. This value should be greater than WM_USER as defined in the Windows header files. If the *hEventWnd* argument is NULL, this argument should be specified as WM_NULL.

Return Value

If the method succeeds, the return value is a non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The use of Windows event notification messages has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the

application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

To prevent this method from blocking the main user interface thread, the application should create a background worker thread and establish a connection by calling **Connect** in that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each client session.

If you specify an event notification window, then the client session will be asynchronous. When a message is posted to the notification window, the low word of the *lParam* parameter contains the event identifier. The high word of *lParam* contains the low word of the error code, if an error has occurred. The *wParam* parameter contains the client handle. One or more of the following event identifiers may be sent:

Constant	Description
TELNET_EVENT_CONNECT	The connection to the server has completed. The high word of the <i>lParam</i> parameter should be checked, since this notification message will be posted if an error has occurred.
TELNET_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
TELNET_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
TELNET_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
TELNET_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
TELNET_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.

To cancel asynchronous notification and return the client to a blocking mode, use the **DisableEvents** methods.

It is recommended that you only establish an asynchronous connection if you understand the implications of doing so. In most cases, it is preferable to create a synchronous connection and create threads for each additional session if more than one active client session is required.

The *dwOptions* argument can be used to specify the threading model that is used by the library when a connection is established. By default, the class instance is initially attached to the thread that created it. From that point on, until the it is released, only the owner may call methods using

that instance of the class. The ownership of the class instance may be transferred from one thread to another using the **AttachThread** method.

Specifying the TELNET_OPTION_FREETHREAD option enables any thread to call any method in that instance of the class, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the class instance is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same instance.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstntv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[CreateSecurityCredentials](#), [Disconnect](#), [GetSecurityInformation](#)

CTelnetClient::CreateSecurityCredentials Method

```
BOOL CreateSecurityCredentials(  
    DWORD dwProtocol,  
    DWORD dwOptions,  
    LPCTSTR lpszUserName,  
    LPCTSTR lpszPassword,  
    LPCTSTR lpszCertStore,  
    LPCTSTR lpszCertName  
);  
  
BOOL CreateSecurityCredentials(  
    LPCTSTR lpszCertStore,  
    LPCTSTR lpszCertName  
);  
  
BOOL CreateSecurityCredentials(  
    LPCTSTR lpszCertName  
);
```

The **CreateSecurityCredentials** method establishes the security credentials for the client session.

Parameters

dwProtocol

A bitmask of supported security protocols. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_SSL	Either SSL 2.0 or SSL 3.0 should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, TLS will be excluded from the list of supported protocols. Both SSL 2.0 and 3.0 have been deprecated and will never be used unless explicitly specified. It is not recommended that you enable either of these protocols for secure connections because it will cause most servers to reject your connection request, even if a version of TLS is also specified.
SECURITY_PROTOCOL_TLS	Either the TLS 1.0, 1.1 or 1.2 protocol should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols.

	This may be necessary for some servers that reject any attempt to use the older SSL protocol and require that only TLS be used.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This is the recommended version of TLS to use with secure connections.

dwOptions

A value which specifies one or options. This member is constructed by using a bitwise operator with any of the following values:

Constant	Description
CREDENTIAL_STORE_CURRENT_USER	The library will attempt to open a store for the current user using the certificate store name provided in this structure. If no options are specified, then this is the default behavior.
CREDENTIAL_STORE_LOCAL_MACHINE	The library will attempt to open a local machine store using the certificate store name provided in this structure. If this option is specified, the library will always search for a local machine store before searching for the store by that name for the current user.
CREDENTIAL_STORE_FILENAME	The certificate store name is a file that contains the certificate and private key that will be used.

lpzUserName

A pointer to a string which specifies the certificate owner's username. A value of NULL specifies that no username is required. Currently this parameter is not used and any value specified will be ignored.

lpszPassword

A pointer to a string which specifies the certificate owner's password. A value of NULL specifies that no password is required. This parameter is only used if a PKCS12 (PFX) certificate file is specified and that certificate has been secured with a password. This value will be ignored the current user or local machine certificate store is specified.

lpszCertStore

A pointer to a string which specifies the name of the certificate store to open. A certificate store is a collection of certificates and their private keys, typically organized by how they are used. If this value is NULL or points to an empty string, the default certificate store "MY" will be used.

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as VeriSign and Thawte act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. This corresponds to the "Personal" store that is displayed by the certificate manager utility and is the default store used by the library.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as VeriSign and Thawte are installed as part of the operating system and periodically updated by Microsoft.

lpszCertName

A pointer to a null terminated string which specifies the name of the certificate to use. The function will first search the certificate store for a certificate with a matching "friendly name"; this is a name for the certificate that is assigned by the user. Note that the name must match completely, but the comparison is not case sensitive. If no matching certificate is found, the function will then attempt to find a certificate that has a matching common name (also called the certificate subject). This comparison is less stringent, and the first partial match will be returned. If this second search fails, the function will return an error indicating that the certificate could not be found.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Example

```
pClient->CreateSecurityCredentials(  
    SECURITY_PROTOCOL_DEFAULT,  
    0,  
    NULL,  
    NULL,  
    lpszCertStore,  
    lpszCertName);
```

```
bConnected = pClient->Connect(lpszHostName,  
                              TELNET_PORT_SECURE,  
                              TELNET_TIMEOUT,  
                              TELNET_OPTION_SECURE);
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstntv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[Connect](#), [DeleteSecurityCredentials](#), [GetSecurityInformation](#), [SECURITYCREDENTIALS](#)

CTelnetClient::DeleteSecurityCredentials Method

```
VOID DeleteSecurityCredentials();
```

The **DeleteSecurityCredentials** method releases the security credentials for the current session.

Parameters

None.

Return Value

None.

Remarks

This method can be used to release the memory allocated to the client or server credentials after a secure connection has been terminated. The security credentials are released when the class destructor is called, so it is normally not required that the application explicitly call this method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstntv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[CreateSecurityCredentials](#)

CTelnetClient::DetachHandle Method

```
HCLIENT DetachHandle();
```

The **DetachHandle** method detaches the client handle associated with the current instance of the class.

Parameters

None.

Return Value

This method returns the client handle associated with the current instance of the class object. If there is no active client session, the value `INVALID_CLIENT` will be returned.

Remarks

This method is used to detach a client handle created by the class for use with the SocketTools API. Once the client handle is detached from the class, no other class member functions may be called. Note that the handle must be explicitly released at some later point by the process or a resource leak will occur.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `cstntv10.lib`

See Also

[AttachHandle](#), [GetHandle](#)

CTelnetClient::DisableEvents Method

```
INT DisableEvents();
```

The **DisableEvents** method disables the event notification mechanism, preventing subsequent event notification messages from being posted to the application's message queue.

This method has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Parameters

None.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is TELNET_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **DisableEvents** method is used to disable event message posting for the specified client session. Although this will immediately prevent any new events from being generated, it is possible that messages could be waiting in the message queue. Therefore, an application must be prepared to handle client event messages after this method has been called.

This method is automatically called if the client has event notification enabled, and the **Disconnect** method is called. The same issues regarding outstanding event messages also applies in this situation, requiring that the application handle event messages that may reference a client handle that is no longer valid.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstntv10.lib

See Also

[EnableEvents](#), [RegisterEvent](#)

CTelnetClient::DisableTrace Method

```
BOOL DisableTrace();
```

The **DisableTrace** method disables the logging of socket function calls to the trace log.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, a value of zero is returned.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstntv10.lib

[Connect](#), [IsConnected](#)

CTelnetClient::EnableEvents Method

```
INT EnableEvents(  
    HWND hEventWnd,  
    UINT uEventMsg  
);
```

The **EnableEvents** method enables event notifications using Windows messages.

This method has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Applications should use the **RegisterEvent** method to register an event handler which is invoked when an event occurs.

Parameters

hEventWnd

Handle to the window which will receive the client notification messages. This parameter must specify a valid window handle. If a NULL handle is specified, event notification will be disabled.

uEventMsg

The message that is received when a client event occurs. This value must be greater than 1024.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is TELNET_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **EnableEvents** method is used to request that notification messages be posted to the specified window whenever a client event occurs. This allows an application to monitor the status of different client operations, such as a file transfer.

The *wParam* argument will contain the client handle, the low word of the *lParam* argument will contain the event ID, and the high word will contain any error code. If no error has occurred, the high word will always have a value of zero. The following events may be generated:

Constant	Description
TELNET_EVENT_CONNECT	The connection to the server has completed. The high word of the <i>lParam</i> parameter should be checked, since this notification message will be posted if an error has occurred.
TELNET_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
TELNET_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
TELNET_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking

	operation. This event is only generated if the client is in asynchronous mode.
TELNET_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
TELNET_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.

To disable event notification, call the **DisableEvents** method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstntv10.lib

See Also

[DisableEvents](#), [RegisterEvent](#)

CTelnetClient::EnableTrace Method

```
BOOL EnableTrace(  
    LPCTSTR lpszTraceFile,  
    DWORD dwTraceFlags  
);
```

The **EnableTrace** method enables the logging of socket function calls to a file.

Parameters

lpszTraceFile

A pointer to a string which specifies the name of the trace log file. If this parameter is NULL or an empty string, the default file name **cstrace.log** is used. The file is stored in the directory specified by the TEMP environment variable, if it is defined; otherwise, the current working directory is used.

dwTraceFlags

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
TRACE_INFO	All function calls are written to the trace file. This is the default value.
TRACE_ERROR	Only those function calls which fail are recorded in the trace file.
TRACE_WARNING	Only those function calls which fail or return values which indicate a warning are recorded in the trace file.
TRACE_HEXDUMP	All functions calls are written to the trace file, plus all the data that is sent or received is displayed, in both ASCII and hexadecimal format.
TRACE_PROCESS	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for multithreaded applications that are using worker threads.

Return Value

If the method succeeds, the return value is non-zero. A return value of zero indicates an error. Failure typically indicates that the tracing library **cstrcv10.dll** cannot be loaded on the local system.

Remarks

When trace logging is enabled, the file is opened, appended to and closed for each socket function call. This makes it possible for an application to append its own logging information, however care should be taken to ensure that the file is closed before the next network operation is performed. To limit the size of the log files, enable and disable logging only around those sections of code that you wish to trace.

Note that the TRACE_HEXDUMP trace level generates very large log files since it includes all of the data exchanged between your application and the server.

Trace method logging is managed on a per-thread basis, not for each client handle. This means that all SocketTools libraries and components share the same settings in the current thread. If you

are using multiple SocketTools libraries or components in your application, you only need to enable logging once.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstntv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[DisableTrace](#)

CTelnetClient::FreezeEvents Method

```
INT FreezeEvents(  
    BOOL bFreeze  
);
```

The **FreezeEvents** method is used to suspend and resume event handling by the client.

Parameters

bFreeze

A non-zero value specifies that event handling should be suspended by the client. A zero value specifies that event handling should be resumed.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is TELNET_ERROR. To get extended error information, call **GetLastError**.

Remarks

This method should be used when the application does not want to process events, such as when a modal dialog is being displayed. When events are suspended, all client events are queued. If events are re-enabled at a later point, those queued events will be sent to the application for processing. Note that only one of each event will be generated. For example, if the client has suspended event handling, and four read events occur, once event handling is resumed only one of those read events will be posted to the client. This prevents the application from being flooded by a potentially large number of queued events.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstntv10.lib

Unicode: Implemented as Unicode and ANSI versions.

CTelnetClient::GetErrorString Method

```
INT GetErrorString(  
    DWORD dwErrorCode,  
    LPTSTR lpszDescription,  
    INT cbDescription  
);  
  
INT GetErrorString(  
    DWORD dwErrorCode,  
    CString& strDescription  
);
```

The **GetErrorString** method is used to return a description of a specific error code. Typically this is used in conjunction with the **GetLastError** method for use with warning dialogs or as diagnostic messages.

Parameters

dwErrorCode

The error code for which a description is returned.

lpszDescription

A pointer to the buffer that will contain a description of the specified error code. This buffer should be at least 128 characters in length. An alternate form of the method accepts a **CString** variable which will contain the error description.

cbDescription

The maximum number of characters that may be copied into the description buffer.

Return Value

If the method succeeds, the return value is the length of the description string. If the method fails, the return value is zero, meaning that no description exists for the specified error code. Typically this indicates that the error code passed to the method is invalid.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cstntv10.lib

Unicode: Implemented as Unicode and ANSI versions.

CTelnetClient::GetLastError Method

```
DWORD GetLastError();  
  
DWORD GetLastError(  
    CString& strDescription  
);
```

Parameters

strDescription

A string which will contain a description of the last error code value when the method returns. If no error has been set, or the last error code has been cleared, this string will be empty.

Return Value

The return value is the last error code value for the current thread. Functions set this value by calling the **SetLastError** method. The Return Value section of each reference page notes the conditions under which the method sets the last error code.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. You should call the **GetLastError** method immediately when a method's return value indicates that an error has occurred. That is because some methods call **SetLastError(0)** when they succeed, clearing the error code set by the most recently failed method.

Most methods will set the last error code value when they fail; a few methods set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or TELNET_ERROR. Those methods which call **SetLastError** when they succeed are noted on the method reference page.

The description of the error code is the same string that is returned by the **GetErrorString** method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cstntv10.lib

See Also

[GetErrorString](#), [SetLastError](#), [ShowError](#)

CTelnetClient::GetMode Method

```
UINT GetMode();
```

The **GetMode** method returns the current client mode.

Parameters

None.

Return Values

If the method succeeds, the return value is the current client mode. If the method fails, the return value is TELNET_ERROR. To get extended error information, call **GetLastError**.

Remarks

The client mode is a combination of one or more flags which determines how the client handles local character echo and character processing. The following values are recognized:

Value	Description
TELNET_MODE_LOCALECHO	The local client is responsible for echoing data entered by the user. By default, this mode is not set which means that the server is responsible for echoing back each character written to it.
TELNET_MODE_BINARY	Data exchanged between the client and server should not be converted or line buffered. If this option is not specified, the high-bit will be cleared on all characters and single linefeeds will be automatically converted to carriage-return/linefeed sequences.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstntv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[SetMode](#)

CTelnetClient::GetSecurityInformation Method

```
BOOL GetSecurityInformation(  
    LPSECURITYINFO LpSecurityInfo  
);
```

The **GetSecurityInformation** method returns security protocol, encryption and certificate information about the current client connection.

Parameters

LpSecurityInfo

A pointer to a [SECURITYINFO](#) structure which contains information about the current client connection. The *dwSize* member of this structure must be initialized to the size of the structure before passing the address of the structure to this method.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

This method is used to obtain security related information about the current client connection to the server. It can be used to determine if a secure connection has been established, what security protocol was selected, and information about the server certificate. Note that a secure connection has not been established, the *dwProtocol* structure member will contain the value SECURITY_PROTOCOL_NONE.

Example

The following example notifies the user if the connection is secure or not:

```
SECURITYINFO securityInfo;  
securityInfo.dwSize = sizeof(SECURITYINFO);  
  
if (pClient->GetSecurityInformation(&securityInfo))  
{  
    if (securityInfo.dwProtocol == SECURITY_PROTOCOL_NONE)  
    {  
        MessageBox(NULL, _T("The connection is not secure"),  
                    _T("Connection"), MB_OK);  
    }  
    else  
    {  
        if (securityInfo.dwCertStatus == SECURITY_CERTIFICATE_VALID)  
        {  
            MessageBox(NULL, _T("The connection is secure"),  
                        _T("Connection"), MB_OK);  
        }  
        else  
        {  
            MessageBox(NULL, _T("The server certificate not valid"),  
                        _T("Connection"), MB_OK);  
        }  
    }  
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstntv10.lib

Unicode: Implemented as Unicode and ANSI versions.

CTelnetClient::GetStatus Method

INT GetStatus();

The **GetStatus** method the current status of the client session.

Parameters

None.

Return Value

If the method succeeds, the return value is the client status code. If the method fails, the return value is TELNET_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetStatus** method returns a numeric code which identifies the current state of the client session. The following values may be returned:

Value	Constant	Description
0	TELNET_STATUS_UNUSED	No connection has been established.
1	TELNET_STATUS_IDLE	The client is current idle and not sending or receiving data.
2	TELNET_STATUS_CONNECT	The client is establishing a connection with the server.
3	TELNET_STATUS_READ	The client is reading data from the server.
4	TELNET_STATUS_WRITE	The client is writing data to the server.
5	TELNET_STATUS_DISCONNECT	The client is disconnecting from the server.

In a multithreaded application, any thread in the current process may call this method to obtain status information for the specified client session.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstntv10.lib

CTelnetClient::GetTerminalType Method

```
INT GetTerminalType(  
    LPCTSTR lpszTermType,  
    INT nMaxLength  
);  
  
INT GetTerminalType(  
    CString& strTermType  
);
```

The **GetTerminalType** method returns the terminal type for the current client session.

Parameters

lpszTermType

Points to a buffer which the current terminal type is copied into. This buffer should be at least 32 characters in length, including the terminating null character. This argument may also be a **CString** object which will contain the terminal type when the method returns.

nMaxLength

Maximum number of characters that may be copied to the buffer, including the terminating null character.

Return Value

If the method succeeds, the return value is the length of the terminal type name. A value of zero indicates that no terminal type has been specified. If the method fails, the return value is TELNET_ERROR. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstntv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[SetTerminalType](#)

CTelnetClient::GetTimeout Method

```
INT GetTimeout();
```

The **GetTimeout** method returns the number of seconds the client will wait for a response from the server. Once the specified number of seconds has elapsed, the method will fail and return to the caller.

Parameters

None.

Return Value

If the method succeeds, the return value is the timeout period in seconds. If the method fails, the return value is TELNET_ERROR. To get extended error information, call **GetLastError**.

Remarks

The timeout value is only used with blocking client connections. A value of zero indicates that the default timeout period of 20 seconds should be used.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstntv10.lib

See Also

[Connect](#), [IsReadable](#), [IsWritable](#), [Read](#), [SetTimeout](#), [Write](#)

CTelnetClient::IsBlocking Method

BOOL IsBlocking();

The **IsBlocking** method is used to determine if the client is currently performing a blocking operation.

Parameters

None.

Return Value

If the client is performing a blocking operation, the method returns a non-zero value. If the client is not performing a blocking operation, or the client handle is invalid, the method returns zero.

Remarks

Because a blocking operation can allow the application to be re-entered (for example, by pressing a button while the operation is being performed), it is possible that another blocking method may be called while it is in progress. Since only one thread of execution may perform a blocking operation at any one time, an error would occur. The **IsBlocking** method can be used to determine if the client is already blocked, and if so, take some other action (such as warning the user that they must wait for the operation to complete).

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstntv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

CTelnetClient::IsConnected Method

```
BOOL IsConnected();
```

The **IsConnected** method is used to determine if the client is currently connected to a server.

Parameters

None.

Return Value

If the client is connected to a server, the method returns a non-zero value. If the client is not connected, or the client handle is invalid, the method returns zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstntv10.lib

See Also

[GetStatus](#), [IsBlocking](#), [IsInitialized](#), [IsReadable](#), [IsWritable](#)

CTelnetClient::IsInitialized Method

```
BOOL IsInitialized();
```

The **IsInitialized** method returns whether or not the class object has been successfully initialized.

Parameters

None.

Return Value

This method returns a non-zero value if the class object has been successfully initialized. A return value of zero indicates that the runtime license key could not be validated or the networking library could not be loaded by the current process.

Remarks

When an instance of the class is created, the class constructor will attempt to initialize the component with the runtime license key that was created when SocketTools was installed. If the constructor is unable to validate the license key or load the networking libraries, this initialization will fail.

If SocketTools was installed with an evaluation license, the application cannot be redistributed to another system. The class object will fail to initialize if the application is executed on another system, or if the evaluation period has expired. To redistribute your application, you must purchase a development license which will include the runtime key that is needed to redistribute your software to other systems. Refer to the Developer's Guide for more information.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstntv10.lib

CTelnetClient::IsReadable Method

```
BOOL IsReadable(  
    INT nTimeout,  
    LPDWORD lpdwAvail  
);
```

The **IsReadable** method is used to determine if data is available to be read from the server.

Parameters

nTimeout

Timeout for server response, in seconds. A value of zero specifies that the connection should be polled without blocking the current thread.

lpdwAvail

A pointer to an unsigned integer which will contain the number of bytes available to read. This parameter may be NULL if this information is not required.

Return Value

If the client can read data from the server within the specified timeout period, the method returns a non-zero value. If the client cannot read any data, the method returns zero.

Remarks

On some platforms, this value will not exceed the size of the receive buffer (typically 64K bytes). Because of differences between TCP/IP stack implementations, it is not recommended that your application exclusively depend on this value to determine the exact number of bytes available. Instead, it should be used as a general indicator that there is data available to be read.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstntv10.lib

CTelnetClient::IsThere Method

BOOL IsThere();

The **IsThere** method reports the response of the client to a "Are you there" command to the telnet server.

Parameters

None.

Return Value

The method returns a non-zero value if the server acknowledges a specific control sequence used to determine if a server is responsive. If the server does not respond, the method will return a value of zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstntv10.lib

See Also

[GetStatus](#), [IsBlocking](#), [IsConnected](#), [IsReadable](#), [IsWritable](#)

CTelnetClient::IsWritable Method

```
BOOL IsWritable(  
    INT nTimeout  
);
```

The **IsWritable** method is used to determine if data can be written to the server.

Parameters

nTimeout

Timeout for server response, in seconds. A value of zero specifies that the connection should be polled without blocking the current thread.

Return Value

If the client can write data to the server within the specified timeout period, the method returns a non-zero value. If the client cannot write any data, the method returns zero.

Remarks

Although this method can be used to determine if some amount of data can be sent to the remote process it does not indicate the amount of data that can be written without blocking the client. In most cases, it is recommended that large amounts of data be broken into smaller logical blocks, typically some multiple of 512 bytes in length.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstntv10.lib

See Also

[GetStatus](#), [IsBlocking](#), [IsConnected](#), [IsInitialized](#), [IsReadable](#), [Write](#)

CTelnetClient::Login Method

```
BOOL Login(  
    LPCTSTR lpszUserName,  
    LPCTSTR lpszPassword  
);
```

The **Login** method attempts to authenticate the user and log them in to the current session.

Parameters

lpszUserName

A pointer to a string which specifies the name of the user to authenticate.

lpszPassword

A pointer to a string which specifies the password to be used when authenticating the user. If the user does not require a password, this parameter may be NULL.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **Login** method is used to authenticate a user, logging them into the server. This method is specifically designed to work with most UNIX based servers, and may work with other servers that use a similar login process. The method works by scanning the data stream for a username prompt and then replying with the specified username. If that is successful, it will then scan for a password prompt and provide the specified password. If no recognized prompt is found, or if the server responds with an error indicating that the username or password is invalid, the method will fail.

If the **Login** method succeeds, the next call to **Read** by the client will return any welcome message to the user. This is typically followed by a command prompt where the user can enter commands to be executed on the server. The data sent by the server during the login process is discarded and not available when the method returns. If the client requires this information, use the **Search** method to automate the login process instead.

Because the **Login** method is designed for UNIX based systems, it may not work with servers running on other operating system platforms such as Windows or VMS. In this case, applications should use the **Search** method to search for the appropriate login prompts in the data stream.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstntv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[Connect](#), [IsConnected](#), [IsReadable](#), [Read](#), [Search](#)

CTelnetClient::Read Method

```
INT Read(  
    LPBYTE lpBuffer,  
    INT cbBuffer  
);  
  
INT Read(  
    CString& strBuffer,  
    INT cbBuffer  
);
```

The **Read** method reads the specified number of bytes from the client socket and copies them into the buffer. The data may be of any type, and is not terminated with a null character.

Parameters

lpBuffer

Pointer to the buffer in which the data will be copied. An alternate form of this method allows a **CString** variable to be passed and data read from the socket will be returned in that string.

cbBuffer

The maximum number of bytes to read and copy into the specified buffer. This value must be greater than zero.

Return Value

If the method succeeds, the return value is the number of bytes actually read. A return value of zero indicates that the server has closed the connection and there is no more data available to be read. If the method fails, the return value is `TELNET_ERROR`. To get extended error information, call **GetLastError**.

Remarks

When **Read** is called and the client is in non-blocking mode, it is possible that the method will fail because there is no available data to read at that time. This should not be considered a fatal error. Instead, the application should simply wait to receive the next asynchronous notification that data is available.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `cstntv10.lib`

See Also

[EnableEvents](#), [IsBlocking](#), [IsReadable](#), [IsWritable](#), [RegisterEvent](#), [Write](#)

CTelnetClient::ReadLine Method

```
BOOL ReadLine(  
    LPTSTR lpszBuffer,  
    LPINT lpnLength  
);  
  
BOOL ReadLine(  
    LPTSTR lpszBuffer,  
    INT nMaxLength  
);  
  
BOOL ReadLine(  
    CString& strBuffer,  
    INT nMaxLength  
);
```

The **ReadLine** method reads up to a line of data from the server and returns it in a string buffer.

Parameters

lpszBuffer

Pointer to the string buffer that will contain the data when the method returns. The string will be terminated with a null character, and will not contain the end-of-line characters. An alternate form of the method accepts a **CString** argument which will contain the line of text returned by the server.

lpnLength

A pointer to an integer value which specifies the length of the buffer. The value should be initialized to the maximum number of characters that can be copied into the string buffer, including the terminating null character. When the method returns, its value will updated with the actual length of the string.

nMaxLength

An integer value which specifies the maximum length of the buffer.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **ReadLine** method reads data from the server and copies into a specified string buffer. Unlike the **Read** method which reads arbitrary bytes of data, this method is specifically designed to return a single line of text data in a string. When an end-of-line character sequence is encountered, the method will stop and return the data up to that point. The string buffer is guaranteed to be null-terminated and will not contain the end-of-line characters.

There are some limitations when using **ReadLine**. The method should only be used to read text, never binary data. In particular, the method will discard nulls, linefeed and carriage return control characters. The Unicode version of this method will return a Unicode string, however it does not support reading raw Unicode data from the socket. Any data read from the socket is internally buffered as octets (eight-bit bytes) and converted to Unicode using the **MultiByteToWideChar** function.

This method will force the thread to block until an end-of-line character sequence is processed, the read operation times out or the server closes its end of the socket connection. If this method is

called with asynchronous events enabled, it will automatically switch the socket into a blocking mode, read the data and then restore the socket to asynchronous operation. If another socket operation is attempted while **ReadLine** is blocked waiting for data from the server, an error will occur. It is recommended that this method only be used with blocking (synchronous) socket connections; if the application needs to establish multiple simultaneous connections, it should create worker threads to manage each connection.

The **Read** and **ReadLine** method calls can be intermixed, however be aware that **Read** will consume any data that has already been buffered by the **ReadLine** method and this may have unexpected results.

Unlike the **Read** method, it is possible for data to be returned in the string buffer even if the return value is zero. Applications should check the length of the string to determine if any data was copied into the buffer. For example, if a timeout occurs while the method is waiting for more data to arrive on the socket, it will return zero; however, data may have already been copied into the string buffer prior to the error condition. It is the responsibility of the application to process that data, regardless of the return value.

Example

```
CString strBuffer;
BOOL bResult;

do
{
    bResult = pClient->ReadLine(strBuffer);

    if (strBuffer.GetLength() > 0)
    {
        // Process the line of data returned in the string
        // buffer; the string is always null-terminated
    }
} while (bResult);

DWORD dwError = pClient->GetLastError();

if (dwError == ST_ERROR_CONNECTION_CLOSED)
{
    // The server has closed its side of the connection and
    // there is no more data available to be read
}
else if (dwError != 0)
{
    // An error has occurred while reading a line of data
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstntv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[IsReadable](#), [Read](#), [Write](#), [WriteLine](#)

CTelnetClient::RegisterEvent Method

```
INT RegisterEvent(  
    UINT nEventId,  
    TELNETEVENTPROC LpEventProc,  
    DWORD_PTR dwParam  
);
```

The **RegisterEvent** method registers an event handler for the specified event.

Parameters

nEventId

An unsigned integer which specifies which event should be registered with the specified callback function. One of the following values may be used:

Constant	Description
TELNET_EVENT_CONNECT	The connection to the server has completed.
TELNET_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
TELNET_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
TELNET_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
TELNET_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
TELNET_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.

LpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **TelnetEventProc** callback function. If this parameter is NULL, the callback for the specified event is disabled.

dwParam

A user-defined integer value that is passed to the callback function. If the application targets the x86 (32-bit) platform, this parameter must be a 32-bit unsigned integer. If the application targets the x64 (64-bit) platform, this parameter must be a 64-bit unsigned integer.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is `TELNET_ERROR`. To get extended error information, call **GetLastError**.

Remarks

The **RegisterEvent** method associates a callback function with a specific event. The event handler is an **TelnetEventProc** function that is invoked when the event occurs. Arguments are passed to the function to identify the client session, the event type and the user-defined value specified when the event handler is registered. If the event occurs because of an error condition, the error code will be provided to the handler.

The callback function specified by the *lpEventProc* parameter must be declared using the **__stdcall** calling convention. This ensures the arguments passed to the event handler are pushed on to the stack in the correct order. Failure to use the correct calling convention will corrupt the stack and cause the application to terminate abnormally.

The *dwParam* parameter is commonly used to identify the class instance which is associated with the event that has occurred. Applications will cast the **this** pointer to a `DWORD_PTR` value when calling this function, and then the event handler will cast it back to a pointer to the class instance. This gives the handler access to the class member variables and methods.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `cstntv10.lib`

See Also

CTelnetClient::Search Method

```
BOOL Search(  
    LPCTSTR lpszString  
);  
  
BOOL Search(  
    LPCTSTR lpszString,  
    LPBYTE lpBuffer,  
    LPDWORD lpdwLength  
);  
  
BOOL Search(  
    LPCTSTR lpszString,  
    HGLOBAL* lpBuffer,  
    LPDWORD lpdwLength  
);  
  
BOOL Search(  
    LPCTSTR lpszString,  
    CString& strBuffer  
);
```

The **Search** method searches for a specific character sequence in the data stream and stops reading if the sequence is encountered.

Parameters

lpszString

A pointer to a string which specifies the sequence of characters to search for in the data stream. This parameter cannot be NULL or point to an empty string.

lpBuffer

A pointer to a byte buffer which will contain the output from the server, or a pointer to a global memory handle which will reference the output when the method returns. If the output from the server is not required, this parameter may be NULL.

lpdwLength

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the *lpBuffer* parameter. If the *lpBuffer* parameter points to a global memory handle, the length value should be initialized to zero. When the method returns, this value will be updated with the actual number of bytes of output stored in the buffer. If the *lpBuffer* parameter is NULL, this parameter should also be NULL.

Return Value

If the method succeeds and the character sequences was found in the data stream, the return value is non-zero. If the method fails or a timeout occurs before the sequence is found, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **Search** method searches for a character sequence in the data stream and stops reading when it is found. This is useful when the client wants to automate responses to the server, such as logging in a user and executing a command. The method collects the output from the server and stores it in the buffer specified by the *lpBuffer* parameter. When the method returns, the buffer will contain everything sent by the server up to and including the search string.

The *lpBuffer* parameter may be specified in one of two ways, depending on the needs of the application. The first method is to pre-allocate a buffer large enough to store the a fixed amount of output. In this case, the *lpBuffer* parameter will point to the buffer that was allocated, the value that the *lpdwLength* parameter points to should be initialized to the size of that buffer. If the server sends more output than can be stored in the buffer, the remaining output will be discarded.

The second method that can be used is have the *lpBuffer* parameter point to a global memory handle which will contain the output when the method returns. In this case, the value that the *lpdwLength* parameter points to must be initialized to zero. It is important to note that the memory handle returned by the method must be freed by the application, otherwise a memory leak will occur. This method is preferred if the client application does not have a general idea of how much output will be generated until the search string is found.

Example

```
CString strOutput;
BOOL bResult;

// Search for the login prompt issued by the server

bResult = pClient->Search(T("ogin: "));

// If the Login: prompt was found, then write out the
// username and search for the Password: prompt; note
// that the username, password and command strings are
// terminated with a carriage-return/linefeed sequence
// which the server will see as the user pressing the
// Enter or Return key on the keyboard

if (bResult)
{
    pClient->Write(lpszUserName);
    bResult = pClient->Search(_T("word: "));
}

// If the Password: prompt was found, write out the
// password and then search for the shell prompt;
// the prompt may be different, depending on what
// operating system and shell is being used

if (bResult)
{
    pClient->Write(lpszPassword);
    bResult = Search(hClient, _T("$ "));
}

// If the shell prompt was found, issue the command
// and capture the output into the strOutput string
// and then write it to standard output

if (bResult)
{
    pClient->Write(lpszCommand);

    if (pClient->Search(_T("$ "), strOutput))
        cout << (LPCTSTR)strOutput << endl;
}
```

CTelnetClient::SetLastError Method

```
VOID SetLastError(  
    DWORD dwErrorCode  
);
```

The **SetLastError** method sets the last error code for the current thread. This method is typically used to clear the last error by specifying a value of zero as the parameter.

Parameters

dwErrorCode

Specifies the last error code for the current thread.

Return Value

None.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. Most methods will set the last error code value when they fail; a few methods set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or TELNET_ERROR. Those methods which call **SetLastError** when they succeed are noted on the method reference page.

Applications can retrieve the value saved by this method by using the **GetLastError** method. The use of **GetLastError** is optional; an application can call the method to determine the specific reason for a method failure.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

CTelnetClient::SetMode Method

```
UINT SetMode(  
    UINT nMode,  
    BOOL bEnable  
);
```

The **SetMode** method sets one or more client modes for the specified session.

Parameters

nMode

The client mode. This value is a combination of one or more flags which determines how the client handles local character echo and character processing. The following values are recognized:

Value	Description
TELNET_MODE_LOCALECHO	The local client is responsible for echoing data entered by the user. By default, this mode is not set which means that the server is responsible for echoing back each character written to it.
TELNET_MODE_BINARY	Data exchanged between the client and server should not be converted or line buffered. If this option is not specified, the high-bit will be cleared on all characters, and single linefeed characters will be converted to carriage-return/linefeed sequences.

bEnable

This boolean flag specifies if the specified mode is to be enabled or disabled.

Return Value

If the method succeeds, the return value is the previous mode. If the method fails, the return value is TELNET_ERROR. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

CTelnetClient::SetTerminalType Method

```
INT SetTerminalType(  
    LPCTSTR lpszTermType  
);
```

The **SetTerminalType** method sets the terminal type for the current client session.

Parameters

lpszTermType

Points to a string which specifies the terminal type.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is TELNET_ERROR. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstntv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[GetTerminalType](#)

CTelnetClient::SetTimeout Method

```
INT SetTimeout(  
    UINT nTimeout  
);
```

The **SetTimeout** method sets the number of seconds the client will wait for a response from the server. Once the specified number of seconds has elapsed, the method will fail and return to the caller.

Parameters

nTimeout

The number of seconds to wait for a blocking operation to complete.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is TELNET_ERROR. To get extended error information, call **GetLastError**.

Remarks

The timeout value is only used with blocking client connections.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

CTelnetClient::ShowError Method

```
INT ShowError(  
    LPCTSTR lpszAppTitle,  
    UINT uType,  
    DWORD dwErrorCode  
);
```

The **ShowError** method displays a message box which describes the specified error.

Parameters

lpszAppTitle

A pointer to a string which specifies the title of the message box that is displayed. If this argument is NULL or omitted, then the default title of "Error" will be displayed.

uType

An unsigned integer which specifies the type of message box that will be displayed. This is the same value that is used by the **MessageBox** method in the Windows API. If a value of zero is specified, then a message box with a single OK button will be displayed. Refer to that method for a complete list of options.

dwErrorCode

Specifies the error code that will be used when displaying the message box. If this argument is zero, then the last error that occurred in the current thread will be displayed.

Return Value

If the method is successful, the return value will be the return value from the **MessageBox** function. If the method fails, it will return a value of zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cstntv10.lib

Unicode: Implemented as Unicode and ANSI versions.

CTelnetClient::Write Method

```
INT Write(  
    LPBYTE lpBuffer,  
    INT cbBuffer  
);  
  
INT Write(  
    LPCTSTR lpszBuffer  
    INT cbBuffer  
);
```

The **Write** method sends the specified number of bytes to the server.

Parameters

lpBuffer

The pointer to the buffer which contains the data that is to be sent to the server. In an alternate form of the method, the pointer is to a string.

cbBuffer

The number of bytes to send from the specified buffer. This value must be greater than zero, unless a pointer to a string buffer is passed as the parameter. In that case, if the value is -1, all of the characters in the string, up to but not including the terminating null character, will be sent to the server.

Return Value

If the method succeeds, the return value is the number of bytes actually written. If the method fails, the return value is TELNET_ERROR. To get extended error information, call **GetLastError**.

Remarks

The return value may be less than the number of bytes specified by the *cbBuffer* parameter. In this case, the data has been partially written and it is the responsibility of the client application to send the remaining data at some later point. For non-blocking clients, the client must wait for the next asynchronous notification message before it resumes sending data.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cstntv10.lib

Unicode: Implemented as Unicode and ANSI versions.

CTelnetClient::WriteLine Method

```
BOOL WriteLine(  
    LPCTSTR lpszBuffer,  
    LPINT lpnLength  
);
```

The **WriteLine** function sends a line of text to the server, terminated by a carriage-return and linefeed.

Parameters

lpszBuffer

The pointer to a string buffer which contains the data that will be sent to the server. All characters up to, but not including, the terminating null character will be written to the socket. The data will always be terminated with a carriage-return and linefeed control character sequence. If this parameter points to an empty string or NULL pointer, then a only a carriage-return and linefeed are written to the socket.

lpnLength

A pointer to an integer value which will contain the number of characters written to the socket, including the carriage-return and linefeed sequence. If this information is not required, a NULL pointer may be specified.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **WriteLine** method writes a line of text to the server and terminates the line with a carriage-return and linefeed control character sequence. Unlike the **Write** method which writes arbitrary bytes of data to the socket, this method is specifically designed to write a single line of text data from a null-terminated string.

If the *lpszBuffer* string is terminated with a linefeed (LF) or carriage return (CR) character, it will be automatically converted to a standard CRLF end-of-line sequence. Because the string will be sent with a terminating CRLF sequence, the value returned in the *lpnLength* parameter will typically be larger than the original string length (reflecting the additional CR and LF characters), unless the string was already terminated with CRLF.

There are some limitations when using **WriteLine**. This method should only be used to send text, never binary data. In particular, it will discard nulls and append linefeed and carriage return control characters to the data stream. The Unicode version of this method will accept a Unicode string, however it does not support writing raw Unicode data to the socket. Unicode strings will be automatically converted to UTF-8 encoding using the **WideCharToMultiByte** function and then written to the socket as a stream of bytes.

This method will force the thread to block until the complete line of text has been written, the write operation times out or the server aborts the connection. If this method is called with asynchronous events enabled, it will automatically switch the socket into a blocking mode, send the data and then restore the socket to asynchronous operation. If another socket operation is attempted while **WriteLine** is blocked sending data to the server, an error will occur. It is recommended that this method only be used with blocking (synchronous) socket connections; if the application needs to establish multiple simultaneous connections, it should create worker

threads to manage each connection.

The **Write** and **WriteLine** methods can be safely intermixed.

Unlike the **Write** function, it is possible for data to have been written to the socket if the return value is zero. For example, if a timeout occurs while the method is waiting to send more data to the server, it will return zero; however, some data may have already been written prior to the error condition. If this is the case, the *lpnLength* argument will specify the number of characters actually written up to that point.

Requirements

Telnet Protocol Data Structures

- SECURITYCREDENTIALS
- SECURITYINFO

SECURITYCREDENTIALS Structure

The **SECURITYCREDENTIALS** structure specifies the information needed by the library to specify additional security credentials, such as a client certificate or private key, when establishing a secure connection.

```
typedef struct _SECURITYCREDENTIALS
{
    DWORD    dwSize;
    DWORD    dwProtocol;
    DWORD    dwOptions;
    DWORD    dwReserved;
    LPCTSTR  lpszHostName;
    LPCTSTR  lpszUserName;
    LPCTSTR  lpszPassword;
    LPCTSTR  lpszCertStore;
    LPCTSTR  lpszCertName;
    LPCTSTR  lpszKeyFile;
} SECURITYCREDENTIALS, *LPSECURITYCREDENTIALS;
```

Members

dwSize

Size of this structure. If the structure is being allocated dynamically, this member must be set to the size of the structure and all other unused structure members must be initialized to a value of zero or NULL.

dwProtocol

A bitmask of supported security protocols. The value of this structure member is constructed by using a bitwise operator with any of the following values:

Constant	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_SSL	Either SSL 2.0 or SSL 3.0 should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, TLS will be excluded from the list of supported protocols. Both SSL 2.0 and 3.0 have been deprecated and will never be used unless explicitly specified. It is not recommended that you enable either of these protocols for secure connections because it will cause most servers to reject your connection request, even if a version of TLS is also specified.
SECURITY_PROTOCOL_TLS	Either the TLS 1.0, 1.1 or 1.2 protocol should be used when establishing a secure connection. The correct protocol is automatically selected, based on

	what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers that reject any attempt to use the older SSL protocol and require that only TLS be used.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This is the recommended version of TLS to use with secure connections.

dwOptions

A value which specifies one or options. This member is constructed by using a bitwise operator with any of the following values:

Constant	Description
CREDENTIAL_STORE_CURRENT_USER	The library will attempt to open a store for the current user using the certificate store name provided in this structure. If no options are specified, then this is the default behavior.
CREDENTIAL_STORE_LOCAL_MACHINE	The library will attempt to open a local machine store using the certificate store name provided in this structure. If this option is specified, the library will always search for a local machine store before searching for the store by that name for the current user.
CREDENTIAL_STORE_FILENAME	The certificate store name is a file that contains the certificate and private key that

will be used.

dwReserved

This structure member is reserved for future use and should always be initialized to zero.

lpszHostName

A pointer to a null terminated string which specifies the hostname that will be used when validating the server certificate. If this member is NULL, then the server certificate will be validated against the hostname used to establish the connection.

lpszUserName

A pointer to a null terminated string which identifies the owner of client certificate. Currently this member is not used by the library and should always be initialized as a NULL pointer.

lpszPassword

A pointer to a null terminated string which specifies the password needed to access the certificate. Currently this member is only used if the CREDENTIAL_STORE_FILENAME option has been specified. If there is no password associated with the certificate, then this member should be initialized as a NULL pointer.

lpszCertStore

A pointer to a null terminated string which specifies the name of the certificate store to open. A certificate store is a collection of certificates and their private keys, typically organized by how they are used. If this value is NULL or points to an empty string, the default certificate store "MY" will be used.

Store Name	Description
------------	-------------

CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as VeriSign and Thawte act as certification authorities.
----	---

MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. This corresponds to the "Personal" store that is displayed by the certificate manager utility and is the default store used by the library.
----	--

ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as VeriSign and Thawte are installed as part of the operating system and periodically updated by Microsoft.
------	--

lpszCertName

A pointer to a null terminated string which specifies the name of the certificate to use. The library will first search the certificate store for a certificate with a matching "friendly name"; this is a name for the certificate that is assigned by the user. Note that the name must match completely, but the comparison is not case sensitive. If no matching certificate is found, the library will then attempt to find a certificate that has a matching common name (also called the certificate subject). This comparison is less stringent, and the first partial match will be returned. If this second search fails, the library will return an error indicating that the certificate could not be found. If the SECURITY_PROTOCOL_SSH protocol has been specified, this member should be NULL.

lpszKeyFile

A pointer to a null terminated string which specifies the name of the file which contains the private key required to establish the connection. This member is only used for SSH connections

and should always be NULL when establishing a secure connection using SSL or TLS.

Remarks

A client application only needs to create this structure if the server requires that the client provide a certificate as part of the process of negotiating the secure session. If a certificate is required, note that it must have a private key associated with it. Attempting to use a certificate that does not have a private key will result in an error during the connection process indicating that the client credentials could not be established.

If you are using a local certificate store, with the certificate and private key stored in the registry, you can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU:" for the current user, or "HKLM:" for the local machine. For example, a certificate store name of "HKLM:MY" would specify the personal certificate store for the local machine, rather than the current user. If neither prefix is specified, then it will default to the certificate store for the current user. You can manage these certificates using the CertMgr.msc Microsoft Management Console (MMC) snap-in.

It is possible to load the certificate from a file rather than from current user's certificate store. The *dwOptions* member should be set to CREDENTIAL_STORE_FILENAME and the *lpzCertStore* member should specify the name of the file that contains the certificate and its private key. The file must be in Private Information Exchange (PFX) format, also known as PKCS#12. These certificate files typically have an extension of .pfx or .p12. Note that if a password was specified when the certificate file was created, it must be provided in the *lpzPassword* member or the library will be unable to access the certificate.

Note that the *lpzUserName* and *lpzPassword* members are values which are used to access the certificate store or private key file. They are not the credentials which are used when establishing the connection with the remote host or authenticating the client session.

The TLS 1.1 and TLS 1.2 protocols are only supported on Windows 7, Windows Server 2008 R2 and later versions of the platform. If these options are specified and the application is running on Windows XP or Windows Vista, the protocol version will be downgraded to TLS 1.0 for backwards compatibility with those platforms.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include ctools10.h

Unicode: Implemented as Unicode and ANSI versions.

SECURITYINFO Structure

This structure contains information about a secure connection that has been established.

```
typedef struct _SECURITYINFO
{
    DWORD        dwSize;
    DWORD        dwProtocol;
    DWORD        dwCipher;
    DWORD        dwCipherStrength;
    DWORD        dwHash;
    DWORD        dwHashStrength;
    DWORD        dwKeyExchange;
    DWORD        dwCertStatus;
    SYSTEMTIME   stCertIssued;
    SYSTEMTIME   stCertExpires;
    LPCTSTR      lpszCertIssuer;
    LPCTSTR      lpszCertSubject;
    LPCTSTR      lpszFingerprint;
} SECURITYINFO, *LPSECURITYINFO;
```

Members

dwSize

Specifies the size of the data structure. This member must always be initialized to **sizeof(SECURITYINFO)** prior to passing the address of this structure to the function. Note that if this member is not initialized, an error will be returned indicating that an invalid parameter has been passed to the function.

dwProtocol

A numeric value which specifies the protocol that was selected to establish the secure connection. One of the following values will be returned:

Constant	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_SSL	Either SSL 2.0 or SSL 3.0 should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, TLS will be excluded from the list of supported protocols. Both SSL 2.0 and 3.0 have been deprecated and will never be used unless explicitly specified. It is not recommended that you enable either of these protocols for secure connections because it will cause most servers to reject your connection request, even if a version of TLS is also specified.
SECURITY_PROTOCOL_TLS	Either the TLS 1.0, 1.1 or 1.2 protocol should be used when establishing a secure connection. The

	<p>correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers that reject any attempt to use the older SSL protocol and require that only TLS be used.</p>
SECURITY_PROTOCOL_TLS10	<p>The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.</p>
SECURITY_PROTOCOL_TLS11	<p>The TLS 1.1 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.</p>
SECURITY_PROTOCOL_TLS12	<p>The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This is the recommended version of TLS to use with secure connections.</p>

dwCipher

A numeric value which specifies the cipher that was selected when establishing the secure connection. One of the following values will be returned:

Constant	Description
SECURITY_CIPHER_RC2	The RC2 block cipher was selected. This is a variable key length cipher which supports keys between 40 and 128 bits, in 8-bit increments.
SECURITY_CIPHER_RC4	The RC4 stream cipher was selected. This is a variable key length cipher which supports keys between 40 and 128 bits, in 8-bit increments.
SECURITY_CIPHER_RC5	The RC5 block cipher was selected. This is a variable key length cipher which supports keys up to 2040 bits, in 8-bit increments.
SECURITY_CIPHER_DES	The DES (Data Encryption Standard) block cipher was selected. This is a fixed key length cipher, using 56-bit

	keys.
SECURITY_CIPHER_DES3	The Triple DES block cipher was selected. This cipher encrypts the data three times using different keys, effectively providing a 168-bit length key.
SECURITY_CIPHER_DESX	A variant of the DES block cipher which XORs an extra 64-bits of the key before and after the plaintext has been encrypted, increasing the key size to 184 bits.
SECURITY_CIPHER_AES	The Advanced Encryption Standard cipher (also known as the Rijndael cipher) is a fixed block size cipher which use a key size of 128, 192 or 256 bits. This cipher is supported on Windows XP SP3 and later versions of the operating system.
SECURITY_CIPHER_SKIPJACK	The Skipjack block cipher was selected. This is a fixed key length cipher, using 80-bit keys.
SECURITY_CIPHER_BLOWFISH	The Blowfish block cipher was selected. This is a variable key length cipher up to 448 bits, using a 64-bit block size.

dwCipherStrength

A numeric value which specifies the strength (the length of the cipher key in bits) of the cipher that was selected. Typically this value will be 128 or 256. 40-bit and 56-bit key lengths are considered weak encryption, and subject to brute force attacks. 128-bit and 256-bit key lengths are considered to be secure, and are the recommended key length for secure communications.

dwHash

A numeric value which specifies the hash algorithm which was selected. One of the following values will be returned:

Constant	Description
SECURITY_HASH_MD5	The MD5 algorithm was selected. Its use has been deprecated and is no longer considered to be cryptographically secure.
SECURITY_HASH_SHA1	The SHA-1 algorithm was selected. Its use has been deprecated and is no longer considered to be cryptographically secure.
SECURITY_HASH_SHA256	The SHA-256 algorithm was selected.
SECURITY_HASH_SHA384	The SHA-384 algorithm was selected.
SECURITY_HASH_SHA512	The SHA-512 algorithm was selected.

dwHashStrength

A numeric value which specifies the strength (the length in bits) of the message digest that was selected.

dwKeyExchange

A numeric value which specifies the key exchange algorithm which was selected. One of the following values will be returned:

--	--

Constant	Description
SECURITY_KEYEX_RSA	The RSA public key algorithm was selected.
SECURITY_KEYEX_KEA	The Key Exchange Algorithm (KEA) was selected. This is an improved version of the Diffie-Hellman public key algorithm.
SECURITY_KEYEX_DH	The Diffie-Hellman key exchange algorithm was selected.
SECURITY_KEYEX_ECDH	The Elliptic Curve Diffie-Hellman key exchange algorithm was selected. This is a variant of the Diffie-Hellman algorithm which uses elliptic curve cryptography. This key exchange algorithm is only supported on Windows XP SP3 and later versions of the operating system.

dwCertStatus

A numeric value which specifies the status of the certificate returned by the secure server. This member only has meaning for connections using the SSL or TLS protocols. One of the following values will be returned:

Constant	Description
SECURITY_CERTIFICATE_VALID	The certificate is valid.
SECURITY_CERTIFICATE_NOMATCH	The certificate is valid, but the domain name does not match the common name in the certificate.
SECURITY_CERTIFICATE_EXPIRED	The certificate is valid, but has expired.
SECURITY_CERTIFICATE_REVOKED	The certificate has been revoked and is no longer valid.
SECURITY_CERTIFICATE_UNTRUSTED	The certificate or certificate authority is not trusted on the local system.
SECURITY_CERTIFICATE_INVALID	The certificate is invalid. This typically indicates that the internal structure of the certificate has been damaged.

stCertIssued

A structure which contains the date and time that the certificate was issued by the certificate authority. If the issue date cannot be determined for the certificate, the SYSTEMTIME structure members will have zero values. This member only has meaning for connections using the SSL or TLS protocols.

stCertExpires

A structure which contains the date and time that the certificate expires. If the expiration date cannot be determined for the certificate, the SYSTEMTIME structure members will have zero values. This member only has meaning for connections using the SSL or TLS protocols.

lpszCertIssuer

A pointer to a string which contains information about the organization that issued the certificate. This string consists of one or more comma-separated tokens. Each token consists of an identifier, followed by an equal sign and a value. If the certificate issuer could not be determined, this member may be NULL. This member only has meaning for connections using the SSL or TLS protocols.

lpszCertSubject

A pointer to a string which contains information about the organization that the certificate was issued to. This string consists of one or more comma-separated tokens. Each token consists of an identifier, followed by an equal sign and a value. If the certificate subject could not be determined, this member may be NULL. This member only has meaning for connections using the SSL or TLS protocols.

lpszFingerprint

A pointer to a string which contains a sequence of hexadecimal values that uniquely identify the server. This member is only used when a connection has been established using the Secure Shell (SSH) protocol.

Terminal Emulation Class Library

Emulate an ANSI or DEC VT-220 character mode display terminal.

Reference

- [Class Methods](#)
- [Data Structures](#)
- [Control Sequences](#)
- [Error Codes](#)

Library Information

Class Name	CTerminalEmulator
File Name	CSNVTV10.DLL
Version	10.0.1468.2518
LibID	53152C92-4EA6-4C06-9ED3-50C79C933F01
Import Library	CSNVTV10.LIB
Dependencies	None

Remarks

The Terminal Emulation library provides a comprehensive API for emulating an ANSI or DEC-VT220 terminal, with full support for all standard escape and control sequences, color mapping and other advanced features. The library methods provide both a high level interface for parsing escape sequences and updating a display, as well as lower level primitives for directly managing the virtual display, such as controlling the individual display cells, moving the cursor position and specifying display attributes.

This class can be used in conjunction with the Remote Command, Secure Shell or Telnet Protocol classes to provide terminal emulation services for an application, or it can be used independently. For example, this class could be used to provide emulation services for a program that connects to a device using an RS-232 serial port.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). If you are using Visual C++ 6.0 it is required that you have Service Pack 6 (SP6) installed. You should install all updates for your development tools and have the current Windows SDK installed. The minimum recommended version of Visual Studio is Visual Studio 2010.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are using Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. It is recommended that you install the current service pack and all critical updates available for your version of the operating system.

This product includes both 32-bit and 64-bit libraries. Native 64-bit CPU support requires the 64-bit version of Windows 7 or later versions of the Windows operating system.

Distribution

When you distribute your application that uses this library, it is recommended that you install the

file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

Terminal Emulation Class Methods

Class	Description
CTerminalEmulator	Constructor which initializes the current instance of the class
~CTerminalEmulator	Destructor which releases resources allocated by the class
Method	Description
AttachHandle	Attach the specified display handle to this instance of the class
Clear	Clear the virtual display
ConvertPos	Convert between pixel and screen coordinates
CopySelectedText	Copy the selected text to the clipboard
Create	Create a new virtual terminal emulation display
DeleteChar	Delete the specified number of characters
DeleteLine	Delete the current line, shifting remaining lines up
DetachHandle	Detach the handle for the current instance of this class
EraseChar	Erase the specified number of characters
EraseLine	Erase the current line
GetAttributes	Return the current display attributes
GetBackColor	Return the current background color
GetCell	Return information about the specified cell in the virtual display
GetCellSize	Return the size of the display character cells
GetColor	Get the current virtual display colors
GetColorMap	Return the virtual display color table
GetCursorPos	Return the current cursor position
GetDisplayInfo	Return information about the virtual display
GetDC	Get the current virtual display device context
GetEmulation	Get the current terminal emulation type
GetFont	Get the current virtual display font
GetForeColor	Return the current foreground color
GetLine	Return a line of text from the virtual display
GetMode	Get the current virtual display mode
GetRect	Return the rectangle for the display window client area
GetScrollPos	Get the display scroll box position
GetSize	Return the current size of the virtual display
GetText	Get the specified block of text from the virtual display

GetWindow	Get the current virtual display window
GetHandle	Return the display handle used by this instance of the class
GetMappedKey	Return the escape sequence for the mapped key
GetScrollRegion	Return the current scrolling region
GetSelectedText	Return the currently selected text
GetTextColor	Return the current text foreground or background color
InsertChar	Insert the specified number of characters
InsertLine	Insert a line, shifting the remaining lines down
IsInitialized	Determine if the class has been successfully initialized
Refresh	Refresh the specified display
Reset	Reset the virtual display
ResetMappedKeys	Reset the mapped key table to default values
Resize	Resize the virtual display
RestoreCursor	Restore the saved cursor position and text attributes
SaveCursor	Save the current cursor position and text attributes
Scroll	Scroll the virtual display
SelectText	Select a region of the virtual display
SetAttributes	Set the current display attributes
SetBackColor	Set the background color for the virtual display
SetBoldColor	Set the bold color for the virtual display
SetCell	Set the value of a character cell in the virtual display
SetColor	Set the virtual display colors
SetColorMap	Set the virtual display color table
SetCursorPos	Set the current cursor position
SetDC	Set the current virtual display device context
SetEmulation	Set the current terminal emulation type
SetFocus	Set the focus on the virtual display
SetFont	Set the current virtual display font
SetForeColor	Set the foreground color for the virtual display
SetMode	Set the current virtual display mode
SetScrollPos	Set the display scroll box position
SetSize	Set the size of the virtual display
SetWindow	Set the current virtual display window
SetMappedKey	Set the escape sequence for the specified key
SetScrollRegion	Set the current scrolling region

SetTextColor	Set the current text foreground or background color
TranslateMappedKey	Translate the keypress to a mapped key escape sequence
Update	Update the window attached to the virtual display
UpdateCaret	Update the display window caret
Write	Write the specified buffer to the virtual display

CTerminalEmulator::CTerminalEmulator Method

`CTerminalEmulator();`

The **CTerminalEmulator** constructor initializes the class library and validates the license key at runtime.

Remarks

If the constructor fails to validate the runtime license, subsequent methods in this class will fail. If the product is installed with an evaluation license, then the application will only function on the development system and cannot be redistributed.

The constructor calls the **NvtInitialize** function to initialize the library, which dynamically loads other system libraries and allocates thread local storage. If you are using this class within another DLL, it is important that you do not create or destroy an instance of the class from within the **DllMain** function because it can result in deadlocks or access violation errors. You should not declare static or global instances of this class within another DLL if it is linked with the C runtime library (CRT) because it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csnvtv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

See Also

[~CTerminalEmulator](#), [IsInitialized](#)

CTerminalEmulator::~CTerminalEmulator

`~CTerminalEmulator();`

The **CTerminalEmulator** destructor releases resources allocated by the current instance of the **CTerminalEmulator** object. It also uninitialized the library if there are no other concurrent uses of the class.

Remarks

When a **CTerminalEmulator** object goes out of scope, the destructor is automatically called to allow the library to free any resources allocated on behalf of the process. Any pending blocking or asynchronous calls in this process are canceled without posting any notification messages, and all handles that were created for the client session are destroyed.

The destructor is not called explicitly by the application.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csnvtv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

CTerminalEmulator::AttachHandle Method

```
VOID AttachHandle(  
    HDISPLAY hDisplay  
);
```

The **AttachHandle** method attaches the specified display handle to the current instance of the class.

Parameters

hDisplay

The handle to the virtual display that will be attached to the current instance of the class object.

Return Value

None.

Remarks

This method is used to attach a display handle created outside of the class using the SocketTools API. Once the handle is attached to the class, the other class member functions may be used with that virtual display.

The virtual display for the current instance of the class will be destroyed when the new handle is attached to the class object. If you want to prevent the display handle from being released, you must call the **DetachHandle** method. Failure to release the detached handle may result in a resource leak in your application.

Note that the *hDisplay* parameter is presumed to be a valid display handle and no checks are performed to ensure that the handle is valid. Specifying an invalid handle will cause subsequent method calls to fail.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csntv10.lib

See Also

[DetachHandle](#), [GetHandle](#)

CTerminalEmulator::Clear Method

```
BOOL Clear(  
    UINT nMode  
);
```

The **Clear** method clears the specified display, erasing the text and clearing any attributes.

Parameters

nMode

Mode which specifies how the display will be cleared. The following values may be used:

Constant	Description
NVT_CLEAR_EOS	The display is cleared from the current cursor position to the end of the display. The cursor position is not changed.
NVT_CLEAR_TOS	The display is cleared from the beginning of the display to the current cursor position. The cursor position is not changed.
NVT_CLEAR_ALL	The entire display is cleared and the cursor is repositioned to the upper left corner of the display.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, it returns zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csntv10.lib

CTerminalEmulator::ConvertPos Method

```
BOOL ConvertPos(  
    INT nMethod,  
    INT xPos,  
    INT yPos,  
    LPPPOINT lppt  
);
```

```
BOOL ConvertPos(  
    INT xPos,  
    INT yPos,  
    LPPPOINT lppt  
);
```

The **ConvertPos** method converts the specified X,Y position and stores the result in the POINT structure provided by the caller.

Parameters

nMethod

An integer value which specifies the conversion method to use. This may be one of the following values:

Constant	Description
NVT_CURSOR_TO_PIXELS	Convert cursor X,Y coordinates to the current window X,Y pixel coordinates. An error is returned if the coordinates are out of bounds for the current display.
NVT_PIXELS_TO_CURSOR	Convert window X,Y pixel coordinates to cursor X,Y coordinates. If the point is outside of the bounds of the display, it is normalized to account for mouse capture.

xPos

An integer value which specifies the X position in the virtual display. This may either be the cursor position or a pixel position, based on the value of the *nMethod* parameter.

yPos

An integer value which specifies the Y position in the virtual display. This may either be the cursor position or a pixel position, based on the value of the *nMethod* parameter.

lppt

A pointer to a POINT structure which will contain the converted coordinates.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, it returns zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csntv10.lib

See Also

CTerminalEmulator::CopySelectedText Method

BOOL CopySelectedText();

The **CopySelectedText** method copies any selected text to the system clipboard.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, it returns zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csntv10.lib

CTerminalEmulator::Create Method

```
BOOL Create(  
    HWND hWnd,  
    HFONT hFont,  
    UINT nEmulation,  
    UINT nColumns,  
    UINT nRows  
);
```

The **Create** method creates a new virtual terminal emulation display using the specified window and font.

Parameters

hWnd

Handle to the window that will be used to display the virtual terminal.

hFont

Handle to the font that will be used with the virtual terminal. This parameter may be NULL, in which case a default fixed-width font will be used. If a font is specified, it must be fixed-width, otherwise the virtual cursor positioning will be incorrect in some cases.

nEmulation

Identifies the virtual terminal emulation type. The following emulation types are currently supported.

Constant	Description
NVT_EMULATION_NONE	The virtual display does not emulate any specific terminal type, and does not process escape sequences.
NVT_EMULATION_ANSI	The virtual display processes ANSI escape sequences for screen management and cursor positioning. This emulation also supports escape sequences to control the foreground and background color. The default keymap for ANSI function key escape sequences will be selected.
NVT_EMULATION_VT100	The virtual display processes DEC VT-100 escape sequences for screen management and cursor positioning. The default keymap for a DEC VT-100 terminal will be selected.
NVT_EMULATION_VT220	The virtual display processes DEC VT-220 escape sequences for screen management and cursor positioning. This emulation also supports DEC VT-320 escape sequences to control the foreground and background color. The default keymap for a DEC VT-220 terminal will be selected.

nColumns

The maximum number of columns used by the virtual display. This value must be at least 5, and no greater than 255.

nRows

The maximum number of rows used by the virtual display. This value must be at least 5, and no

greater than 127.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero.

Remarks

The default colors for the display is a black background and white foreground. If ANSI terminal emulation is selected, bold characters will be displayed on a white background and blue foreground.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csntv10.lib

See Also

[AttachHandle](#), [DetachHandle](#)

CTerminalEmulator::DeleteChar Method

```
BOOL DeleteChar(  
    INT nChars  
);
```

The **DeleteChar** method deletes the specified number of characters from the display, shifting the characters that follow to the left. The characters are deleted from the current cursor position.

Parameters

nChars

Number of characters to delete from the display.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, it returns zero.

Remarks

This method does not change the current cursor position. To erase characters from the display without affecting the characters that follow, use the **EraseChar** method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csntv10.lib

See Also

[Clear](#), [DeleteLine](#), [EraseChar](#), [EraseLine](#)

CTerminalEmulator::DeleteLine Method

```
BOOL DeleteLine();
```

The **DeleteLine** method deletes the current line, shifting up the lines that follow.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, it returns zero.

Remarks

This method does not change the current cursor position. To erase a line from the display without affecting the lines that follow, use the **EraseLine** method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csntv10.lib

See Also

[Clear](#), [DeleteChar](#), [EraseChar](#), [EraseLine](#)

CTerminalEmulator::DetachHandle Method

```
HDISPLAY DetachHandle();
```

The **DetachHandle** method detaches the display handle associated with the current instance of the class.

Parameters

None.

Return Value

This method returns the display handle associated with the current instance of the class object. If there is no virtual display associated with that instance of the class, the value `INVALID_DISPLAY` will be returned.

Remarks

This method is used to detach a display handle created by the class for use with the SocketTools API. Once the handle is detached from the class, no other class methods may be called. Note that the handle must be explicitly released at some later point by the process or a resource leak will occur.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csnvtv10.lib`

See Also

[AttachHandle](#), [GetHandle](#)

CTerminalEmulator::EraseChar Method

```
BOOL EraseChar(  
    INT nChars  
);
```

The **EraseChar** method erases the specified number of characters from the display, without affecting the position of the characters that follow. The characters are erased from the current cursor position.

Parameters

nChars

Number of characters to erase from the display.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, it returns zero.

Remarks

This method does not change the current cursor position. To delete characters from the display and shift the remaining characters to the left, use the **DeleteChar** method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csntv10.lib

See Also

[Clear](#), [DeleteChar](#), [DeleteLine](#), [EraseLine](#)

CTerminalEmulator::EraseLine Method

```
BOOL EraseLine(  
    UINT nMode  
);
```

The **EraseLine** method erases the current line without affecting the lines that follow.

Parameters

nMode

Mode which specifies how the line will be erased. The following values may be used:

Value	Description
0	The line is erased from the current cursor position to the end of the line.
1	The line is cleared from the beginning of the line to the current cursor position.
2	The entire line is cleared.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, it returns zero.

Remarks

This method does not change the current cursor position. To delete a line from the display and shift the remaining lines up, use the **DeleteLine** method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csntv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

CTerminalEmulator::GetAttributes Method

```
UINT GetAttributes();
```

The **GetAttributes** method returns the current display attributes which have been set, either explicitly by the client or as the result of an escape sequence parsed by the emulator.

Parameters

None.

Return Value

If the method succeeds, the return value the current display attributes. If the method fails, the return value is NVT_ERROR.

The following table lists the valid attributes:

Constant	Description
NVT_ATTRIBUTE_NORMAL	Normal, default attributes.
NVT_ATTRIBUTE_REVERSE	Foreground and background cell colors are reversed.
NVT_ATTRIBUTE_BOLD	The character is displayed using a higher intensity color.
NVT_ATTRIBUTE_DIM	The character is displayed using a lower intensity color.
NVT_ATTRIBUTE_UNDERLINE	The character is displayed with an underline.
NVT_ATTRIBUTE_HIDDEN	The character is stored in display memory, but not shown.
NVT_ATTRIBUTE_PROTECT	The character is protected and cannot be cleared.

One or more attributes may be combined using a bitwise Or operator. Certain attributes, such as NVT_ATTRIBUTE_BOLD and NVT_ATTRIBUTE_DIM are mutually exclusive.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csntv10.lib

See Also

[GetCell](#), [SetAttributes](#)

CTerminalEmulator::GetBackColor Method

```
COLORREF GetBackColor();
```

The **GetColor** method returns the background color used by the current display.

Parameters

None.

Return Value

If the method succeeds, the return value is the RGB value of the background color. If the method fails, it returns zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csntv10.lib

See Also

[GetForeColor](#), [SetBackColor](#), [SetBoldColor](#), [SetColor](#), [SetBackColor](#)

CTerminalEmulator::GetCell Method

```
BOOL GetCell(  
    INT xPos,  
    INT yPos  
    TCHAR* pChar  
    UINT* pAttributes  
);  
  
BOOL GetCell(  
    TCHAR* pChar  
    UINT* pAttributes  
);
```

The **GetCell** method returns information about the specified character cell in the virtual display.

Parameters

xPos

An integer value which specifies the X cursor position in the display. If this argument is omitted or has the value -1, then the current position in the display is used.

yPos

An integer value which specifies the Y cursor position in the display. If this argument is omitted or has the value -1, then the current position in the display is used.

pChar

A pointer to a buffer that will contain the character in the specified cell when the method returns. If this argument is NULL, then no character is returned.

pAttributes

A pointer to an unsigned integer value which specifies the attributes for the specified character cell. If this argument is NULL, then no attribute information is returned.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, it returns zero. Failure typically indicates that the X or Y position is invalid, or that a virtual display has not been created.

Remarks

The attribute value returned by the **GetCell** method may be one or more of the following values:

Constant	Description
NVT_ATTRIBUTE_NORMAL	Normal, default attributes.
NVT_ATTRIBUTE_REVERSE	Foreground and background cell colors are reversed.
NVT_ATTRIBUTE_BOLD	The character is displayed using a higher intensity color.
NVT_ATTRIBUTE_DIM	The character is displayed using a lower intensity color.
NVT_ATTRIBUTE_UNDERLINE	The character is displayed with an underline.
NVT_ATTRIBUTE_HIDDEN	The character is stored in display memory, but not shown.
NVT_ATTRIBUTE_PROTECT	The character is protected and cannot be cleared.

One or more attributes may be combined using a bitwise Or operator. Certain attributes, such as

NVT_ATTRIBUTE_BOLD and NVT_ATTRIBUTE_DIM are mutually exclusive.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csntv10.lib

See Also

[GetAttributes](#), [GetCellSize](#), [SetAttributes](#)

CTerminalEmulator::GetCellSize Method

```
BOOL GetCellSize(  
    LPSIZE lpCellSize  
);  
  
BOOL GetCellSize(  
    LPINT lpnWidth  
    LPINT lpnHeight  
);
```

The **GetCellSize** method returns the size of a character cell in pixels.

Parameters

lpCellSize

A pointer to a `SIZE` structure which will contain the size of a character cell in pixels when the method returns.

lpnWidth

A pointer to an integer which will contain the width of a character cell in pixels when the method returns.

lpnHeight

A pointer to an integer which will contain the height of a character cell in pixels when the method returns.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, it returns zero. Failure typically indicates that the virtual display has not been created.

Remarks

The **GetCellSize** method is used to determine the size of a character cell in the display. This can be useful when the application needs to determine where a display cell is physically located within the virtual display window.

To convert between display and window coordinates, use the **ConvertPos** method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csnvtv10.lib`

See Also

[ConvertPos](#), [GetCell](#)

CTerminalEmulator::GetColor Method

```
COLORREF GetColor(  
    UINT nColorIndex,  
    BOOL bForeground  
);
```

The **GetColor** method returns the color used by the virtual display to display text with a specific attribute.

Parameters

nColorIndex

The index into the virtual display color table. It may be one of the following values.

Value	Description
NVT_COLOR_NORMAL	The colors displayed for normal text. These are the default colors used with the display.
NVT_COLOR_REVERSE	The colors displayed for text with the reverse attribute set. This is only used when emulation is enabled.
NVT_COLOR_BOLD	The colors displayed for text with the bold attribute set. This is only used when emulation is enabled.
NVT_COLOR_REVERSEBOLD	The colors displayed for text with the reverse and bold attributes set. This is only used when emulation is enabled.

bForeground

A boolean flag which specifies if the color is a foreground color, used when displaying text, or a background color.

Return Value

If the method succeeds, the return value is the RGB value of the specified color. If the method fails, it returns zero.

Remarks

The default colors for the display is a black background and white foreground. Bold characters are displayed on a white background and blue foreground.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csntvt10.lib

See Also

[GetBackColor](#), [GetForeColor](#), [SetBackColor](#), [SetBoldColor](#), [SetColor](#), [SetForeColor](#)

CTerminalEmulator::GetColorMap Method

```
BOOL GetColorMap(  
    COLORREF* lpColor,  
    INT nMaxColors  
);
```

The **GetColorMap** method returns the virtual display color table which determines what RGB values are used to display foreground and background text color attributes.

Parameters

lpColor

A pointer to an array of COLORREF values which will contain the color values currently being used in the virtual display.

nMaxColors

The maximum number of colors which may be stored in the color array. The minimum value for this parameter is 1, and the maximum value is 16.

Return Value

If the method succeeds, the return value is a non-zero value. If the method fails, the return value is zero. Failure indicates that the handle to the virtual display is invalid, the pointer to the color table is NULL or the maximum number of color values is invalid.

Remarks

When the emulator processes an escape sequence that changes the current foreground or background color, the actual RGB color value is determined by looking up the value in the virtual display's color table. The **GetColorMap** method is useful for determining what values are being used when a color attribute is set. The emulator currently supports a maximum of sixteen (16) color values, and the index into the table corresponds to the color as defined by the standard for ANSI terminals:

Index	Color	Default (Hex)	Default (Integer)	Default (RGB)
0	Black	0	0	RGB(0,0,0)
1	Red	000000A0h	160	RGB(160,0,0)
2	Green	0000A000h	40960	RGB(0,160,0)
3	Yellow	0000A0A0h	41120	RGB(160,160,0)
4	Blue	00A00000h	10485760	RGB(0,0,160)
5	Magenta	00A000A0h	10485920	RGB(160,0,160)
6	Cyan	00A0A000h	10526720	RGB(0,160,160)
7	White	00E0E0E0h	14737632	RGB(224,224,224)
8	Gray	00C0C0C0h	12632256	RGB(192,192,192)
9	Light Red	008080FFh	8421631	RGB(255,128,128)
10	Light Green	0090EE90h	9498256	RGB(144,238,144)
11	Light Yellow	00C0FFFFh	12648447	RGB(255,255,192)
12	Light Blue	00E6D8ADh	15128749	RGB(173,216,230)

13	Light Magenta	00FFC0FFh	16761087	RGB(255,192,255)
14	Light Cyan	00FFFFE0h	16777184	RGB(224,255,255)
15	High White	00FFFFFFh	16777215	RGB(255,255,255)

A standard ANSI color terminal supports eight standard colors (0-7). To select a foreground color, you add 30 to the color index and pass that value as a parameter to the SGR (select graphic rendition) escape sequence. To select a background color, you add 40 to the color index. For example, to set the current foreground color to white and the background color to blue, you could send the following escape sequence:

```
ESC [ 37;44 m
```

Note that if you wanted to set the foreground color to a bold version of standard yellow, you would first set the bold attribute, and then use the index value of 3, such as:

```
ESC [ 1;33m
```

GetColorMap is typically used in conjunction with the **SetColorMap** method to load the current color values and then make selective changes to the actual RGB color value that is used when a color attribute is set. Note that changes to the color map will only affect new characters as they are displayed, not any previously displayed characters.

Example

The following example will load the current color table for the virtual display and change the standard white color attribute to use the same value as the high-intensity white:

```
COLORREF rgbColor[16];

if (pDisplay->GetColorMap(rgbColor, 16) )
{
    rgbColor[7] = rgbColor[15];
    pDisplay->SetColorMap(rgbColor, 16);
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csntv10.lib

Unicode: Implemented as Unicode and ANSI versions.

CTerminalEmulator::GetCursorPos Method

```
BOOL GetCursorPos(  
    LPINT LpnCursorX,  
    LPINT LpnCursorY  
);
```

The **GetCursorPos** method returns the current cursor column and row position on the virtual display.

Parameters

lpnCursorX

Address of the variable that will be set to the column of the current cursor position. If this argument is a NULL pointer, the argument is ignored.

lpnCursorY

Address of the variable that will be set to the row of the current cursor position. If this argument is a NULL pointer, the argument is ignored.

Return Value

If the method succeeds, the return value is a non-zero value. If the handle to the virtual display is invalid, the method will return zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csntv10.lib

See Also

CTerminalEmulator::GetDC Method

```
HDC GetDC();
```

The **GetDC** returns the device context that has been specified for the virtual display.

Parameters

None.

Return Value

If the method succeeds, the return value is a handle to the device context. If the method fails, or no device context has been specified, the return value is NULL.

Remarks

Normally there is no device context explicitly set for the display. Instead, the device context is dynamically created and released when the virtual display is updated.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csntv10.lib

See Also

[SetDC](#), [Update](#)

CTerminalEmulator::GetDisplayInfo Method

```
BOOL GetDisplayInfo(  
    LPNVTDISPLAYINFO Lpvdi  
);
```

The **GetDisplayInfo** method returns information about the specified virtual display.

Parameters

lpvdi

Pointer to a [NVTDISPLAYINFO](#) structure which contains information about the virtual display, including the display window, font, cursor and scrolling position.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, it returns zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csntv10.lib

See Also

[GetCursorPos](#), [GetFont](#), [GetMode](#), [GetRect](#), [GetScrollPos](#)

CTerminalEmulator::GetEmulation Method

```
UINT GetEmulation();
```

The **GetEmulation** method returns the current virtual terminal emulation type.

Parameters

None.

Return Value

If the method succeeds, the return value is the terminal emulation type and may contain one of the following values:

Value	Description
NVT_EMULATION_NONE	The virtual display does not emulate any specific terminal type, and does not process any escape sequences.
NVT_EMULATION_ANSI	The virtual display will process ANSI escape sequences. The default keymap for an ANSI console is loaded.
NVT_EMULATION_VT100	The virtual display will process DEC VT100 escape sequences. The default keymap for a VT100 terminal is loaded.
NVT_EMULATION_VT220	The virtual display will process DEC VT220 escape sequences. The default keymap for a VT220 terminal is loaded.

If the method fails, because an invalid display handle was specified, the return value will be NVT_ERROR.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csntv10.lib

See Also

[Create](#), [Reset](#), [SetEmulation](#)

CTerminalEmulator::GetFont Method

```
HFONT GetFont();
```

The **GetFont** method returns the current font handle being used by the virtual display.

Parameters

None.

Return Value

If the method succeeds, the return value is a handle to the font. If the method fails, it returns NULL.

Remarks

The handle returned by this method should not be released, and the font object should never be directly modified by the application. Functions that return information about the font, such as **GetTextMetrics**, may be safely called.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csntv10.lib

See Also

[Create](#), [SetFont](#)

CTerminalEmulator::GetForeColor Method

```
COLORREF GetForeColor();
```

The **GetColor** method returns the foreground color used by the current display.

Parameters

None.

Return Value

If the method succeeds, the return value is the RGB value of the foreground color. If the method fails, it returns zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csntv10.lib

See Also

CTerminalEmulator::GetHandle Method

```
HDISPLAY GetHandle();
```

The **GetHandle** method returns the display handle associated with the current instance of the class.

Parameters

None.

Return Value

This method returns the display handle associated with the current instance of the class object. If there is no virtual display associated with that instance of the class, the value `INVALID_DISPLAY` will be returned.

Remarks

This method is used to obtain the client handle created by the class for use with the SocketTools API.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csnvtv10.lib`

See Also

[AttachHandle](#), [DetachHandle](#), [IsInitialized](#)

CTerminalEmulator::GetLine Method

```
INT GetLine(  
    INT nRow,  
    LPTSTR lpszBuffer,  
    INT nMaxLength  
);
```

```
INT GetLine(  
    INT nRow,  
    CString& strBuffer  
);
```

The **GetLine** method copies a block of text from the specified virtual display into a string buffer.

Parameters

nRow

The row in the virtual display to return the line of text from. The first row in the display is zero. If the value -1 is specified, the row where the cursor is currently located will be used.

lpszBuffer

Pointer to the buffer that the display text will be copied to, terminated with a null character character.

cbBuffer

Maximum number of characters that may be copied into the specified buffer, including the null character terminator.

Return Value

If the method succeeds, the return value is the number of characters copied into the buffer, not including the null character terminator. If the method fails, it returns zero.

Remarks

The **GetLine** method allows the application to copy the contents of the display at a specific row. Note that the buffer must be large enough to accommodate the text and the null character terminator. Unlike the **GetText** method, any trailing whitespace in the specified row is not copied to the buffer.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csntv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[GetText](#), [Update](#), [Write](#)

CTerminalEmulator::GetMappedKey Method

```
BOOL GetMappedKey(  
    UINT nMappedKey,  
    LPTSTR lpszKeyBuffer,  
    UINT cchKeyBuffer  
);
```

```
BOOL GetMappedKey(  
    UINT nMappedKey,  
    CString& strKeyBuffer  
);
```

The **GetMappedKey** method returns the escape sequence mapped to the specified key.

Parameters

nMappedKey

The key which is an index into the display key mapping table. This defines the values returned by special (method) keys for the current emulation.

lpszKeyBuffer

Address of the buffer which will receive the escape sequence mapped to the specified key. This argument may also be a **CString** object which will contain the mapped key string when the method returns.

cchKeyBuffer

The maximum number of characters that may be copied into the key buffer string, including the terminating null character.

Return Value

If the method succeeds, the return value is non-zero and the escape sequence for the mapped key is copied into the specified buffer. If the key has not been mapped, and there is no default escape sequence defined, then the method will return zero.

Remarks

The **GetMappedKey** method returns the escape sequence that has been mapped to a special key. This method can be used to determine what sequence of characters should be sent in response to a keypress (for example, what sequence should be sent to a server when the user presses the F1 method key). If a sequence has not been explicitly mapped through a call to **SetMappedKey**, the default sequence for the current emulation will be returned.

Note that the current display mode, such as whether or not the emulator is in application mode or not, should be considered when determining which mapped key to use. For example, if the emulator is not in application mode and the user presses the up-arrow key, the sequence mapped to the NVT_UP key should be sent to the server. However, if the emulator is in application mode, the sequence mapped to the NVT_APPUP key should be sent instead. This is automatically handled by the **TranslateMappedKey** method, so it is recommended that it be used when mapping a virtual keypress to the appropriate escape sequence.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csntv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[GetMode](#), [ResetMappedKeys](#), [SetMode](#), [SetMappedKey](#), [TranslateMappedKey](#)

CTerminalEmulator::GetMode Method

```
UINT GetMode();
```

The **GetMode** method returns the current virtual display modes.

Parameters

None.

Return Value

If the method succeeds, the return value is the display mode for the virtual display. If the method fails, it returns zero.

Remarks

The display mode is a combination of one or more flags which determines how the emulator handles automatic line wrapping, caret display, and other methods. The following values are recognized.

Constant	Description
NVT_MODE_AUTOWRAP	The emulator will automatically wrap to the next line when a character is written to the last column on the virtual display.
NVT_MODE_SHOWCARET	The emulator will display a caret when the display receives the focus.
NVT_MODE_BLOCKCARET	The emulator will display a block carat that is the height of the selected font characters. If this mode is not set, the caret is displayed as an underline.
NVT_MODE_BELL	The emulator will beep when a BEL character is processed.
NVT_MODE_CRLF	The cursor will automatically be positioned at the first column when a linefeed character is processed.
NVT_MODE_CRNL	The cursor will automatically advance to the next row when a carriage return character is processed.
NVT_MODE_APPCURSOR	The emulator cursor keys are placed in application mode. This mode changes the default key mappings used when the cursor (arrow) keys are translated. This corresponds to the application mode supported by DEC VT terminals.
NVT_MODE_APPKEYPAD	The emulator keypad keys are placed in application mode. This mode changes the default key mappings used when the keypad keys are translated. This corresponds to the application keypad mode supported by DEC VT terminals.
NVT_MODE_ORIGIN	The emulator is in origin mode. If enabled, the cursor cannot be positioned outside of the current scrolling region. Otherwise, the cursor can be positioned at any valid location on the virtual display.
NVT_MODE_COLOR	The emulator supports the use of escape sequences to change the foreground and background colors. This option is enabled by default if emulating an ANSI console or DEC VT220 terminal.
NVT_MODE_TABOVER	The emulator will clear the character cells between the current

	cursor position and the next tab stop when the HT (horizontal tab) control sequence is processed. By default this mode is disabled, and the cursor is simply positioned at the next tab stop.
NVT_MODE_HSCROLL	The emulator will display a horizontal scroll bar if the number of visible columns are less than that total number of columns in the virtual display. Disabling this mode prevents a horizontal scrollbar from being displayed, regardless of the number of visible columns. By default, this mode is enabled.
NVT_MODE_VSCROLL	The emulator will display a vertical scroll bar if the number of visible rows are less than that total number of rows in the virtual display. Disabling this mode prevents a vertical scrollbar from being displayed, regardless of the number of visible rows. By default, this mode is enabled.
NVT_MODE_NOREFRESH	The emulator will not automatically refresh the window after any change has been made to the virtual display, including changes in the cursor position or display mode. This allows the caller to make a sequence of changes, and then update the display all at one time to prevent a flicker effect.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnavt10.lib

See Also

[GetEmulation](#), [GetDisplayInfo](#), [SetMode](#)

CTerminalEmulator::GetRect Method

```
BOOL GetRect(  
    LPRECT lprc  
);
```

The **GetRect** returns the client rectangle for the virtual display window.

Parameters

lpRect

Pointer to a RECT structure which will contain the client rectangle values when the method returns.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, it returns zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csntv10.lib

See Also

CTerminalEmulator::GetScrollPos Method

```
INT GetScrollPos(  
    INT nScrollBar  
);
```

The **GetScrollPos** method gets the position of the scroll box for the specified scroll bar.

Parameters

nScrollBar

Specifies the scroll bar to return the position for. This parameter can be one of the following values:

Constant	Description
SB_HORZ	Gets the position of the scroll box in the display's standard horizontal scroll bar.
SB_VERT	Gets the position of the scroll box in the display's standard vertical scroll bar.

Return Value

If the method succeeds, the return value is the position of the scroll box. If the method fails, it returns -1.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csntv10.lib

See Also

[SetScrollPos](#)

CTerminalEmulator::GetScrollRegion Method

```
BOOL GetScrollRegion(  
    LPINT lpnTop,  
    LPINT lpnBottom  
);
```

The **GetScrollRegion** method returns the top and bottom rows of the current scrolling region.

Parameters

lpnTop

Address of the variable that will be set to the top row of the current scrolling region. If no scrolling region has been defined, the value will be 0, the first row in the virtual display. If a NULL pointer is passed as the value, this argument will be ignored.

lpnBottom

Address of the variable that will be set to the bottom row of the current scrolling region. If no scrolling region has been defined, the value will be one less than the maximum number of rows in the virtual display. If a NULL pointer is passed as the value, this argument will be ignored.

Return Value

If the method succeeds, it will return zero. If the handle to the display is invalid, the method will return zero.

Remarks

The **GetScrollRegion** method allows an application to determine the top and bottom rows of the current scrolling region. By default, the scrolling region is the entire virtual display, however this may be changed through a call to **SetScrollRegion** or an ANSI escape sequence. If the display is in origin mode, note that the cursor cannot be positioned outside of the current scrolling region.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csntv10.lib

See Also

CTerminalEmulator::GetSelectedText Method

```
INT GetSelectedText(  
    LPTSTR lpszBuffer,  
    INT nMaxLength  
);
```

```
INT GetSelectedText(  
    CString& strBuffer  
);
```

The **GetSelectedText** method copies the currently selected text into the specified buffer.

Parameters

lpszBuffer

Pointer to the buffer that the selected text will be copied to, terminated with a null character character. This argument may also be a **CString** object which will contain the selected text when the method returns.

nMaxLength

Maximum number of characters that may be copied into the specified buffer, including the null character terminator.

Return Value

If the method succeeds, the return value is the number of characters copied into the buffer, not including the null character terminator. If the method fails, it returns zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csntv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[CopySelectedText](#), [SelectText](#)

CTerminalEmulator::GetSize Method

```
BOOL GetSize(  
    LPSIZE lpSize  
);  
  
BOOL GetSize(  
    LPINT lpnWidth,  
    LPINT lpnHeight  
);
```

The **GetSize** returns the size of the virtual display in columns and rows.

Parameters

lpRect

Pointer to a SIZE structure which will contain the size of the virtual display.

lpnWidth

Pointer to an integer which will contain the number of columns in the virtual display when the method returns. If a NULL pointer is passed as the argument, this value is ignored.

lpnHeight

Pointer to an integer which will contain the number of rows in the virtual display when the method returns. If a NULL pointer is passed as the argument, this value is ignored.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, it returns zero.

Remarks

The **GetSize** method returns the number of columns and rows in the virtual display. To convert this to pixels, use the **GetCellSize** method to determine the size of a character cell and multiply that by the number of columns and/or rows.

Example

```
// Calculate the size of the client area in pixels  
// for the virtual display  
  
INT cxCell = 0, cyCell = 0;  
INT cxDisplay = 0, cyDisplay = 0;  
  
if (pDisplay->GetCellSize(&cxCell, &cyCell))  
{  
    INT nColumns, nRows;  
    if (pDisplay->GetSize(&nColumns, &nRows))  
    {  
        cxDisplay = nColumns * cxCell;  
        cyDisplay = nRows * cyCell;  
    }  
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csntv10.lib

See Also

CTerminalEmulator::GetText Method

```
INT GetText(  
    INT xPos,  
    INT yPos,  
    LPTSTR lpszBuffer,  
    INT nLength  
);  
  
INT GetText(  
    INT xPos,  
    INT yPos,  
    CString& strBuffer,  
    INT nLength  
);  
  
INT GetText(  
    LPTSTR lpszBuffer,  
    INT nLength  
);  
  
INT GetText(  
    CString& strBuffer,  
    INT nLength  
);
```

The **GetText** method copies a block of text from the specified virtual display into a string buffer.

Parameters

xPos

The starting column where the display text will be copied from. If the method is called where this argument is omitted, the text will be copied from the current cursor position.

yPos

The starting row where the display text will be copied from. If the method is called where this argument is omitted, the text will be copied from the current cursor position.

lpszBuffer

Pointer to the buffer that the display text will be copied to, terminated with a null character character. This argument may also be a **CString** object which will contain the text when the method returns.

nLength

Maximum number of characters that may be copied into the specified buffer, including the null character terminator. If a **CString** object is passed to the method, this value may be -1 which specifies that all of the text from the specified position to the last column and row should be copied to the buffer.

Return Value

If the method succeeds, the return value is the number of characters copied into the buffer, not including the null character terminator. If the method fails, it returns zero.

Remarks

The **GetText** method allows the application to copy the contents of the display at a specific location. Note that the buffer must be large enough to accommodate the text and the null

character terminator. To copy an entire row of text in the display, use the **GetLine** method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csntv10.lib

Unicode: Implemented as Unicode and ANSI versions.

CTerminalEmulator::GetTextColor Method

```
BOOL GetTextColor(  
    COLORREF *LprgbColor,  
    BOOL bForeground  
);
```

The **GetTextColor** method returns the current foreground or background text color.

Parameters

lprgbColor

A pointer to a COLORREF variable which will contain the current foreground or background text color.

bForeground

A boolean value which determines if the foreground or background color is returned. A value of TRUE indicates that the foreground color should be returned, otherwise the background color is returned.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. Failure indicates that the handle to the display is invalid, the display does not support text color attributes, or the pointer to the color value is NULL.

Remarks

This method is used to return the current foreground or background color, as determined by the text attribute. The RGB color value for a color attribute is determined by the virtual display's color table.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csntv10.lib

[GetDisplayInfo](#)

CTerminalEmulator::InsertChar Method

```
BOOL InsertChar(  
    INT nChars  
);
```

The **InsertChar** method inserts one or more space characters at the current cursor position.

Parameters

nChars

Number of space characters to insert at the current cursor position.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, it returns zero.

Remarks

This method does not change the cursor position. Inserting space characters may cause the virtual display to scroll.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csntv10.lib

See Also

[DeleteChar](#), [EraseChar](#), [InsertLine](#)

CTerminalEmulator::InsertLine Method

```
BOOL InsertLine();
```

The **InsertLine** method inserts an empty line at the current row, shifting the remaining lines down.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, it returns zero.

Remarks

This method does not change the cursor position. Inserting a line may cause the virtual display to scroll.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csntv10.lib

See Also

[DeleteLine](#), [EraseLine](#), [InsertChar](#)

CTerminalEmulator::IsInitialized Method

```
BOOL IsInitialized();
```

The **IsInitialized** method returns whether or not the class object has been successfully initialized.

Parameters

None.

Return Value

This method returns a non-zero value if the class object has been successfully initialized. A return value of zero indicates that the runtime license key could not be validated or the networking library could not be loaded by the current process.

Remarks

When an instance of the class is created, the class constructor will attempt to initialize the component with the runtime license key that was created when SocketTools was installed. If the constructor is unable to validate the license key or load the networking libraries, this initialization will fail.

If SocketTools was installed with an evaluation license, the application cannot be redistributed to another system. The class object will fail to initialize if the application is executed on another system, or if the evaluation period has expired. To redistribute your application, you must purchase a development license which will include the runtime key that is needed to redistribute your software to other systems. Refer to the Developer's Guide for more information.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

CTerminalEmulator::Refresh Method

```
BOOL Refresh(  
    BOOL bUpdate  
);
```

The **Refresh** method refreshes the specified virtual display, updating the current scroll position and caret.

Parameters

bUpdate

Boolean flags which specifies if the display window is to be updated. If set, the window client area is invalidated and the virtual display is redrawn.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, it returns zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csntv10.lib

CTerminalEmulator::Reset Method

```
BOOL Reset(  
    HWND hWnd,  
    HFONT hFont,  
    UINT nColumns,  
    UINT nRows  
);
```

```
BOOL Reset(  
    UINT nColumns,  
    UINT nRows  
);
```

The **Reset** resets the virtual terminal display, using the new window, font, columns and rows. This method should be used when the virtual display must be attached to a different window, or the number of rows or columns must be changed.

Parameters

hWnd

Handle to the window that will be used to display the virtual terminal. This parameter may be NULL, in which case the current window will be used.

hFont

Handle to the font that will be used with the virtual terminal. This parameter may be NULL, in which case the current font will be used. If a font is specified, it must be fixed-width, otherwise the virtual cursor positioning will be incorrect in some cases.

nColumns

The maximum number of columns used by the virtual display. A value of zero specifies that the same number of columns should be used. If a non-zero value is specified, it must be at least 5, and no greater than 255.

nRows

The maximum number of rows used by the virtual display. A value of zero specifies that the same number of columns should be used. If a non-zero value is specified, it must be at least 5, and no greater than 127.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero.

Remarks

This method will clear the display and reset the current text attributes.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csntv10.lib

CTerminalEmulator::Resize Method

```
BOOL Resize(  
    INT cxClient,  
    INT cyClient  
);
```

The **Resize** method resizes the virtual display to the specified width and height.

Parameters

cxClient

New width of the display window in pixels. If this value is zero, the width of the virtual display remains unchanged.

cyClient

New height of the display window in pixels. If this value is zero, the height of the virtual display remains unchanged.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, it returns zero.

Remarks

This method resizes the virtual display and updates the scrolling information. Typically this method is called when the display window receives a WM_SIZE message, causing the virtual display to match the size of the window's client area.

This method will not change the size of the display window. To change the size of the display window, use the **SetWindowPos** method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csntv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

CTerminalEmulator::RestoreCursor Method

```
BOOL RestoreCursor();
```

The **RestoreCursor** method restores the cursor position and text attributes to their previous values.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, it returns zero.

Remarks

Use the **SaveCursor** method to save the current cursor position and text attributes. This method may only be called once for each time that the cursor position is saved.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csntv10.lib

See Also

CTerminalEmulator::SaveCursor Method

BOOL SaveCursor();

The **SaveCursor** method saves the current cursor position and text attributes.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, it returns zero.

Remarks

Use the **RestoreCursor** method to restore the cursor position and text attributes to their previous values.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csntv10.lib

See Also

[GetCursorPos](#), [RestoreCursor](#), [SetCursorPos](#), [UpdateCaret](#), [Update](#)

CTerminalEmulator::Scroll Method

```
BOOL Scroll(  
    BOOL bScrollUp  
);
```

The **Scroll** method scrolls the virtual display up or down and updates the scroll box position if necessary.

Parameters

bScrollUp

Boolean flag which specifies if the virtual display is scrolled up or down.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, it returns zero.

Remarks

This method does not change the current cursor position. The **Refresh** method should be called to update the window attached to the virtual display.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csntv10.lib

See Also

CTerminalEmulator::SelectText Method

```
BOOL SelectText(  
    LPRECT lprc,  
    DWORD dwOptions  
);
```

The **SelectText** method selects or unselects a region of the virtual display.

Parameters

lprc

A pointer to a region of the display to select. The coordinates must be in display cursor coordinates, not pixels. If this parameter is NULL, any selected text in the display is unselected.

dwOptions

One or more options which specifies how the region will be selected. These options may be combined using a bitwise Or operator. The following values may be used:

Constant	Description
NVT_SELECT_DEFAULT	The default selection option. If there is a region of the display already selected, it will be cleared and the new region is selected.
NVT_SELECT_CLIPBOARD	Copy the selected text to the clipboard. If this option is not specified, the selected text is buffered and may be copied at a later point.
NVT_SELECT_NOREFRESH	The display is not refreshed when the region is selected. This is useful if the application is going to be selecting multiple regions of the display, or combining more than one region, in order to minimize output to the window.
NVT_SELECT_NOBUFFER	Do not buffer the text in the selected region of the display. The display will show any text as being selected, but it will not be available to be copied by the application. This can be useful if the application is going to select multiple regions and combine them.
NVT_SELECT_COMBINE	If there is already a region of the display that has been selected, the new region is combined with the previous region, selecting all of the text.
NVT_SELECT_UNSELECT	Unselect the specified region of the display.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, it returns zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csntv10.lib

See Also

CTerminalEmulator::SetAttributes Method

```
UINT SetAttributes(  
    UINT nAttributes  
);
```

The **SetAttributes** method sets the current display attributes.

Parameters

nAttributes

An unsigned integer value which specifies the new display attributes. This may be one or more of the following values:

Constant	Description
NVT_ATTRIBUTE_NORMAL	Normal, default attributes.
NVT_ATTRIBUTE_REVERSE	Foreground and background cell colors are reversed.
NVT_ATTRIBUTE_BOLD	The character is displayed using a higher intensity color.
NVT_ATTRIBUTE_DIM	The character is displayed using a lower intensity color.
NVT_ATTRIBUTE_UNDERLINE	The character is displayed with an underline.
NVT_ATTRIBUTE_HIDDEN	The character is stored in display memory, but not shown.
NVT_ATTRIBUTE_PROTECT	The character is protected and cannot be cleared.

Return Value

If the method succeeds, the return value is the previous display attributes. If the method fails, the return value is 0xFFFFFFFF.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csntv10.lib

See Also

[GetAttributes](#), [GetCell](#)

CTerminalEmulator::SetBackColor Method

```
BOOL SetBackColor(  
    COLORREF rgbBackground  
);
```

The **SetBackColor** sets the background color used by the virtual display.

Parameters

rgbBackground

The background color specified as a 32-bit RGB value.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, it returns zero.

Remarks

This method sets the background color for normal, reverse, bold and reverse-bold text attributes. To set the background color for a specific attribute, use the **SetColor** method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csntv10.lib

See Also

[GetBackColor](#), [GetColor](#), [GetForeColor](#), [SetBoldColor](#), [SetColor](#), [SetForeColor](#)

CTerminalEmulator::SetBoldColor Method

```
BOOL SetBoldColor(  
    COLORREF rgbBold  
);
```

The **SetBoldColor** sets the color used by the virtual display to display text with the bold attribute enabled.

Parameters

rgbBold

The bold attribute color specified as a 32-bit RGB value.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, it returns zero.

Remarks

This method sets the foreground color for the bold and reverse-bold text attributes. To set the color for a specific attribute, use the **SetColor** method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csntv10.lib

See Also

[GetColor](#), [SetBackColor](#), [SetColor](#), [SetForeColor](#)

CTerminalEmulator::SetCell Method

```
BOOL SetCell(  
    INT xPos,  
    INT yPos,  
    TCHAR nChar  
    UINT nAttributes  
);
```

```
BOOL SetCell(  
    TCHAR nChar  
    UINT nAttributes  
);
```

The **SetCell** method sets the value of the specified cell in the virtual display.

Parameters

xPos

An integer value which specifies the cell column in the virtual display. If this argument is omitted or a value of -1 is specified, the cell at the current cursor position will be used.

yPos

An integer value which specifies the cell row in the virtual display. If this argument is omitted or a value of -1 is specified, the cell at the current cursor position will be used.

nChar

The character that should be displayed at the specified location in the virtual display

nAttributes

An unsigned integer which specifies the attributes for the character in the virtual display. The attributes may be one or more of the following values, combined using a bitwise Or operator:

Constant	Description
NVT_ATTRIBUTE_NORMAL	Normal, default attributes.
NVT_ATTRIBUTE_REVERSE	Foreground and background cell colors are reversed.
NVT_ATTRIBUTE_BOLD	The character is displayed using a higher intensity color.
NVT_ATTRIBUTE_DIM	The character is displayed using a lower intensity color.
NVT_ATTRIBUTE_UNDERLINE	The character is displayed with an underline.
NVT_ATTRIBUTE_HIDDEN	The character is stored in display memory, but not shown.
NVT_ATTRIBUTE_PROTECT	The character is protected and cannot be cleared.

Note that certain attributes, such as NVT_ATTRIBUTE_BOLD and NVT_ATTRIBUTE_DIM are mutually exclusive.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it returns zero. Failure typically indicates that the virtual display has not been created, or that the row and/or column values are outside of the bounds of the display.

Remarks

The **SetCell** method is used to modify a specific character cell in the virtual display, changing both the character and the attributes for that cell. Unlike the higher level methods such as **Write** which process character strings and escape sequences, the **GetCell** and **SetCell** methods allow direct, low-level access to the virtual display in memory. After one or more cells are modified using this function, you should call the **Refresh** method to redraw the virtual display.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csntv10.lib

See Also

[GetAttributes](#), [GetCell](#), [Refresh](#), [SetAttributes](#), [Write](#)

CTerminalEmulator::SetColor Method

```
BOOL SetColor(  
    UINT nColorIndex,  
    COLORREF dwColor,  
    BOOL bForeground  
);
```

The **SetColor** method sets the colors used by the virtual display. Each display has a color table which specifies the foreground and background colors used when displaying text with a specific attribute.

Parameters

nColorIndex

The index into the virtual display color table. It may be one of the following values.

Constant	Description
NVT_COLOR_NORMAL	The colors displayed for normal text. These are the default colors used with the display.
NVT_COLOR_REVERSE	The colors displayed for text with the reverse attribute set. This is only used when emulation is enabled.
NVT_COLOR_BOLD	The colors displayed for text with the bold attribute set. This is only used when emulation is enabled.
NVT_COLOR_REVERSEBOLD	The colors displayed for text with the reverse and bold attributes set. This is only used when emulation is enabled.

dwColor

The RGB color value that will be used.

bForeground

A boolean flag which specifies if the color is a foreground color, used when displaying text, or a background color.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, it returns zero.

Remarks

The default colors for the display is a black background and white foreground. Bold characters are displayed on a white background and blue foreground.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csntv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[GetColor](#), [SetBackColor](#), [SetBoldColor](#), [SetForeColor](#)

CTerminalEmulator::SetColorMap Method

```
BOOL SetColorMap(  
    COLORREF *lpColor,  
    INT nColors  
);
```

The **SetColorMap** method modifies the virtual display color table which determines what RGB values are used to display foreground and background text color attributes.

Parameters

lpColor

A pointer to an array of COLORREF values which specifies the values to be used by the emulator when setting a color attribute. If this value is NULL, the default color table will be loaded.

nColors

The number of colors which are stored in the array. The minimum value for this parameter is 1, and the maximum value is 16.

Return Value

If the method succeeds, the return value is a non-zero value. If the method fails, the return value is zero. Failure indicates that the handle to the virtual display is invalid or the number of color values is invalid.

Remarks

When the emulator processes an escape sequence that changes the current foreground or background color, the actual RGB color value is determined by looking up the value in the virtual display's color table. The **SetColorMap** method is useful for changing what values are being used when a color attribute is set. The emulator currently supports a maximum of sixteen (16) color values, and the index into the table corresponds to the color as defined by the standard for ANSI terminals:

Index	Color	Default (Hex)	Default (Integer)	Default (RGB)
0	Black	0	0	RGB(0,0,0)
1	Red	000000A0h	160	RGB(160,0,0)
2	Green	0000A000h	40960	RGB(0,160,0)
3	Yellow	0000A0A0h	41120	RGB(160,160,0)
4	Blue	00A00000h	10485760	RGB(0,0,160)
5	Magenta	00A000A0h	10485920	RGB(160,0,160)
6	Cyan	00A0A000h	10526720	RGB(0,160,160)
7	White	00E0E0E0h	14737632	RGB(224,224,224)
8	Gray	00C0C0C0h	12632256	RGB(192,192,192)
9	Light Red	008080FFh	8421631	RGB(255,128,128)
10	Light Green	0090EE90h	9498256	RGB(144,238,144)
11	Light Yellow	00C0FFFFh	12648447	RGB(255,255,192)

12	Light Blue	00E6D8ADh	15128749	RGB(173,216,230)
13	Light Magenta	00FFC0FFh	16761087	RGB(255,192,255)
14	Light Cyan	00FFFFE0h	16777184	RGB(224,255,255)
15	High White	00FFFFFFh	16777215	RGB(255,255,255)

A standard ANSI color terminal supports eight standard colors (0-7). To select a foreground color, you add 30 to the color index and pass that value as a parameter to the SGR (select graphic rendition) escape sequence. To select a background color, you add 40 to the color index. For example, to set the current foreground color to white and the background color to blue, you could send the following escape sequence:

```
ESC [ 37;44 m
```

Note that if you wanted to set the foreground color to a bold version of standard yellow, you would first set the bold attribute, and then use the index value of 3, such as:

```
ESC [ 1;33m
```

The **SetColorMap** method is used to modify the actual color displayed by the emulator. For example, if the emulator processes an escape sequence which sets the current foreground color to white, the actual color displayed could be changed to light green. Passing a NULL pointer as the second parameter restores the original color map back to the default values. Note that changes to the color map will only affect new characters as they are displayed, not any previously displayed characters.

Example

The following example will load the current color table for the virtual display and change the standard white color attribute to use the same value as the high-intensity white:

```
COLORREF rgbColor[16];

if (pDisplay->GetColorMap(rgbColor, 16) )
{
    rgbColor[7] = rgbColor[15];
    pDisplay->SetColorMap(rgbColor, 16);
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csntv10.lib

CTerminalEmulator::SetCursorPos Method

```
BOOL SetCursorPos(  
    INT nCursorX,  
    INT nCursorY  
);
```

The **SetCursorPos** method sets the current cursor column and row position on the virtual display.

Parameters

nCursorX

New cursor column position. If this value is greater than the maximum number of columns, the current position is set to the last column on the display. The first column on the display is zero.

nCursorY

New cursor row position. If this value is greater than the maximum number of rows, the current position is set to the last row on the display. The first row on the display is zero.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, it will return a value of zero. Typically this would indicate that the virtual display has not been created.

Remarks

The **SetCursorPos** method sets the current cursor position on the virtual display. If the display is in origin mode (a scrolling region has been set), then the cursor row position is bound by the current region.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csntv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[GetCursorPos](#)

CTerminalEmulator::SetDC Method

```
BOOL SetDC(  
    HDC hDC  
);
```

The **SetDC** method sets the device context to be used by the virtual display when updating the window.

Parameters

hDC

Handle to the device context. This parameter may be NULL, any device context that is currently associated with the virtual display will be removed. Note that the application still has the responsibility for deleting the device context, otherwise a handle leak will occur.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, it returns zero.

Remarks

It is not required that the device context be explicitly set by the application. By default, the class will use a device context created using the window attached to the virtual display. If a device context is specified by the application, it must be released when it is no longer needed.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csntv10.lib

See Also

[GetDC](#), [Update](#)

CTerminalEmulator::SetEmulation Method

```
BOOL SetEmulation(  
    UINT nEmulation  
);
```

The **SetEmulation** method specifies the type of terminal emulation to be performed by the virtual display.

Parameters

nEmulation

Identifies the virtual terminal emulation type. The following emulation types are currently supported.

Value	Description
NVT_EMULATION_NONE	The virtual display does not emulate any specific terminal type, and does not process any escape sequences.
NVT_EMULATION_ANSI	The virtual display will process ANSI escape sequences. The default keymap for an ANSI console is loaded.
NVT_EMULATION_VT100	The virtual display will process DEC VT100 escape sequences. The default keymap for a VT100 terminal is loaded.
NVT_EMULATION_VT220	The virtual display will process DEC VT220 escape sequences. The default keymap for a VT220 terminal is loaded.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, it returns zero.

Remarks

Changing the emulation type will not affect the current display.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csntv10.lib

See Also

[GetEmulation](#), [GetMode](#), [Reset](#), [SetMode](#)

CTerminalEmulator::SetFocus Method

```
BOOL SetFocus(  
    BOOL bFocus  
);
```

The **SetFocus** method sets or removes the focus from the virtual display. This method should be called when the display window receives or loses focus.

Parameters

bFocus

A boolean flag which specifies that the display should receive or lose focus.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, it returns zero.

Remarks

When the virtual display receives focus, it updates the current cursor position and displays the caret. When the display loses focus, the caret is hidden. This method should be called in response to the display window receiving the WM_SETFOCUS and WM_KILLFOCUS messages.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csntv10.lib

See Also

CTerminalEmulator::SetFont Method

```
BOOL SetFont(  
    HFONT hFont  
);  
  
BOOL SetFont(  
    LPTSTR lpszFontName,  
    INT nFontSize  
);
```

The **SetFont** sets the font that will be used when updating the display. The specified font must be fixed-width, otherwise the virtual cursor positioning will be incorrect in some cases.

Parameters

hFont

Handle to the font that will be used with the virtual terminal. This parameter may be NULL, in which case a default fixed-width font will be used.

lpszFontName

A pointer to a string which specifies the name of the font that will be loaded. If a NULL pointer or an empty string is passed as the value, the default **Terminal** font will be used.

nFontSize

The point size of the font that will be loaded. If this value is zero, a default point size will be used.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, it returns zero.

Remarks

If the previous font was a default font created by the library as the result of a NULL font handle being passed to a method, it will be released. However, if the previous font was created by the application, the **DeleteObject** method must be called to release it.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csntv10.lib

See Also

[GetFont](#)

CTerminalEmulator::SetForeColor Method

```
BOOL SetForeColor(  
    COLORREF rgbForeground  
);
```

The **SetForeColor** sets the foreground color used by the virtual display.

Parameters

rgbForeground

The foreground color specified as a 32-bit RGB value.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, it returns zero.

Remarks

This method sets the foreground color for the normal and reverse text attributes. To set the foreground color for a specific attribute, use the **SetColor** method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csntv10.lib

CTerminalEmulator::SetMappedKey Method

```
BOOL SetMappedKey(  
    UINT nMappedKey,  
    LPCTSTR lpszKeyBuffer  
);
```

The **SetMappedKey** method maps an escape sequence to the specified key.

Parameters

nMappedKey

The key which is an index into the display key mapping table. This defines the values returned by special (method) keys for the current emulation.

lpszKeyBuffer

Pointer to a string which defines the sequence of characters that are to be mapped to the specified key. Passing an empty string or NULL pointer will delete the current sequence mapped to the key and restore the default value, if one has been defined.

Return Value

If the method succeeds, the return value is non-zero and the escape sequence is mapped to the specified key. If the key value is invalid or could not be mapped, then the method will return zero.

Remarks

The **SetMappedKey** method maps an escape sequence to a special key. This method can be used to specify what sequence of characters should be sent in response to a keypress (for example, what sequence should be sent to a server when the user presses the F1 method key). There are a number of default sequences that are mapped to the method and cursor keys, based on the current emulation. Calling this method will override the default sequence for a key, if one has been defined.

The following special keys are defined:

Value	Constant	Description	Value	Constant	Description
0	NVT_F1	F1 method key	26	NVT_UP	Cursor up key
1	NVT_F2	F2 method key	27	NVT_DOWN	Cursor down key
2	NVT_F3	F3 method key	28	NVT_LEFT	Cursor left key
3	NVT_F4	F4 method key	29	NVT_RIGHT	Cursor right key
4	NVT_F5	F5 method key	30	NVT_INSERT	Insert key
5	NVT_F6	F6 method key	31	NVT_DELETE	Delete key
6	NVT_F7	F7 method key	32	NVT_HOME	Home key
7	NVT_F8	F8 method key	33	NVT_END	End key
8	NVT_F9	F9 method key	34	NVT_PGUP	Page up key
9	NVT_F10	F10 method key	35	NVT_PGDN	Page down key
10	NVT_F11	F11 method key	36	NVT_APPUP	Up arrow key
11	NVT_F12	F12 method key	37	NVT_APPDOWN	Down arrow key
12	NVT_SF1	Shift F1 method key	38	NVT_APPLEFT	Left arrow key
13	NVT_SF2	Shift F2 method key	39	NVT_APPRIGHT	Right arrow key
14	NVT_SF3	Shift F3 method key	40	NVT_APPENTER	Keypad enter key
15	NVT_SF4	Shift F4 method key	41	NVT_KEYPAD0	Numeric keypad 0
16	NVT_SF5	Shift F5 method key	42	NVT_KEYPAD1	Numeric keypad 1

17	NVT_SF6	Shift F6 method key	43	NVT_KEYPAD2	Numeric keypad 2
18	NVT_SF7	Shift F7 method key	44	NVT_KEYPAD3	Numeric keypad 3
19	NVT_SF8	Shift F8 method key	45	NVT_KEYPAD4	Numeric keypad 4
20	NVT_SF9	Shift F9 method key	46	NVT_KEYPAD5	Numeric keypad 5
21	NVT_SF10	Shift F10 method key	47	NVT_KEYPAD6	Numeric keypad 6
22	NVT_SF11	Shift F11 method key	48	NVT_KEYPAD7	Numeric keypad 7
23	NVT_SF12	Shift F12 method key	49	NVT_KEYPAD8	Numeric keypad 8
24	NVT_ENTER	Enter key	50	NVT_KEYPAD9	Numeric keypad 9
25	NVT_ERASE	Backspace key			

Requirements

CTerminalEmulator::SetMode Method

```
BOOL SetMode(  
    UINT nMode,  
    BOOL bEnable  
);
```

The **SetMode** method sets one or more display modes for the specified virtual display.

Parameters

nMode

The virtual display mode bitmask. This value is a combination of one or more flags which determines how the emulator handles automatic line wrapping, caret display, and other methods. The following values may be specified.

NVT_MODE_AUTOWRAP	The emulator will automatically wrap to the next line when a character is written to the last column on the virtual display.
NVT_MODE_SHOWCARET	The emulator will display a caret when the display receives the focus.
NVT_MODE_BLOCKCARET	The emulator will display a block carat that is the height of the selected font characters. If this mode is not set, the caret is displayed as an underline.
NVT_MODE_BELL	The emulator will beep when a BEL character is processed.
NVT_MODE_CRLF	The cursor will automatically be positioned at the first column when a linefeed character is processed.
NVT_MODE_CRNL	The cursor will automatically advance to the next row when a carriage return character is processed.
NVT_MODE_APPCURSOR	The emulator cursor keys are placed in application mode. This mode changes the default key mappings used when the cursor (arrow) keys are translated. This corresponds to the application mode supported by DEC VT terminals.
NVT_MODE_APPKEYPAD	The emulator keypad keys are placed in application mode. This mode changes the default key mappings used when the keypad keys are translated. This corresponds to the application keypad mode supported by DEC VT terminals.
NVT_MODE_ORIGIN	The emulator is in origin mode. If enabled, the cursor cannot be positioned outside of the current scrolling region. Otherwise, the cursor can be positioned at any valid location on the virtual display.
NVT_MODE_COLOR	The emulator supports the use of escape sequences to change the foreground and background colors. This option is enabled by default if emulating an ANSI console or DEC VT220 terminal.
NVT_MODE_TABOVER	The emulator will clear the character cells between the current cursor position and the next tab stop when the HT

	(horizontal tab) control sequence is processed. By default this mode is disabled, and the cursor is simply positioned at the next tab stop.
NVT_MODE_HSCROLL	The emulator will display a horizontal scroll bar if the number of visible columns are less than the total number of columns in the virtual display. Disabling this mode prevents a horizontal scroll bar from being displayed, regardless of the number of visible columns. By default, this mode is enabled.
NVT_MODE_VSCROLL	The emulator will display a vertical scroll bar if the number of visible rows are less than the total number of rows in the virtual display. Disabling this mode prevents a vertical scroll bar from being displayed, regardless of the number of visible rows. By default, this mode is enabled.
NVT_MODE_NOREFRESH	The emulator will not automatically refresh the window after any change has been made to the virtual display, including changes in the cursor position or display mode. This allows the caller to make a sequence of changes, and then update the display all at one time to prevent a flicker effect.

bEnable

This boolean flag specifies if the specified mode is to be enabled or disabled.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, it returns zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csnavt10.lib

See Also

CTerminalEmulator::SetScrollPos Method

```
BOOL SetScrollPos(  
    INT nScrollBar,  
    INT nScrollPos  
);
```

The **SetScrollPos** method sets the position of the scroll box for the specified scroll bar and redraws the scroll bar to reflect the new position of the scroll box.

Parameters

nScrollBar

Specifies the scroll bar to be set. This parameter can be one of the following values:

Value	Description
SB_HORZ	Sets the position of the scroll box in the display's standard horizontal scroll bar.
SB_VERT	Sets the position of the scroll box in the display's standard vertical scroll bar.

nScrollPos

Specifies the new row or column of the scroll box. The position must be within the scrolling range.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, it returns zero.

Remarks

This method should always be used to change the scroll box position. The **SetScrollPos** method will result in unpredictable behavior if used on the virtual display window.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csntv10.lib

See Also

[GetScrollPos](#), [Scroll](#), [Update](#)

CTerminalEmulator::SetScrollRegion Method

```
BOOL SetScrollRegion(  
    INT nTop,  
    INT nBottom  
);
```

The **SetScrollRegion** method sets the top and bottom rows of the current scrolling region.

Parameters

nTop

The top row of the current scrolling region. If this value is greater than the bottom scrolling region row or the total number of rows in the display, it will be silently adjusted.

nBottom

The bottom row of the current scrolling region. If this value is less than zero or the top scrolling region row, it will be silently adjusted.

Return Value

If the method succeeds, it will return zero. If the handle to the display is invalid, the method will return zero.

Remarks

The **SetScrollRegion** method allows an application to set the current scrolling region for the virtual display. This specifies the region (between the top and bottom rows) in which text will normally scroll. If the display is in origin mode, the cursor cannot be positioned outside of the scrolling region.

The minimum scrolling region that may be defined is two rows. If a scrolling region is specified that is less than two rows, the method will fail and the current scrolling region will remain unchanged. Specifying values of -1 for both arguments will reset the scrolling region to the default values (the full display).

The DEC STBM escape sequence is used to set or clear the scrolling region of the virtual display.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csntv10.lib

See Also

[GetMode](#), [SetMode](#), [SetScrollRegion](#)

CTerminalEmulator::SetSize Method

```
BOOL SetSize(  
    LPSIZE lpSize  
);  
  
BOOL SetSize(  
    INT nColumns,  
    INT nRows  
);
```

The **SetSize** sets the size of the virtual display.

Parameters

lpRect

Pointer to a SIZE structure which specifies the new size of the virtual display. The width should be specified in columns and the height should be specified in rows.

nColumns

The number of columns in the virtual display.

nRows

The number of rows in the virtual display.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, it returns zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csntv10.lib

CTerminalEmulator::SetTextColors Method

```
BOOL SetTextColors(  
    COLORREF rgbColor,  
    BOOL bForeground  
);
```

The **SetTextColors** method changes the current foreground or background text color.

Parameters

rgbColor

A color value which specifies the current foreground or background text color. The RGB macro can be used to specify the red, green and blue values for the color.

bForeground

A boolean value which determines if the foreground or background color is changed. A value of TRUE indicates that the foreground color should be changed, otherwise the background color is changed.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. Failure indicates that the handle to the display is invalid or that the current display does not support color text attributes.

Remarks

This method is used to change the current foreground or background color, as determined by the text attribute. Note that changing the current foreground or background text color does not affect the virtual display color table. To change how color attributes are mapped to an RGB color value, use the **SetColorMap** method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csntv10.lib

See Also

[GetColorMap](#), [GetTextColor](#), [SetColorMap](#)

CTerminalEmulator::SetWindow Method

```
BOOL SetWindow(  
    HWND hWnd  
);
```

The **SetWindow** method sets the window used by the virtual display.

Parameters

hWnd

Handle to the window that will be used by the virtual display. This parameter cannot be NULL.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, it returns zero.

Remarks

This method will clear the display and reset the current text attributes.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csntv10.lib

See Also

CTerminalEmulator::TranslateMappedKey Method

```
BOOL TranslateMappedKey(  
    UINT nKey,  
    UINT nFlags,  
    UINT * lpnMappedKey,  
    LPTSTR lpszKeyBuffer,  
    UINT cchBuffer  
);
```

```
BOOL TranslateMappedKey(  
    UINT nKey,  
    UINT nFlags,  
    UINT * lpnMappedKey,  
    CString& strKeyBuffer  
);
```

The **TranslateMappedKey** method translates a virtual key press to an escape sequence based on the current terminal emulation that has been selected.

Parameters

nKey

The virtual key code for the specified key.

nFlags

The scan code, key-transition code, previous key state, and context code for the specified key.

lpnMappedKey

A pointer to an unsigned integer which will contain the index into the keymap table when the method returns. This is the same value used with the **GetMappedKey** and **SetMappedKey** method. If the index into the keymap is not required, this parameter can be NULL.

lpszKeyBuffer

Address of the buffer to receive the escape sequence mapped to the specified key. If the mapped key string is not required, this parameter can be NULL.

cchBuffer

The maximum number of characters that can be copied into the key buffer, including the terminating null character. If the *lpszKeyBuffer* parameter is NULL, this value must be zero.

Return Value

If the virtual key can be mapped to an escape sequence, the method will return a non-zero value. If the key is not mapped, or one of the arguments is invalid, the method will return zero.

Remarks

The **TranslateMappedKey** method allows an application to map a virtual key code to an escape sequence that is appropriate for the type of terminal that is being emulated. For example, it will return the escape sequence for the F1 method key when passed the VK_F1 key value. This method should be called when the WM_KEYDOWN message is processed by an application so that it may send the correct sequence to the server.

This method should only be called in response to a keyboard message such as WM_KEYDOWN. To determine if a specific key has been mapped to an escape sequence, use the **GetMappedKey** method.

Example

```
case WM_KEYDOWN:
/*
 * If the Num Lock key is pressed, then set the terminal into application
 * keypad mode. This will change how the TranslateMappedKey method will
 * translate the keypad keys.
 *
 * Note that the terminal may also be placed into application keypad mode
 * if emulating a DEC VT terminal and the DECNKM escape sequence is sent
 * by the host.
 */
if (wParam == VK_NUMLOCK)
    pDisplay->SetMode(NVT_MODE_APPKEYPAD, !(GetKeyState(VK_NUMLOCK) & 1));
else
{
    BOOL bMapped;
    UINT nMappedKey;
    TCHAR szKey[128];

    bMapped = pDisplay->TranslateMappedKey(wParam, HIWORD(lParam),
                                           &nMappedKey, szKey, 128);

    if (bMapped)
        pTelnet->Write(szKey);
}
break;
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csntv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

CTerminalEmulator::Update Method

BOOL Update();

The **Update** method updates the window attached to the virtual display.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, it returns zero.

Remarks

This method should be called when the display window receives a WM_PAINT message. If the **SetDC** method has not been called to explicitly set the display device context, this method will acquire one for the display window. In this case, the application should not create device context for the window or call the **BeginPaint** and **EndPaint** methods.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csntv10.lib

[Refresh](#), [Resize](#), [SetDC](#), [SetScrollPos](#), [SetWindow](#)

CTerminalEmulator::UpdateCaret Method

BOOL UpdateCaret();

The **UpdateCaret** method updates the position of the caret in the display window to the current cursor position.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, it returns zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csntv10.lib

CTerminalEmulator::Write Method

```
BOOL Write(  
    LPBYTE lpBuffer,  
    INT cbBuffer  
);  
  
BOOL Write(  
    LPCTSTR lpszBuffer,  
    INT cbBuffer  
);  
  
BOOL Write(  
    TCHAR nChar,  
    INT nCount  
);
```

The **Write** method writes the contents of the specified buffer to the virtual display.

Parameters

lpBuffer

Pointer to the buffer which contains the data to be written to the virtual display. This may also specify a string which contains the characters to be written to the display.

cbBuffer

Number of bytes to write to the display. If the buffer is a string, this value may be -1, in which case all characters up to the terminating null character will be written to the display.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, it returns zero.

Remarks

This method writes the data at the current cursor location. Control characters are recognized by this method and processed accordingly. If ANSI emulation is enabled, embedded escape sequences will also be parsed and processed.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csntv10.lib

Terminal Emulation Data Structures

- NVTDISPLAYINFO

NVTDISPLAYINFO Structure

This structure is used by the [GetDisplayInfo](#) method to return information about the specified virtual terminal display. No member of this structure should be modified directly by the application.

```
typedef struct _NVTDISPLAYINFO {
    HWND    hWnd;
    HFONT   hFont;
    INT     xPos;
    INT     yPos;
    INT     cxClient;
    INT     cyClient;
    INT     cxChar;
    INT     cyChar;
    INT     nScrollCol;
    INT     nScrollRow;
    INT     nMaxScrollCol;
    INT     nMaxScrollRow;
} NVTDISPLAYINFO, *LPNVTDISPLAYINFO;
```

Members

hWnd

The handle to the terminal emulation display window.

hFont

The handle to the current font.

xPos

The current display x coordinate.

yPos

The current display y coordinate.

cxClient

The width of the client window in pixels.

cyClient

The height of the client window in pixels.

cxChar

The width of the current font in pixels.

cyChar

The height of the current font in pixels.

nScrollCol

The current horizontal scrolling column.

nScrollRow

The current vertical scrolling row.

nMaxScrollCol

The maximum horizontal scrolling column.

nMaxScrollRow

The maximum vertical scrolling row.

	14		Yellow
	15		High White

Control Character Sequences

<CTL>G	Ring audible bell, if enabled
<CTL>H	Move cursor one character backwards
<CTL>I	Move cursor forward to next tabstop
<CTL>J	Move cursor down to next line
<CTL>M	Move cursor to beginning of line
<CTL>N	Select G1 character set
<CTL>O	Select G0 character set
<CTL>Z	Abort current escape sequence
	Erase and move cursor one character backwards

Text Message Class Library

Send text messages to a mobile communications device using a gateway service.

Reference

- [Class Methods](#)
- [Data Structures](#)
- [Error Codes](#)

Library Information

Class Name	CTextMessage
File Name	CSTXTV10.DLL
Version	10.0.1468.2518
LibID	1F65A283-7BC8-4F5B-B739-D211EAF1CA35
Import Library	CSTXTV10.LIB
Dependencies	None

Overview

Short Message Service (SMS) is a text messaging service used by mobile communication devices to exchange brief text messages. Most service providers also provide gateway servers that can be used to send messages to a wireless device on their network using standard email protocols. The **CTextMessage** class provides methods that can be used to determine the provider associated with a specific telephone number and send a text message to the device using the provider's mail gateway.

This library has been designed to assist developers in sending text message notifications as part of their application. For example, it can be used to enable your software to automatically send notifications when a specific event occurs, such as an error condition. This library is not designed to be used with software that will send out a large number of text messages to many users, and there are limitations on the number of messages that may be sent to different phone numbers over a short period of time. Because many recipients must pay a fee for each text message they receive, text messages should only be sent to those who explicitly request them.

Note: This class library only supports service providers in North America and cannot be used to send text messages to mobile devices that use providers outside of the United States and Canada.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). If you are using Visual C++ 6.0 it is required that you have Service Pack 6 (SP6) installed. You should install all updates for your development tools and have the current Windows SDK installed. The minimum recommended version of Visual Studio is Visual Studio 2010.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are using Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. It is recommended that you install the current service pack and all critical updates available for your version of the operating system.

This product includes both 32-bit and 64-bit libraries. Native 64-bit CPU support requires the 64-bit version of Windows 7 or later versions of the Windows operating system.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

Text Message Class Methods

Class	Description
CTextMessage	Constructor which initializes the current instance of the class
~CTextMessage	Destructor which releases resources allocated by the class
Method	Description
DisableRelay	Disable the relaying of messages through another mail server
DisableTrace	Disable logging of network function calls
EnableRelay	Enable the relaying of messages through another mail server
EnableTrace	Enable logging of network function calls to a text file
EnumProviders	Enumerate the available wireless service providers
GetAddress	Return the email address associated with the specified phone number.
GetErrorString	Return a description for the specified error code
GetFirstProvider	Return information about the first supported wireless service provider
GetGateway	Return information about the gateway server for the specified phone number
GetLastError	Return the last error code
GetNextProvider	Return information about the next supported wireless service provider
GetProvider	Return information about the wireless service provider for the specified phone number
GetTimeout	Return the amount of time until an operation times out
IsInitialized	Determine if the class has been successfully initialized
IsRelaying	Determine if relaying through another mail server has been enabled
SendMessage	Send a text message to the specified mobile device
SetLastError	Set the last error code
SetTimeout	Set the amount of time to wait before an operation times out
ShowError	Display a message box with a description of the specified error

CTextMessage::CTextMessage Method

`CTextMessage();`

The **CTextMessage** constructor initializes the class library and validates the license key at runtime.

Remarks

If the constructor fails to validate the runtime license, subsequent methods in this class will fail. If the product is installed with an evaluation license, then the application will only function on the development system and cannot be redistributed.

The constructor calls the **SmsInitialize** function to initialize the library, which dynamically loads other system libraries and allocates thread local storage. If you are using this class within another DLL, it is important that you do not create or destroy an instance of the class from within the **DllMain** function because it can result in deadlocks or access violation errors. You should not declare static or global instances of this class within another DLL if it is linked with the C runtime library (CRT) because it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `cstxtv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

See Also

[~CTextMessage](#), [IsInitialized](#)

CNetMessage::~~CNetMessage

`~CNetMessage();`

The **CNetMessage** destructor releases resources allocated by the current instance of the **CNetMessage** object. It also uninitialized the library if there are no other concurrent uses of the class.

Remarks

When a **CNetMessage** object goes out of scope, the destructor is automatically called to allow the library to free any resources allocated on behalf of the process. Any pending blocking or asynchronous calls in this process are canceled without posting any notification messages, and all handles that were created for the client session are destroyed.

The destructor is not called explicitly by the application.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `cstxtv10.lib`

See Also

[CNetMessage](#)

CTextMessage::DisableRelay Method

```
VOID DisableRelay();
```

The **DisableRelay** method disables the relaying of text messages through another mail server.

Parameters

None.

Return Value

None.

Remarks

The **DisableRelay** method sets an internal flag that specifies that messages should not be relayed through another mail server. When using the default SMTP service, this means that the library will attempt to send the message directly to the gateway used by the wireless service provider. Relaying is only enabled when the **EnableRelay** method is called.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstxtv10.lib

CNetMessage::DisableTrace Method

```
BOOL DisableTrace();
```

The **DisableTrace** method disables the logging of socket function calls to the trace log.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, a value of zero is returned.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstxtv10.lib

See Also

[EnableTrace](#)

CTextMessage::EnableRelay Method

```
BOOL EnableRelay(  
    LPCTSTR lpszHostName,  
    UINT nHostPort,  
    LPCTSTR lpszUserName,  
    LPCTSTR lpszPassword,  
    DWORD dwOptions,  
);  
  
BOOL EnableRelay(  
    LPCTSTR lpszHostName,  
    UINT nHostPort,  
);  
  
BOOL EnableRelay();
```

The **EnableRelay** method enables the relaying of messages through another mail server.

Parameters

lpszHostName

A pointer to a string that specifies the hostname or IP address of the mail server that the messages will be relayed through. If this parameter is NULL or an empty string, then message relaying will be disabled.

nHostPort

An integer value that specifies the port number that should be used to establish the connection with the mail server. If this value is zero, then the default SMTP port will be used.

lpszUserName

A pointer to a string that specifies the user name that will be used to authenticate the session with the mail server. If the server does not require authentication, this parameter can be NULL or an empty string.

lpszPassword

A pointer to a string that specifies the password that will be used to authenticate the session with the mail server. If the server does not require authentication, this parameter can be NULL or an empty string.

dwOptions

An integer value which specifies one or more options.

Constant	Description
SMS_OPTION_NONE	No additional options specified. This is the default value.
SMS_OPTION_SECURE	This option specifies that SSL/TLS will be used to establish a secure, encrypted connection with the mail server. For some servers, it may be required to connect to them securely and this option will be enabled automatically.

Return Value

If the method succeeds and relaying is enabled, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

When a text message is sent using the SMTP service, the default action is to attempt to connect directly to the wireless service provider's gateway server. However, many residential Internet service providers (ISPs) do not permit their customers to connect to third-party mail servers and will block the outbound connection. Some wireless service providers may also reject messages that originate from residential IP addresses.

To resolve this issue, the developer should allow the user to specify an alternate mail server that will relay the message to the wireless service provider. For residential users, this will typically be the mail server provided by their ISP. For business users, this will usually be their corporate mail server. The **EnableRelay** method is used to specify the connection information for the mail server and the **SendMessage** method will relay messages through that server.

Calling the **EnableRelay** method without any arguments will enable relaying through the mail server specified by a previous call to the method. The **EnableRelay** method must be called at least once with arguments to enable relaying. To temporarily disable relaying, call the **DisableRelay** method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstxtv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

CNetMessage::EnableTrace Method

```
BOOL EnableTrace(  
    LPCTSTR lpszTraceFile,  
    DWORD dwTraceFlags  
);
```

The **EnableTrace** method enables the logging of socket function calls to a file.

Parameters

lpszTraceFile

A pointer to a string which specifies the name of the trace log file. If this parameter is NULL or an empty string, the default file name **cstrace.log** is used. The file is stored in the directory specified by the TEMP environment variable, if it is defined; otherwise, the current working directory is used.

dwTraceFlags

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
TRACE_INFO	All function calls are written to the trace file. This is the default value.
TRACE_ERROR	Only those function calls which fail are recorded in the trace file.
TRACE_WARNING	Only those function calls which fail or return values which indicate a warning are recorded in the trace file.
TRACE_HEXDUMP	All functions calls are written to the trace file, plus all the data that is sent or received is displayed, in both ASCII and hexadecimal format.
TRACE_PROCESS	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for multithreaded applications that are using worker threads.

Return Value

If the method succeeds, the return value is non-zero. A return value of zero indicates an error. Failure typically indicates that the tracing library **cstrcv10.dll** cannot be loaded on the local system.

Remarks

When trace logging is enabled, the file is opened, appended to and closed for each socket function call. This makes it possible for an application to append its own logging information, however care should be taken to ensure that the file is closed before the next network operation is performed. To limit the size of the log files, enable and disable logging only around those sections of code that you wish to trace.

Note that the TRACE_HEXDUMP trace level generates very large log files since it includes all of the data exchanged between your application and the server.

Trace method logging is managed on a per-thread basis, not for each client handle. This means that all SocketTools libraries and components share the same settings in the current thread. If you

are using multiple SocketTools libraries or components in your application, you only need to enable logging once.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstxtv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[DisableTrace](#)

CTextMessage::EnumProviders Method

```
INT EnumProviders(  
    LPSMSPROVIDER lpProviders,  
    INT nMaxProviders,  
);
```

The **EnumProviders** method enumerates the supported wireless service providers and populates an array of **SMSPROVIDER** structures.

Parameters

lpProviders

A pointer to an array of **SMSPROVIDER** structures that will be populated with information about each service provider. If this parameter is NULL, the method will return the number of service providers that are known.

nMaxProviders

An integer value which specifies the maximum number of service providers that may be enumerated by this method. If this parameter is zero, the method will return the number of service providers that are known. If the *lpProviders* parameter is NULL, this value should be zero.

Return Value

If the method succeeds, the return value is the number of known service providers. If the method fails, the return value is **SMS_ERROR**. To get extended error information, call **GetLastError**. If the *lpProviders* parameter is not NULL and the *nMaxProviders* parameter indicates the array is not large enough to store all of the provider information, this method will fail with an error indicating that the buffer is too small.

Remarks

The **EnumProviders** method is used to enumerate all of the supported wireless service providers, populating an array of **SMSPROVIDER** structures that contains information about each provider, such as their name, domain, region of the country they service and the maximum message size they will accept. Typically this would be used to update a user interface control such as a listbox or drop-down combobox, enabling a user to select a preferred service provider.

The **GetFirstProvider** and **GetNextProvider** methods offer an alternative way to enumerate the available service providers.

To obtain information about a single service provider, use the **GetProvider** method.

Example

```
SMSPROVIDER smsProviders[MAXPROVIDERS];  
  
INT nProviders = pTextMessage->EnumProviders(smsProviders, MAXPROVIDERS);  
if (nProviders == SMS_ERROR)  
{  
    pTextMessage->ShowError();  
}  
else  
{  
    for (INT nIndex = 0; nIndex < nProviders; nIndex++)  
        pComboBox->AddString(smsProviders[nIndex].szName);  
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstxtv10.lib

Unicode: Implemented as Unicode and ANSI versions.

CTextMessage::GetAddress Method

```
BOOL GetAddress(  
    LPCTSTR LpszPhoneNumber,  
    LPTSTR LpszAddress,  
    INT nMaxLength,  
);
```

```
BOOL GetAddress(  
    LPCTSTR LpszPhoneNumber,  
    CString& strAddress  
);
```

The **GetAddress** method returns the email address associated with the specified phone number.

Parameters

LpszPhoneNumber

A pointer to a string that specifies the phone number of the mobile device.

LpszAddress

A pointer to a string that will contain the email address associated with the specified phone number when the method returns. If MFC or ATL is being used, an alternate version of this function will return the address in a **CString** type variable.

nMaxLength

The maximum number of characters that may be copied into the string buffer.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **GetAddress** method is used to determine the email address associated with a mobile device. Sending an email message to this address will forward that message to the device as a text message. Internally, this method calls **GetGateway** and returns the address specified in the SMSGATEWAY structure.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstxtv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

CErrorMessage::GetErrorString Method

```
INT GetErrorString(  
    DWORD dwErrorCode,  
    LPTSTR lpszDescription,  
    INT cbDescription  
);
```

```
INT GetErrorString(  
    DWORD dwErrorCode,  
    CString& strDescription  
);
```

The **GetErrorString** method is used to return a description of a specific error code. Typically this is used in conjunction with the **GetLastError** method for use with warning dialogs or as diagnostic messages.

Return Value

If the method succeeds, the return value is the length of the description string. If the method fails, the return value is zero, meaning that no description exists for the specified error code. Typically this indicates that the error code passed to the method is invalid.

Parameters

dwErrorCode

The error code for which a description is returned.

lpszDescription

A pointer to the buffer that will contain a description of the specified error code. This buffer should be at least 128 characters in length. An alternate form of the method accepts a **CString** variable which will contain the error description.

cbDescription

The maximum number of characters that may be copied into the description buffer.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cstxtv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[GetLastError](#), [SetLastError](#), [ShowError](#)

CTextMessage::GetFirstProvider Method

```
BOOL GetFirstProvider(  
    LPSMSPROVIDER lpProvider  
);
```

The **GetFirstProvider** method returns information about the first supported wireless service provider.

Parameters

lpProvider

A pointer to an [SMSPROVIDER](#) structure that will contain information about the service provider. This parameter cannot be NULL.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **SmsGetLastError**.

Remarks

The **GetFirstProvider** method is used in conjunction with **GetNextProvider** to enumerate all of the supported wireless providers available to the client. These two methods can be used as an alternative to the **EnumProviders** method.

Example

```
SMSPROVIDER smsProvider;  
  
BOOL bResult = pTextMessage->GetFirstProvider(&smsProvider);  
while (bResult)  
{  
    pListBox->AddString(smsProvider.szName);  
    bResult = pTextMessage->GetNextProvider(&smsProvider);  
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstxtv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[EnumProviders](#), [GetGateway](#), [GetNextProvider](#), [SMSPROVIDER](#)

CTextMessage::GetGateway Method

```
BOOL GetGateway(  
    LPCTSTR lpszPhoneNumber,  
    LPCTSTR lpszProvider,  
    LPSMSGATEWAY lpGateway  
);
```

```
BOOL GetGateway(  
    LPCTSTR lpszPhoneNumber,  
    LPSMSGATEWAY lpGateway  
);
```

The **GetGateway** method returns text message service information for a phone number.

Parameters

lpszPhoneNumber

A pointer to a string which specifies the telephone number that you wish to obtain information about. Any whitespace, punctuation or other non-numeric characters in the string will be ignored. This parameter cannot be NULL.

lpszProvider

A pointer to a string which specifies the preferred service provider for this telephone number. If the preferred service provider is unknown, this parameter can be omitted or specify a NULL pointer and the default provider will be selected.

lpGateway

A pointer to an [SMSGATEWAY](#) structure that will contain information about the text message gateway when the method returns. This includes information such as the name of the provider, the server that will accept text messages for this phone number, and the recipient address that should be used. This parameter cannot be NULL.

Return Value

If the method succeeds and relaying is enabled, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **GetGateway** method returns information about the service provider and mail gateway for a specific phone number, and can be used to determine if a given phone number is assigned to a mobile device capable of receiving text messages. This is done by sending an query to a server that will check the phone number against a database of known providers and the phone numbers that have been allocated for wireless devices. If the phone number is valid, information will be returned about the provider that is responsible for that number along with information about its text message gateway service.

If the *lpszProvider* parameter is not NULL, this will identify a preferred provider for the phone number specified. In the United States and Canada, most wireless common carriers are required to provide wireless number portability (WNP) which allows a customer to continue to use their current phone number even if they switch to another service provider. This can result in a situation where a specific phone number is shown as allocated to one provider, but in actuality that user has switched to a different provider. For example, a user may have originally purchased a phone and service with AT&T and then later switched to Verizon, but decided to keep their phone number. In this case, if Verizon was not specified as the preferred provider, the library would

attempt to send the message to the AT&T gateway, since that was the original provider who allocated the phone number.

For most applications, the correct way to handle the situation in which a user may have switched to a different service provider is to allow them to select an alternate service provider in your user interface. For example, you could display a drop-down list of available service providers, populated using the **EnumProviders** method. If they select a preferred provider, then you would pass that value to this method. If they do not, then specify a NULL pointer and the default provider will be selected.

This method sends an HTTP query to the server **api.sockettools.com** to obtain information about the phone number and wireless service provider. This requires that the local system can establish a standard network connection over port 80. If the client cannot connect to the server, the method will fail and an appropriate error will be returned. The server imposes a limit on the maximum number of connections that can be established and the maximum number of requests that can be issued per minute. If this method is called multiple times over a short period, the library may also force the application to block briefly. Server responses are cached per session, so calling this method multiple times using the same phone number will not increase the request count.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstxtv10.lib

Unicode: Implemented as Unicode and ANSI versions.

CErrorMessage::GetLastError Method

```
DWORD GetLastError();  
  
DWORD GetLastError(  
    CString& strDescription  
);
```

Parameters

strDescription

A string which will contain a description of the last error code value when the method returns. If no error has been set, or the last error code has been cleared, this string will be empty.

Return Value

The return value is the last error code value for the current thread. Functions set this value by calling the **SetLastError** method. The Return Value section of each reference page notes the conditions under which the method sets the last error code.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. You should call the **GetLastError** method immediately when a method's return value indicates that an error has occurred. That is because some methods call **SetLastError(0)** when they succeed, clearing the error code set by the most recently failed method.

Most methods will set the last error code value when they fail; a few methods set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or SMS_ERROR. Those methods which call **SetLastError** when they succeed are noted on the method reference page.

The description of the error code is the same string that is returned by the **GetErrorString** method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cstxtv10.lib

See Also

[GetErrorString](#), [SetLastError](#), [ShowError](#)

CTextMessage::GetNextProvider Method

```
BOOL GetNextProvider(  
    LPSMSPROVIDER lpProvider,  
);
```

The **GetNextProvider** method returns information about the next supported wireless service provider.

Parameters

lpProvider

A pointer to an [SMSPROVIDER](#) structure that will contain information about the service provider. This parameter cannot be NULL.

Return Value

If the method succeeds, the return value is non-zero. If the last service provider has been enumerated or the method fails, the return value is zero. To get extended error information, call **SmsGetLastError**.

Remarks

The **GetNextProvider** method is used in conjunction with **GetFirstProvider** to enumerate all of the supported wireless providers available to the client. These two methods can be used as an alternative to the **EnumProviders** method.

Example

```
SMSPROVIDER smsProvider;  
  
BOOL bResult = pTextMessage->GetFirstProvider(&smsProvider);  
while (bResult)  
{  
    pListBox->AddString(smsProvider.szName);  
    bResult = pTextMessage->GetNextProvider(&smsProvider);  
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstxtv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[EnumProviders](#), [GetGateway](#), [GetNextProvider](#), [SMSPROVIDER](#)

CTextMessage::GetProvider Method

```
BOOL GetProvider(  
    LPCTSTR lpszPhoneNumber,  
    LPSMSPROVIDER lpProvider  
);
```

```
BOOL GetProvider(  
    LPCTSTR lpszPhoneNumber,  
    LPTSTR lpszProvider,  
    INT nMaxLength  
);
```

```
BOOL GetProvider(  
    LPCTSTR lpszPhoneNumber,  
    CString& strProvider  
);
```

The **GetProvider** method returns information about the service provider for the specified phone number.

Parameters

lpszPhoneNumber

A pointer to a string which specifies the telephone number that you wish to obtain information about. Any whitespace, punctuation or other non-numeric characters in the string will be ignored. This parameter cannot be NULL.

lpProvider

A pointer to an [SMS PROVIDER](#) structure that will contain information about the service provider for the specified phone number.

lpszProvider

A pointer to a string that will contain the name of the wireless service provider associated with the specified phone number when the method returns. If MFC or ATL is being used, an alternate version of this function will return the address in a **CString** type variable.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string.

Return Value

If the method succeeds and relaying is enabled, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **GetProvider** method returns information about the service provider associated with a phone number. This is done by sending an query to a server that will check the phone number against a database of known providers and the phone numbers that have been allocated for wireless devices. If the phone number is valid, information will be returned about the provider that is responsible for that number.

Because most wireless carriers in the United States and Canada must provide for wireless number portability, there is the possibility that the provider information returned may no longer correspond to the telephone number. It is recommended that you provide your end-user with the ability to specify an alternate preferred provider to use when sending the text message. For more

information, refer to the **GetGateway** method.

This method sends an HTTP query to the server **api.sockettools.com** to obtain information about the wireless service provider. This requires that the local system can establish a standard network connection over port 80. If the client cannot connect to the server, the method will fail and an appropriate error will be returned. The server imposes a limit on the maximum number of connections that can be established and the maximum number of requests that can be issued per minute. If this method is called multiple times over a short period, the library may also force the application to block briefly. Server responses are cached per session, so calling this method multiple times using the same phone number will not increase the request count.

For a list of all supported wireless service providers, use the **EnumProviders** method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstxtv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[EnumProviders](#), [GetGateway](#), [SMS PROVIDER](#)

CTextMessage::GetTimeout Method

```
INT GetTimeout();
```

The **GetTimeout** method returns the number of seconds the client will wait for a response from the server. Once the specified number of seconds has elapsed, the method will fail and return to the caller.

Parameters

None.

Return Value

If the method succeeds, the return value is the timeout period in seconds. If the method fails, the return value is SMS_ERROR. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cstxtv10.lib

See Also

[EnableRelay](#), [SendMessage](#), [SetTimeout](#)

CNetMessage::IsInitialized Method

```
BOOL IsInitialized();
```

The **IsInitialized** method returns whether or not the class object has been successfully initialized.

Parameters

None.

Return Value

This method returns a non-zero value if the class object has been successfully initialized. A return value of zero indicates that the runtime license key could not be validated or the networking library could not be loaded by the current process.

Remarks

When an instance of the class is created, the class constructor will attempt to initialize the component with the runtime license key that was created when SocketTools was installed. If the constructor is unable to validate the license key or load the networking libraries, this initialization will fail.

If SocketTools was installed with an evaluation license, the application cannot be redistributed to another system. The class object will fail to initialize if the application is executed on another system, or if the evaluation period has expired. To redistribute your application, you must purchase a development license which will include the runtime key that is needed to redistribute your software to other systems. Refer to the Developer's Guide for more information.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

[DisableRelay](#), [EnableRelay](#), [SendMessage](#)

CTextMessage::SendMessage Method

```
BOOL SendMessage(  
    DWORD dwServiceType,  
    LPCTSTR lpszProvider,  
    LPCTSTR lpszPhoneNumber,  
    LPCTSTR lpszSender,  
    LPCTSTR lpszMessage  
);
```

```
BOOL SendMessage(  
    LPSMSSERVICE lpService,  
    LPSMSMESSAGE lpMessage  
);
```

The **SendMessage** method sends a text message to the specified mobile device.

Parameters

dwServiceType

An unsigned integer value which identifies the type of service being used to send the message. Currently there is only one valid service type, **SMS_SERVICE_SMTP** which sends the message to a mail gateway provided by the wireless service provider. This parameter is included for future expansion when multiple alternative services may be used to send the message.

lpszProvider

A pointer to a string that identifies the wireless service provider that is responsible for the specified phone number. If the service provider is unknown, this parameter can be NULL or an empty string. In that case, the default provider for the phone number will be used.

lpszPhoneNumber

A pointer to a string that specifies the phone number for the mobile device. This can be a standard E.164 formatted number or an unformatted number. Any extraneous whitespace, punctuation or other non-numeric characters in the string will be ignored. This parameter cannot be NULL.

lpszSender

A pointer to a string which identifies the sender of the message and should specify a valid email address. If the recipient replies to the message, the reply will be sent to this address. This parameter cannot be NULL.

lpszMessage

A pointer to a null terminated string that contains the message to be sent to the recipient. In most cases, a message should not exceed 160 characters in length, although some service providers may accept longer messages. If a message exceeds the maximum number of characters accepted by a service provider, the message may be ignored or it may be split into multiple messages.

lpService

A pointer to an [SMSSERVICE](#) structure that identifies the messaging service that will be used to send the text message. The default service sends the message through the mail server gateway for the wireless service provider associated with the recipient's phone number. This parameter cannot be NULL.

lpMessage

A pointer to an [SMSMESSAGE](#) structure that contains information about the message to be sent, including the sender, the recipient and the text message itself. This parameter cannot be NULL.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **SendMessage** method is used to send a text message to a mobile device. This API is designed to support multiple methods of sending text messages, with the default method sending the message through a server gateway established by the wireless service provider.

SMS_SERVICE_SMTP

This message service sends the message through the wireless service provider's mail gateway using the SMTP protocol. However, it is important to note that many of these gateways will not accept messages from a client that is connected to them using a residential Internet service provider. If the application is being run on a system that uses a residential provider, that service provider may also block outbound connections to all mail servers other than their own. These anti-spam measures typically require that most end-user applications specify a relay mail server rather than submitting the message directly to the wireless provider's gateway.

Because most wireless carriers in the United States and Canada must provide for wireless number portability, there is the possibility that the provider information returned may no longer correspond to the telephone number. It is recommended that you provide your end-user with the ability to specify an alternate preferred provider to use when sending the text message. For more information, refer to the **GetGateway** method.

This service also sends an HTTP query to the server **api.sockettools.com** to obtain information about the phone number and wireless service provider. This requires that the local system can establish a standard network connection over port 80. If the client cannot connect to the server, the function will fail and an appropriate error will be returned. The server imposes a limit on the maximum number of connections that can be established and the maximum number of requests that can be issued per minute. If this method is called multiple times over a short period, the library may also force the application to block briefly. Server responses are cached per session, so calling this method multiple times using the same phone number will not increase the request count.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

CNetMessage::SetLastError Method

```
VOID SetLastError(  
    DWORD dwErrorCode  
);
```

The **SetLastError** method sets the last error code for the current thread. This method is typically used to clear the last error by specifying a value of zero as the parameter.

Parameters

dwErrorCode

Specifies the last error code for the current thread.

Return Value

None.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. Most methods will set the last error code value when they fail; a few methods set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or SMS_ERROR. Those methods which call **SetLastError** when they succeed are noted on the method reference page.

Applications can retrieve the value saved by this method by using the **GetLastError** method. The use of **GetLastError** is optional; an application can call the method to determine the specific reason for a method failure.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cstxtv10.lib

See Also

[GetErrorString](#), [GetLastError](#), [ShowError](#)

CNetMessage::SetTimeout Method

```
INT SetTimeout(  
    UINT nTimeout  
);
```

The **SetTimeout** method sets the number of seconds the client will wait for a response from the server. Once the specified number of seconds has elapsed, the blocking method will fail and return to the caller.

Parameters

nTimeout

The number of seconds until a blocking operation fails. Setting this parameter to zero will use the default timeout period.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is SMS_ERROR. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cstxtv10.lib

CErrorMessage::ShowError Method

```
INT ShowError(  
    LPCTSTR lpszAppTitle,  
    UINT uType,  
    DWORD dwErrorCode  
);
```

The **ShowError** method displays a message box which describes the specified error.

Parameters

lpszAppTitle

A pointer to a string which specifies the title of the message box that is displayed. If this argument is NULL or omitted, then the default title of "Error" will be displayed.

uType

An unsigned integer which specifies the type of message box that will be displayed. This is the same value that is used by the **MessageBox** method in the Windows API. If a value of zero is specified, then a message box with a single OK button will be displayed. Refer to that method for a complete list of options.

dwErrorCode

Specifies the error code that will be used when displaying the message box. If this argument is zero, then the last error that occurred in the current thread will be displayed.

Return Value

If the method is successful, the return value will be the return value from the **MessageBox** function. If the method fails, it will return a value of zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cstxtv10.lib

Unicode: Implemented as Unicode and ANSI versions.

Text Message Data Structures

- SMSGATEWAY
- SMSMESSAGE
- SMSPROVIDER
- SMSSERVICE

MSGGATEWAY Structure

This structure contains information about a text message gateway server and the recipient.

```
typedef struct _MSGGATEWAY
{
    INT      nGatewayId;
    INT      nCountryCode;
    INT      nAreaCode;
    INT      nExchange;
    INT      nMessageLength;
    DWORD    dwReserved;
    TCHAR    szProvider[SMS_MAXPROVIDERNAMELEN];
    TCHAR    szDomain[SMS_MAXDOMAINNAMELEN];
    TCHAR    szServer[SMS_MAXMAILSERVERLEN];
    TCHAR    szAddress[SMS_MAXMAILADDRESSLEN];
} SMSCHANNEL, *LPSMSCHANNEL;
```

Members

nGatewayId

An integer value which identifies the gateway record. This value is used internally and an application should not depend on the value not changing over time for a specific telephone number. As new area codes are introduced, the provider database will be updated to reflect these changes and that can result in a change to the gateway ID associated with a specific telephone number.

nCountryCode

An integer value which specifies the ITU country calling code associated with the service provider. Currently this value will always be 1, which is the country code used by North American service providers. If the service provider database is expanded to include additional countries in the future, this value will identify the country of origin.

nAreaCode

An integer value which specifies the Numbering Plan Area (NPA) code, commonly known as the area code. For the United States and Canada, area codes are assigned by the North American Numbering Plan Administration (NANPA). In North America, the area code is digits 1-3 for a 10-digit telephone number. This value, along with the exchange, is used to determine which company provides wireless service for a specific telephone number.

nExchange

An integer value which specifies the exchange area. In North America, the exchange is digits 4-6 for a 10-digit telephone number. This value, along with the area code, is used to determine which company provides wireless service for a specific telephone number.

nMessageLength

An integer value which specifies the maximum number of characters that the service provider will accept for a single text message. If the message exceeds this number of characters, the service provider may reject the message, or it may split the message into multiple messages.

dwReserved

A value reserved for internal use.

szProvider

A pointer to a string which identifies the name of the service provider that is associated with the specified telephone number. Note that this value may not represent the actual company that is

providing the wireless service.

szDomain

A pointer to a string which identifies the gateway domain name used by the service provider to accept text messages for their customer. This domain name is used to determine the actual name of the gateway mail server that is responsible for accepting messages.

szServer

A pointer to a string which identifies the host name or IP address of the mail server used to accept text messages for the specified service provider. In some cases, a provider may have multiple gateway servers and this value will represent the preferred mail server for the domain.

szAddress

A pointer to a string which contains the complete email address that should be used when sending the text message through the gateway mail server. Different service providers can have slightly different rules about how the address is formatted, but it typically is a combination of the telephone number and the gateway domain name.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Unicode: Implemented as Unicode and ANSI versions.

SMSMESSAGE Structure

This structure provides information about a text message.

```
typedef struct _SMSMESSAGE
{
    DWORD dwFormat;
    DWORD dwLength;
    DWORD dwFlags;
    DWORD dwReserved;
    LPCTSTR lpszProvider;
    LPCTSTR lpszPhoneNumber;
    LPCTSTR lpszSender;
    LPCTSTR lpszMessage;
} SMSMESSAGE, *LPSMSMESSAGE;
```

Members

dwFormat

An integer value which specifies the format of the message message. This member is included for future use where a service provider supports multiple message formats based on different versions of the protocol. The default value for this member is SMS_FORMAT_TEXT.

dwLength

An integer value which specifies the length of the message. If this member is zero, the length will be automatically calculated based on the length of the *lpszMessage* text that is terminated by a null character. If this value is larger than the actual length of the message text, it will be ignored.

dwFlags

An integer value which specifies one or more message options.

Constant	Description
SMS_MESSAGE_DEFAULT	The default value used with standard text messages.
SMS_MESSAGE_URGENT	The text message should be flagged as urgent. For messages that are sent through a mail gateway, this will set the header to indicate that it is a high priority message. Note that service providers handle urgent messages differently and some may ignore the message priority.

dwReserved

Reserved for future use. This value should always be zero.

lpszProvider

A pointer to a null terminated string which specifies the name of the preferred wireless service provider responsible for handling the message. If this member is NULL or an empty string, the default provider assigned to the recipient's phone number will be used. This structure member is only used with SMS_SERVICE_SMTP messages and is ignored for other message services.

lpszPhoneNumber

A pointer to a null terminated string which specifies the recipient's phone number. This can be a standard E.164 formatted number or an unformatted number. Any extraneous whitespace, punctuation or other non-numeric characters in the string will be ignored. This structure member cannot be NULL.

lpszSender

A pointer to a null terminated string which identifies the sender of the message. For SMS_SERVICE_SMTP messages, this string should be a valid email address. For other services, this string may specify a phone number or shortcode. This structure member cannot be NULL.

lpszMessage

A pointer to a null terminated string that contains the message to be sent to the recipient. In most cases, a message should not exceed 160 characters in length, although some service providers may accept longer messages. If a message exceeds the maximum number of characters accepted by a service provider, the message may be ignored or it may be split into multiple messages.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Unicode: Implemented as Unicode and ANSI versions.

See Also

[SendMessage](#), [SMSSERVICE](#)

SMSPROVIDER Structure

This structure contains information about a wireless service provider.

```
typedef struct _SMSPROVIDER
{
    INT        nProviderId;
    INT        nCountryCode;
    INT        nRegionCode;
    INT        nMessageLength;
    DWORD      dwFlags;
    DWORD      dwReserved;
    TCHAR      szGuid[SMS_MAXPROVIDERGUIDLEN];
    TCHAR      szName[SMS_MAXPROVIDERNAMELEN];
    TCHAR      szCompany[SMS_MAXCOMPANYNAMELEN];
    TCHAR      szDomain[SMS_MAXDOMAINNAMELEN];
} SMSPROVIDER, *LPSMSPROVIDER;
```

Members

nProviderId

An integer value which identifies the provider record. This value is used internally and an application should not depend on the value not changing over time for a specific service provider. To uniquely identify a provider, use the *szGuid* member of the structure, which is guaranteed not to change as providers are added and removed from the database.

nCountryCode

An integer value which specifies the ITU country calling code associated with the service provider. Currently this value will always be 1, which is the country code used by North American service providers. If the service provider database is expanded to include additional countries in the future, this value will identify the country of origin.

nRegionCode

An integer value which identifies the region that the service provider covers. In North America, each region consists of multiple states and/or provinces. If a provider services multiple regions, this will identify the primary region where they provide coverage.

Constant	Description
SMS_REGION_NATIONAL 0	All regions. This region code is used for service providers that have national coverage and do not exclusively provide service within one or more specific geographical regions.
SMS_REGION_NORTH_EAST_ATLANTIC 1	Northeastern Atlantic region which includes Connecticut, Maine, Massachusetts, New Hampshire, New Brunswick, Newfoundland, Nova Scotia, Rhode Island and Vermont.
SMS_REGION_MIDDLE_ATLANTIC 2	Middle Atlantic region which includes New Jersey, New York, Delaware, District of Columbia, Maryland, Pennsylvania, Quebec, Virginia and West Virginia.
SMS_REGION_EAST_NORTH_CENTRAL 3	Northeastern central region which includes Illinois, Indiana, Michigan, Ohio and

	Wisconsin.
SMS_REGION_SOUTH_ATLANTIC 4	Southern Atlantic region which includes Florida, Georgia, North Carolina and South Carolina.
SMS_REGION_EAST_SOUTH_CENTRAL 5	Southeastern central region which includes Alabama, Kentucky, Mississippi and Tennessee.
SMS_REGION_WEST_NORTH_CENTRAL 6	Northwestern central region which includes Iowa, Kansas, Manitoba, Minnesota, Missouri, Nebraska, North Dakota, Ontario and South Dakota.
SMS_REGION_WEST_SOUTH_CENTRAL 7	Southwestern central region which includes Arkansas, Louisiana, Oklahoma and Texas.
SMS_REGION_MOUNTAIN 8	Mountain region which includes Alberta, Arizona, Colorado, Idaho, Montana, Nevada, New Mexico, Northwest Territories, Saskatchewan, Utah and Wyoming.
SMS_REGION_PACIFIC 9	Pacific region which includes Alaska, British Columbia, California, Hawaii, Oregon, Washington and Yukon.

nMessageLength

An integer value which specifies the maximum number of characters that the service provider will accept for a single text message. If the message exceeds this number of characters, the service provider may reject the message, or it may split the message into multiple messages.

dwFlags

An unsigned integer value which specifies one or more flags that provides additional information about the service provider. This value is constructed by using a bitwise operator with any of the following constants:

Constant	Description
SMS_PROVIDER_DEFAULT 0	A standard service provider. Typically this means that customers have a service contract for their mobile device and pay monthly access and service charges.
SMS_PROVIDER_PREPAID 1	A service provider that offers pre-paid calling cards or fixed month-to-month payments that do not require long-term service contracts.

dwReserved

A value reserved for internal use.

szGuid

A pointer to a string which uniquely identifies the service provider. The string is in a standard format used for globally unique identifiers (GUIDs) and is guaranteed to not change for the service provider it has been assigned to.

szName

A pointer to a string which specifies the name of service provider. Note that this value may not represent the actual company that is providing the wireless service.

szCompany

A pointer to a string which specifies the name of the company associated with the service provider. This may be the same as name of the service provider itself or it may be the name of a parent company that owns the service provider.

szDomain

A pointer to a string which identifies the gateway domain name used by the service provider to accept text messages for their customer. This domain name is used to determine the actual name of the gateway mail server that is responsible for accepting messages.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Unicode: Implemented as Unicode and ANSI versions.

SMSSERVICE Structure

This structure provides information about the service used to send a text message.

```
typedef struct _SMSSERVICE
{
    DWORD dwServiceType;
    DWORD dwAuthType;
    DWORD dwVersion;
    DWORD dwTimeout;
    DWORD dwOptions;
    DWORD dwReserved;
    LPCTSTR lpszResource;
    LPCTSTR lpszAccount;
    LPCTSTR lpszUserName;
    LPCTSTR lpszPassword;
} SMSSERVICE, *LPSMSSERVICE;
```

Members

dwServiceType

An integer value which identifies the type of service that will be used to send the message. This member can be one of the following values:

Constant	Description
SMS_SERVICE_SMTP	The text message will be sent through the mail gateway for the specified service provider. This service uses SMTP to submit the message for delivery, either directly to the server provider's mail gateway server or through a relay server. This is the default service type.

dwAuthType

An integer value which identifies the type of authentication used with the service. This member can be one of the following values:

Constant	Description
SMS_AUTH_DEFAULT	The default authentication method for this service type should be used. Most applications should use this value unless a service type provides multiple authentication methods.
SMS_AUTH_USERNAME	The service requires authentication using a username and password. This value can be used with an SMTP service that requires user authentication and is typically needed when using a mail server relay. For the SMS_SERVICE_SMTP service, this is the default authentication method.

dwVersion

An integer value which identifies the interface version for the service being used. This member is included for future use where a service may support multiple versions of their interface and should normally be set to the value SMS_VERSION_DEFAULT.

dwTimeout

An integer value which specifies the amount of time in seconds that a function will wait for a

response from the service. If this value is zero, a default timeout period of 20 seconds will be used. If the service does not respond within this time period, the function will fail.

dwOptions

An integer value which specifies one or more options.

Constant	Description
SMS_OPTION_NONE	No additional options for the service.
SMS_OPTION_SECURE	This option specifies that SSL/TLS will be used to establish a secure, encrypted connection with the service. For some services, it may be required to connect to them securely and this option will be enabled automatically.

dwReserved

Reserved for future use. This value should always be zero.

lpszResource

A pointer to a null terminated string that specifies a resource for the service. Typically this will be either a fully qualified domain name or a URL. For gateways using SMTP, this string should identify the mail server. An alternate port number can also be specified by appending it to the hostname, separated by a colon. For example, **smtp.company.com:587** would connect to the server on port 587. If you are specifying an IPv6 address with an alternate port number, the address must be enclosed in brackets. For services where a domain name or resource URL is not required, this member will be ignored and can be NULL.

lpszAccount

A pointer to a null terminated string that specifies an account name or identifier. Some service providers may require a unique account name or a token (application ID) in conjunction with other credentials. This member is not used with mail gateways and ignored if the service type is SMS_SERVICE_SMTP. If no account name is required for session authentication, this member can be NULL.

lpszUserName

A pointer to a null terminated string that specifies a user name to authenticate the session. If the authentication type is SMS_AUTH_USERNAME this member must specify a valid user name. If no authentication is required, this member may be NULL. Note that some service providers may use terminology other than "username" with their documentation; this member will always specify the first of a pair of authentication tokens.

lpszPassword

A pointer to a null terminated string that specifies the password used to authenticate the session. If the authentication type is SMS_AUTH_USERNAME this member must specify a valid password. If no authentication is required, this member may be NULL. Note that some service providers may use terminology other than "password" with their documentation; this member will always specify the second of a pair of authentication tokens.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Unicode: Implemented as Unicode and ANSI versions.

CWebStorage Application Storage Class Library

The CWebStorage class provides data storage for applications.

Reference

- [Class Methods](#)
- [Constants](#)
- [Data Structures](#)
- [Error Codes](#)

Library Information

Class Name	CWebStorage
File Name	CSWEBV10.DLL
Version	10.0.1468.2518
LibID	62AB4693-FFA1-4A6F-BC44-FDC113EB2C68
Import Library	CSWEBV10.LIB
Dependencies	None

Overview

The CWebStorage class enables an application to store and manage data remotely. These methods use secure services provided by SocketTools API servers and do not require third-party party APIs or accounts with other cloud service providers.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). If you are using Visual C++ 6.0 it is required that you have Service Pack 6 (SP6) installed. You should install all updates for your development tools and have the current Windows SDK installed. The minimum recommended version of Visual Studio is Visual Studio 2010.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are using Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. It is recommended that you install the current service pack and all critical updates available for your version of the operating system.

This product includes both 32-bit and 64-bit libraries. Native 64-bit CPU support requires the 64-bit version of Windows 7 or later versions of the Windows operating system.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

CWebStorage Class Methods

Class	Description
CWebStorage	Constructor which initializes the current instance of the class
~CWebStorage	Destructor which releases resources allocated by the class
Method	Description
Cancel	Cancel a storage operation that is currently in progress
CloseStorage	Close the storage container and release resources allocated for the client session
CompareFile	Compare the contents of a stored object with a local file
CompareData	Compare the contents of a stored object with a memory buffer
CompareText	Compare the contents of a stored object with a string
CopyObject	Copy a storage object to a new location and optionally rename the object label
DeleteObject	Delete an existing storage object
DownloadFile	Download the contents of a stored object to a local file
DisableTrace	Disable logging of method calls to the trace log file
EnableTrace	Enable logging of method calls to a log file
EnumObjects	Enumerate all storage objects that match the specified label or content type
GetAccountId	Return the current web services account identifier
GetData	Download the contents of a storage object to a memory buffer
GetErrorString	Return a description for the specified error code
GetFile	Download the contents of a storage object to a local file
GetFirstApplication	Return information about the first registered application
GetFirstObject	Return information about the first object that matches search criteria
GetHandle	Return the storage handle used by this instance of the class
GetLastError	Return the last error code
GetNextApplication	Return information about the next registered application
GetNextObject	Return information about the next object that matches search criteria
GetObjectInformation	Retrieve the metadata for the specified storage object
GetObjectSize	Return the size of the specified storage object
GetStorageQuota	Return quota limits assigned to your storage account
GetStorageId	Return the returns the current storage container ID
GetTimeout	Get the number of seconds until a storage operation times out
GetTransferStatus	Return status information about the progress of a data transfer
IsBlocking	Determine if the session waiting for a response from the storage server
IsConnected	Determine if the client is connected to the storage server

IsInitialized	Determine if the class has been successfully initialized
MoveObject	Move a storage object to a new location and optionally rename the object label
OpenStorage	Open a storage container and return a handle for the client session
PutData	Upload the contents of a memory buffer and return information about the new object
PutFile	Upload the contents of a local file and return information about the new object
RegisterAppId	Register a new application identifier used to store and retrieve data
RegisterEvent	Register an event handler to receive notifications for the session
RenameObject	Change the label associated with a storage object
ResetStorage	Resets the application storage container and deletes all stored objects
SetLastError	Set the last error code
SetTimeout	Set the number of seconds until a storage operation times out
ShowError	Display a message box with a description of the specified error
UnregisterAppId	Unregister the application identifier and delete all associated storage objects
UnregisterEvent	Unregister an event handler and stop receiving notifications for the session
UploadFile	Upload the contents of a local file
ValidateAppId	Validate the specified application identifier
ValidateLabel	Check the specified string to ensure it is a valid object label

CWebStorage::CWebStorage

`CWebStorage()`;

The **CWebStorage** constructor initializes the class library and validates the license key at runtime.

Remarks

If the constructor fails to validate the runtime license, subsequent methods in this class will fail. If the product is installed with an evaluation license, then the application will only method on the development system and cannot be redistributed.

The constructor calls the **WebInitialize** function to initialize the library, which dynamically loads other system libraries and allocates thread local storage. If you are using this class within another DLL, it is important that you do not create or destroy an instance of the class from within the **DllMain** function because it can result in deadlocks or access violation errors.

You should not declare static or global instances of this class within another DLL if it is linked with the C runtime library (CRT) because it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `cswebv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

See Also

[~CWebStorage](#), [IsInitialized](#), [WebInitialize](#)

CWebStorage::~~CWebStorage

`~CWebStorage();`

The **CWebStorage** destructor releases resources allocated by the current instance of the **CWebStorage** object. It also uninitialized the library if there are no other concurrent uses of the class.

Remarks

When a **CWebStorage** object goes out of scope, the destructor is automatically called to allow the library to free any resources allocated on behalf of the process. Any pending blocking or asynchronous calls in this process are canceled without posting any notification messages, and all handles that were created for the client session are destroyed.

The destructor is not called explicitly by the application.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `cswebv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

See Also

[CWebStorage](#), [IsConnected](#), [IsInitialized](#)

CWebStorage::Cancel Method

```
BOOL Cancel();
```

The **Cancel** method cancels the current data transfer in progress.

Parameters

None.

Return Value

If the method succeeds, the return value is a non-zero. If the method fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

The **Cancel** method will cancel the current data transfer and abort the connection to the storage server. This method will fail if an active data transfer (either an upload or download) is not in progress.

This would typically be used within an event handler to cancel an operation as the contents of an object are being read or written. There is no mechanism to resume a canceled data transfer and this method should only be used when absolutely necessary.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswebv10.lib

See Also

[GetTransferStatus](#), [RegisterEvent](#)

CWebStorage::CloseStorage Method

```
BOOL CloseStorage();
```

The **CloseStorage** method closes the open storage container.

Parameters

None.

Return Value

If the method succeeds, the return value is a non-zero. If the method fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

The **CloseStorage** method must be called after all operations using the storage container have completed. The access token granted to the application will be released and the memory allocated for the session cache will be freed.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswebv10.lib

See Also

[GetHandle](#), [OpenStorage](#)

CWebStorage::CompareData Method

```
BOOL CompareData(  
    LPCTSTR lpszObjectLabel,  
    LPCVOID lpvBuffer,  
    DWORD dwLength  
);
```

The **CompareData** method compares the contents of a stored object with the data provided by the caller.

Parameters

lpszObjectLabel

A pointer to a null terminated string which specifies the label of the object to be compared.

lpvBuffer

A pointer to a buffer that contains the data to be compared against the storage object.

dwLength

An unsigned integer which specifies the length of the data buffer to be compared.

Return Value

If the method succeeds, the return value is a non-zero and the data matches the contents of the stored object. If the method fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

The **CompareData** method performs a binary comparison of the data in the specified buffer with the contents of the storage object on the server. The *dwLength* parameter must match the size of the stored object exactly, or this method will fail. Partial comparisons are not supported by this method.

If you wish to compare the contents of a text object, it is recommended that you use **CompareText**. This method ensures that Unicode text is compared correctly.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cswebv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[CompareFile](#), [CompareText](#), [GetObjectInformation](#)

CWebStorage::CompareFile Method

```
BOOL CompareFile(  
    LPCTSTR lpszObjectLabel,  
    LPCTSTR lpszLocalFile  
);
```

The **CompareFile** method compares the contents of a stored object with a local file.

Parameters

lpszObjectLabel

A pointer to a null terminated string which specifies the label of the object to be compared.

lpszLocalFile

A pointer to a null terminated string that specifies the name of the local file. If a path is not specified, the file will be created in the current working directory.

Return Value

If the method succeeds, the return value is a non-zero and the contents of the file matches the stored object. If the method fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

The **CompareFile** method performs a binary comparison of the contents of a local file with a stored object on the server. The contents of the file must be identical to the contents of the stored object or the method will fail.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cswebv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[CompareData](#), [CompareText](#), [GetObjectInformation](#)

CWebStorage::CompareText Method

```
BOOL CompareText(  
    LPCTSTR lpszObjectLabel,  
    LPCTSTR lpszObjectText,  
    INT cchObjectText  
);
```

The **CompareText** method compares the contents of a stored object with the string provided by the caller.

Parameters

lpszObjectLabel

A pointer to a null terminated string which specifies the label of the object to be compared.

lpszObjectText

A pointer to a null terminated string which contains the text to be compared with the stored object.

cchObjectText

The number of characters in the *lpszObjectText* string to be compared. This value may be -1, in which case the string length will be determined by counting the number of characters up to the terminating null.

Return Value

If the method succeeds, the return value is a non-zero and the data matches the contents of the stored object. If the method fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

The **CompareText** method performs a text comparison of the characters in the string with the contents of the storage object on the server. The string length must match the amount of text in the stored object exactly, or this function will fail. Partial comparisons are not supported by this function.

Unicode strings will be automatically converted from UTF-16 to UTF-8 encoding in the same way the **PutData** method does when storing text objects.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswebv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

CWebStorage::CopyObject Method

```
BOOL CopyObject(  
    LPCTSTR lpszOldLabel,  
    LPCTSTR lpszNewLabel,  
    DWORD dwStorageType,  
    LPWEB_STORAGE_OBJECT lpObject  
);
```

The **CopyObject** method creates a copy of an existing storage object using a new label.

Parameters

lpszOldLabel

A pointer to a null terminated string which specifies the label of the existing storage object to be copied. This parameter must specify a valid object label and cannot be a NULL pointer or an empty string.

lpszNewLabel

A pointer to a null terminated string which specifies the name of the new storage object that will be created. This parameter may be NULL or point to an empty string, in which case the label name is not changed. In this case, the **dwStorageType** parameter cannot be WEB_STORAGE_DEFAULT.

dwStorageType

An integer value that identifies the storage container type. If this parameter is omitted, the value WEB_STORAGE_DEFAULT will be used. One of the following values can be specified:

Constant	Description
WEB_STORAGE_DEFAULT (0)	The default storage type. If this value is specified, the new object will be created using the same storage type as the original storage object.
WEB_STORAGE_GLOBAL (1)	Global storage. Objects stored using this storage type are available to all users. Any changes made to objects using this storage type will affect all users of the application. Unless there is a specific need to limit access to the objects stored by the application to specific domains, local machines or users, it is recommended that you use this storage type when creating new objects.
WEB_STORAGE_DOMAIN (2)	Local domain storage. Objects stored using this storage type are only available to users in the same local domain, as defined by the domain name or workgroup name assigned to the local system. If the domain or workgroup name changes, objects previously stored using this storage type will not be available to the application.
WEB_STORAGE_MACHINE (3)	Local machine storage. Objects stored using this storage type are only available to users on the same local machine. The local machine is identified by unique characteristics of the system, including the boot volume GUID. Objects previously stored using this storage type will not be available on that system if the boot disk is

	reformatted.
WEB_STORAGE_USER (4)	Current user storage. Objects stored using this storage type are only available to the current user logged in on the local machine. The user identifier is based on the Windows user SID that is assigned when the user account is created. If the user account is deleted, the objects previously stored using this storage type will not be available to the application.

lpObject

A pointer to a [WEB_STORAGE_OBJECT](#) structure that will contain information about the new storage object. If this information is not required, this parameter may be omitted or a NULL pointer.

Return Value

If the method succeeds, the return value is a non-zero. If the method fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

The **CopyObject** method is used to create a copy of an existing storage object. It may be used to duplicate an object with a different label, or it may be used to copy the object to a new storage container type. For example, it can copy an object originally created using WEB_STORAGE_USER to a new object stored using WEB_STORAGE_MACHINE.

Copied objects are assigned their own unique ID and are not linked to one another. Any subsequent changes made to the original object will not affect the copied object. Attempting to copy an object to itself or another existing object will result in an error.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cswebv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[DeleteObject](#), [MoveObject](#), [RenameObject](#)

CWebStorage::DeleteObject Method

```
BOOL DeleteObject(  
    LPCTSTR lpszObjectLabel  
);
```

The **DeleteObject** method deletes an object from the storage container.

Parameters

lpszObjectLabel

A pointer to a null terminated string which specifies the label of the object to be deleted.

Return Value

If the method succeeds, the return value is a non-zero. If the method fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

The **DeleteObject** method permanently deletes the storage object and its associated data from the server. Deleted objects cannot be recovered by the application. To remove all objects stored in the container, use the **ResetStorage** method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstoools10.h

Import Library: cswebv10.lib

Unicode: Implemented as Unicode and ANSI versions.

CWebStorage::DisableTrace Method

```
BOOL DisableTrace();
```

The **DisableTrace** method disables the logging of socket function calls to the trace log.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, a value of zero is returned.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswebv10.lib

[EnableTrace](#)

CWebStorage::DownloadFile Method

```
BOOL DownloadFile(  
    LPCTSTR lpszLocalFile,  
    LPCTSTR lpszObjectLabel,  
    LPWEB_STORAGE_OBJECT LpObject  
);
```

```
BOOL DownloadFile(  
    LPCTSTR lpszLocalFile,  
    LPCTSTR lpszObjectLabel,  
    LPCTSTR lpszAppId,  
    DWORD dwStorageType,  
    DWORD dwTimeout,  
    LPWEB_STORAGE_OBJECT LpObject,  
    WEBEVENTPROC LpEventProc,  
    DWORD_PTR dwParam  
);
```

The **DownloadFile** method downloads the contents of a storage object and copies it to a local file.

Parameters

lpszLocalFile

A pointer to a null terminated string that specifies the name of the local file that will be created or overwritten with the contents of the storage object. If a path is not specified, the file will be created in the current working directory.

lpszObjectLabel

A pointer to a null terminated string that specifies the label of the object that should be retrieved from the server.

lpszAppId

A pointer to null terminated string which specifies the application ID for the storage container. The application ID is a string that uniquely identifies the application and can only contain letters, numbers, the period and the underscore character. If this parameter is NULL or an empty string, the default identifier **SocketTools.Storage.Default** will be used.

dwStorageType

An integer value that identifies the storage container type. If this parameter is omitted, WEB_STORAGE_GLOBAL will be used as the default. One of the following values can be specified:

Constant	Description
WEB_STORAGE_GLOBAL (1)	Global storage. Objects stored using this storage type are available to all users. Any changes made to objects using this storage type will affect all users of the application. Unless there is a specific need to limit access to the objects stored by the application to specific domains, local machines or users, it is recommended that you use this storage type when creating new objects.
WEB_STORAGE_DOMAIN (2)	Local domain storage. Objects stored using this storage type are only available to users in the same local domain,

	as defined by the domain name or workgroup name assigned to the local system. If the domain or workgroup name changes, objects previously stored using this storage type will not be available to the application.
WEB_STORAGE_MACHINE (3)	Local machine storage. Objects stored using this storage type are only available to users on the same local machine. The local machine is identified by unique characteristics of the system, including the boot volume GUID. Objects previously stored using this storage type will not be available on that system if the boot disk is reformatted.
WEB_STORAGE_USER (4)	Current user storage. Objects stored using this storage type are only available to the current user logged in on the local machine. The user identifier is based on the Windows user SID that is assigned when the user account is created. If the user account is deleted, the objects previously stored using this storage type will not be available to the application.

dwTimeout

An integer value that specifies a timeout period in seconds. If this value is zero, a default timeout period will be used.

lpObject

A pointer to a [WEB_STORAGE_OBJECT](#) structure that will contain additional information about the object that has been downloaded. This parameter may be omitted or NULL if the information is not required.

lpEventProc

Specifies the procedure-instance address of the application defined callback method. For more information about the callback method, see the description of the **WebEventProc** callback method. If this parameter is omitted or NULL, no callback method will be invoked during the data transfer.

dwParam

A user-defined integer value that is passed to the callback method specified by *lpEventProc*. If the application targets the x86 (32-bit) platform, this parameter must be a 32-bit unsigned integer. If the application targets the x64 (64-bit) platform, this parameter must be a 64-bit unsigned integer.

Return Value

If the method succeeds, the return value is a non-zero. If the method fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

The **DownloadFile** method downloads the contents of the storage object and stores it in a local file. Unlike the **GetFile** method, it is not required that you explicitly open a storage container using the **OpenStorage** method prior to calling this method.

Additional metadata about the object will be returned in the [WEB_STORAGE_OBJECT](#) structure provided by the caller, such as the date and time the object was created, the content type and the SHA-256 hash of the object contents.

If you are downloading a large object and want your application to receive progress updates during the data transfer, provide a pointer to a static callback function as the *lpEventProc* parameter. That function will receive event notifications as the data is being downloaded.

Example

```
WEB_STORAGE_OBJECT webObject;

// Download the object from global storage to a local file
if (pStorage->DownloadFile(lpszObjectLabel, lpszLocalFile, &webObject))
{
    // The object was downloaded, display the metadata
    _tprintf(_T("Object:  %s\n"), webObject.szObjectId);
    _tprintf(_T("Label:   %s\n"), webObject.szLabel);
    _tprintf(_T("Size:    %lu\n"), webObject.dwObjectSize);
    _tprintf(_T("Digest:  %s\n"), webObject.szDigest);
    _tprintf(_T("Content: %s\n"), webObject.szContent);
}
else
{
    // The object could not be retrieved, display the error
    CString strError;

    pStorage->GetLastError(strError);
    _tprintf(_T("Unable to retrieve \"%s\" (%s)\n"), lpszObjectLabel,
(LPCTSTR)strError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cswebv10.lib

Unicode: Implemented as Unicode and ANSI versions.

CWebStorage::EnableTrace Method

```
BOOL EnableTrace(  
    LPCTSTR lpszTraceFile,  
    DWORD dwTraceFlags  
);
```

The **EnableTrace** method enables the logging of socket method calls to a file.

Parameters

lpszTraceFile

A pointer to a string which specifies the name of the trace log file. If this parameter is NULL or an empty string, the default file name **cstrace.log** is used. The file is stored in the directory specified by the TEMP environment variable, if it is defined; otherwise, the current working directory is used.

dwTraceFlags

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
TRACE_INFO	All method calls are written to the trace file. This is the default value.
TRACE_ERROR	Only those method calls which fail are recorded in the trace file.
TRACE_WARNING	Only those method calls which fail or return values which indicate a warning are recorded in the trace file.
TRACE_HEXDUMP	All methods calls are written to the trace file, plus all the data that is sent or received is displayed, in both ASCII and hexadecimal format.
TRACE_PROCESS	All method calls in the current process are logged, rather than only those methods in the current thread. This option is useful for multithreaded applications that are using worker threads.

Return Value

If the method succeeds, the return value is non-zero. A return value of zero indicates an error. Failure typically indicates that the tracing library **cstrcv10.dll** cannot be loaded on the local system.

Remarks

When trace logging is enabled, the file is opened, appended to and closed for each socket method call. This makes it possible for an application to append its own logging information, however care should be taken to ensure that the file is closed before the next network operation is performed. To limit the size of the log files, enable and disable logging only around those sections of code that you wish to trace.

Note that the TRACE_HEXDUMP trace level generates very large log files since it includes all of the data exchanged between your application and the server.

Trace method logging is managed on a per-thread basis, not for each client handle. This means that all SocketTools libraries and components share the same settings in the current thread. If you

are using multiple SocketTools libraries or components in your application, you only need to enable logging once.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswebv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[DisableTrace](#)

CWebStorage::EnumObjects Method

```
BOOL EnumObjects(  
    LPCTSTR lpszMatchLabel,  
    LPCTSTR lpszContentType,  
    LPWEB_STORAGE_OBJECT& lpObjects,  
    DWORD& dwObjects  
);  
  
DWORD EnumObjects(  
    LPCTSTR lpszMatchLabel,  
    LPCTSTR lpszContentType  
);
```

The **EnumObjects** method enumerates all storage objects that match the specified label or content type.

Parameters

lpszMatchLabel

A pointer to a null terminated string which specifies the value to match against the object labels in the container. The string may contain wildcard characters similar to those use with the Windows filesystem. A "?" character matches any single character, and "*" matches any number of characters in the label. If this value is a NULL pointer or an empty string, all objects in the container will be matched.

lpszContentType

A pointer to a null terminated string which specifies the content type of the objects to be enumerated. If this value is a NULL pointer or an empty string, the content type is ignored and all matching objects are returned.

lpObjects

A pointer to an array of [WEB_STORAGE_OBJECT](#) structures that will contain information about the enumerated objects. If this parameter is NULL, then no object information is returned.

lpdwObjects

A pointer to an unsigned integer that will contain the number of objects enumerated by this method. If the *lpObjects* parameter points to an array of [WEB_STORAGE_OBJECT](#) structures, this parameter must be initialized to the maximum size of the array being passed to the method. If the *lpObjects* parameter is NULL, this value must be initialized to zero, and when the method returns it will contain the number of matching objects.

Return Value

If the method succeeds, the return value is a non-zero. If the method fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

The **EnumObjects** method can be used to enumerate the number of objects that match a given label, content type or both. If a content type is specified, it must be a valid MIME media content type designated using the type/subtype nomenclature. For example, "text/plain" or "image/jpeg". An invalid MIME type will cause the method to fail.

This method can be used in two ways. If the *lpObjects* parameter is NULL and the value passed by reference in the *lpdwObjects* parameter is initialized to zero, the method will return the number of matching objects in *lpdwObjects*. This can be used to dynamically determine the size of the

lpObjects array instead of declaring a fixed-size array in your application.

If the *lpObjects* parameter is not NULL, then the value referenced by *lpdwObjects* must be initialized to the maximum size of the array that *lpObjects* points to. It is important to note that if either parameter is not initialized correctly, it can result in memory corruption and/or an unhandled exception.

There is an alternative version of **EnumObjects** which only returns a count of objects that match the specified content type and/or object label name, without returning information about the objects. This can be used to determine how many objects match the given criteria prior to requesting the object metadata.

The **GetFirstObject** and **GetNextObject** methods can be used to iterate through all matching storage objects without allocating memory to store all of the matching objects. Using **GetFirstObject** and **GetNextObject** is more efficient when the container contains a large number of objects that match the specified label and/or content type.

Example

```
DWORD dwObjects = 0;
LPWEB_STORAGE_OBJECT lpObjects = NULL;

if (pStorage->EnumObjects(_T("*.pdf"), NULL, lpObjects, dwObjects))
{
    // Print information about each object
    for (DWORD dwIndex = 0; dwIndex < dwObjects; dwIndex++)
    {
        _tprintf(_T("Object: %s\n"), lpObjects[dwIndex].szObjectId);
        _tprintf(_T("Label: %s\n"), lpObjects[dwIndex].szLabel);
        _tprintf(_T("Size: %lu\n"), lpObjects[dwIndex].dwObjectSize);
        _tprintf(_T("Digest: %s\n"), lpObjects[dwIndex].szDigest);
        _tprintf(_T("Content: %s\n"), lpObjects[dwIndex].szContent);

        if (dwObjects > 1 && dwIndex < dwObjects - 1)
            _tprintf(_T("\n"));
    }
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswebv10.lib

Unicode: Implemented as Unicode and ANSI versions.

CWebStorage::GetAccountId Method

```
BOOL GetAccountId(  
    LPCTSTR lpszAccountId,  
    INT nMaxLength  
);  
  
BOOL GetAccountId(  
    CString& strAccountId  
);
```

The **GetAccountId** method returns the web services account ID associated with the current session.

Parameters

lpszAccountId

A pointer to a null-terminated string that will contain the account ID when the method returns. This parameter cannot be NULL and must be at least 35 characters in length. An alternate form of the method accepts a **CString** variable which will contain the account ID.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the *lpszAccountId* string parameter, including the terminating null character.

Return Value

If the method succeeds, the return value is a non-zero. If the method fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

The account ID is a string that uniquely identifies the web services account that is associated with the session. The account ID corresponds with your product serial number and runtime license key, but it is not identical to either of those values.

If you are using an evaluation license, the account ID is temporary and only valid during the evaluation period. After the evaluation period has expired, the account ID is revoked and objects stored using this ID will be deleted. It is not recommended that you store critical application data using an evaluation license.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswebv10.lib

Unicode: Implemented as Unicode and ANSI versions.

CWebStorage::GetErrorString Method

```
INT GetErrorString(  
    DWORD dwErrorCode,  
    LPTSTR lpszDescription,  
    INT cbDescription  
);  
  
INT GetErrorString(  
    DWORD dwErrorCode,  
    CString& strDescription  
);
```

The **GetErrorString** method is used to return a description of a specific error code. Typically this is used in conjunction with the **GetLastError** method for use with warning dialogs or as diagnostic messages.

Parameters

dwErrorCode

The error code for which a description is returned.

lpszDescription

A pointer to the buffer that will contain a description of the specified error code. This buffer should be at least 128 characters in length. An alternate form of the method accepts a **CString** variable which will contain the error description.

cbDescription

The maximum number of characters that may be copied into the description buffer.

Return Value

If the method succeeds, the return value is the length of the description string. If the method fails, the return value is zero, meaning that no description exists for the specified error code. Typically this indicates that the error code passed to the method is invalid.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cswebv10.lib

Unicode: Implemented as Unicode and ANSI versions.

CWebStorage::GetData Method

```
BOOL GetData(  
    LPCTSTR lpszObjectLabel,  
    LPBYTE lpBuffer,  
    LPDWORD lpdwLength,  
    LPWEB_STORAGE_OBJECT lpObject,  
);
```

```
BOOL GetData(  
    LPCTSTR lpszObjectLabel,  
    HGLOBAL * lphgblBuffer,  
    LPDWORD lpdwLength,  
    LPWEB_STORAGE_OBJECT lpObject,  
);
```

```
BOOL GetData(  
    LPCTSTR lpszObjectLabel,  
    LPTSTR lpszBuffer,  
    INT nMaxLength,  
    LPWEB_STORAGE_OBJECT lpObject,  
);
```

```
BOOL GetData(  
    LPCTSTR lpszObjectLabel,  
    CString& strBuffer,  
    LPWEB_STORAGE_OBJECT lpObject,  
);
```

The **GetData** method retrieves the contents of a storage object and copies it to the memory buffer that is provided. Additional information about the object is optionally returned to the caller.

Parameters

lpszObjectLabel

A pointer to a null terminated string that specifies the label of the object that should be retrieved from the server.

lpBuffer

A pointer to a byte array which will contain the object's data. When this version of the method is called, the buffer must be pre-allocated by the application and large enough to store all of the data or the method will fail. The *lpdwLength* parameter must be initialized with the maximum size of the byte array, and will be updated with the actual number of bytes copied into the buffer when the method returns.

lphgblBuffer

A pointer to a HGLOBAL memory handle. When this version of the method returns, the handle will reference a block of memory allocated by the **GlobalAlloc** function and the *lpdwLength* parameter will contain the number of bytes copied. To obtain a pointer to the data, the application must call the **GlobalLock** function. It is the responsibility of the application to free the global memory handle when it is no longer needed.

lpszBuffer

A pointer to a string buffer which will contain the object's text when the method returns. When this version of the method is called, the string will be populated with the object contents and terminated with a null character. The *nMaxLength* parameter must specify the maximum

number of characters that can be copied into the string, including the terminating null. This version of the function should only be used with text and must never be used with binary data.

strBuffer

A **CString** which will contain the object's text when the method returns. This version of the method requires the application be compiled with MFC or ATL support. This version of the function should only be used with text and must never be used with binary data.

lpdwLength

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the *lpBuffer* parameter. If the *lpBuffer* parameter points to a global memory handle, the length value should be initialized to zero. When the method returns, this value will be updated with the actual length of the file that was downloaded.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the *lpzBuffer* string buffer provided by the caller. This value must be large enough to contain the entire contents of the object, including the terminating null character.

lpObject

A pointer to a [WEB_STORAGE_OBJECT](#) structure that will contain additional information about the object. This parameter may be omitted or NULL if the information is not required.

Return Value

If the method succeeds, the return value is a non-zero. If the method fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

The **GetData** method is used to retrieve a stored object from the server and copy it into a local buffer. The method may be used in one of several ways, depending on the needs of the application. The first method is to pre-allocate a buffer large enough to store the contents of the object. In this case, the *lpBuffer* parameter will point to the buffer that was allocated and the value that the *lpdwLength* parameter points to should be initialized to the size of that buffer.

The second method that can be used is to provide a pointer to an HGLOBAL global memory handle which will contain the file data when the method returns. In this case, the value that the *lpdwLength* parameter points to must be initialized to zero. It is important to note that the memory handle returned by the method must be freed by the application, otherwise a memory leak will occur. See the example code below.

The third method is to provide a string buffer which will contain the contents of a text object. The *nMaxLength* parameter must specify a size large enough to contain the entire object text, including a terminating null character. If the **PutData** method was previously used to store UTF-16 encoded text, you must use a byte array to retrieve that data. This method only recognizes UTF-8 encoded text and considers UTF-16 encoded text to be binary data. This version of the method should never be used to retrieve data from an object that does not contain text.

If you wish to retrieve the contents of an object and store it in a file, use the **GetFile** method.

Additional metadata about the object can be returned in a [WEB_STORAGE_OBJECT](#) structure provided by the caller, such as the date and time the object was created, the content type and the SHA-256 hash of the object contents.

Example

```

HGLOBAL hgblBuffer = (HGLOBAL)NULL;
DWORD dwLength = 0;
LPCTSTR lpszObjectLabel = _T("MyAppData");

// Open the default global storage container
if (!pStorage->OpenStorage(WEB_STORAGE_GLOBAL))
{
    _tprintf(_T("Unable to open global storage\n"));
    return;
}

// Return the file data into block of global memory allocated by
// the GlobalAlloc method; the handle to this memory will be
// returned in the hgblBuffer parameter
if (pStorage->GetData(lpszObjectLabel, &hgblBuffer, &dwLength))
{
    // Lock the global memory handle, returning a pointer to the
    // resource data
    LPBYTE lpBuffer = (LPBYTE)GlobalLock(hgblBuffer);

    // After the data has been used, the handle must be unlocked
    // and freed, otherwise a memory leak will occur
    GlobalUnlock(hgblBuffer);
    GlobalFree(hgblBuffer);
}
else
{
    // The GetData method failed
    _tprintf(_T("Unable to retrieve object \"%s\"\n"), lpszObjectLabel);
}

```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswebv10.lib

Unicode: Implemented as Unicode and ANSI versions.

CWebStorage::GetFile Method

```
BOOL GetFile(  
    LPCTSTR lpszLocalFile,  
    LPCTSTR lpszObjectLabel,  
    LPWEB_STORAGE_OBJECT lpObject  
);
```

The **GetFile** method downloads the contents of a storage object and copies it to a local file.

Parameters

lpszLocalFile

A pointer to a null terminated string that specifies the name of the local file that will be created or overwritten with the contents of the storage object. If a path is not specified, the file will be created in the current working directory.

lpszObjectLabel

A pointer to a null terminated string that specifies the label of the object that should be retrieved from the server.

lpObject

A pointer to a [WEB_STORAGE_OBJECT](#) structure that will contain additional information about the object. This parameter may be omitted or NULL if the information is not required.

Return Value

If the method succeeds, the return value is a non-zero. If the method fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

If you are downloading a large object and want your application to receive progress updates during the data transfer, use the **RegisterEvent** method and provide a pointer to a static callback function that will receive event notifications.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `cswebv10.lib`

GetFirstApplication Method

```
BOOL GetFirstApplication(  
    LPWEB_STORAGE_APPLICATION LpAppInfo  
);
```

The **GetFirstApplication** method returns information about the first registered application for the current storage account.

Parameters

LpAppInfo

A pointer to a [WEB_STORAGE_APPLICATION](#) structure that will contain information about the registered application when the function returns. This parameter cannot be NULL.

Return Value

If the method succeeds, the return value is a non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **GetFirstApplication** method returns information about the first registered application. It is used in conjunction with the **GetNextApplication** method to enumerate all of the registered application IDs associated with your storage account.

The cached application ID information used by this method is shared by the entire process. Attempting to enumerate all registered application IDs in multiple threads at the same time can yield unexpected results. It is recommended that multi-threaded clients use a critical section to ensure that only a single thread is enumerating the AppIDs at any one time.

Example

```
WEB_STORAGE_APPLICATION webApp;  
  
if (pStorage->GetFirstApplication(&webApp))  
{  
    do  
    {  
        // Print information for each registered application  
        _tprintf(_T("AppId: %s\n"), webApp.szAppId);  
        _tprintf(_T("Key: %s\n"), webApp.szApiKey);  
        _tprintf(_T("LUID: %s\n"), webApp.szLuid);  
        _tprintf(_T("Tokens: %lu\n"), webApp.dwTokens);  
        _tprintf(_T("\n"));  
    }  
    while (pStorage->GetNextApplication(&webApp));  
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswebv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[GetNextApplication](#), [RegisterAppId](#), [UnregisterAppId](#)

GetFirstObject Method

```
BOOL GetFirstObject(  
    LPWEB_STORAGE_OBJECT LpObject  
);  
  
BOOL GetFirstObject(  
    LPCTSTR LpszMatchLabel,  
    LPWEB_STORAGE_OBJECT LpObject  
);  
  
BOOL GetFirstObject(  
    LPCTSTR LpszMatchLabel,  
    LPCTSTR LpszContentType,  
    LPWEB_STORAGE_OBJECT LpObject  
);
```

The **GetFirstObject** method returns information about the first storage object that matches the specified label or content type.

Parameters

LpszMatchLabel

A pointer to a null terminated string which specifies the value to match against the object labels in the container. The string may contain wildcard characters similar to those use with the Windows filesystem. A "?" character matches any single character, and "*" matches any number of characters in the label. If this parameter is omitted, a NULL pointer or an empty string, all objects in the container will be matched.

LpszContentType

A pointer to a null terminated string which specifies the content type of the objects to be enumerated. If this parameter is omitted, a NULL pointer or an empty string, the content type is ignored and all matching objects are returned. If a content type is specified, it must be a valid MIME media content type designated using the type/subtype nomenclature.

LpObject

A pointer to a [WEB_STORAGE_OBJECT](#) structure that will contain information about the storage object when the function returns. This parameter cannot be NULL.

Return Value

If the function succeeds, the return value is a non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **GetFirstObject** method returns information about the first object that matches a given label, content type or both. It is used in conjunction with the **GetNextObject** method to enumerate all of the matching objects in the storage container.

This method provides an alternative to the **EnumObjects** method, which populates an array of [WEB_STORAGE_OBJECT](#) structures. In some cases, iterating over each object in a loop may be preferred to preallocating memory for an array to store every matching object. Using **GetFirstObject** and **GetNextObject** is more efficient when the container contains a large number of objects that match the specified label and/or content type.

You cannot intermix calls between **GetFirstObject** and **EnumObjects**. The **EnumObjects** method will reset the internal object cache for the client session and subsequent calls to **GetNextObject**

will fail.

Example

```
WEB_STORAGE_OBJECT webObject;

if (pStorage->GetFirstObject(&webObject))
{
    do
    {
        // Print information about each object
        _tprintf(_T("Object: %s\n"), webObject.szObjectId);
        _tprintf(_T("Label: %s\n"), webObject.szLabel);
        _tprintf(_T("Size: %lu\n"), webObject.dwObjectSize);
        _tprintf(_T("Digest: %s\n"), webObject.szDigest);
        _tprintf(_T("Content: %s\n"), webObject.szContent);
        _tprintf(_T("\n"));
    }
    while (pStorage->GetNextObject(&webObject));
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswebv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[EnumObjects](#), [GetNextObject](#)

CWebStorage::GetHandle Method

```
HSTORAGE GetHandle();
```

The **GetHandle** method returns the storage handle associated with the current instance of the class.

Parameters

None.

Return Value

This method returns the client handle associated with the current instance of the class object. If there is no active client session, the value `INVALID_HANDLE` will be returned.

Remarks

This method is used to obtain the storage handle created by the class for use with the SocketTools API.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `cswebv10.lib`

See Also

[IsInitialized](#)

CWebStorage::GetLastError Method

```
DWORD GetLastError();  
  
DWORD GetLastError(  
    CString& strDescription  
);
```

Parameters

strDescription

A string which will contain a description of the last error code value when the method returns. If no error has been set, or the last error code has been cleared, this string will be empty.

Return Value

The return value is the last error code value for the current thread. Methods set this value by calling the **SetLastError** method. The Return Value section of each reference page notes the conditions under which the method sets the last error code.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. You should call the **GetLastError** method immediately when a method's return value indicates that an error has occurred. That is because some methods call **SetLastError(0)** when they succeed, clearing the error code set by the most recently failed method.

Most methods will set the last error code value when they fail; a few methods set it when they succeed. Method failure is typically indicated by a return value such as FALSE, NULL, INVALID_HANDLE or WEBAPI_ERROR. Those methods which call **SetLastError** when they succeed are noted on the method reference page.

The description of the error code is the same string that is returned by the **GetErrorString** method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cswebv10.lib

See Also

[GetErrorString](#), [SetLastError](#), [ShowError](#)

GetNextApplication Function

```
BOOL GetNextApplication(  
    LPWEB_STORAGE_APPLICATION LpAppInfo  
);
```

The **GetNextApplication** method returns information about the next registered application for the current storage account.

Parameters

LpAppInfo

A pointer to a [WEB_STORAGE_APPLICATION](#) structure that will contain information about the registered application when the function returns. This parameter cannot be NULL.

Return Value

If the method succeeds, the return value is a non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **GetNextApplication** method returns information about the next registered application after initially calling the **GetFirstApplication** method. It is used to enumerate all of the registered application IDs associated with your storage account.

The cached application ID information used by this method is shared by the entire process. Attempting to enumerate all registered application IDs in multiple threads at the same time can yield unexpected results. It is recommended that multi-threaded clients use a critical section to ensure that only a single thread is enumerating the AppIDs at any one time.

Example

```
WEB_STORAGE_APPLICATION webApp;  
  
if (pStorage->GetFirstApplication(&webApp))  
{  
    do  
    {  
        // Print information for each registered application  
        _tprintf(_T("AppId: %s\n"), webApp.szAppId);  
        _tprintf(_T("Key: %s\n"), webApp.szApiKey);  
        _tprintf(_T("LUID: %s\n"), webApp.szLuid);  
        _tprintf(_T("Tokens: %lu\n"), webApp.dwTokens);  
        _tprintf(_T("\n"));  
    }  
    while (pStorage->GetNextApplication(&webApp));  
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswebv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[GetFirstApplication](#), [RegisterAppId](#), [UnregisterAppId](#)

GetNextObject Method

```
BOOL GetNextObject(  
    LPWEB_STORAGE_OBJECT lpObject  
);
```

The **GetNextObject** method returns information about the next storage object that matches the specified label or content type.

Parameters

lpObject

A pointer to a [WEB_STORAGE_OBJECT](#) structure that will contain information about the storage object when the function returns. This parameter cannot be NULL.

Return Value

If the function succeeds, the return value is a non-zero. If the function fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **GetNextObject** method returns information about the next object that matches the label and/or content type that was specified by the **GetFirstObject** method. This method may only be called after **GetFirstObject** has been called, otherwise it will fail.

When all matching objects have been returned to the caller, this method will return zero (FALSE) and the **GetLastError** method will return NO_ERROR. Any other error code indicates an underlying problem with the request, such as an invalid parameter passed to the function.

You cannot intermix calls between **GetNextObject** and **EnumObjects**. The **EnumObjects** method will reset the internal object cache for the client session and subsequent calls to **GetNextObject** will fail.

Example

```
WEB_STORAGE_OBJECT webObject;  
  
if (pStorage->GetFirstObject(&webObject))  
{  
    do  
    {  
        // Print information about each object  
        _tprintf(_T("Object: %s\n"), webObject.szObjectId);  
        _tprintf(_T("Label: %s\n"), webObject.szLabel);  
        _tprintf(_T("Size: %lu\n"), webObject.dwObjectSize);  
        _tprintf(_T("Digest: %s\n"), webObject.szDigest);  
        _tprintf(_T("Content: %s\n"), webObject.szContent);  
        _tprintf(_T("\n"));  
    }  
    while (pStorage->GetNextObject(&webObject));  
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cswebv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[EnumObjects](#), [GetFirstObject](#)

CWebStorage::GetObjectInformation Method

```
BOOL GetObjectInformation(  
    LPCTSTR lpszObjectLabel,  
    LPWEB_STORAGE_OBJECT lpObject  
);
```

The **GetObjectInformation** method retrieves the metadata for a storage object.

Parameters

lpszObjectLabel

A pointer to a null terminated string that specifies the label of the storage object.

lpObject

A pointer to a [WEB_STORAGE_OBJECT](#) structure that will contain additional information about the object. This parameter cannot be a NULL pointer.

Return Value

If the method succeeds, the return value is a non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **GetObjectInformation** method is used to retrieve the metadata for a stored object on the server, such as the date and time the object was created, the content type and the SHA-256 hash of the object contents. This method can also be used as a simple method to determine if the specified object exists without the overhead of requesting the server attempt to retrieve the contents of an object.

Although storage object labels are similar to Windows file names, they are case-sensitive. When requesting information about an object, your application must specify the label name exactly as it was created. The object label cannot contain wildcard characters.

If you are only interested in obtaining the size of a stored object, you can use the **GetObjectSize** method.

To obtain information about how much storage your applications are using and the total number of stored objects, use the **GetStorageQuota** method.

Example

```
WEB_STORAGE_OBJECT webObject;  
  
// Get information about the object  
if (pStorage->GetObjectInformation(lpszObjectLabel, &webObject))  
{  
    // The object exists, display the metadata  
    _tprintf(_T("Object:  %s\n"), webObject.szObjectId);  
    _tprintf(_T("Label:   %s\n"), webObject.szLabel);  
    _tprintf(_T("Size:    %lu\n"), webObject.dwObjectSize);  
    _tprintf(_T("Digest:  %s\n"), webObject.szDigest);  
    _tprintf(_T("Content: %s\n"), webObject.szContent);  
}  
else  
{  
    // The object does not exist, display the error  
    CString strError;
```

```
    pStorage->GetLastError(strError);
    _tprintf(_T("Unable to get information on \"%s\" (%s)\n"), lpszObjectLabel,
(LPCTSTR)strError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswebv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[GetFile](#), [GetData](#), [GetObjectSize](#), [GetStorageQuota](#), [PutFile](#), [PutData](#)

CWebStorage::GetObjectSize Method

```
DWORD GetObjectSize(  
    LPCTSTR lpszObjectLabel  
);  
  
BOOL GetObjectSize(  
    LPCTSTR lpszObjectLabel,  
    LPDWORD lpdwObjectSize  
);
```

The **GetObjectSize** method returns the size of the stored object.

Parameters

lpszObjectLabel

A pointer to a null terminated string that specifies the label of the storage object. This parameter cannot be a NULL pointer.

lpdwObjectSize

A pointer to an unsigned integer value that will contain the size of the object. If this parameter is NULL, the parameter is ignored and the method only checks for the existence of an object that matches the specified label.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

The **GetObjectSize** method is used to retrieve the size of a stored object on the server. This method can also be used as a simple method to determine if the specified object exists. An object size of zero means the object exists, but currently has no data associated with it.

If the first version of this method is called, where the object size is a return value, you can distinguish between an error and an empty object by calling the **GetLastError** method. If the last error code is NO_ERROR then the object exists, but it has no data associated with it. Any other error code value indicates the reason the object size could not be returned.

If the second version of this method is used and the *lpdwObjectSize* parameter is not NULL, its value is initialized to zero when the method is called, and updated with the object size when the method returns.

Although storage object labels are similar to Windows file names, they are case-sensitive. When requesting the size of an object, your application must specify the label name exactly as it was created. The object label cannot contain wildcard characters.

The **GetObjectInformation** method can be used to obtain the metadata associated with the storage object, including the size, content type, creation date and a SHA-256 digest of the data.

To obtain information about how much storage your applications are using and the total number of stored objects, use the **GetStorageQuota** method.

Example

```
// Check if the object exists  
DWORD dwObjectSize = 0;
```

```
if (pStorage->GetObjectSize(lpszObjectLabel, &dwObjectSize))
{
    // The object exists, display the size in bytes
    _tprintf(_T("The size of \"%s\" is %lu bytes\n"), lpszObjectLabel,
dwObjectSize);
}
else
{
    // The object size could not be determined, display the error
    CString strError;

    pStorage->GetErrorString(strError);
    _tprintf(_T("Unable to get the size of \"%s\" (%s)\n"), lpszObjectLabel,
(LPCTSTR)strError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswebv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[GetData](#), [GetObjectInformation](#), [GetStorageQuota](#), [PutData](#)

CWebStorage::GetStorageId Method

```
BOOL GetStorageId(  
    LPCTSTR lpszStorageId,  
    INT nMaxLength  
);  
  
BOOL GetStorageId(  
    CString & strStorageId  
);
```

The **GetStorageId** method returns the current storage container ID.

Parameters

lpszStorageId

A pointer to a null-terminated string that will contain the storage ID when the method returns. This parameter cannot be NULL and must be at least 35 characters in length. An alternate version of this method accepts a **CString** parameter if the application is compiled with support for MFC or ATL.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the *lpszStorageId* string parameter, including the terminating null character.

Return Value

If the method succeeds, the return value is a non-zero. If the method fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

The storage ID is a string that identifies the storage container that was opened with the **OpenStorage** method. The storage ID is associated with your account ID and development license and is guaranteed to be a unique value.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cswebv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[GetAccountId](#), [OpenStorage](#)

CWebStorage::GetStorageQuota Method

```
BOOL GetStorageQuota(  
    LPWEB_STORAGE_QUOTA lpQuota  
);
```

The **GetStorageQuota** method returns quota limits assigned to your development account.

Parameters

lpQuota

A pointer to a [WEB_STORAGE_QUOTA](#) structure that will contain information the quota limits for your account when the method returns. This parameter cannot be NULL.

Return Value

If the method succeeds, the return value is a non-zero. If the method fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

The **GetStorageQuota** method can be used to determine how much storage space is available to your application. The *ulBytesFree* structure member will tell you how many bytes of storage you have available, and the *dwObjectSize* member will tell you the maximum size of any individual storage object. In addition to the bytes allocated for storage, there is also a limit on the total number of objects that your application may create which is specified by the *dwObjectLimit* member.

Accounts that are created with an evaluation license have much lower quota limits than a standard account and should be used for testing purposes only. After the evaluation period has ended, all objects stored using the evaluation license will be deleted.

Example

```
CWebStorage appStorage;  
WEB_STORAGE_QUOTA appQuota;  
  
// Display storage account usage and limits  
if (appStorage.GetStorageQuota(&appQuota))  
{  
    _tprintf(_T("Objects Used: %lu\n"), appQuota.dwObjects);  
    _tprintf(_T("Object Limit: %lu\n"), appQuota.dwObjectLimit);  
    _tprintf(_T("Object Size: %lu\n"), appQuota.dwObjectSize);  
    _tprintf(_T("Bytes Used: %I64u\n"), appQuota.ulBytesUsed);  
    _tprintf(_T("Bytes Free: %I64u\n"), appQuota.ulBytesFree);  
    _tprintf(_T("Storage Limit: %I64u\n"), appQuota.ulStorageLimit);  
}  
else  
{  
    // Unable to get the quota information for this account  
    CString strError;  
  
    appStorage.GetErrorString(strError);  
    _tprintf(_T("Unable to get the account quota (%s)\n"), (LPCTSTR)strError);  
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswebv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[GetObjectInformation](#), [GetObjectSize](#), [WEB_STORAGE_QUOTA](#)

CWebStorage::GetTimeout Method

```
INT GetTimeout();
```

The **GetTimeout** method returns the number of seconds the client will wait for a response from the storage server. Once the specified number of seconds has elapsed, the method will fail and return to the caller.

Parameters

None.

Return Value

If the method succeeds, the return value is the timeout period in seconds. If the method fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

The default timeout period is 10 seconds.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswebv10.lib

See Also

[OpenStorage](#), [SetTimeout](#)

CWebStorage::GetTransferStatus Method

```
LPWEB_STORAGE_TRANSFER lpStatus  
);
```

The **GetTransferStatus** method returns information about the current data transfer in progress.

Parameters

lpStatus

A pointer to a [WEB_STORAGE_TRANSFER](#) structure which contains information about the status of the current data transfer.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

The **GetTransferStatus** method returns information about the current data transfer, including the average number of bytes transferred per second and the estimated amount of time until the transfer completes. If there is no data currently being transferred, this method will return the status of the last successful data transfer.

In a multithreaded application, any thread in the current process may call this method to obtain status information for the storage session.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswebv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[Cancel](#), [GetData](#), [PutData](#), [RegisterEvent](#)

CWebStorage::IsBlocking Method

BOOL IsBlocking();

The **IsBlocking** method is used to determine if the client is currently performing a blocking operation.

Parameters

None.

Return Value

If the client is performing a blocking operation, the method returns a non-zero value. If the client is not performing a blocking operation, or the client handle is invalid, the method returns zero.

Remarks

Because a blocking operation can potentially allow the application to be re-entered, it is possible that another blocking method may be called while it is in progress. Because only one thread of execution may perform a blocking operation at any one time, an error would occur. The **IsBlocking** method can be used to determine if the storage client is already blocked, and if so, take some other action (such as warning the user that they must wait for the operation to complete).

If your application attempts to perform multiple operations simultaneously, such as downloading multiple stored objects to the local system, each client session should be isolated in its own thread. This will avoid potential situations where a request is refused because a blocking data transfer is already in progress on the current thread.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswebv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[Cancel](#), [GetFile](#), [GetData](#), [IsConnected](#), [IsInitialized](#), [PutFile](#), [PutData](#)

CWebStorage::IsConnected Method

BOOL IsConnected();

The **IsConnected** method is used to determine if a connection has been established with the storage server.

Parameters

None.

Return Value

If the client is connected to a server, the method returns a non-zero value. If the client is not connected, or the client handle is invalid, the method returns zero. To get extended error information, call the **GetLastError** method.

Remarks

The client does not maintain a continuous, persistent connection with the storage server. The connection may be closed and reopened internally as needed. If the client session has been idle for a period of time, this method can return zero.

If the **GetLastError** method returns `ST_ERROR_NOT_CONNECTED` it means the client session is valid, however it not currently connected to the storage server. The next call to store or retrieve an object will the cause the client to reconnect automatically.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `cswebv10.lib`

See Also

[IsBlocking](#), [IsInitialized](#)

CWebStorage::IsInitialized Method

BOOL IsInitialized();

The **IsInitialized** method returns whether or not the class object has been successfully initialized.

Return Value

This method returns a non-zero value if the class object has been successfully initialized. A return value of zero indicates that the runtime license key could not be validated or the networking library could not be loaded by the current process.

Remarks

When an instance of the class is created, the class constructor will attempt to initialize the component with the runtime license key that was created when SocketTools was installed. If the constructor is unable to validate the license key or load the networking libraries, this initialization will fail.

If SocketTools was installed with an evaluation license, the application cannot be redistributed to another system. The class object will fail to initialize if the application is executed on a different system, or if the evaluation period has expired. To redistribute your application, you must purchase a development license which will include the runtime key that is needed to redistribute your software to other systems. Refer to the Developer's Guide for more information.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswebv10.lib

See Also

[CWebStorage](#), [IsBlocking](#), [IsConnected](#)

CWebStorage::MoveObject Method

```
BOOL MoveObject(  
    LPCTSTR lpszOldLabel,  
    LPCTSTR lpszNewLabel,  
    DWORD dwStorageType,  
    LPWEB_STORAGE_OBJECT lpObject  
);
```

The **MoveObject** method moves an existing object to a different storage container.

Parameters

lpszOldLabel

A pointer to a null terminated string which specifies the name of the existing storage object to be moved. This parameter must specify a valid object label and cannot be a NULL pointer or an empty string.

lpszNewLabel

A pointer to a null terminated string which specifies a new label for the storage object being moved. This parameter may be NULL or point to an empty string, in which case the label name is not changed.

dwStorageType

An integer value that identifies the storage container type. If this parameter is omitted, the object is renamed and not moved to another container. One of the following values may be specified:

Constant	Description
WEB_STORAGE_GLOBAL (1)	Global storage. Objects stored using this storage type are available to all users. Any changes made to objects using this storage type will affect all users of the application. Unless there is a specific need to limit access to the objects stored by the application to specific domains, local machines or users, it is recommended that you use this storage type when creating new objects.
WEB_STORAGE_DOMAIN (2)	Local domain storage. Objects stored using this storage type are only available to users in the same local domain, as defined by the domain name or workgroup name assigned to the local system. If the domain or workgroup name changes, objects previously stored using this storage type will not be available to the application.
WEB_STORAGE_MACHINE (3)	Local machine storage. Objects stored using this storage type are only available to users on the same local machine. The local machine is identified by unique characteristics of the system, including the boot volume GUID. Objects previously stored using this storage type will not be available on that system if the boot disk is reformatted.
WEB_STORAGE_USER (4)	Current user storage. Objects stored using this storage type are only available to the current user logged in on

the local machine. The user identifier is based on the Windows user SID that is assigned when the user account is created. If the user account is deleted, the objects previously stored using this storage type will not be available to the application.

lpObject

A pointer to a [WEB_STORAGE_OBJECT](#) structure that will contain information about the new storage object. If this information is not required, this parameter may be omitted or a NULL pointer.

Return Value

If the method succeeds, the return value is a non-zero. If the method fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

The **MoveObject** method is used to move an existing storage object to a new container. For example, it can move an object originally created using `WEB_STORAGE_USER` to the `WEB_STORAGE_MACHINE` container. The *dwStorageType* parameter must specify a valid storage container type and cannot be `WEB_STORAGE_DEFAULT`.

If the *dwStorageType* parameter specifies the same container that the object is currently in, and the *lpzNewLabel* parameter specifies a new label name, this method will simply rename the existing object and is effectively the same as calling the **RenameObject** method.

To duplicate an existing storage object, use the **CopyObject** method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `cswebv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

CWebStorage::OpenStorage Method

```
BOOL OpenStorage(  
    DWORD dwStorageType  
);
```

```
BOOL OpenStorage(  
    LPCTSTR lpszAppId,  
    DWORD dwStorageType  
);
```

The **OpenStorage** method establishes a connection with the server and opens the storage container associated with the specified storage type.

Parameters

lpszAppId

A pointer to null terminated string which specifies the application ID for the storage container. The application ID is a string that uniquely identifies the application and can only contain letters, numbers, the period and the underscore character. If this parameter is omitted, NULL or an empty string, the default identifier **SocketTools.Storage.Default** will be used.

dwStorageType

An integer value that identifies the storage container type. If this parameter is omitted, the WEB_STORAGE_GLOBAL container will be opened. One of the following values may be specified:

Constant	Description
WEB_STORAGE_GLOBAL (1)	Global storage. Objects stored using this storage type are available to all users. Any changes made to objects using this storage type will affect all users of the application. Unless there is a specific need to limit access to the objects stored by the application to specific domains, local machines or users, it is recommended that you use this storage type when creating new objects.
WEB_STORAGE_DOMAIN (2)	Local domain storage. Objects stored using this storage type are only available to users in the same local domain, as defined by the domain name or workgroup name assigned to the local system. If the domain or workgroup name changes, objects previously stored using this storage type will not be available to the application.
WEB_STORAGE_MACHINE (3)	Local machine storage. Objects stored using this storage type are only available to users on the same local machine. The local machine is identified by unique characteristics of the system, including the boot volume GUID. Objects previously stored using this storage type will not be available on that system if the boot disk is reformatted.
WEB_STORAGE_USER (4)	Current user storage. Objects stored using this storage type are only available to the current user logged in on the local machine. The user identifier is based on the

Windows user SID that is assigned when the user account is created. If the user account is deleted, the objects previously stored using this storage type will not be available to the application.

Return Value

If the method succeeds, the return value is a handle to the storage container. If the method fails, the return value is `INVALID_HANDLE`. To get extended error information, call the **GetLastError** method.

Remarks

The **OpenStorage** method opens the specified storage container and requests an access token for the application. This is the first method that must be called prior to accessing any stored objects.

The application ID is a string that uniquely identifies the application requesting the access and must have been previously registered with the server by calling the **RegisterAppId** method. If the *lpzAppId* parameter is `NULL` or an empty string, the method will use a default internal ID that is allocated for each storage account. You can use this default ID if you wish to share data between all of the applications you create.

The storage type specifies the type of container that objects will be stored in. In most cases, we recommend using `WEB_STORAGE_GLOBAL` which means that stored objects will be accessible to all users of your application. However, you can limit access to the stored objects based on the local domain, local machine ID or the current user SID.

If you specify anything other than global storage, objects can be orphaned if the system configuration changes. For example, if `WEB_STORAGE_MACHINE` is specified the objects that are stored can only be accessed from that system. If the system is reconfigured (for example, the boot volume formatted and Windows is reinstalled) the unique identifier for that system will change and the previous objects that were stored by your application can no longer be accessed.

It is advisable to store critical application data and configuration information using `WEB_STORAGE_GLOBAL` and use other non-global storage containers for configuration information that is unique to that system and/or user which is not critical and can be easily recreated.

If a storage container was previously opened, calling this method will automatically close the current container and open the new container specified by the *dwStorageType* parameter. This can change the internal handle value used to reference the container and the old handle will no longer be valid.

Example

```
CWebStorage appStorage;
LPCTSTR lpzAppId = _T("MyCompany.WebTest.1");
LPCTSTR lpzLocalFile = _T("TestDocument.pdf");
LPCTSTR lpzObjectLabel = _T("TestDocument.pdf");
WEB_STORAGE_OBJECT webObject = { 0, };

// Register the application ID which identifies the application
if (!appStorage.RegisterAppId(lpzAppId))
{
    tprintf(_T("Unable to register the application ID"));
    _exit(0);
}
```

```

// Open the application storage container
if (!appStorage.OpenStorage(lpszAppId, WEB_STORAGE_GLOBAL);
{
    _tprintf(_T("Unable to open global storage for this application"));
    _exit(0);
}

// Upload a local file to the storage server and return information
// about the stored object when it completes
if (appStorage.PutFile(lpszLocalFile, lpszObjectLabel, &webObject))
{
    // Print information about the object that was created
    _tprintf(_T("Object: %s\n"), webObject.szObjectId);
    _tprintf(_T("Label: %s\n"), webObject.szLabel);
    _tprintf(_T("Size: %lu\n"), webObject.dwObjectSize);
    _tprintf(_T("Digest: %s\n"), webObject.szDigest);
    _tprintf(_T("Content: %s\n"), webObject.szContent);
}
else
{
    // The upload failed, display error information
    CString strError;

    appStorage.GetLastError(strError);
    _tprintf(_T("Cannot store \"%s\" (%s)\n"), lpszLocalFile,
(LPCTSTR)strError);
}

// Release the handle allocated for this storage session
appStorage.CloseStorage();

```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstoools10.h

Import Library: cswebv10.lib

Unicode: Implemented as Unicode and ANSI versions.

CWebStorage::PutData Method

```
BOOL PutData(  
    LPCTSTR lpszObjectLabel,  
    LPCVOID lpvBuffer,  
    DWORD dwLength,  
    LPWEB_STORAGE_OBJECT LpObject  
);
```

```
BOOL PutData(  
    LPCTSTR lpszObjectLabel,  
    LPCTSTR lpszObjectText,  
    INT cchObjectText,  
    LPWEB_STORAGE_OBJECT LpObject  
);
```

```
BOOL PutData(  
    LPCTSTR lpszObjectLabel,  
    LPCVOID lpvBuffer,  
    DWORD dwLength,  
    LPCTSTR lpszContentType,  
    DWORD dwAttributes,  
    LPWEB_STORAGE_OBJECT LpObject  
);
```

The **PutData** method stores the contents of buffer to a container and returns information about the new object.

Parameters

lpszObjectLabel

A pointer to a null terminated string that specifies the label of the storage object that will be created or replaced. This parameter cannot be NULL or a zero-length string. The method will fail if the label contains any illegal characters.

lpvBuffer

A pointer to a buffer that contains the data to be stored. If this parameter is NULL, the *dwLength* parameter must have a value of zero and a storage object will be created which has no data associated with it.

dwLength

An unsigned integer value that specifies the number of bytes that will be copied from the *lpvBuffer* parameter and stored in the object. If the *lpvBuffer* parameter is NULL, this value must be zero or the method will fail.

lpszObjectText

A pointer to a null terminated string which is used with an alternate version of this method. The string will be stored as a text object and the *cchObjectText* parameter will specify the number of characters to be stored.

cchObjectText

An integer value that specifies the number of characters that will be copied from the *lpszObjectText* string and stored in the object. If the *lpszObjectText* parameter is NULL, this value must be zero or the method will fail. If this parameter is omitted, the length of the string will be calculated by counting the number of characters up to the terminating null.

lpzContentType

A pointer to a null terminated string that identifies the contents of the buffer being stored. If this parameter is omitted, a NULL pointer, or specifies a zero-length string, the method will attempt to automatically determine the content type based on the object label and the contents of the buffer.

dwAttributes

An unsigned integer that specifies the attributes associated with the storage object. If this parameter is omitted, the default value `WEB_OBJECT_NORMAL` will be used. This value can be a combination of one or more of the following bitflags using a bitwise OR operation:

Value	Constant	Description
0	<code>WEB_OBJECT_DEFAULT</code>	Default object attributes. This value is used to indicate the object can be modified, or that the attributes for a previously existing object should not be changed.
1	<code>WEB_OBJECT_NORMAL</code>	A normal object that that can be read and modified by the application. This is the default attribute for new objects that are created by the application.
2	<code>WEB_OBJECT_READONLY</code>	A read-only object that can only be read by the application. Attempts to modify or replace the contents of the object will fail. Read-only objects can be deleted.
4	<code>WEB_OBJECT_HIDDEN</code>	A hidden object. Objects with this attribute are not returned when enumerated using the EnumObjects method. The object can only be accessed directly when specifying its label.

lpObject

A pointer to a [WEB_STORAGE_OBJECT](#) structure that will contain additional information about the object that was created or replaced. This parameter may be omitted or NULL if the information is not required.

Return Value

If the method succeeds, the return value is a non-zero. If the method fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

The **PutData** method uploads the contents of a buffer to the current storage container. The content type, which identifies the type of data stored in the object, and its attributes may be specified by the caller or default values may be used.

If a content type is provided, it must specify a valid MIME media type and subtype. For example, normal text files have a content type of **text/plain** while an XML-formatted text file would have a content type of **text/xml**. Files that contain unstructured binary data are typically identified as **application/octet-stream**.

If the label identifies an object that already exists in the container, and that object was created with the `WEB_OBJECT_READONLY` attribute, this method will fail. To replace a read-only object, the application must explicitly move, rename or delete the existing object.

If **PutData** method is used to store the contents of a string as a text object, the string should be terminated with a null character and cannot contain embedded nulls. If the Unicode version of this function is called, the contents of the string will be normalized prior to being converted to UTF-8 using canonical composition, where decomposed characters are combined to create their canonical precomposed equivalent.

The size of the text object that is created can be different from the length of the string buffer passed to this method, depending on how the text has been encoded and stored. This will almost always be the case when the Unicode version of this function is called because the UTF-16 string will be converted and stored as UTF-8 encoded text. This encoding will typically increase the size of the stored object unless the string only contains ASCII characters.

The version of the **PutData** method which accepts a string should only be used to store textual data in a null terminated string, and should never be used to store binary data. If you wish to create or update an object which contains binary data, you should always use use a byte array.

If you want to upload the contents of a file, the **PutFile** method simplifies this process. The example code below demonstrates how the Windows API can be used to read from a local file and store the contents using **PutData**.

If you are storing a large amount of data and want your application to receive progress updates during the data transfer, use the **RegisterEvent** method and provide a pointer to a static callback method that will receive event notifications.

Example

```
HANDLE hFile = INVALID_HANDLE_VALUE;
LPBYTE lpContents = NULL;
DWORD dwLength = 0;
BOOL bFileRead = FALSE;
WEB_STORAGE_OBJECT webObject;

// Open a file on the local system and read the contents
// into a buffer that will be stored on the server
hFile = CreateFile(lpszLocalFile,
                  GENERIC_READ,
                  0,
                  NULL,
                  OPEN_EXISTING,
                  FILE_ATTRIBUTE_NORMAL,
                  NULL);

if (hFile == INVALID_HANDLE_VALUE)
{
    // Unable to open the file
    return;
}

// Get the size of the file and allocate a buffer large
// enough to store the contents of the file
dwLength = GetFileSize(hFile, NULL);
lpContents = (LPBYTE)LocalAlloc(LPTR, dwLength + 1);

if (lpContents == NULL)
{
    // Memory allocation failed
    return;
}
```

```

bFileRead = ReadFile(hFile, lpContents, dwLength, &dwLength, NULL);
CloseHandle(hFile);

if (!bFileRead)
{
    // Unable to read the contents of the file
    return;
}

// Store the contents of the buffer, identifying it as an unstructured
// stream of bytes, and the object is created with read/write access
if (pStorage->PutData(lpszObjectLabel, lpContents, dwLength, &webObject))
{
    // The object was created or replaced, display the metadata
    _tprintf(_T("Object:  %s\n"), webObject.szObjectId);
    _tprintf(_T("Label:   %s\n"), webObject.szLabel);
    _tprintf(_T("Size:    %lu\n"), webObject.dwObjectSize);
    _tprintf(_T("Digest:  %s\n"), webObject.szDigest);
    _tprintf(_T("Content: %s\n"), webObject.szContent);
}
else
{
    // The object could not be created
    CString strError;

    pStorage->GetLastError(strError);
    _tprintf(_T("Unable to create \"%s\" (%s)\n"), lpszObjectLabel,
(LPCTSTR)strError);
}

```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswebv10.lib

Unicode: Implemented as Unicode and ANSI versions.

CWebStorage::PutFile Method

```
BOOL PutFile(  
    LPCTSTR lpszLocalFile,  
    LPCTSTR lpszObjectLabel,  
    LPWEB_STORAGE_OBJECT lpObject  
  
    LPCTSTR lpszLocalFile,  
    LPCTSTR lpszObjectLabel,  
    LPCTSTR lpszContentType,  
    DWORD dwAttributes,  
    LPWEB_STORAGE_OBJECT lpObject  
);
```

The **PutFile** method uploads the contents of a local file to a storage container and returns information about the new object.

Parameters

lpszLocalFile

A pointer to a null terminated string that specifies the name of the local file that will be uploaded. If a path is not specified, the file will be read from the current working directory. The current user must have read access to the file, and an error will be returned if the method cannot obtain an exclusive lock on the file during the upload process.

lpszObjectLabel

A pointer to a null terminated string that specifies the label of the storage object that will be created or replaced. This parameter cannot be NULL or a zero-length string. The method will fail if the label contains any illegal characters.

lpszContentType

A pointer to a null terminated string that identifies the contents of the file being uploaded. If this parameter is omitted, a NULL pointer, or specifies a zero-length string, the method will attempt to automatically determine the content type based on the file name extension and the contents of the file.

dwAttributes

An unsigned integer that specifies the attributes associated with the storage object. If this parameter is omitted, a default value of WEB_OBJECT_NORMAL will be used. This value can be a combination of one or more of the following bitflags using a bitwise OR operation:

Value	Constant	Description
0	WEB_OBJECT_DEFAULT	Default object attributes. This value is used to indicate the object can be modified, or that the attributes for a previously existing object should not be changed.
1	WEB_OBJECT_NORMAL	A normal object that that can be read and modified by the application. This is the default attribute for new objects that are created by the application.
2	WEB_OBJECT_READONLY	A read-only object that can only be read by the application. Attempts to modify or replace the

		contents of the object will fail. Read-only objects can be deleted.
4	WEB_OBJECT_HIDDEN	A hidden object. Objects with this attribute are not returned when enumerated using the EnumObjects method. The object can only be accessed directly when specifying its label.

lpObject

A pointer to a [WEB_STORAGE_OBJECT](#) structure that will contain additional information about the object. This parameter may be omitted or NULL if the information is not required.

Return Value

If the method succeeds, the return value is a non-zero. If the method fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

The **PutFile** method uploads the contents of a local file to the current storage container. The content type, which identifies the type of data stored in the object, and its attributes may be specified by the caller or default values may be used.

If a content type is provided, it must specify a valid MIME media type and subtype. For example, normal text files have a content type of **text/plain** while an XML-formatted text file would have a content type of **text/xml**. Files that contain unstructured binary data are typically identified as **application/octet-stream**. If the content type is not explicitly specified, an attempt will be made to identify it automatically based on contents of the file and the file extension.

If the label identifies an object that already exists in the container, and that object was created with the WEB_OBJECT_READONLY attribute, this method will fail. To replace a read-only object, the application must first move, rename or delete the existing object.

The **ValidateLabel** method can be used to ensure a label is valid prior to calling this method. Refer to that method for more information about the difference between Windows file names and object labels

If you are uploading a large file and want your application to receive progress updates during the data transfer, use the **RegisterEvent** method and provide a pointer to a static callback method that will receive event notifications.

Example

```

WEB_STORAGE_OBJECT webObject;

// Upload a local file to the storage container, automatically
// determining the content type with normal read/write access
if (pStorage->PutFile(lpszLocalFile, lpszObjectLabel, &webObject))
{
    // The file was uploaded, display the object metadata
    _tprintf(_T("Object:  %s\n"), webObject.szObjectId);
    _tprintf(_T("Label:   %s\n"), webObject.szLabel);
    _tprintf(_T("Size:    %lu\n"), webObject.dwObjectSize);
    _tprintf(_T("Digest:  %s\n"), webObject.szDigest);
    _tprintf(_T("Content: %s\n"), webObject.szContent);
}
else
{
    // The file could not be uploaded, display the error

```

```
    CString strError;

    pStorage->GetLastError(strError);
    _tprintf(_T("Unable to store \"%s\" (%s)\n"), lpszLocalFile,
(LPCTSTR)strError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

CWebStorage::RegisterAppId Method

```
BOOL RegisterAppId(  
    LPCTSTR lpszAppId  
);
```

The **RegisterAppId** method registers a unique application identifier with the server.

Parameters

lpszAppId

A pointer to a null terminated string which identifies the application requesting access. This parameter cannot be NULL or point to a zero-length string. If the application ID contains illegal characters, the method will fail. See the remarks below on the recommended method for identifying your application.

Return Value

If the method succeeds, the return value is a non-zero. If the method fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

The **RegisterAppId** method registers an application ID with the server which uniquely identifies the application that is requesting access to the storage container. The ID must only consist of ASCII letters, numbers, the period and underscore character. Whitespace characters and non-ASCII Unicode characters are not permitted. The maximum length of an application ID string is 64 characters, including the terminating null character.

It is recommended that you use a standard format for the application ID that consists of your company name, application name and optionally a version number. For example:

- MyCompany.MyApplication
- MyCompany.MyApplication.1

It is important to note that with these two example IDs, although they are similar, they reference two different applications. Objects stored using the first ID will not be accessible using the second ID. If you want to store objects that should be shared between all versions of the application, it is recommended that you use the first form, without the version number. If you want to store objects that should only be accessible to a specific version of your application, then it is recommended that you use the second form that includes the version number.

It is safe to call this method with an application ID that was previously registered. If the provided application ID has already been registered, this method will succeed. You can choose to call this method every time your application starts to ensure the application has been registered correctly.

If you no longer wish to use an application ID you have previously registered, you can call the **UnregisterAppId** method. Exercise caution when unregistering an application. This will cause all objects stored using that ID to be deleted by the storage server. Once an application ID has been unregistered, the operation is permanent. Calling **UnregisterAppId** and then **RegisterAppId** again using the same ID will force the system to create new access tokens for your application. You will not be able to regain access to the objects that were previously stored using that ID.

The application ID is intended to be an application defined human-readable string that uniquely identifies your application. If you want to obtain the internal storage ID associated with your application, use the **GetStorageId** method. The storage ID is a fixed-length string of letters and

numbers guaranteed to be unique across all applications that you register.

It is not required for your application to create a unique application ID. Each storage account has a default internal application ID named **SocketTools.Storage.Default**. This default ID is used if a NULL pointer or an empty string is specified to methods like **OpenStorage**. It is intended to identify storage available to all applications that you create.

To enumerate the application IDs registered with your storage account, use the **GetFirstApplication** and **GetNextApplication** methods.

Example

```
CWebStorage appStorage;
LPCTSTR lpszAppId = _T("MyCompany.WebTest.1");
LPCTSTR lpszLocalFile = _T("TestDocument.pdf");
LPCTSTR lpszObjectLabel = _T("TestDocument.pdf");
WEB_STORAGE_OBJECT webObject = { 0, };

// Register the application ID which identifies the application
if (!appStorage.RegisterAppId(lpszAppId))
{
    tprintf(_T("Unable to register the application ID"));
    _exit(0);
}

// Open the application storage container
if (!appStorage.OpenStorage(lpszAppId, WEB_STORAGE_GLOBAL);
{
    tprintf(_T("Unable to open global storage for this application"));
    _exit(0);
}

// Upload a local file to the storage server and return information
// about the stored object when it completes
if (appStorage.PutFile(lpszLocalFile, lpszObjectLabel, &webObject))
{
    // Print information about the object that was created
    _tprintf(_T("Object: %s\n"), webObject.szObjectId);
    _tprintf(_T("Label: %s\n"), webObject.szLabel);
    _tprintf(_T("Size: %I64u\n"), webObject.dwObjectSize);
    _tprintf(_T("Digest: %s\n"), webObject.szDigest);
    _tprintf(_T("Content: %s\n"), webObject.szContent);
}
else
{
    // The upload failed, display error information
    CString strError;

    appStorage.GetLastError(strError);
    _tprintf(_T("Unable to upload \"%s\" (%s)\n"), lpszLocalFile,
(LPCTSTR)strError);
}

// Release the handle allocated for this storage session
appStorage.CloseStorage();
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswebv10.lib

Unicode: Implemented as Unicode and ANSI versions.

CWebStorage::RegisterEvent Method

```
BOOL RegisterEvent(  
    UINT nEventId,  
    WEBEVENTPROC lpEventProc,  
    DWORD_PTR dwParam  
);
```

The **RegisterEvent** method registers an event handler for the specified event.

Parameters

nEventId

An unsigned integer which specifies which event should be registered with the specified callback method. This parameter cannot be zero. The following values may be used:

Constant	Description
WEB_EVENT_CONNECT (1)	The connection to the storage server has been established and the session has been authenticated. This is the first event that occurs when initiating an operation to create or retrieve a storage object.
WEB_EVENT_DISCONNECT (2)	The connection to the storage server has been closed and the session is terminating. This is the last event that occurs after completing an operation to create or retrieve a storage object.
WEB_EVENT_READ (4)	The contents of an object is being read from the storage container. This event occurs only once after the operation has been initiated by the application. This event can also be generated if there is an error during the process of retrieving the object contents from the container.
WEB_EVENT_WRITE (8)	The contents of an object is being written to the storage container. This event occurs only once after the operation has been initiated by the application. This event can also be generated if there is an error during the process of submitting the object contents to the container.
WEB_EVENT_TIMEOUT (16)	The operation has exceeded the specified timeout period. The application may attempt to retry the operation or report an error to the user. This event typically indicates a connectivity problem with the storage server.
WEB_EVENT_CANCEL (32)	The operation has been canceled. This event occurs after the application calls the Cancel method while an object is being stored or retrieved.
WEB_EVENT_PROGRESS (64)	A storage operation is in progress. This event periodically occurs as the contents of a storage object is being read or written from the container. To retrieve information about the status of the operation, the application should register a handler for this event and call the GetTransferStatus method from within that handler.

lpEventProc

Specifies the procedure-instance address of the application defined callback method. For more information about the callback method, see the description of the **WebEventProc** callback method. If this parameter is NULL, the callback for the specified event is disabled.

dwParam

A user-defined integer value that is passed to the callback method specified by *lpEventProc*. If the application targets the x86 (32-bit) platform, this parameter must be a 32-bit unsigned integer. If the application targets the x64 (64-bit) platform, this parameter must be a 64-bit unsigned integer.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

The **RegisterEvent** method associates a static callback method with a specific event. The event handler is a **WebEventProc** function that is invoked when the event occurs. Arguments are passed to the method to identify the storage handle, the event type and the user-defined value specified when the event handler is registered. If the event occurs because of an error condition, the error code will be provided to the handler.

Events are only generated as the result of a call to the **GetFile**, **GetData**, **PutFile** and **PutData** methods. Other storage methods will not generate event notifications.

This method is typically used to register an event handler that is invoked while the contents of a storage object is being transferred. The WEB_EVENT_PROGRESS event will only be generated periodically during the transfer to ensure the application is not flooded with event notifications. It is guaranteed that at least one WEB_EVENT_PROGRESS notification will occur at the beginning of the transfer, and one at the end of the transfer when it has completed.

The callback function specified by the *lpEventProc* parameter must be declared using the **__stdcall** calling convention. This ensures the arguments passed to the event handler are pushed on to the stack in the correct order. Failure to use the correct calling convention will corrupt the stack and cause the application to terminate abnormally.

The *dwParam* parameter is commonly used to identify the class instance which is associated with the event that has occurred. Applications will cast the **this** pointer to a DWORD_PTR value when calling this function, and then the event handler will cast it back to a pointer to the class instance. This gives the handler access to the class member variables and methods.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswebv10.lib

Unicode: Implemented as Unicode and ANSI versions.

CWebStorage::RenameObject Method

```
BOOL RenameObject(  
    LPCTSTR lpszOldLabel,  
    LPCTSTR lpszNewLabel  
);
```

The **RenameObject** method changes the label associated with the storage object.

Parameters

lpszOldLabel

A pointer to a null terminated string which specifies the name of the existing storage object to be renamed. This parameter must specify a valid object label and cannot be a NULL pointer or an empty string.

lpszNewLabel

A pointer to a null terminated string which specifies a new label for the storage object being moved. This parameter may not be NULL or point to an empty string.

Return Value

If the method succeeds, the return value is a non-zero. If the method fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

The **RenameObject** method is used to change the label for an existing storage object. Although storage object labels are similar to Windows file names, they are case-sensitive. When renaming an object, your application must specify the original label name exactly as it was created. The object label cannot contain wildcard characters.

To duplicate an existing storage object, use the **CopyObject** method. If you need to move the object to a different storage container, use the **MoveObject** method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cswebv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[CopyObject](#), [DeleteObject](#), [MoveObject](#)

CWebStorage::ResetStorage Method

```
BOOL ResetStorage();
```

The **ResetStorage** method resets the application storage container and deletes all stored objects.

Parameters

None.

Return Value

If the method succeeds, the return value is a non-zero. If the method fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

The storage container contains information for each of the objects that have been stored using the handle returned by the **OpenStorage** method. Each of these objects are associated with both the application ID and the storage type that was specified by the caller. This method instructs the server to reset the container back to its initial state, deleting all of the objects that were stored in it.

Exercise caution when using this method. The reset operation is immediate and the objects that are stored in the container are permanently deleted. They cannot be recovered by your application.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswebv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[DeleteObject](#), [OpenStorage](#), [RegisterAppId](#), [UnregisterAppId](#)

CWebStorage::SetLastError Method

```
VOID SetLastError(  
    DWORD dwErrorCode  
);
```

The **SetLastError** method sets the last error code for the current thread. This method is typically used to clear the last error by specifying a value of zero as the parameter.

Parameters

dwErrorCode

Specifies the last error code for the current thread.

Return Value

None.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. Most methods will set the last error code value when they fail; a few methods set it when they succeed. Method failure is typically indicated by a return value such as FALSE, NULL, INVALID_HANDLE or WEBAPI_ERROR. Those methods which call **SetLastError** when they succeed are noted on the method reference page.

Applications can retrieve the value saved by this method by using the **GetLastError** method. An application can call the method to determine the specific reason for a method failure.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cswebv10.lib

See Also

[GetErrorString](#), [GetLastError](#), [ShowError](#)

CWebStorage::SetTimeout Method

```
DWORD SetStorageTimeout(  
    HSTORAGE hStorage,  
    DWORD dwTimeout  
);
```

The **SetTimeout** method sets the number of seconds the client will wait for a response from the storage server. Once the specified number of seconds has elapsed, the method will fail and return to the caller.

Parameters

hClient

Handle to the client session.

dwTimeout

The number of seconds to wait for a storage operation to complete.

Return Value

If the method succeeds, the return value is the previous timeout period for the session. If the method fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

The default timeout period is 10 seconds. The minimum timeout period is 5 seconds, and the maximum timeout period is 60 seconds. Values outside of this range will be normalized internally and will not cause the method to fail.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswebv10.lib

See Also

[GetTimeout](#), [OpenStorage](#)

CWebStorage::ShowError Method

```
INT ShowError(  
    LPCTSTR lpszAppTitle,  
    UINT uType,  
    DWORD dwErrorCode  
);
```

The **ShowError** method displays a message box which describes the specified error.

Parameters

lpszAppTitle

A pointer to a string which specifies the title of the message box that is displayed. If this argument is NULL or omitted, then the default title of "Error" will be displayed.

uType

An unsigned integer which specifies the type of message box that will be displayed. This is the same value that is used by the **MessageBox** method in the Windows API. If a value of zero is specified, then a message box with a single OK button will be displayed. Refer to that method for a complete list of options.

dwErrorCode

Specifies the error code that will be used when displaying the message box. If this argument is zero, then the last error that occurred in the current thread will be displayed.

Return Value

If the method is successful, the return value will be the return value from the **MessageBox** method. If the method fails, it will return a value of zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cswebv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[GetErrorString](#), [GetLastError](#), [SetLastError](#)

CWebStorage::UnregisterAppId Method

```
BOOL UnregisterAppId(  
    LPCTSTR lpszAppId  
);
```

The **UnregisterAppId** method unregisters the application identifier and deletes all associated storage objects.

Parameters

lpszAppId

A pointer to a null terminated string which specifies the application ID to be deleted. This parameter cannot be NULL or point to a zero-length string. If the application ID contains illegal characters, the method will fail.

Return Value

If the method succeeds, the return value is a non-zero. If the method fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

The **UnregisterAppId** method deletes the internal storage identifier associated with the application ID and revokes all access tokens that were granted for the application. This operation is immediate and permanent.

Exercise caution when using this method. This will permanently delete all objects that were stored for the specified application. Calling **UnregisterAppId** and then **RegisterAppId** again using the same ID will force the system to create new access tokens for your application. You will not be able to regain access to the objects that were previously stored using that ID.

This method cannot be used to unregister the default storage application ID **SocketTools.Storage.Default**. If this ID is specified, the method will fail with an error indicating that the ID is invalid.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `cswebv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

See Also

CWebStorage::UnregisterEvent Method

```
BOOL RegisterEvent(  
    UINT nEventId  
);
```

The **UnregisterEvent** method removes an event handler for the specified event.

Parameters

nEventId

An unsigned integer which specifies which event should be registered with the specified callback method. This parameter cannot be zero. The following values may be used:

Constant	Description
WEB_EVENT_CONNECT (1)	The connection to the storage server has been established and the session has been authenticated. This is the first event that occurs when initiating an operation to create or retrieve a storage object.
WEB_EVENT_DISCONNECT (2)	The connection to the storage server has been closed and the session is terminating. This is the last event that occurs after completing an operation to create or retrieve a storage object.
WEB_EVENT_READ (4)	The contents of an object is being read from the storage container. This event occurs only once after the operation has been initiated by the application. This event can also be generated if there is an error during the process of retrieving the object contents from the container.
WEB_EVENT_WRITE (8)	The contents of an object is being written to the storage container. This event occurs only once after the operation has been initiated by the application. This event can also be generated if there is an error during the process of submitting the object contents to the container.
WEB_EVENT_TIMEOUT (16)	The operation has exceeded the specified timeout period. The application may attempt to retry the operation or report an error to the user. This event typically indicates a connectivity problem with the storage server.
WEB_EVENT_CANCEL (32)	The operation has been canceled. This event occurs after the application calls the Cancel method while an object is being stored or retrieved.
WEB_EVENT_PROGRESS (64)	A storage operation is in progress. This event periodically occurs as the contents of a storage object is being read or written from the container. To retrieve information about the status of the operation, the application should register a handler for this event and call the GetTransferStatus method from within that handler.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

The **UnregisterEvent** method removes the association between a specific event and its callback function. This method can be used if the application no longer requires the event notification. All event handlers for the client session are automatically removed when the **CloseStorage** method is called.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswebv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[Cancel](#), [GetTransferStatus](#), [RegisterEvent](#), [WebEventProc](#),

CWebStorage::UploadFile Method

```
BOOL UploadFile(  
    LPCTSTR lpszLocalFile,  
    LPCTSTR lpszObjectLabel,  
    LPWEB_STORAGE_OBJECT LpObject  
);  
  
BOOL UploadFile(  
    LPCTSTR lpszLocalFile,  
    LPCTSTR lpszObjectLabel,  
    LPCTSTR lpszAppId,  
    DWORD dwStorageType,  
    DWORD dwAttributes,  
    DWORD dwTimeout,  
    LPWEB_STORAGE_OBJECT LpObject,  
    WEBEVENTPROC LpEventProc,  
    DWORD_PTR dwParam  
);
```

The **UploadFile** method uploads the contents of a local file and creates or overwrites a storage object.

Parameters

lpszLocalFile

A pointer to a null terminated string that specifies the name of the local file that will be created or overwritten with the contents of the storage object. If a path is not specified, the file will be created in the current working directory.

lpszObjectLabel

A pointer to a null terminated string that specifies the label of the object that should be retrieved from the server.

lpszAppId

A pointer to null terminated string which specifies the application ID for the storage container. The application ID is a string that uniquely identifies the application and can only contain letters, numbers, the period and the underscore character. If this parameter is omitted, NULL or an empty string, the default identifier **SocketTools.Storage.Default** will be used.

dwStorageType

An integer value that identifies the storage container type. If this parameter is omitted, the default value of WEB_STORAGE_GLOBAL will be used. One of the following values may be specified:

Constant	Description
WEB_STORAGE_GLOBAL (1)	Global storage. Objects stored using this storage type are available to all users. Any changes made to objects using this storage type will affect all users of the application. Unless there is a specific need to limit access to the objects stored by the application to specific domains, local machines or users, it is recommended that you use this storage type when creating new objects.
WEB_STORAGE_DOMAIN	Local domain storage. Objects stored using this storage

(2)	type are only available to users in the same local domain, as defined by the domain name or workgroup name assigned to the local system. If the domain or workgroup name changes, objects previously stored using this storage type will not be available to the application.
WEB_STORAGE_MACHINE (3)	Local machine storage. Objects stored using this storage type are only available to users on the same local machine. The local machine is identified by unique characteristics of the system, including the boot volume GUID. Objects previously stored using this storage type will not be available on that system if the boot disk is reformatted.
WEB_STORAGE_USER (4)	Current user storage. Objects stored using this storage type are only available to the current user logged in on the local machine. The user identifier is based on the Windows user SID that is assigned when the user account is created. If the user account is deleted, the objects previously stored using this storage type will not be available to the application.

dwAttributes

An unsigned integer that specifies the attributes associated with the storage object. If this parameter is omitted, a default value of `WEB_OBJECT_NORMAL` will be used. This value can be a combination of one or more of the following bitflags using a bitwise OR operation:

Value	Constant	Description
0	<code>WEB_OBJECT_DEFAULT</code>	Default object attributes. This value is used to indicate the object can be modified, or that the attributes for a previously existing object should not be changed.
1	<code>WEB_OBJECT_NORMAL</code>	A normal object that that can be read and modified by the application. This is the default attribute for new objects that are created by the application.
2	<code>WEB_OBJECT_READONLY</code>	A read-only object that can only be read by the application. Attempts to modify or replace the contents of the object will fail. Read-only objects can be deleted.
4	<code>WEB_OBJECT_HIDDEN</code>	A hidden object. Objects with this attribute are not returned when enumerated using the <code>CWebStorage::EnumObjects</code> method. The object can only be accessed directly when specifying its label.

dwTimeout

An unsigned integer value that specifies a timeout period in seconds. If this value is zero, a default timeout period will be used.

lpObject

A pointer to a [WEB_STORAGE_OBJECT](#) structure that will contain additional information about the object that has been downloaded. This parameter may be NULL if the information is not required.

lpEventProc

Specifies the procedure-instance address of the application defined callback method. For more information about the callback method, see the description of the **WebEventProc** callback function. If this parameter is NULL, no callback function will be invoked during the data transfer.

dwParam

A user-defined integer value that is passed to the callback function specified by *lpEventProc*. If the application targets the x86 (32-bit) platform, this parameter must be a 32-bit unsigned integer. If the application targets the x64 (64-bit) platform, this parameter must be a 64-bit unsigned integer.

Return Value

If the method succeeds, the return value is a non-zero. If the method fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

The **UploadFile** method uploads the contents of a local file and either creates a new storage object, or replaces an object if one already exists with the same label. The **UploadFile** method provides a simpler interface that defaults to uploading an object to the global storage container.

If the label identifies an object that already exists in the container, and that object was created with the WEB_OBJECT_READONLY attribute, this method will fail. To replace a read-only object, the application must explicitly move, rename or delete the existing object.

Additional metadata about the object will be returned in the WEB_STORAGE_OBJECT structure provided by the caller, such as the date and time the object was created, the content type and the SHA-256 hash of the object contents.

If you are uploading a large file and want your application to receive progress updates during the data transfer, provide a pointer to a static callback function as the *lpEventProc* parameter. That function will receive event notifications as the data is being uploaded.

Example

```
CWebStorage appStorage;
WEB_STORAGE_OBJECT webObject;

// Upload a local file to the global storage container
if (appStorage.UploadFile(lpszLocalFile, lpszObjectLabel, &webObject))
{
    // The object was uploaded, display the metadata
    _tprintf(_T("Object:  %s\n"), webObject.szObjectId);
    _tprintf(_T("Label:   %s\n"), webObject.szLabel);
    _tprintf(_T("Size:    %lu\n"), webObject.dwObjectSize);
    _tprintf(_T("Digest:  %s\n"), webObject.szDigest);
    _tprintf(_T("Content: %s\n"), webObject.szContent);
}
else
{
    // The object could not be uploaded, display the error
    CString strError;

    appStorage.GetLastError(strError);
    _tprintf(_T("Unable to upload \"%s\" (%s)\n"), lpszLocalFile,
(LPCTSTR)strError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswebv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

CWebStorage::ValidateAppId Method

```
BOOL ValidateAppId(  
    LPCTSTR lpszAppId  
);
```

The **ValidateAppId** method validates the specified application identifier.

Parameters

lpszAppId

A pointer to a null terminated string which specifies the application ID to be validated. This parameter cannot be NULL or point to a zero-length string. If the application ID contains illegal characters, the method will fail.

Return Value

If the method succeeds, the return value is a non-zero. If the method fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

The **ValidateAppId** method is used to determine if the specified application identifier is valid and has been previously registered using the **RegisterAppId** method. The ID must only consist of ASCII letters, numbers, the period and underscore character. Whitespace characters and non-ASCII Unicode characters are not permitted. The maximum length of an application ID string is 64 characters, including the terminating null character.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswebv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[RegisterAppId](#), [UnregisterAppId](#), [ValidateLabel](#)

CWebStorage::ValidateLabel Method

```
BOOL ValidateLabel(  
    LPCTSTR lpszObjectLabel  
);
```

The **ValidateLabel** method validates the specified object label.

Parameters

lpszObjectLabel

A pointer to a null terminated string which specifies the object label to be validated. This parameter cannot be NULL or point to a zero-length string.

Return Value

If the method succeeds, the return value is a non-zero. If the method fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

Object labels are similar to Windows file names, except they are case-sensitive. The maximum length of a label string is 512 characters, including the terminating null character. Leading and trailing whitespace (spaces, tabs, linebreaks, etc.) are ignored in label names.

Illegal characters include ASCII and Unicode control characters 1 through 31, single quotes (39), double quotes (34), less than symbol (60), greater than symbol (62), pipe (124), asterisk (42) and question mark (63). A null character (0) specifies the end of the label and any subsequent characters are ignored. It is not possible to embed null characters in the label name.

Label names may contain forward slash (47) characters and backslash (92) characters, however it is important to note that objects are not stored in a hierarchical structure. An application can create its own folder-like structure to the labels it creates, but this structure is not imposed or enforced by the library.

If the application is built to use Unicode, labels can contain Unicode characters which are internally encoded as UTF-8. This is important to consider if you have an project built using a multi-byte (ANSI) character set and it needs to access an object that was created using Unicode characters. In that case, the ANSI application must be prepared to handle UTF-8 encoded names and display them appropriately.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: cswebv10.lib

Unicode: Implemented as Unicode and ANSI versions.

CWebStorage Data Structures

- SYSTEMTIME
- WEB_STORAGE_APPLICATION
- WEB_STORAGE_QUOTA
- WEB_STORAGE_OBJECT
- WEB_STORAGE_TRANSFER

SYSTEMTIME Structure

The **SYSTEMTIME** structure represents a date and time using individual members for the month, day, year, weekday, hour, minute, second, and millisecond.

```
typedef struct _SYSTEMTIME
{
    WORD wYear;
    WORD wMonth;
    WORD wDayOfWeek;
    WORD wDay;
    WORD wHour;
    WORD wMinute;
    WORD wSecond;
    WORD wMilliseconds;
} SYSTEMTIME, *LPSYSTEMTIME;
```

Members

wYear

Specifies the current year. The year value must be greater than 1601.

wMonth

Specifies the current month. January is 1, February is 2 and so on.

wDayOfWeek

Specifies the current day of the week. Sunday is 0, Monday is 1 and so on.

wDay

Specifies the current day of the month

wHour

Specifies the current hour.

wMinute

Specifies the current minute

wSecond

Specifies the current second.

wMilliseconds

Specifies the current millisecond.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include windows.h.

WEB_STORAGE_APPLICATION Structure

The **WEB_STORAGE_APPLICATION** structure contains information about a registered application.

```
typedef struct _WEB_STORAGE_APPLICATION
{
    TCHAR        szAppId[64];
    TCHAR        szApiKey[64];
    TCHAR        szLuid[64];
    DWORD        dwTokens;
    DWORD        dwReserved;
    SYSTEMTIME   stCreated;
    SYSTEMTIME   stUpdated;
} WEB_STORAGE_APPLICATION, *LPWEB_STORAGE_APPLICATION;
```

Members

szAppId

A null-terminated string which contains the application ID that was registered using the **RegisterAppId** method.

szApiKey

A null-terminated string which contains the API key value that is used internally by the storage services. The AppID is effectively the human readable alias for this key value used to identify the stored objects for the application. This value is guaranteed to be unique across all applications registered with the storage service.

szLuid

A null-terminated string which specifies a locally unique value associated with the registered application. This value is used internally by the storage service and guaranteed to be unique to the storage account that has registered the application. Note that there are no functions that currently accept the application LUID as parameter, but you may choose to use this value in your own application for other purposes.

dwTokens

An unsigned integer value which specifies the number of access tokens associated with the registered application. Typically there is only one access token associated with a given AppID at any one time, although it is possible that the API may allocate additional access tokens under some circumstances.

dwReserved

An unsigned integer value that is reserved for future use. This value will always be zero.

stCreated

A SYSTEMTIME structure that specifies the date and time the AppID was registered. This value is represented using Coordinated Universal Time (UTC) and is not adjusted for the local time zone.

stUpdated

A SYSTEMTIME structure that specifies the date and time the AppID object was last updated. This value is represented using Coordinated Universal Time (UTC) and is not adjusted for the local time zone. When a storage object is first created, this value will be the same as the object creation time.

Remarks

This structure is used in conjunction with the **GetFirstApplication** and **GetNextApplication**

methods which enumerate all registered applications for the current storage account.

To adjust the creation and update times to account for the local time zone, use the **SystemTimeToTzSpecificLocalTime** function. If you prefer to use FILETIME values, use the **SystemTimeToFileTime** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include cstools10.h

Unicode: Implemented as Unicode and ANSI versions.

WEB_STORAGE_OBJECT Structure

The **WEB_STORAGE_OBJECT** structure contains information about an individual storage object.

```
typedef struct _WEB_STORAGE_OBJECT
{
    TCHAR        szObjectId[64];
    TCHAR        szLabel[512];
    TCHAR        szDigest[128];
    TCHAR        szContent[128];
    DWORD        dwAttributes;
    DWORD        dwObjectSize;
    SYSTEMTIME   stCreated;
    SYSTEMTIME   stModified;
} WEB_STORAGE_OBJECT, *WEB_STORAGE_OBJECT;
```

Members

szObjectId

A null-terminated string which contains the unique identifier associated with this object. Object IDs are guaranteed to be unique for each storage object that is created by the application. The maximum length of an object ID is 64 characters, including the terminating null character.

szLabel

A null-terminated string which contains the label assigned to the object by the application. Object labels are case-sensitive and must be unique for each object. An application uses labels to reference an object with a human-recognizable name, rather than referencing them by their object ID. The maximum length of an object label is 512 characters, including the terminating null character.

szDigest

A null-terminated string which specifies the digest of the object contents, computed using an SHA-256 hash. The maximum length of the *szDigest* string is 128 characters, including the terminating null character. However, the digest value is always represented as a string of hexadecimal numbers that is exactly 64 characters long. It is important to note that even a zero-length object will have a digest, which is the standard SHA-256 NULL hash value.

szContent

A null-terminated string which specifies the MIME content type for the storage object. The content type is determined by the object label and evaluating the contents of the object. It is also possible for the application to explicitly specify the content type of the object when it is created.

dwAttributes

An unsigned integer value that specifies the attributes for the storage object. The object attributes are comprised of one or more bitflags:

Value	Constant	Description
0	WEB_OBJECT_DEFAULT	Default object attributes. This value is used to indicate the object can be modified, or that the attributes for a previously existing object should not be changed.
1	WEB_OBJECT_NORMAL	A normal object that that can be read and modified by the application. This is the default

		attribute for new objects that are created by the application.
2	WEB_OBJECT_READONLY	A read-only object that can only be read by the application. Attempts to modify or replace the contents of the object will fail. Read-only objects can be deleted.
4	WEB_OBJECT_HIDDEN	A hidden object. Objects with this attribute are not returned when enumerated using the EnumObjects method. The object can only be accessed directly when specifying its label.

dwObjectSize

An unsigned integer value that specifies the size of the storage object in bytes. The maximum size of an individual object is determined by the storage quota limits established for the account.

stCreated

A SYSTEMTIME structure that specifies the date and time the storage object was created. This value is represented using Coordinated Universal Time (UTC) and is not adjusted for the local time zone.

stModified

A SYSTEMTIME structure that specifies the date and time the storage object was last modified. This value is represented using Coordinated Universal Time (UTC) and is not adjusted for the local time zone. When a storage object is first created, this value will be the same as the object creation time.

Remarks

The object content type will always be in the format **type/subtype** where the type specifies a common media type (e.g.: text, audio, video, etc.) and subtype specifies the specific content. The most common content type for text files is **text/plain**. If the content type is unknown, the default content type is **application/octet-stream**.

Text objects may also optionally include the character encoding as part of the content type. For example, if an object contains UTF-8 encoded text, the content type may be returned as **text/plain; charset=utf-8**. If your application is parsing the content types, you must check if a character encoding was also included in the value. Text objects that do not specify an encoding either contain ASCII or text which uses the system code page. Unicode text will always be stored using UTF-8 encoding.

To adjust the object creation and modification times to account for the local time zone, use the **SystemTimeToTzSpecificLocalTime** method. If you prefer to use FILETIME values, use the **SystemTimeToFileTime** method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include ctools10.h

Unicode: Implemented as Unicode and ANSI versions.

WEB_STORAGE_QUOTA Structure

The **WEB_STORAGE_QUOTA** structure contains information about the current storage account data usage and limits. This structure is used with the **GetStorageQuota** method.

```
typedef struct _WEB_STORAGE_QUOTA
{
    DWORD        dwObjects;
    DWORD        dwObjectLimit;
    DWORD        dwObjectSize;
    ULONGLONG    ulBytesUsed;
    ULONGLONG    ulBytesFree;
    ULONGLONG    ulStorageLimit;
} WEB_STORAGE_QUOTA, *LPWEB_STORAGE_QUOTA;
```

Members

dwObjects

An unsigned integer value which specifies the number of storage objects allocated for the account. This value may not exceed the total number of objects specified by the *dwObjectLimit* member.

dwObjectLimit

An unsigned integer value which specifies the maximum number of storage objects that may be created. In addition to the limit on the total amount of storage that may be used, there is a limit on the total number of objects that may be created by all applications.

dwObjectSize

An unsigned integer value which specifies the maximum size of an individual storage object. In addition to a limit on the total amount of storage used and the number of objects created, each object stored by the application cannot exceed this size.

ulBytesUsed

An unsigned 64-bit integer value which specifies the total number of bytes of data allocated for all storage objects. This value may not exceed the total number of bytes of storage available, which is specified by the *ulStorageLimit* member.

ulBytesFree

An unsigned 64-bit integer value which specifies the number of bytes available for the storage of new objects. This value reflects the total amount of available storage across all applications registered with the development account. If this value is zero, your storage account has reached its storage limit.

ulStorageLimit

An unsigned 64-bit integer value which specifies the maximum number of bytes of data storage available. This limit applies to all applications registered with the development account.

Remarks

Storage quota limits are assigned for each SocketTools development account. The **GetStorageQuota** method will populate this structure with information about the limits on your account. Accounts that are created with an evaluation license have much lower quota limits than a standard account and should be used for testing purposes only. After the evaluation period has ended, all objects stored using the evaluation license will be deleted.

These values do not represent limits on storage usage by a specific application. Quotas limits

apply to all applications that are registered with the development account, which is identified with the runtime license key used to initialize the class instance.

If your storage quota has been exceeded, either because the total number of objects or the total bytes of storage has reached their limit, your applications will be unable to create new objects. Your application can continue to access existing objects, regardless of your current quota limits.

To free storage space, use the **DeleteObject** method to delete individual storage objects that are no longer needed by your application, or use the **ResetStorage** method to delete all objects in a container.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include `cstools10.h`

See Also

[DeleteObject](#), [GetStorageQuota](#), [ResetStorage](#)

WEB_STORAGE_TRANSFER Structure

This structure is used by the **CWebStorage::GetTransferStatus** method to return information about a data transfer in progress.

```
typedef struct _WEB_STORAGE_TRANSFER
{
    TCHAR        szObjectLabel[512];
    DWORD        dwStorageType;
    DWORD        dwBytesTotal;
    DWORD        dwBytesCopied;
    DWORD        dwBytesPerSecond;
    DWORD        dwTimeElapsed;
    DWORD        dwTimeEstimated;
} WEB_STORAGE_TRANSFER, *LPWEB_STORAGE_TRANSFER
```

Members

szObjectLabel

A null-terminated string that specifies the label for the object that is being retrieved, created or replaced.

dwStorageType

An integer value that identifies the storage container type. This will be one of the following values:

Constant	Description
WEB_STORAGE_GLOBAL (1)	Global storage. Objects stored using this storage type are available to all users. Any changes made to objects using this storage type will affect all users of the application. Unless there is a specific need to limit access to the objects stored by the application to specific domains, local machines or users, it is recommended that you use this storage type when creating new objects.
WEB_STORAGE_DOMAIN (2)	Local domain storage. Objects stored using this storage type are only available to users in the same local domain, as defined by the domain name or workgroup name assigned to the local system. If the domain or workgroup name changes, objects previously stored using this storage type will not be available to the application.
WEB_STORAGE_MACHINE (3)	Local machine storage. Objects stored using this storage type are only available to users on the same local machine. The local machine is identified by unique characteristics of the system, including the boot volume GUID. Objects previously stored using this storage type will not be available on that system if the boot disk is reformatted.
WEB_STORAGE_USER (4)	Current user storage. Objects stored using this storage type are only available to the current user logged in on the local machine. The user identifier is based on the Windows user SID that is assigned when the user account

is created. If the user account is deleted, the objects previously stored using this storage type will not be available to the application.

dwBytesTotal

An unsigned integer which specifies the total number of bytes that will be transferred. If the object is being downloaded to the local host, this is the size of the stored object. If the data is being uploaded from the local host to be stored on the server, it is the size of the buffer or local file.

dwBytesCopied

An unsigned integer which specifies the total number of bytes that have been copied.

dwBytesPerSecond

The average number of bytes that have been copied per second.

dwTimeElapsed

The number of seconds that have elapsed since the file transfer started.

dwTimeEstimated

The estimated number of seconds until the data transfer is completed. This is based on the average number of bytes transferred per second.

Whois Protocol Class Library

Request registration information for an Internet domain name.

Reference

- [Class Methods](#)
- [Error Codes](#)

Library Information

Class Name	CWhoisClient
File Name	CSWHOV10.DLL
Version	10.0.1468.2518
LibID	A1E831CF-F84F-48B1-9710-D012B50AB6D5
Import Library	CSWHOV10.LIB
Dependencies	None
Standards	RFC 954

Overview

The Whois protocol library provides an interface for requesting registration information for an Internet domain name. When a domain name is registered, the organization that registers the domain must provide certain contact information along with technical information such as the primary name servers for that domain. The library provides an API for requesting that information and returning it to the program so that it can be displayed or processed. This library would be most commonly used to query the server at **whois.internic.net** to obtain information about a specific Internet domain name or an administrative contact at that domain.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). If you are using Visual C++ 6.0 it is required that you have Service Pack 6 (SP6) installed. You should install all updates for your development tools and have the current Windows SDK installed. The minimum recommended version of Visual Studio is Visual Studio 2010.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are using Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. It is recommended that you install the current service pack and all critical updates available for your version of the operating system.

This product includes both 32-bit and 64-bit libraries. Native 64-bit CPU support requires the 64-bit version of Windows 7 or later versions of the Windows operating system.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

Whois Protocol Class Methods

Class	Description
CWhoisClient	Constructor which initializes the current instance of the class
~CWhoisClient	Destructor which releases resources allocated by the class
Method	Description
AttachHandle	Attach the specified client handle to this instance of the class
AttachThread	Attach the specified client handle to another thread
Cancel	Cancel the current blocking operation
Connect	Connect to the specified server
DetachHandle	Detach the handle for the current instance of this class
DisableEvents	Disable asynchronous event notification
DisableTrace	Disable logging of socket function calls to the trace log
Disconnect	Disconnect from the current server
EnableEvents	Enable asynchronous event notification
EnableTrace	Enable logging of socket function calls to a file
FreezeEvents	Suspend or resume event handling by the calling process
GetErrorString	Return a description for the specified error code
GetHandle	Return the client handle used by this instance of the class
GetLastError	Return the last error code
GetStatus	Return the current client status.
GetTimeout	Return the number of seconds until an operation times out
IsBlocking	Determine if the client is blocked, waiting for information
IsConnected	Determine if the client is connected to the server
IsInitialized	Determine if the class has been successfully initialized
IsReadable	Determine if there is data available to be read from the server
Read	Read data returned by the server
RegisterEvent	Register an event callback function
Search	Search for the specified record
SetLastError	Set the last error code
SetTimeout	Set the number of seconds until an operation times out
ShowError	Display a message box with a description of the specified error
WhoisEventProc	Callback method that processes events generated by the client

CWhoisClient::CWhoisClient Method

`CWhoisClient();`

The **CWhoisClient** constructor initializes the class library and validates the license key at runtime.

Remarks

If the constructor fails to validate the runtime license, subsequent methods in this class will fail. If the product is installed with an evaluation license, then the application will only function on the development system and cannot be redistributed.

The constructor calls the **WhoisInitialize** function to initialize the library, which dynamically loads other system libraries and allocates thread local storage. If you are using this class within another DLL, it is important that you do not create or destroy an instance of the class from within the **DllMain** function because it can result in deadlocks or access violation errors. You should not declare static or global instances of this class within another DLL if it is linked with the C runtime library (CRT) because it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `cswhov10.lib`

Unicode: Implemented as Unicode and ANSI versions.

See Also

[~CWhoisClient](#), [IsInitialized](#)

CWhoisClient::~CWhoisClient

`~CWhoisClient();`

The **CWhoisClient** destructor releases resources allocated by the current instance of the **CWhoisClient** object. It also uninitialized the library if there are no other concurrent uses of the class.

Remarks

When a **CWhoisClient** object goes out of scope, the destructor is automatically called to allow the library to free any resources allocated on behalf of the process. Any pending blocking or asynchronous calls in this process are canceled without posting any notification messages, and all handles that were created for the client session are destroyed.

The destructor is not called explicitly by the application.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `cswhov10.lib`

Unicode: Implemented as Unicode and ANSI versions.

See Also

[CWhoisClient](#)

CWhoisClient::AttachHandle Method

```
VOID AttachHandle(  
    HCLIENT hClient  
);
```

The **AttachHandle** method attaches the specified client handle to the current instance of the class.

Parameters

hClient

The handle to the client session that will be attached to the current instance of the class object.

Return Value

None.

Remarks

This method is used to attach a client handle created outside of the class using the SocketTools API. Once the client handle is attached to the class, the other class member functions may be used with that client session.

If a client handle already has been created for the class, that handle will be released when the new handle is attached to the class object. If you want to prevent the previous client session from being terminated, you must call the **DetachHandle** method. Failure to release the detached handle may result in a resource leak in your application.

Note that the *hClient* parameter is presumed to be a valid client handle and no checks are performed to ensure that the handle is valid. Specifying an invalid client handle will cause subsequent method calls to fail.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswhov10.lib

See Also

[AttachThread](#), [DetachHandle](#), [GetHandle](#)

CWhoisClient::AttachThread Method

```
DWORD AttachThread(  
    DWORD dwThreadId  
);
```

The **AttachThread** method attaches the specified client handle to another thread.

Parameters

dwThreadId

The ID of the thread that will become the new owner of the handle. A value of zero specifies that the current thread should become the owner of the client handle.

Return Value

If the method succeeds, the return value is the thread ID of the previous owner. If the method fails, the return value is WHOIS_ERROR. To get extended error information, call **GetLastError**.

Remarks

When a client handle is created, it is associated with the current thread that created it. Normally, if another thread attempts to perform an operation using that handle, an error is returned since it does not own the handle. This is used to ensure that other threads cannot interfere with an operation being performed by the owner thread. In some cases, it may be desirable for one thread in a client application to create the client handle, and then pass that handle to another worker thread. The **AttachThread** method can be used to change the ownership of the handle to the new worker thread. By preserving the return value from the method, the original owner of the handle can be restored before the worker thread terminates.

This method should be called by the new thread immediately after it has been created, and if the new thread does not release the handle itself, the ownership of the handle should be restored to the parent thread before it terminates. Under no circumstances should **AttachThread** be used to forcibly release a handle allocated by another thread while a blocking operation is in progress. To cancel an operation, use the **Cancel** method and then release the handle after the blocking method exits and control is returned to the current thread.

Note that the *dwThreadId* parameter is presumed to be a valid thread ID and no checks are performed to ensure that the thread actually exists. Specifying an invalid thread ID will orphan the client handle used by the class until the destructor is called.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswhov10.lib

See Also

[AttachHandle](#), [Cancel](#), [Connect](#), [DetachHandle](#), [Disconnect](#), [GetHandle](#)

CWhoisClient::Cancel Method

```
INT Cancel();
```

The **Cancel** method cancels any outstanding blocking operation in the client, causing the blocking method to fail. The application may then retry the operation or terminate the client session.

Parameters

None.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is WHOIS_ERROR. To get extended error information, call **GetLastError**.

Remarks

When the **Cancel** method is called, the blocking method will not immediately fail. An internal flag is set which causes the blocking operation to exit with an error. This means that the application cannot cancel an operation and immediately perform some other operation. Instead it must allow the calling stack to unwind, returning back to the blocking operation before making any further function calls.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswhov10.lib

[IsBlocking](#)

CWhoisClient::Connect Method

```
BOOL Connect(  
    LPCTSTR lpszRemoteHost,  
    UINT nRemotePort,  
    UINT nTimeout,  
    DWORD dwReserved,  
    HWND hEventWnd,  
    UINT uEventMsg  
);
```

The **Connect** method establishes a connection with the specified server.

Parameters

lpszRemoteHost

A pointer to the name of the server to connect to; this may be a fully-qualified domain name or an IP address.

nRemotePort

The port number the server is listening on; a value of zero specifies that the default port number should be used. For standard connections, the default port number is 43.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwReserved

A reserved argument. This value should always be zero.

hEventWnd

The handle to the event notification window. This window receives messages which notify the client of various asynchronous network events that occur. If this argument is NULL, then the client session will be blocking and no network events will be sent to the client.

uEventMsg

The message identifier that is used when an asynchronous network event occurs. This value should be greater than WM_USER as defined in the Windows header files. If the *hEventWnd* argument is NULL, this argument should be specified as WM_NULL.

Return Value

If the method succeeds, the return value is a non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The use of Windows event notification messages has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

To prevent this method from blocking the main user interface thread, the application should create a background worker thread and establish a connection by calling **Connect** in that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each client session.

If you specify an event notification window, then the client session will be asynchronous. When a message is posted to the notification window, the low word of the *lParam* parameter contains the event identifier. The high word of *lParam* contains the low word of the error code, if an error has occurred. The *wParam* parameter contains the client handle. One or more of the following event identifiers may be sent:

Constant	Description
WHOIS_EVENT_CONNECT	The connection to the server has completed. The high word of the <i>lParam</i> parameter should be checked, since this notification message will be posted if an error has occurred.
WHOIS_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
WHOIS_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
WHOIS_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
WHOIS_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
WHOIS_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.

To cancel asynchronous notification and return the client to a blocking mode, use the **DisableEvents** methods.

It is recommended that you only establish an asynchronous connection if you understand the implications of doing so. In most cases, it is preferable to create a synchronous connection and create threads for each additional session if more than one active client session is required.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `cswhov10.lib`

Unicode: Implemented as Unicode and ANSI versions.

See Also

[DisableEvents](#), [Disconnect](#), [EnableEvents](#), [RegisterEvent](#)

CWhoisClient::DetachHandle Method

```
HCLIENT DetachHandle();
```

The **DetachHandle** method detaches the client handle associated with the current instance of the class.

Parameters

None.

Return Value

This method returns the client handle associated with the current instance of the class object. If there is no active client session, the value `INVALID_CLIENT` will be returned.

Remarks

This method is used to detach a client handle created by the class for use with the SocketTools API. Once the client handle is detached from the class, no other class member functions may be called. Note that the handle must be explicitly released at some later point by the process or a resource leak will occur.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `cswhov10.lib`

See Also

[AttachHandle](#), [GetHandle](#)

CWhoisClient::DisableEvents Method

```
INT DisableEvents();
```

The **DisableEvents** method disables the event notification mechanism, preventing subsequent event notification messages from being posted to the application's message queue.

This method has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Parameters

None.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is WHOIS_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **DisableEvents** method is used to disable event message posting for the specified client session. Although this will immediately prevent any new events from being generated, it is possible that messages could be waiting in the message queue. Therefore, an application must be prepared to handle client event messages after this method has been called.

This method is automatically called if the client has event notification enabled, and the **Disconnect** method is called. The same issues regarding outstanding event messages also applies in this situation, requiring that the application handle event messages that may reference a client handle that is no longer valid.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswhov10.lib

See Also

[EnableEvents](#), [RegisterEvent](#)

CWhoisClient::DisableTrace Method

```
BOOL DisableTrace();
```

The **DisableTrace** method disables the logging of socket function calls to the trace log.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, a value of zero is returned.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswhov10.lib

See Also

[EnableTrace](#)

CWhoisClient::Disconnect Method

VOID Disconnect();

The **Disconnect** method terminates the connection with the server, closing the socket and releasing the memory allocated for the client session.

Parameters

None.

Return Value

None.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswhov10.lib

See Also

[Connect](#), [IsConnected](#)

CWhoisClient::EnableEvents Method

```
INT EnableEvents(  
    HWND hEventWnd,  
    UINT uEventMsg  
);
```

The **EnableEvents** method enables event notifications using Windows messages.

This method has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Applications should use the **RegisterEvent** method to register an event handler which is invoked when an event occurs.

Parameters

hEventWnd

Handle to the window which will receive the client notification messages. This parameter must specify a valid window handle. If a NULL handle is specified, event notification will be disabled.

uEventMsg

The message that is received when a client event occurs. This value must be greater than 1024.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is WHOIS_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **EnableEvents** method is used to request that notification messages be posted to the specified window whenever a client event occurs. This allows an application to monitor the status of different client operations, such as a file transfer.

The *wParam* argument will contain the client handle, the low word of the *lParam* argument will contain the event ID, and the high word will contain any error code. If no error has occurred, the high word will always have a value of zero. The following events may be generated:

Constant	Description
WHOIS_EVENT_CONNECT	The connection to the server has completed. The high word of the <i>lParam</i> parameter should be checked, since this notification message will be posted if an error has occurred.
WHOIS_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
WHOIS_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
WHOIS_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking

	operation. This event is only generated if the client is in asynchronous mode.
WHOIS_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
WHOIS_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.

To disable event notification, call the **DisableEvents** method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswhov10.lib

[DisableEvents](#), [RegisterEvent](#)

CWhoisClient::EnableTrace Method

```
BOOL EnableTrace(  
    LPCTSTR lpszTraceFile,  
    DWORD dwTraceFlags  
);
```

The **EnableTrace** method enables the logging of socket function calls to a file.

Parameters

lpszTraceFile

A pointer to a string which specifies the name of the trace log file. If this parameter is NULL or an empty string, the default file name **cstrace.log** is used. The file is stored in the directory specified by the TEMP environment variable, if it is defined; otherwise, the current working directory is used.

dwTraceFlags

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
TRACE_INFO	All function calls are written to the trace file. This is the default value.
TRACE_ERROR	Only those function calls which fail are recorded in the trace file.
TRACE_WARNING	Only those function calls which fail or return values which indicate a warning are recorded in the trace file.
TRACE_HEXDUMP	All functions calls are written to the trace file, plus all the data that is sent or received is displayed, in both ASCII and hexadecimal format.
TRACE_PROCESS	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for multithreaded applications that are using worker threads.

Return Value

If the method succeeds, the return value is non-zero. A return value of zero indicates an error. Failure typically indicates that the tracing library **cstrcv10.dll** cannot be loaded on the local system.

Remarks

When trace logging is enabled, the file is opened, appended to and closed for each socket function call. This makes it possible for an application to append its own logging information, however care should be taken to ensure that the file is closed before the next network operation is performed. To limit the size of the log files, enable and disable logging only around those sections of code that you wish to trace.

Note that the TRACE_HEXDUMP trace level generates very large log files since it includes all of the data exchanged between your application and the server.

Trace method logging is managed on a per-thread basis, not for each client handle. This means that all SocketTools libraries and components share the same settings in the current thread. If you

are using multiple SocketTools libraries or components in your application, you only need to enable logging once.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswhov10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[DisableTrace](#)

CWhoisClient::FreezeEvents Method

```
INT FreezeEvents(  
    BOOL bFreeze  
);
```

The **FreezeEvents** method is used to suspend and resume event handling by the client.

Parameters

bFreeze

A non-zero value specifies that event handling should be suspended by the client. A zero value specifies that event handling should be resumed.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is WHOIS_ERROR. To get extended error information, call **GetLastError**.

Remarks

This method should be used when the application does not want to process events, such as when a modal dialog is being displayed. When events are suspended, all client events are queued. If events are re-enabled at a later point, those queued events will be sent to the application for processing. Note that only one of each event will be generated. For example, if the client has suspended event handling, and four read events occur, once event handling is resumed only one of those read events will be posted to the client. This prevents the application from being flooded by a potentially large number of queued events.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswhov10.lib

CWhoisClient::GetErrorString Method

```
INT GetErrorString(  
    DWORD dwErrorCode,  
    LPTSTR lpszDescription,  
    INT cbDescription  
);  
  
INT GetErrorString(  
    DWORD dwErrorCode,  
    CString& strDescription  
);
```

The **GetErrorString** method is used to return a description of a specific error code. Typically this is used in conjunction with the **GetLastError** method for use with warning dialogs or as diagnostic messages.

Parameters

dwErrorCode

The error code for which a description is returned.

lpszDescription

A pointer to the buffer that will contain a description of the specified error code. This buffer should be at least 128 characters in length. An alternate form of the method accepts a **CString** variable which will contain the error description.

cbDescription

The maximum number of characters that may be copied into the description buffer.

Return Value

If the method succeeds, the return value is the length of the description string. If the method fails, the return value is zero, meaning that no description exists for the specified error code. Typically this indicates that the error code passed to the method is invalid.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswhov10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[GetLastError](#), [SetLastError](#), [ShowError](#)

CWhoisClient::GetHandle Method

```
HCLIENT GetHandle();
```

The **GetHandle** method returns the client handle associated with the current instance of the class.

Parameters

None.

Return Value

This method returns the client handle associated with the current instance of the class object. If there is no active client session, the value `INVALID_CLIENT` will be returned.

Remarks

This method is used to obtain the client handle created by the class for use with the SocketTools API.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `cswhov10.lib`

CWhoisClient::GetLastError Method

```
DWORD GetLastError();  
  
DWORD GetLastError(  
    CString& strDescription  
);
```

Parameters

strDescription

A string which will contain a description of the last error code value when the method returns. If no error has been set, or the last error code has been cleared, this string will be empty.

Return Value

The return value is the last error code value for the current thread. Functions set this value by calling the **SetLastError** method. The Return Value section of each reference page notes the conditions under which the method sets the last error code.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. You should call the **GetLastError** method immediately when a method's return value indicates that an error has occurred. That is because some methods call **SetLastError(0)** when they succeed, clearing the error code set by the most recently failed method.

Most methods will set the last error code value when they fail; a few methods set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or WHOIS_ERROR. Those methods which call **SetLastError** when they succeed are noted on the method reference page.

The description of the error code is the same string that is returned by the **GetErrorString** method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: cswhov10.lib

See Also

[GetErrorString](#), [SetLastError](#), [ShowError](#)

CWhoisClient::GetStatus Method

```
INT GetStatus();
```

The **GetStatus** method the current status of the client session.

Parameters

None.

Return Value

If the method succeeds, the return value is the client status code. If the method fails, the return value is WHOIS_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetStatus** method returns a numeric code which identifies the current state of the client session. The following values may be returned:

Value	Constant	Description
0	WHOIS_STATUS_UNUSED	No connection has been established.
1	WHOIS_STATUS_IDLE	The client is current idle and not sending or receiving data.
2	WHOIS_STATUS_CONNECT	The client is establishing a connection with the server.
3	WHOIS_STATUS_READ	The client is reading data from the server.
4	WHOIS_STATUS_WRITE	The client is writing data to the server.
5	WHOIS_STATUS_DISCONNECT	The client is disconnecting from the server.

In a multithreaded application, any thread in the current process may call this method to obtain status information for the specified client session. To obtain status information about a file transfer, use the **GetTransferStatus** method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswhov10.lib

See Also

[IsBlocking](#), [IsInitialized](#), [IsReadable](#)

CWhoisClient::GetTimeout Method

```
INT GetTimeout();
```

The **GetTimeout** method returns the number of seconds the client will wait for a response from the server. Once the specified number of seconds has elapsed, the method will fail and return to the caller.

Parameters

None.

Return Value

If the method succeeds, the return value is the timeout period in seconds. If the method fails, the return value is WHOIS_ERROR. To get extended error information, call **GetLastError**.

Remarks

The timeout value is only used with blocking client connections. A value of zero indicates that the default timeout period of 20 seconds should be used.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswhov10.lib

See Also

[Connect](#), [IsReadable](#), [Read](#), [SetTimeout](#)

CWhoisClient::IsBlocking Method

BOOL IsBlocking();

The **IsBlocking** method is used to determine if the client is currently performing a blocking operation.

Parameters

None.

Return Value

If the client is performing a blocking operation, the method returns a non-zero value. If the client is not performing a blocking operation, or the client handle is invalid, the method returns zero.

Remarks

Because a blocking operation can allow the application to be re-entered (for example, by pressing a button while the operation is being performed), it is possible that another blocking method may be called while it is in progress. Since only one thread of execution may perform a blocking operation at any one time, an error would occur. The **IsBlocking** method can be used to determine if the client is already blocked, and if so, take some other action (such as warning the user that they must wait for the operation to complete).

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswhov10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[Cancel](#), [GetStatus](#), [IsConnected](#), [IsInitialized](#), [IsReadable](#), [Read](#)

CWhoisClient::IsConnected Method

```
BOOL IsConnected();
```

The **IsConnected** method is used to determine if the client is currently connected to a server.

Parameters

None.

Return Value

If the client is connected to a server, the method returns a non-zero value. If the client is not connected, or the client handle is invalid, the method returns zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswhov10.lib

See Also

[GetStatus](#), [IsBlocking](#), [IsInitialized](#), [IsReadable](#)

CWhoisClient::IsInitialized Method

```
BOOL IsInitialized();
```

The **IsInitialized** method returns whether or not the class object has been successfully initialized.

Parameters

None.

Return Value

This method returns a non-zero value if the class object has been successfully initialized. A return value of zero indicates that the runtime license key could not be validated or the networking library could not be loaded by the current process.

Remarks

When an instance of the class is created, the class constructor will attempt to initialize the component with the runtime license key that was created when SocketTools was installed. If the constructor is unable to validate the license key or load the networking libraries, this initialization will fail.

If SocketTools was installed with an evaluation license, the application cannot be redistributed to another system. The class object will fail to initialize if the application is executed on another system, or if the evaluation period has expired. To redistribute your application, you must purchase a development license which will include the runtime key that is needed to redistribute your software to other systems. Refer to the Developer's Guide for more information.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswhov10.lib

See Also

[CWhoisClient](#), [IsBlocking](#), [IsConnected](#)

CWhoisClient::IsReadable Method

```
BOOL IsReadable(  
    INT nTimeout,  
    LPDWORD LpdwAvail  
);
```

The **IsReadable** method is used to determine if data is available to be read from the server.

Parameters

nTimeout

Timeout for server response, in seconds. A value of zero specifies that the connection should be polled without blocking the current thread.

lpdwAvail

A pointer to an unsigned integer which will contain the number of bytes available to read. This parameter may be NULL if this information is not required.

Return Value

If the client can read data from the server within the specified timeout period, the method returns a non-zero value. If the client cannot read any data, the method returns zero.

Remarks

On some platforms, this value will not exceed the size of the receive buffer (typically 64K bytes). Because of differences between TCP/IP stack implementations, it is not recommended that your application exclusively depend on this value to determine the exact number of bytes available. Instead, it should be used as a general indicator that there is data available to be read.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswhov10.lib

See Also

[GetStatus](#), [IsBlocking](#), [IsConnected](#), [IsInitialized](#)

CWhoisClient::Read Method

```
INT Read(  
    LPBYTE lpBuffer,  
    INT cbBuffer  
);  
  
INT Read(  
    CString& strBuffer,  
    INT cbBuffer  
);
```

The **Read** method reads the specified number of bytes from the client socket and copies them into the buffer. The data may be of any type, and is not terminated with a null character.

Parameters

lpBuffer

Pointer to the buffer in which the data will be copied. An alternate form of this method allows a **CString** variable to be passed and data read from the socket will be returned in that string.

cbBuffer

The maximum number of bytes to read and copy into the specified buffer. This value must be greater than zero.

Return Value

If the method succeeds, the return value is the number of bytes actually read. A return value of zero indicates that the server has closed the connection and there is no more data available to be read. If the method fails, the return value is WHOIS_ERROR. To get extended error information, call **GetLastError**.

Remarks

When **Read** is called and the client is in non-blocking mode, it is possible that the method will fail because there is no available data to read at that time. This should not be considered a fatal error. Instead, the application should simply wait to receive the next asynchronous notification that data is available.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswhov10.lib

See Also

[EnableEvents](#), [IsBlocking](#), [IsReadable](#), [RegisterEvent](#)

CWhoisClient::RegisterEvent Method

```
INT RegisterEvent(  
    UINT nEventId,  
    WHOISEVENTPROC LpEventProc,  
    DWORD_PTR dwParam  
);
```

The **RegisterEvent** method registers an event handler for the specified event.

Parameters

nEventId

An unsigned integer which specifies which event should be registered with the specified callback function. One of the following values may be used:

Constant	Description
WHOIS_EVENT_CONNECT	The connection to the server has completed.
WHOIS_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
WHOIS_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
WHOIS_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
WHOIS_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
WHOIS_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.

LpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **WhoisEventProc** callback function. If this parameter is NULL, the callback for the specified event is disabled.

dwParam

A user-defined integer value that is passed to the callback function. If the application targets the x86 (32-bit) platform, this parameter must be a 32-bit unsigned integer. If the application targets the x64 (64-bit) platform, this parameter must be a 64-bit unsigned integer.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is `WHOIS_ERROR`. To get extended error information, call **GetLastError**.

Remarks

The **RegisterEvent** method associates a callback function with a specific event. The event handler is an **WhoisEventProc** function that is invoked when the event occurs. Arguments are passed to the function to identify the client session, the event type and the user-defined value specified when the event handler is registered. If the event occurs because of an error condition, the error code will be provided to the handler.

The callback function specified by the *lpEventProc* parameter must be declared using the **__stdcall** calling convention. This ensures the arguments passed to the event handler are pushed on to the stack in the correct order. Failure to use the correct calling convention will corrupt the stack and cause the application to terminate abnormally.

The *dwParam* parameter is commonly used to identify the class instance which is associated with the event that has occurred. Applications will cast the **this** pointer to a `DWORD_PTR` value when calling this function, and then the event handler will cast it back to a pointer to the class instance. This gives the handler access to the class member variables and methods.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `cswhov10.lib`

CWhoisClient::Search Method

```
INT Search(  
    LPCTSTR lpszKeyword,  
    UINT nSearchType  
);
```

The **Search** method submits the specified keyword to the server.

Parameters

lpszKeyword

Points to a string which specifies the query keyword. It may be a handle, name or mailbox.

nSearchType

The type of search being performed. One of the following values may be used:

Constant	Description
WHOIS_SEARCH_ANY	Search for any record that matches the specified keyword.
WHOIS_SEARCH_HANDLE	Search only for handles that match the specified keyword.
WHOIS_SEARCH_MAILBOX	Search only for mailboxes that match the specified keyword.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is WHOIS_ERROR. To get extended error information, call **GetLastError**.

Example

```
CWhoisClient whoisClient;  
  
// Connect to the WHOIS server at whois.internic.net  
if (whoisClient.Connect(_T("whois.internic.net")) == FALSE)  
{  
    whoisClient.ShowError();  
    return;  
}  
  
// Request information about the sockettools.com domain name  
if (whoisClient.Search(_T("sockettools.com")) == WHOIS_ERROR)  
{  
    whoisClient.ShowError();  
    whoisClient.Disconnect();  
    return;  
}  
  
// Read the response from the server, which contains information  
// about the domain and the registry that maintains the record  
CString strResult;  
CString strBuffer;  
INT nResult;  
  
do  
{  
    if ((nResult = whoisClient.Read(strBuffer)) > 0)  
        strResult += strBuffer;
```

```
}  
while (nResult > 0);  
  
// If there was an error reading the data, alert the user  
if (nResult == WHOIS_ERROR)  
    whoisClient.ShowError();  
  
whoisClient.Disconnect();
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswhov10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

CWhoisClient::SetLastError Method

```
VOID SetLastError(  
    DWORD dwErrorCode  
);
```

The **SetLastError** method sets the last error code for the current thread. This method is typically used to clear the last error by specifying a value of zero as the parameter.

Parameters

dwErrorCode

Specifies the last error code for the current thread.

Return Value

None.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. Most methods will set the last error code value when they fail; a few methods set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or WHOIS_ERROR. Those methods which call **SetLastError** when they succeed are noted on the method reference page.

Applications can retrieve the value saved by this method by using the **GetLastError** method. The use of **GetLastError** is optional; an application can call the method to determine the specific reason for a method failure.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cshov10.lib

See Also

[GetErrorString](#), [GetLastError](#), [ShowError](#)

CWhoisClient::SetTimeout Method

```
INT SetTimeout(  
    UINT nTimeout  
);
```

The **SetTimeout** method sets the number of seconds the client will wait for a response from the server. Once the specified number of seconds has elapsed, the method will fail and return to the caller.

Parameters

nTimeout

The number of seconds to wait for a blocking operation to complete.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is WHOIS_ERROR. To get extended error information, call **GetLastError**.

Remarks

The timeout value is only used with blocking client connections.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswhov10.lib

See Also

CWhoisClient::ShowError Method

```
INT ShowError(  
    LPCTSTR lpszAppTitle,  
    UINT uType,  
    DWORD dwErrorCode  
);
```

The **ShowError** method displays a message box which describes the specified error.

Parameters

lpszAppTitle

A pointer to a string which specifies the title of the message box that is displayed. If this argument is NULL or omitted, then the default title of "Error" will be displayed.

uType

An unsigned integer which specifies the type of message box that will be displayed. This is the same value that is used by the **MessageBox** method in the Windows API. If a value of zero is specified, then a message box with a single OK button will be displayed. Refer to that method for a complete list of options.

dwErrorCode

Specifies the error code that will be used when displaying the message box. If this argument is zero, then the last error that occurred in the current thread will be displayed.

Return Value

If the method is successful, the return value will be the return value from the **MessageBox** function. If the method fails, it will return a value of zero.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: cswhov10.lib

Unicode: Implemented as Unicode and ANSI versions.

Library Information

File Name	CSDNSV10.DLL
Version	10.0.1468.2518
LibID	F247C1C3-4DB3-4DF2-A16E-88E2B97B5119
Import Library	CSDNSV10.LIB
Dependencies	None
Standards	RFC 1034

Overview

The Domain Name Services (DNS) protocol is what applications use to resolve domain names into Internet addresses as well as provide other information about a domain. All of the SocketTools libraries provide basic domain name resolution functionality, but the Domain Name Services library gives an application direct control over what servers are queried, the amount of time spent waiting for a response and the type of information that is returned.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). If you are using Visual C++ 6.0 it is required that you have Service Pack 6 (SP6) installed. You should install all updates for your development tools and have the current Windows SDK installed. The minimum recommended version of Visual Studio is Visual Studio 2010.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are using Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. It is recommended that you install the current service pack and all critical updates available for your version of the operating system.

This product includes both 32-bit and 64-bit libraries. Native 64-bit CPU support requires the 64-bit version of Windows 7 or later versions of the Windows operating system.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

Domain Name Service Functions

Function	Description
DnsAttachThread	Attach the specified client handle to another thread
DnsCancel	Cancel an outstanding nameserver query
DnsCloseHandle	Close the current client session
DnsCreateHandle	Create a new handle for the current client session
DnsDisableTrace	Disable logging of socket function calls to the trace log
DnsEnableTrace	Enable logging of socket function calls to a file
DnsEnumHostAliases	Enumerate the aliases for the specified host name or address
DnsEnumMailExchanges	Return a list of mail exchanges for the specified host name or IP address
DnsFormatAddress	Convert a numeric IPv4 address to a string
DnsGetAddress	Convert an IPv4 address string in dotted notation to a numeric IP address
DnsGetAddressFamily	Return the address family for the specified IP address
DnsGetDefaultHostFile	Return the fully qualified path name of the default host file on the local system
DnsGetErrorString	Return a description for the specified error code
DnsGetHostAddress	Return the IP address for the specified hostname
DnsGetHostByAddress	Return a pointer to data for the specified host IP address
DnsGetHostByName	Return a pointer to data for the specified host name
DnsGetHostFile	Return the name of the current host file
DnsGetHostInfo	Return additional information for the specified host
DnsGetHostName	Return the host name for the specified IP address
DnsGetHostServices	Return a list of services supported by the specified host
DnsGetLastError	Return the last error code
DnsGetLocalAddress	Return the IP address for the local host
DnsGetLocalDomain	Return the local domain name for the current session
DnsGetLocalName	Return the local host name
DnsGetMailExchange	Return the host that processes mail for the specified domain
DnsGetRecord	Return record data for the current host
DnsGetResolverAddress	Return address of last nameserver that resolved query
DnsGetResolverOptions	Return the current resolver options for the specified client session
DnsGetRetryCount	Get the number of times the query is sent to each server
DnsGetServerAddress	Return the address of the specified nameserver
DnsGetServerPort	Return the port of the specified nameserver
DnsGetTimeout	Get the number of seconds until a query times out
DnsHostNameToUnicode	Converts the canonical form of a host name to its Unicode version
DnsInitialize	Initialize the library and validate the specified license key at runtime

DnsMatchHostName	Match a host name against of list of addresses including wildcards
DnsNormalizeHostName	Return the canonical form of a host name
DnsRegisterServer	Add a nameserver address to the current session
DnsReset	Reset the current client state
DnsSetHostFile	Specify the name of an alternate file to use when resolving hostnames and IP addresses
DnsSetLastError	Set the last error code
DnsSetLocalDomain	Set the local domain name for the current session
DnsSetResolverOptions	Set the resolver options for the specified client session
DnsSetRetryCount	Set the number of times the query is sent to each server
DnsSetTimeout	Set the number of seconds until a query times out
DnsUninitialize	Terminates the use of the library
DnsUnregisterServer	Remove a nameserver address from the current session

DnsAttachThread Function

```
DWORD WINAPI DnsAttachThread(  
    HCLIENT hClient  
    DWORD dwThreadId  
);
```

The **DnsAttachThread** function attaches the specified client handle to another thread.

Parameters

hClient

Handle to the client session.

dwThreadId

The ID of the thread that will become the new owner of the handle. A value of zero specifies that the current thread should become the owner of the client handle.

Return Value

If the function succeeds, the return value is the thread ID of the previous owner. If the function fails, the return value is DNS_ERROR. To get extended error information, call **DnsGetLastError**.

Remarks

When a client handle is created, it is associated with the current thread that created it. Normally, if another thread attempts to perform an operation using that handle, an error is returned since it does not own the handle. This is used to ensure that other threads cannot interfere with an operation being performed by the owner thread. In some cases, it may be desirable for one thread in a client application to create the client handle, and then pass that handle to another worker thread. The **DnsAttachThread** function can be used to change the ownership of the handle to the new worker thread. By preserving the return value from the function, the original owner of the handle can be restored before the worker thread terminates.

This function should be called by the new thread immediately after it has been created, and if the new thread does not release the handle itself, the ownership of the handle should be restored to the parent thread before it terminates. Under no circumstances should **DnsAttachThread** be used to forcibly release a handle allocated by another thread while a blocking operation is in progress. To cancel an operation, use the **DnsCancel** function and then release the handle after the blocking function exits and control is returned to the current thread.

Note that the *dwThreadId* parameter is presumed to be a valid thread ID and no checks are performed to ensure that the thread actually exists. Specifying an invalid thread ID will orphan the handle until the **DnsUninitialize** function is called.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csdnsv10.lib

See Also

[DnsCancel](#), [DnsCloseHandle](#), [DnsCreateHandle](#), [DnsUninitialize](#)

DnsCancel Function

```
INT WINAPI DnsCancel(  
    HCLIENT hClient  
);
```

The **DnsCancel** function cancels any outstanding queries initiated by the client.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is DNS_ERROR. To get extended error information, call **DnsGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csdnsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[DnsGetMailExchange](#), [DnsGetRecord](#)

DnsCloseHandle Function

```
INT WINAPI DnsCloseHandle(  
    HCLIENT hClient  
);
```

The **DnsCloseHandle** function closes the handle and releases any memory allocated for the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is DNS_ERROR. To get extended error information, call **DnsGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csdnsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[DnsCreateHandle](#), [DnsUninitialize](#), [DnsUnregisterServer](#)

DnsCreateHandle Function

```
HCLIENT WINAPI DnsCreateHandle(  
    INT nTimeout,  
    INT nRetries,  
    DWORD dwOptions  
);
```

The **DnsCreateHandle** function creates a new handle which can be used to query the default nameservers configured for the local host.

Parameters

nTimeout

The number of seconds that the client will wait for a response before failing the query. The constant `DNS_TIMEOUT` can be used to specify the default timeout period of 15 seconds.

nRetries

The number of attempts the client will make to resolve a query after a timeout. The constant `DNS_RETRIES` can be used to specify the default retry count of 4.

dwOptions

An unsigned integer that specifies one or more resolver options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
<code>DNS_OPTION_NONE</code>	No additional resolver options specified. This is the default value, and it is recommended that most applications do not specify additional options unless the implications of doing so are understood.
<code>DNS_OPTION_PROMOTE</code>	Promotes the server that successfully completed the last query to the first server that will be used to resolve subsequent queries. This option can improve performance in some cases where one or more of the registered servers are non-responsive. This option takes precedence over the <code>DNS_OPTION_ROTATE</code> option.
<code>DNS_OPTION_ROTATE</code>	Enables a round-robin selection of nameservers when performing queries. Normally each nameserver is queried in the same order. This option rotates the available nameservers so a different server is used with each query.
<code>DNS_OPTION_AUTHONLY</code>	Require the answer from the nameserver to be authoritative, not from the server's cache. This option is included for future expansion as most servers do not support this feature and will ignore it.
<code>DNS_OPTION_PRIMARY</code>	Queries are only accepted from the primary nameserver. This option is included for future expansion as most servers do not support this feature and will ignore it.

DNS_OPTION_NORECURSE	Disable the sending of recursive queries to the nameserver. Specifying this option will disable the bit in the DNS request header that specifies recursion is desired.
DNS_OPTION_NOSEARCH	Disable additional queries of higher domains in the search list if the host name cannot be resolved. If this option is specified, and the host name cannot be resolved using the local domain name an error is returned immediately. This option is ignored if no local domain has been specified or if the DNS_OPTION_NOSUFFIX option has been specified.
DNS_OPTION_NOSUFFIX	Disable additional queries using the local domain name if the host name is not a fully qualified domain name and cannot be resolved. This option is ignored if no local domain has been specified.
DNS_OPTION_NONAMECHECK	Disable checking the host name for invalid characters, such as the underscore and control characters. By default, host names are checked to ensure they're valid before submitting a query to the nameserver.
DNS_OPTION_FREETHREAD	This option specifies the handle returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the handle is synchronized across multiple threads.

Return Value

If the function succeeds, the return value is a handle to a client session. If the function fails, the return value is `INVALID_CLIENT`. To get extended error information, call **DnsGetLastError**.

Remarks

The **DnsCreateHandle** function returns a handle to the application which can be used to perform nameserver queries. By default, the library will use the nameservers which are configured for the local host. To determine the IP addresses of those nameservers, use the **DnsGetServerAddress** function.

To specify alternate nameservers, either as replacements for or additions to the default nameservers, use the **DnsRegisterServer** function.

It is recommended that most applications do not specify any resolver options and use the default behavior. Specifying these options without understanding how they can affect standard queries can result in unexpected failures. In particular, caution should be used when specifying the `DNS_OPTION_NORECURSE` and `DNS_OPTION_NOSEARCH` options as they change the normal process of resolving a host name.

Specifying the `DNS_OPTION_FREETHREAD` option enables any thread to call any function using the handle, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the handle is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same

handle.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csdnsv10.lib

See Also

[DnsCloseHandle](#), [DnsGetResolverOptions](#), [DnsGetServerAddress](#), [DnsInitialize](#), [DnsRegisterServer](#),
[DnsSetLocalDomain](#), [DnsSetResolverOptions](#)

DnsDisableTrace Function

```
BOOL WINAPI DnsDisableTrace();
```

The **DnsDisableTrace** function disables the logging of socket function calls to the trace log.

Parameters

None.

Return Value

If the function succeeds, the return value is non-zero. A return value of zero indicates an error. Failure typically indicates that the tracing library **cstrcv10.dll** cannot be loaded on the local system.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csdnsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[DnsEnableTrace](#)

DnsEnableTrace Function

```
BOOL WINAPI DnsEnableTrace(  
    LPCTSTR lpszTraceFile,  
    DWORD dwTraceFlags  
);
```

The **DnsEnableTrace** function enables the logging of socket function calls to a file.

Parameters

lpszTraceFile

A pointer to a string which specifies the name of the trace log file. If this parameter is NULL or an empty string, the default file name **cstrace.log** is used. The file is stored in the directory specified by the TEMP environment variable, if it is defined; otherwise, the current working directory is used.

dwTraceFlags

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
TRACE_INFO	All function calls are written to the trace file. This is the default value.
TRACE_ERROR	Only those function calls which fail are recorded in the trace file.
TRACE_WARNING	Only those function calls which fail or return values which indicate a warning are recorded in the trace file.
TRACE_HEXDUMP	All functions calls are written to the trace file, plus all the data that is sent or received is displayed, in both ASCII and hexadecimal format.
TRACE_PROCESS	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for multithreaded applications that are using worker threads.

Return Value

If the function succeeds, the return value is non-zero. A return value of zero indicates an error. Failure typically indicates that the tracing library **cstrcv10.dll** cannot be loaded on the local system.

Remarks

When trace logging is enabled, the file is opened, appended to and closed for each socket function call. This makes it possible for an application to append its own logging information, however care should be taken to ensure that the file is closed before the next network operation is performed. To limit the size of the log files, enable and disable logging only around those sections of code that you wish to trace.

Note that the TRACE_HEXDUMP trace level generates very large log files since it includes all of the data exchanged between your application and the remote host.

Trace function logging is managed on a per-thread basis, not for each client handle. This means that all SocketTools libraries and components share the same settings in the current thread. If you

are using multiple SocketTools libraries or components in your application, you only need to enable logging once.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csdnsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[DnsDisableTrace](#)

DnsEnumHostAliases Function

```
INT WINAPI DnsEnumHostAliases(  
    HCLIENT hClient,  
    LPCTSTR lpszHostName,  
    LPTSTR *lpszHostAlias,  
    INT nMaxAliases  
);
```

The **DnsEnumHostAliases** function returns a list of aliases for the specified host name or IP address.

Parameters

hClient

Handle to the client session.

lpszHostName

Pointer to the string that contains the hostname to be resolved. If a fully qualified domain name is not provided, the default local domain will be used. This value may also be an IP address.

lpszHostAlias

Pointer to an array of string pointers which specify one or more host aliases. If the application needs to store these values, a local copy should be made because they are invalidated when another host name is resolved.

nMaxAliases

The maximum number of aliases in the array. This parameter must have a value of at least one, or an error will be returned.

Return Value

If the function succeeds, the return value is the number of host aliases. If the function fails, the return value is DNS_ERROR. To get extended error information, call **DnsGetLastError**.

Remarks

The application must never attempt to modify the host aliases or free any of the values. This function uses an internal data structure to store the host information and only one copy of this structure is allocated per thread. The application must copy any information it needs before issuing any other function calls.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csdnsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[DnsGetHostAddress](#), [DnsGetHostName](#)

DnsEnumMailExchanges Function

```
INT WINAPI DnsEnumMailExchanges(  
    HCLIENT hClient,  
    LPCTSTR lpszHostName,  
    LPTSTR *lpszMailExchanges,  
    INT nMaxMailExchanges  
);
```

The **DnsEnumMailExchanges** function returns a list of mail exchanges for the specified host name or IP address.

Parameters

hClient

Handle to the client session.

lpszHostName

Pointer to the string that contains the hostname or domain name to be queried.

lpszMailExchanges

Pointer to an array of string pointers which specify one or more mail exchanges. If the application needs to store these values, a local copy should be made because they are invalidated when another host name is resolved. The list of mail exchange records is sorted in priority order, from highest (i.e., those whose preference value is smallest) to lowest.

nMaxMailExchanges

The maximum number of mail exchanges in the array. If this parameter is 0, then the function will return the number of mail exchanges, but the list of mail exchanges will not be output in *lpszMailExchanges*.

Return Value

If the function succeeds, the return value is the number of mail exchanges. If the function fails, the return value is DNS_ERROR. To get extended error information, call **DnsGetLastError**.

Remarks

The application must never attempt to modify the mail exchange host names or free any of the values. This function uses an internal data structure to store the host information and only one copy of this structure is allocated per thread. The application must copy any information it needs before issuing any other function calls.

Example

```
// Count the number of mail exchanges  
if ((nMX = DnsEnumMailExchanges(hClient,szHostName, NULL, 0)) == DNS_ERROR)  
{  
    dwError = DnsGetLastError();  
    DnsGetErrorString(dwError, szError, BUFSIZE);  
    printf("DnsEnumMailExchanges failed for %s: %s\n", szHostName, szError);  
}  
else  
{  
    int nIndex;  
    printf("%d MX for %s\n",nMX, szHostName);  
  
    // Allocate memory for the list of mail exchanges
```

```
lpszMailExchanges = (LPTSTR *)malloc(nMX * sizeof(LPTSTR));

// Retrieve the list of mail exchanges
nMX = DnsEnumMailExchanges(hClient, szHostName, lpszMailExchanges, nMX);

for (nIndex = 0; nIndex < nMX; nIndex++)
    printf("#%d: %s\n", nIndex+1, *lpszMailExchanges++);

free(lpszMailExchanges);
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csdnsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

DnsFormatAddress Function

```
INT WINAPI DnsFormatAddress(  
    LPINTERNET_ADDRESS lpAddress,  
    LPTSTR lpszAddress,  
    INT nMaxLength  
);
```

The **DnsFormatAddress** function converts a numeric IPv4 or IPv6 address to a string.

Parameters

lpAddress

A pointer to an INTERNET_ADDRESS structure which specifies the numeric IPv4 or IPv6 address to be converted into a string.

lpszAddress

A pointer to a null-terminated array of characters which will contain the converted IPv4 address in dot-notation. This string should be at least 16 characters in length.

nMaxLength

The maximum number of characters which may be copied in to the string buffer.

Return Value

If the function succeeds, the return value is the length of the string buffer. If the function fails, the return value is zero. To get extended error information, call **DnsGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csdnsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

DnsGetAddress Function

```
INT WINAPI DnsGetAddress(  
    LPCTSTR lpszAddress,  
    INT nAddressFamily,  
    LPINTERNET_ADDRESS lpAddress  
);
```

The **DnsGetAddress** function converts an address string to a numeric IPv4 or IPv6 address.

Parameters

lpszAddress

A pointer to a string which specifies an IPv4 address in dotted notation.

nAddressFamily

An integer value which specifies the type of IP address. If this parameter is zero, the address family will be determined automatically based on the format of the address string. If this parameter is `DNS_ADDRESS_IPV4`, the address must be in IPv4 format, and if it is `DNS_ADDRESS_IPV6`, the address must be in IPv6 format.

lpAddress

A pointer to an `INTERNET_ADDRESS` structure that will contain the numeric form of the IPv4 or IPv6 address in network byte order when the function returns.

Return Value

If the function succeeds, the return value is the address family for the IP address. If the function fails, the return value is `DNS_ERROR`. To get extended error information, call **DnsGetLastError**.

Remarks

This function will only accept a string that is in the proper format for an IP address, and cannot be used to resolve a host name. To perform host name resolution, use the **DnsGetHostAddress** function. To convert a numeric address to an address string, use the **DnsFormatAddress** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csdnsv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

See Also

[DnsGetMailExchange](#), [DnsGetRecord](#), [INTERNET_ADDRESS](#)

DnsGetAddressFamily Function

```
INT WINAPI DnsGetAddressFamily(  
    LPCTSTR LpszAddress  
);
```

The **DnsGetAddressFamily** function returns the address family for the specified IP address.

Parameters

lpszAddress

A pointer to a string which specifies an IPv4 or IPv6 address.

Return Value

If the function succeeds, the return value is DNS_ADDRESS_IPV4 if the address is in IPv4 format, or DNS_ADDRESS_IPV6 if the address is in IPv6 format. If the address string is not in a recognized format, it returns DNS_ADDRESS_ANY.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csdnsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

DnsGetDefaultHostFile Function

```
INT WINAPI DnsGetDefaultHostFile(  
    LPTSTR lpszFileName,  
    INT nMaxLength  
);
```

The **DnsGetDefaultHostFile** function returns the fully qualified path name of the host file on the local system. The host file is used as a database that maps an IP address to one or more hostnames, and is used by the **DnsGetHostAddress** and **DnsGetHostName** function. The file is a plain text file, with each line in the file specifying a record, and each field separated by spaces or tabs. The format of the file must be as follows:

```
ipaddress hostname [hostalias ...]
```

For example, one typical entry maps the name "localhost" to the local loopback IP address. This would be entered as:

```
127.0.0.1 localhost
```

The hash character (#) may be used to specify a comment in the file, and all characters after it are ignored up to the end of the line. Blank lines are ignored, as are any lines which do not follow the required format.

The default hosts file is stored in C:\Windows\system32\drivers\etc\hosts and may or may not exist on a given system. Note that there is no extension for this file.

Parameters

lpszFileName

Pointer to a string buffer that will contain the fully qualified file name to the default host file. It is recommended that this buffer be at least MAX_PATH characters in size. This parameter may be NULL, in which case the function will return the length of the string, not including the terminating null byte.

nMaxLength

The maximum number of characters that may be copied to the string buffer.

Return Value

If the function succeeds, the return value is length of the string. A return value of zero indicates that the default host file could not be determined for the current platform. To get extended error information, call **DnsGetLastError**.

Remarks

This function only returns the default location of the host file and does not determine if the file actually exists. It is not required that a host file be present on the system.

The default host file is processed before performing a nameserver lookup when resolving a hostname into an IP address, or an IP address into a hostname.

To specify an alternate local host file, use the **DnsSetHostFile** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csdns10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[DnsGetHostAddress](#), [DnsGetHostFile](#), [DnsGetHostName](#), [DnsSetHostFile](#)

DnsGetErrorString Function

```
INT WINAPI DnsGetErrorString(  
    DWORD dwErrorCode,  
    LPTSTR lpszDescription,  
    INT nMaxLength  
);
```

The **DnsGetErrorString** function is used to return a description of a specific error code. Typically this is used in conjunction with the **DnsGetLastError** function for use with warning dialogs or as diagnostic messages.

Parameters

dwErrorCode

The last-error code for which a description is returned.

lpszDescription

A pointer to the buffer that will contain a description of the specified error code. This buffer should be at least 128 characters in length.

nMaxLength

The maximum number of characters that may be copied into the description buffer.

Return Value

If the function succeeds, the return value is the length of the description string. If the function fails, the return value is 0, meaning that no description exists for the specified error code. Typically this indicates that the error code passed to the function is invalid.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csdnsv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

See Also

[DnsGetLastError](#), [DnsSetLastError](#)

DnsGetHostAddress Function

```
INT WINAPI DnsGetHostAddress(  
    HCLIENT hClient,  
    INT nAddressFamily,  
    LPCTSTR lpszHostName,  
    LPTSTR lpszHostAddress,  
    INT nMaxLength  
);
```

The **DnsGetHostAddress** function resolves the specified host name, storing the IP address in the provided buffer.

Parameters

hClient

Handle to the client session.

nAddressFamily

An integer value which specifies the type of address that should be returned. A value of `DNS_ADDRESS_IPV4` specifies that the IPv4 address for the host should be returned. A value of `DNS_ADDRESS_IPV6` specifies that the IPv6 address for the host should be returned. A value of `DNS_ADDRESS_ANY` specifies that if the host only has an IPv6 address, that value should be returned, otherwise return the IPv4 address for the host.

lpszHostName

Pointer to the string that contains the hostname to be resolved. If a fully qualified domain name is not provided, the default local domain will be used.

lpszHostAddress

Pointer to the buffer that will contain the IP address, stored as a string in dot notation. This buffer should be at least 48 characters in length to accommodate both IPv4 and IPv6 addresses. The format of the address is determined by the address family specified.

nMaxLength

The maximum length of the string buffer. The maximum length of the buffer must include the terminating null character.

Return Value

If the function succeeds, the return value is the number of characters copied into the host address buffer. If the function fails, the return value is `DNS_ERROR`. To get extended error information, call **DnsGetLastError**.

Remarks

The **DnsGetHostAddress** function may return an address in either IPv4 or IPv6 format, depending on the address family that is specified and what records exist for the host. If your application does not support the IPv6 address format, you must specify the *nAddressFamily* parameter as `DNS_ADDRESS_IPV4` to prevent the possibility of an IPv6 address being returned.

If the *nAddressFamily* parameter is specified as `DNS_ADDRESS_ANY`, this function will first check for an IPv4 address record for the host. If it exists, it will return that address. If the host does not have an IPv4 address, it will then check for an IPv6 address record and return that address. This gives preference to IPv4 addresses, but your application should never depend on this behavior. In the future, this function may change to give preference to IPv6 addresses.

To determine what format an address is in, use the **DnsGetAddressFamily** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csdnsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[DnsEnumHostAliases](#), [DnsGetAddressFamily](#), [DnsGetHostName](#), [DnsGetMailExchange](#),
[DnsGetRecord](#)

DnsGetHostByAddress Function

```
LPHOSTENT WINAPI DnsGetHostByAddress(  
    HCLIENT hClient,  
    LPVOID lpvAddress,  
    INT cbAddress,  
    INT nAddressFamily  
);
```

The **DnsGetHostByAddress** function returns a pointer to a [HOSTENT](#) structure which contains the results of a successful search for the host specified by address parameter.

Parameters

hClient

Handle to the client session.

lpvAddress

Pointer to an integer IPv4 address in network byte order.

cbAddress

The length of the address in bytes; this value should always be 4.

nAddressFamily

The type of address being resolved; this value should always be `DNS_ADDRESS_IPV4` as defined in the Windows Sockets header file.

Return Value

If the function succeeds, the return value is a pointer to a `HOSTENT` structure. If the function fails, the return value is `NULL`. To get extended error information, call **DnsGetLastError**.

Remarks

The application must never attempt to modify this structure or to free any of its components. Only one copy of this structure is allocated per thread, so the application should copy any information it needs before issuing any other function calls. To convert an IPv4 address string in dotted notation to a 32-bit IP address, use the **DnsGetAddress** function.

This function is included for compatibility with existing applications which already use the `HOSTENT` structure. Because this function returns a pointer to a complex structure, it may not be suitable for some programming languages.

This function is not compatible with IPv6 addresses. For applications that must support both IPv4 and IPv6 address formats, use the **DnsGetHostAddress** and **DnsGetHostName** functions.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csdnsv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

See Also

[DnsGetHostAddress](#), [DnsGetHostByName](#), [DnsGetHostInfo](#), [DnsGetHostName](#), [DnsGetHostServices](#), [DnsGetRecord](#), [DnsGetResolverAddress](#), [DnsRegisterServer](#)

DnsGetHostByName Function

```
LPHOSTENT WINAPI DnsGetHostByName(  
    HCLIENT hClient,  
    LPCTSTR lpszHostName  
);
```

The **DnsGetHostByName** function returns a pointer to a [HOSTENT](#) structure which contains the results of a successful search for the host specified in the name parameter.

Parameters

hClient

Handle to the client session.

lpszHostName

Pointer to the string that contains the hostname to be resolved. If a fully qualified domain name is not provided, the default local domain will be used.

Return Value

If the function succeeds, the return value is a pointer to a [HOSTENT](#) structure. If the function fails, the return value is NULL. To get extended error information, call **DnsGetLastError**.

Remarks

The application must never attempt to modify this structure or to free any of its components. Only one copy of this structure is allocated per thread, so the application should copy any information it needs before issuing any other function calls. This function will automatically resolve an IP address passed as a string, converting it to numeric form and calling the **DnsGetHostByAddress** function.

This function is included for compatibility with existing applications which already use the [HOSTENT](#) structure. Because this function returns a pointer to a complex structure, it may not be suitable for some programming languages.

This function is not compatible with IPv6 addresses. For applications that must support both IPv4 and IPv6 address formats, use the **DnsGetHostAddress** and **DnsGetHostName** functions.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csdnsv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

See Also

[DnsGetHostAddress](#), [DnsGetHostByAddress](#), [DnsGetHostInfo](#), [DnsGetHostName](#),
[DnsGetHostServices](#), [DnsGetMailExchange](#), [DnsGetRecord](#), [DnsGetResolverAddress](#),
[DnsRegisterServer](#)

DnsGetHostFile Function

```
INT WINAPI DnsGetHostFile(  
    HCLIENT hClient,  
    LPTSTR lpszFileName,  
    INT nMaxLength  
);
```

The **DnsGetHostFile** function returns the name of the host file previously set using the **DnsSetHostFile** function. The host file is used as a database that maps an IP address to one or more hostnames, and is used by the **DnsGetHostAddress** and **DnsGetHostName** function.

Parameters

hClient

Handle to the client session.

lpszFileName

Pointer to a string buffer that will contain the host file name. It is recommended that this buffer be at least MAX_PATH characters in size. This parameter may be NULL, in which case the function will return the length of the string, not including the terminating null character.

nMaxLength

The maximum number of characters that may be copied to the string buffer.

Return Value

If the function succeeds, the return value is length of the string. A return value of zero indicates that no host file has been specified or the function was unable to determine the file name. To get extended error information, call **DnsGetLastError**. If the last error is zero, this indicates that no host file name has been specified for the current thread. If the last error is non-zero, this indicates the reason that the function failed.

Remarks

This function only returns the name of the host file that is cached in memory for the current thread. The contents of the file on the disk may have changed after the file was loaded into memory. To reload the host file or clear the cache, call the **DnsSetHostFile** function.

If a host file has been specified, it is processed before the default host file when resolving a hostname into an IP address, or an IP address into a hostname. If the host name or address is not found, or no host file has been specified, a nameserver lookup is performed.

The host file returned by this function may be different than the default host file for the local system. To determine the file name for the default host file, use the **DnsGetDefaultHostFile** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csdnsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

DnsGetHostInfo Function

```
INT WINAPI DnsGetHostInfo(  
    HCLIENT hClient,  
    LPCTSTR lpszHostName,  
    LPTSTR lpszBuffer,  
    INT nMaxLength  
);
```

The **DnsGetHostInfo** function returns the HINFO record for the specified hostname. This information, if it is provided, typically specifies the operating system type and hardware platform.

Parameters

hClient

Handle to the client session.

lpszHostName

Pointer to the string which specifies the host name that information will be returned for.

lpszBuffer

Pointer to the buffer which will contain the host information returned by the nameserver.

nMaxLength

Maximum number of characters that may be copied into the specified buffer, including the null character terminator.

Return Value

If the function succeeds, the length of the host information buffer is returned. A return value of zero indicates that no information is available for the specified host. If the function fails, the return value is DNS_ERROR. To get extended error information, call **DnsGetLastError**.

Remarks

Many systems do not maintain HINFO records for a site since that information can potentially be used to compromise system security. The information is typically used for administrative purposes with internal networks.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csdnsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[DnsGetHostByAddress](#), [DnsGetHostByName](#), [DnsGetHostServices](#), [DnsGetMailExchange](#), [DnsGetRecord](#), [DnsGetResolverAddress](#), [DnsRegisterServer](#)

DnsGetHostName Function

```
INT WINAPI DnsGetHostName(  
    HCLIENT hClient,  
    LPCTSTR lpszHostAddress,  
    LPTSTR lpszHostName,  
    INT nMaxLength  
);
```

The **DnsGetHostName** function resolves the specified IP address, storing the fully qualified host name in the provided buffer.

Parameters

hClient

Handle to the client session.

lpszHostAddress

Pointer to a string that specifies an IPv4 or IPv6 formatted address.

lpszHostName

Pointer to the buffer that will contain the fully qualified domain name for the specified host. This buffer should be at least 64 characters in length.

nMaxLength

The maximum length of the string buffer.

Return Value

If the function succeeds, the return value is the number of characters copied into the host name buffer. If the function fails, the return value is DNS_ERROR. To get extended error information, call **DnsGetLastError**.

Remarks

The **DnsGetHostName** function first looks to see if there is an entry in the local host file for the specified IP address, and if one exists, it will return the host name for that address. If you do not want to use the local host file at all, and only return an host name if a DNS query resolves the address, use the **DnsGetRecord** function and specify a record type of DNS_RECORD_PTR.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csdnsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[DnsEnumHostAliases](#), [DnsGetHostByAddress](#), [DnsGetHostByName](#), [DnsGetHostAddress](#)

DnsGetHostServices Function

```
INT WINAPI DnsGetHostServices(  
    HCLIENT hClient,  
    LPCTSTR lpszHostName,  
    INT nProtocol,  
    LPTSTR lpszBuffer,  
    INT nMaxLength  
);
```

The **DnsGetHostServices** function returns the WKS (Well Known Services) record for the specified hostname and protocol. This information, if it is provided, typically specifies the names of those services supported on the host.

Parameters

hClient

Handle to the client session.

lpszHostName

Pointer to the string which specifies the host name that information will be returned for.

nProtocol

The protocol for those services that information should be returned about. The following protocols are recognized:

Value	Constant	Description
6	DNS_PROTOCOL_TCP	Services that use the Transmission Control Protocol (TCP)
17	DNS_PROTOCOL_UDP	Services that use the User Datagram Protocol (UDP)

lpszBuffer

Pointer to the buffer which will contain the host information returned by the nameserver.

nMaxLength

Maximum number of characters that may be copied into the specified buffer, including the null character terminator.

Return Value

If the function succeeds, the length of the host services buffer is returned. A return value of zero indicates that no information is available for the specified host. If the function fails, the return value is DNS_ERROR. To get extended error information, call **DnsGetLastError**.

Remarks

Many systems do not maintain complete services records for a site since that information can potentially be used to compromise system security. An application should not depend on this information being available for any given record.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csdnsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[DnsGetRecord](#), [DnsGetResolverAddress](#), [DnsRegisterServer](#)

DnsGetLastError Function

```
DWORD WINAPI DnsGetLastError();
```

Parameters

None.

Return Value

The return value is the calling thread's last-error code value. Functions set this value by calling the **DnsSetLastError** function. The Return Value section of each reference page notes the conditions under which the function sets the last-error code.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. You should call the **DnsGetLastError** function immediately when a function's return value indicates that an error has occurred. That is because some functions call **DnsSetLastError(0)** when they succeed, clearing the error code set by the most recently failed function.

Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or DNS_ERROR. Those functions which call **DnsSetLastError** when they succeed are noted on the function reference page.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csdnsv10.lib

See Also

[DnsGetErrorString](#), [DnsSetLastError](#)

DnsGetLocalAddress Function

```
INT WINAPI DnsGetLocalAddress(  
    HCLIENT hClient,  
    INT nAddressFamily,  
    LPTSTR lpszAddress,  
    INT nMaxLength  
);
```

The **DnsGetLocalAddress** function returns the IP address for the local host.

hClient

Handle to the client session.

nAddressFamily

An integer value which specifies the type of address that should be returned. A value of `DNS_ADDRESS_IPV4` specifies that the IPv4 address for the host should be returned. A value of `DNS_ADDRESS_IPV6` specifies that the IPv6 address for the host should be returned. A value of `DNS_ADDRESS_ANY` specifies that if the host only has an IPv6 address, that value should be returned, otherwise return the IPv4 address for the host.

lpszAddress

Pointer to the buffer that will contain the IP address, stored as a string in dot notation. This buffer should be at least 40 characters in length to accommodate both IPv4 and IPv6 addresses.

nMaxLength

The maximum length of the string buffer.

Return Value

If the function succeeds, the return value is the number of characters copied into the host address buffer. If the function fails, the return value is `DNS_ERROR`. To get extended error information, call **DnsGetLastError**.

Remarks

The **DnsGetLocalAddress** function may return an address in either IPv4 or IPv6 format, depending on the address family that is specified and what records exist for the host. If your application does not support the IPv6 address format, you must specify the *nAddressFamily* parameter as `DNS_ADDRESS_IPV4` to prevent the possibility of an IPv6 address being returned.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csdnsv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

DnsGetLocalDomain Function

```
INT WINAPI DnsGetLocalDomain(  
    HCLIENT hClient,  
    LPTSTR lpszDomain,  
    INT nMaxLength  
);
```

The **DnsGetLocalDomain** function copies the local domain name into the specified buffer. The value returned is the same value that was set with the **DnsSetLocalDomain** function. If no local domain name has been set, an empty string is returned.

Parameters

hClient

Handle to the client session.

lpszDomain

Pointer to the buffer that is used to store the local domain name. If no local domain name has been set, this buffer will be set to zero length.

nMaxLength

The maximum number of bytes to copy into the buffer, including the null character terminator.

Return Value

If the function succeeds, the return value is the length of the domain name string. A return value of zero indicates that no local domain name has been set. If the function fails, the return value is DNS_ERROR. To get extended error information, call **DnsGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csdnsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

DnsGetLocalName Function

```
INT WINAPI DnsGetLocalName(  
    HCLIENT hClient,  
    LPTSTR lpszLocalName,  
    INT nMaxLength  
);
```

The **DnsGetLocalName** function returns the local host name.

Parameters

hClient

Handle to the client session.

lpszLocalName

Pointer to a string buffer that will contain the local host name. It is recommended that this buffer be at least 64 characters in size.

nMaxLength

The maximum number of characters that may be copied to the string buffer.

Return Value

If the function succeeds, the return value is the length of the local host name. If the function fails, the return value is DNS_ERROR. To get extended error information, call **DnsGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csdnsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[DnsGetMailExchange](#), [DnsGetRecord](#)

DnsGetMailExchange Function

```
INT WINAPI DnsGetMailExchange(  
    HCLIENT hClient,  
    LPCTSTR lpszHostName,  
    LPINT lpnPreference,  
    LPTSTR lpszBuffer,  
    INT nMaxLength  
);
```

The **DnsGetMailExchange** function returns the mail exchange (MX) record information for the specified domain. This information, if it is provided, identifies a server responsible for processing mail for the given domain.

Parameters

hClient

Handle to the client session.

lpszHostName

Pointer to the string which specifies the host name that information will be returned for.

lpnPreference

Pointer to the integer which will contain the preference for the specified mail exchange host.

lpszBuffer

Pointer to the buffer which will contain the host information returned by the nameserver.

nMaxLength

Maximum number of characters that may be copied into the specified buffer, including the null character terminator.

Return Value

If the function succeeds, the length of the buffer is returned. A return value of zero indicates that no information is available for the specified host. If the function fails, the return value is DNS_ERROR. To get extended error information, call **DnsGetLastError**.

Remarks

The mail exchange record is typically used by mail delivery agents to determine what system is responsible for accepting mail addressed to a given domain. This function will return the first MX record provided by the server. Note that some domains may have multiple mail servers. To enumerate all of the mail exchange records for a domain, use the **DnsEnumMailExchanges** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csdnsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

DnsGetRecord Function

```
INT WINAPI DnsGetRecord(  
    HCLIENT hClient,  
    LPCTSTR lpszHostName,  
    INT nRecordType,  
    LPTSTR lpszBuffer,  
    INT nMaxLength  
);
```

The **DnsGetRecord** function returns the specified record information for the given hostname.

Parameters

hClient

Handle to the client session.

lpszHostName

Pointer to the string which specifies the host name that information will be returned for.

nRecordType

The record type for the information that should be returned. The following record types are recognized:

Value	Constant	Description
0	DNS_RECORD_NONE	No record type
1	DNS_RECORD_ADDRESS	IPv4 host address
2	DNS_RECORD_NS	Authoritative nameserver
5	DNS_RECORD_CNAME	Canonical host name (alias)
6	DNS_RECORD_SOA	Start of Authority
11	DNS_RECORD_WKS	Well known services
12	DNS_RECORD_PTR	Domain name
13	DNS_RECORD_HINFO	Host information
14	DNS_RECORD_MINFO	Mailbox information
15	DNS_RECORD_MX	Mail exchange host
16	DNS_RECORD_TXT	Text strings
28	DNS_RECORD_AAAA	IPv6 host address
29	DNS_RECORD_LOC	Location information
100	DNS_RECORD_UINFO	User information
101	DNS_RECORD_UID	User ID
102	DNS_RECORD_GID	Group ID

lpszBuffer

Pointer to the buffer which will contain the host information returned by the nameserver.

nMaxLength

Maximum number of characters that may be copied into the specified buffer, including the null character terminator.

Return Value

If the function succeeds, the length of the information buffer is returned. A return value of zero indicates that no information for that record is available for the specified host. If the function fails, the return value is `DNS_ERROR`. To get extended error information, call **DnsGetLastError**.

Remarks

The **DnsGetRecord** function can be used to resolve a host name into an IPv4 address using the record type `DNS_RECORD_ADDRESS`, or an IPv6 address using the record type `DNS_RECORD_AAAA`. It can also be used to perform a reverse lookup and resolve an IP address into a host name by using the record type `DNS_RECORD_PTR`.

To determine the host that serves as the primary or master DNS for a zone, the record name should be specified as the domain name (e.g.: `microsoft.com`) and the record type should be `DNS_RECORD_SOA`. The value returned will be the fully qualified domain name for host.

Note that this function does not reference a local host file when resolving host names or addresses. If the record lookup fails, this function will return an error even if there's an entry for the host in the file that has been specified by a call to **DnsSetHostFile**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csdnsv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

DnsGetResolverAddress Function

```
INT WINAPI DnsGetResolverAddress(  
    HCLIENT hClient,  
    LPTSTR lpszAddress,  
    INT nMaxLength  
);
```

The **DnsGetResolverAddress** returns the address of the nameserver that resolved the last query.

Parameters

hClient

Handle to the client session.

lpszAddress

A pointer to a string buffer that will contain the address of the nameserver when the function returns. This buffer should be large enough to store both IPv4 and IPv6 addresses, with a minimum length of 40 characters. If this parameter is NULL, it will be ignored.

nMaxLength

The maximum number of characters that can be copied into the string buffer. If this value is zero, the *lpszAddress* parameter will be ignored and the function will return the length of the address.

Return Value

If the function succeeds, the return value is the length of the address, not including the terminating null character. If the function fails, the return value is DNS_ERROR. To get extended error information, call **DnsGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csdnsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

DnsGetResolverOptions Function

```
DWORD WINAPI DnsGetResolverOptions(  
    HCLIENT hClient  
);
```

The **DnsGetResolverOptions** function returns the options that have been set for the client session.

Parameters

hClient

Handle to the client session

Return Value

If the function succeeds, the return value is the resolver options set for the client session. If the client handle is invalid or no resolver options have been specified, the function will return zero.

Remarks

The **DnsGetResolverOptions** function can be used to determine which resolver options have been specified for the client session. For a list of the available options, refer to the documentation for the **DnsSetResolverOptions** function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csdnsv10.lib

See Also

DnsGetRetryCount Function

```
INT WINAPI DnsGetRetryCount(  
    HCLIENT hClient  
);
```

The **DnsGetRetryCount** returns the retry count for the current client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the retry count. If the function fails, the return value is DNS_ERROR. To get extended error information, call **DnsGetLastError**.

Remarks

The retry count determines the amount of time the client will wait for a response from each query, the effective amount of time the client will wait increases with each nameserver and the total number of retries specified. For example, two nameservers registered with the client, with a default of 4 retries per nameserver and a timeout value of 10 seconds, would cause the client to wait a total of 80 seconds until it returns an error indicating that it was unable to resolve the query.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csdnsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

DnsGetServerAddress Function

```
INT WINAPI DnsGetServerAddress(  
    HCLIENT hClient,  
    INT nServer,  
    LPTSTR lpszAddress,  
    INT nMaxLength  
);
```

The **DnsGetServerAddress** function returns the address of the registered nameserver.

Parameters

hClient

Handle the client session.

nServer

The index into the client's nameserver table. This index is the same value that is passed to the **DnsRegisterServer** function when the nameserver is registered.

lpszAddress

A pointer to a string buffer that will contain the address of the nameserver when the function returns. This buffer should be large enough to store both IPv4 and IPv6 addresses, with a minimum length of 40 characters. If this parameter is NULL, it will be ignored.

nMaxLength

The maximum number of characters that can be copied into the string buffer. If this value is zero, the *lpszAddress* parameter will be ignored and the function will return the length of the address.

Return Value

If the function succeeds, the return value is the length of the address, not including the terminating null character. If the function fails, the return value is DNS_ERROR. To get extended error information, call **DnsGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csdnsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

DnsGetServerPort Function

```
INT WINAPI DnsGetServerPort(  
    HCLIENT hClient,  
    INT nServer  
);
```

The **DnsGetServerPort** function returns the port number registered to the specified nameserver.

Parameters

hClient

Handle the client session.

nServer

The index into the client's nameserver table. This index is the same value that is passed to the **DnsRegisterServer** function when the nameserver is registered.

Return Value

If the function succeeds, the return value is the specified port number. If the function fails, the return value is DNS_ERROR. To get extended error information, call **DnsGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csdnsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

DnsGetTimeout Function

```
INT WINAPI DnsGetTimeout(  
    HCLIENT hClient  
);
```

The **DnsGetTimeout** function returns the timeout value for the current client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the timeout period. If the function fails, the return value is DNS_ERROR. To get extended error information, call **DnsGetLastError**.

Remarks

The timeout value determines the amount of time the client will wait for a response from each query, the effective amount of time the client will wait increases with each nameserver and the total number of retries specified. For example, two nameservers registered with the client, with a default of 4 retries per nameserver and a timeout value of 10 seconds, would cause the client to wait a total of 80 seconds until it returns an error indicating that it was unable to resolve the query.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csdnsv10.lib

DnsHostNameToUnicode Function

```
INT WINAPI DnsHostNameToUnicode(  
    LPCTSTR lpszHostName,  
    LPTSTR lpszUnicodeName,  
    INT nMaxLength  
);
```

The **DnsHostNameToUnicode** function converts the canonical form of a host name to its Unicode version.

Parameters

lpszHostName

Pointer to the host name as a null-terminated string. This parameter cannot be a NULL pointer or a zero length string.

lpszUnicodeName

Pointer to the string buffer that will contain the original Unicode version of the host name, including the terminating null character. It is recommended that this buffer be at least 256 characters in size. This parameter cannot be a NULL pointer.

nMaxLength

The maximum number of characters that can be copied to the *lpszUnicodeName* string buffer. This parameter cannot be zero, and must include the terminating null character.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer. If the function fails, the return value is DNS_ERROR. To get extended error information, call **DnsGetLastError**.

Remarks

The **DnsHostNameToUnicode** function will convert the encoded ASCII version of a host name to its Unicode version. Although any valid host name is accepted by this function, it is intended to convert a Punycode encoded host name to its original Unicode character encoding.

If the Unicode version of this function is used, the value returned in *lpszUnicodeName* will be a Unicode string using UTF-16 encoding. If the ANSI version of this function, the value returned will be a Unicode string using UTF-8 encoding. To display a UTF-8 encoded host name, your application will need to convert it to UTF-16 using the **MultiByteToWideChar** function.

Although this function performs checks to ensure that the *lpszHostName* parameter is in the correct format and does not contain any illegal characters or malformed encoding, it does not validate the existence of the domain name. To check if the host name exists and has a valid IP address, use the [DnsGetHostAddress](#) function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csdns10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

DnsInitialize Function

```
BOOL WINAPI DnsInitialize(  
    LPCTSTR lpszLicenseKey,  
    LPINITDATA lpData  
);
```

The **DnsInitialize** function initializes the library and validates the specified license key at runtime.

Parameters

lpszLicenseKey

Pointer to a string that specifies the runtime license key to be validated. If this parameter is NULL, the library will validate the development license installed on the local system.

lpData

Pointer to an INITDATA data structure. This parameter may be NULL if the initialization data for the library is not required.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **DnsGetLastError**. All other client functions will fail until a license key has been successfully validated.

Remarks

This must be the first function that an application calls before using any of the other functions in the library. When a NULL license key is specified, the library will only function on the development system. Before redistributing the application to an end-user, you must insure that this function is called with a valid license key.

If the *lpData* argument is specified, it must point to an INITDATA structure which has been initialized by setting the *dwSize* member to the size of the structure. All other structure members should be set to zero. If the function is successful, then the INITDATA structure will be filled with identifying information about the library.

Although it is only required that **DnsInitialize** be called once for the current process, it may be called multiple times; however, each call must be matched by a corresponding call to **DnsUninitialize**.

This function dynamically loads other system libraries and allocates thread local storage. If you are calling the functions in this library from within another DLL, it is important that you do not call the **DnsInitialize** or **DnsUninitialize** functions from the **DllMain** function because it can result in deadlocks or access violation errors. If the DLL is linked with the C runtime library (CRT), it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csdnsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

DnsMatchHostName Function

```
BOOL WINAPI DnsMatchHostName(  
    HCLIENT hClient,  
    LPCTSTR lpszHostName,  
    LPCTSTR lpszHostMask  
    BOOL bResolve  
);
```

The **DnsMatchHostName** function matches a host name against one or more strings that may contain wildcards.

Parameters

hClient

Handle to the client session.

lpszHostName

A pointer to a string which specifies the host name or IP address to match.

lpszHostMask

A pointer to a string which specifies one or more values to match against the host name. The asterisk character can be used to match any number of characters in the host name, and the question mark can be used to match any single character. Multiple values may be specified by separating them with a semicolon.

bResolve

A boolean value which specifies if the host name or IP address should be resolved when matching the host against the mask string. If this parameter is non-zero, two checks against the host mask string will be performed; once for the host name specified and once for its IP address. If this parameter is zero, then the match is made only against the host name string provided.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **DnsGetLastError**.

Remarks

The **DnsMatchHostName** function provides a convenient way for an application to determine if a given host name matches one or more mask strings which may contain wildcard characters. For example, the host name could be "www.microsoft.com" and the host mask string could be "*.microsoft.com". In this example, the function would return a non-zero value indicating the host name matched the mask. However, if the mask string was "*.net" then the function would return zero, indicating that there was no match. Multiple mask values can be combined by separating them with a semicolon; for example, the mask "*.com;*.org" would match any host name in either the .com or .org top-level domains.

If an internationalized domain name (IDN) is specified, it will be converted internally to an ASCII string using Punycode encoding. The host mask will be matched against this encoded version of the host name, not its Unicode version.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csdnsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

DnsNormalizeHostName Function

```
INT WINAPI DnsNormalizeHostName(  
    LPCTSTR LpszHostName,  
    LPTSTR LpszNormalized,  
    INT nMaxLength  
);
```

The **DnsNormalizeHostName** function returns the canonical form of a host name in the specified buffer.

Parameters

LpszHostName

Pointer to the host name as a null-terminated string. This parameter cannot be a NULL pointer or a zero length string.

LpszNormalized

Pointer to the string buffer that will contain the canonical form of the host name, including the terminating null character. It is recommended that this buffer be at least 256 characters in size. This parameter cannot be a NULL pointer.

nMaxLength

The maximum number of characters that can be copied to the *LpszNormalized* string buffer. This parameter cannot be zero, and must include the terminating null character.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer. If the function fails, the return value is DNS_ERROR. To get extended error information, call **DnsGetLastError**.

Remarks

The **DnsNormalizeHostName** function will remove all leading and trailing whitespace characters from the host name and fold all upper-case characters to lower-case. If an internationalized domain name (IDN) containing Unicode characters is passed to this function, it will be converted to an ASCII compatible format for domain names.

If the Unicode version of this function is used, the host name will be converted from UTF-16 to UTF-8 and then processed. If you are unsure if an internationalized domain name will be specified as the host name, it is recommended that you use the Unicode version.

Although this function performs checks to ensure that the *LpszHostName* parameter is in the correct format and does not contain any illegal characters or malformed encoding, it does not validate the existence of the domain name. To check if the host name exists and has a valid IP address, use the [DnsGetHostAddress](#) function.

It is recommended that you use this function if your application needs to store the host name, and if accepts a host name as user input. It is not necessary to call this function prior to calling the other DNS API functions that accept a host name as a parameter. Those functions already normalize the host name and perform checks to ensure it is in the correct format.

If the *LpszHostName* parameter specifies a valid IPv4 or IPv6 address string instead of a host name, this function will return a copy of that IP address in the buffer provided by the caller. This allows the function to be used in cases where a user may input either a host name or IP address. To determine if the IP address has a corresponding host name, use the [DnsGetHostName](#) method.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csdnsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

DnsRegisterServer Function

```
INT WINAPI DnsRegisterServer(  
    HCLIENT hClient,  
    INT nServer,  
    LPCTSTR lpszHostAddress,  
    INT nPort  
);
```

The **DnsRegisterServer** function registers a nameserver with the current client session. The nameserver is used to resolve queries issued by the client, such as returning the IP address for a given host name. At least one nameserver must be registered by the client before queries are issued.

Parameters

hClient

Handle to the client session.

nServer

The index into the client nameserver table. This index, starting at 0, is used to specify which slot in the client's nameserver table will be used to store the nameserver information.

lpszHostAddress

A pointer to a string that specifies the IP address of the nameserver to be registered. Note that hostnames cannot be specified.

nPort

The port number that the specified nameserver is accepting queries on. This value may be set to zero, in which case it will use the default port value.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is DNS_ERROR. To get extended error information, call **DnsGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csdnsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[DnsCreateHandle](#), [DnsGetServerAddress](#), [DnsGetServerPort](#), [DnsUnregisterServer](#)

DnsReset Function

```
INT WINAPI DnsReset(  
    HCLIENT hClient  
);
```

The **DnsReset** function resets the current state of the client session. The timeout and retry counts are set to their default values, the local domain name is cleared and all registered servers are removed from the client nameserver table.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is DNS_ERROR. To get extended error information, call **DnsGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csdnsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[DnsRegisterServer](#), [DnsSetLocalDomain](#), [DnsSetRetryCount](#), [DnsSetTimeout](#), [DnsUnregisterServer](#)

DnsSetHostFile Function

```
INT WINAPI DnsSetHostFile(  
    HCLIENT hClient,  
    LPCTSTR lpszFileName  
);
```

The **DnsSetHostFile** function specifies the name of an alternate file to use when resolving hostnames and IP addresses. The host file is used as a database that maps an IP address to one or more hostnames, and is used by the **DnsGetHostAddress** and **DnsGetHostName** functions. The file is a plain text file, with each line in the file specifying a record, and each field separated by spaces or tabs. The format of the file must be as follows:

```
ipaddress hostname [hostalias ...]
```

For example, one typical entry maps the name "localhost" to the local loopback IP address. This would be entered as:

```
127.0.0.1 localhost
```

The hash character (#) may be used to specify a comment in the file, and all characters after it are ignored up to the end of the line. Blank lines are ignored, as are any lines which do not follow the required format.

Parameters

hClient

Handle to the client session.

lpszFileName

Pointer to a string that specifies the name of the file. If the parameter is NULL, then the current host file is cleared from the cache and only the default host file will be used to resolve hostnames and addresses.

Return Value

If the function succeeds, the return value is the number of entries in the host file. A return value of DNS_ERROR indicates failure. To get extended error information, call **DnsGetLastError**.

Remarks

This function loads the file into memory allocated for the current thread. If the contents of the file have changed after the function has been called, those changes will not be reflected when resolving hostnames or addresses. To reload the host file from disk, call this function again with the same file name. To remove the alternate host file from memory, specify a NULL pointer as the parameter.

If a host file has been specified, it is processed before the default host file when resolving a hostname into an IP address, or an IP address into a hostname. If the host name or address is not found, or no host file has been specified, a nameserver lookup is performed.

To determine if an alternate host file has been specified, use the **DnsGetHostFile** function. A return value of zero indicates that no alternate host file has been cached for the current thread.

A system may have a default host file, which is used to resolve hostnames before performing a nameserver lookup. To determine the name of this file, use the **DnsGetDefaultHostFile** function. It is not necessary to specify this default host file, since it is always used to resolve host names and addresses.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csdnsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

DnsSetLastError Function

```
VOID WINAPI DnsSetLastError(  
    DWORD dwErrorCode  
);
```

The **DnsSetLastError** function sets the error code for the current thread. This function is typically used to clear the last error by passing a value of zero as the parameter.

Parameters

dwErrorCode

Specifies the error code for the current thread. A value of zero clears the last error code.

Return Value

None.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or DNS_ERROR. Those functions which call **DnsSetLastError** when they succeed are noted on the function reference page.

Applications can retrieve the value saved by this function by using the **DnsGetLastError** function. The use of **DnsGetLastError** is optional; an application can call the function to determine the specific reason for a function failure.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csdnsv10.lib

DnsSetLocalDomain Function

```
INT WINAPI DnsSetLocalDomain(  
    HCLIENT hClient,  
    LPCTSTR lpszDomain  
);
```

Parameters

hClient

Handle to the client session.

lpszDomain

Pointer to the string which contains the local domain name. This is used as a default value when a query does not explicitly specify a domain name.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is DNS_ERROR. To get extended error information, call **DnsGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csdnsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

DnsSetResolverOptions Function

```
DWORD WINAPI DnsSetResolverOptions(  
    HCLIENT hClient,  
    DWORD dwOptions  
);
```

The **DnsSetResolverOptions** function changes the resolver options for the specified client session.

Parameters

hClient

Handle to the client session.

dwOptions

An unsigned integer that specifies one or more resolver options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
DNS_OPTION_NONE	No additional resolver options specified. This is the default value, and it is recommended that most applications do not specify additional options unless the implications of doing so are understood.
DNS_OPTION_PROMOTE	Promotes the server that successfully completed the last query to the first server that will be used to resolve subsequent queries. This option can improve performance in some cases where one or more of the registered servers are non-responsive. This option takes precedence over the DNS_OPTION_ROTATE option.
DNS_OPTION_ROTATE	Enables a round-robin selection of nameservers when performing queries. Normally each nameserver is queried in the same order. This option rotates the available nameservers so a different server is used with each query.
DNS_OPTION_AUTHONLY	Require the answer from the nameserver to be authoritative, not from the server's cache. This option is included for future expansion as most servers do not support this feature and will ignore it.
DNS_OPTION_PRIMARY	Queries are only accepted from the primary nameserver. This option is included for future expansion as most servers do not support this feature and will ignore it.
DNS_OPTION_NORECURSE	Disable the sending of recursive queries to the nameserver. Specifying this option will disable the bit in the DNS request header that specifies recursion is desired.
DNS_OPTION_NOSEARCH	Disable additional queries of higher domains in the

	search list if the host name cannot be resolved. If this option is specified, and the host name cannot be resolved using the local domain name an error is returned immediately. This option is ignored if no local domain has been specified or if the DNS_OPTION_NOSUFFIX option has been specified.
DNS_OPTION_NOSUFFIX	Disable additional queries using the local domain name if the host name is not a fully qualified domain name and cannot be resolved. This option is ignored if no local domain has been specified.
DNS_OPTION_NONAMECHECK	Disable checking the host name for invalid characters, such as the underscore and control characters. By default, host names are checked to ensure they're valid before submitting a query to the nameserver.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **DnsGetLastError**.

Remarks

The **DnsSetResolverOptions** function changes the resolver options for the specified client session, modifying how nameserver queries are processed. It is recommended that most applications do not specify any resolver options and use the default behavior. Specifying these options without understanding how they can affect standard queries can result in unexpected failures. In particular, caution should be used when specifying the DNS_OPTION_NORECURSE and DNS_OPTION_NOSEARCH options as they change the normal process of resolving a host name.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csdnsv10.lib

DnsSetRetryCount Function

```
INT WINAPI DnsSetRetryCount(  
    HCLIENT hClient,  
    INT nRetries  
);
```

The **DnsSetRetryCount** function sets the number of attempts that the client will make attempting to resolve a query. When used in conjunction with the **DnsSetTimeout** function, it determines the total amount of time the client will spend attempting to resolve a query.

Parameters

hClient

Handle to the client session.

nRetries

The number of attempts the client will make, per nameserver, to resolve a query.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is DNS_ERROR. To get extended error information, call **DnsGetLastError**.

Remarks

The retry count determines the amount of time the client will wait for a response from each query, the effective amount of time the client will wait increases with each nameserver and the total number of retries specified. For example, two nameservers registered with the client, with a default of 4 retries per nameserver and a timeout value of 10 seconds, would cause the client to wait a total of 80 seconds until it returns an error indicating that it was unable to resolve the query.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csdnsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

DnsSetTimeout Function

```
INT WINAPI DnsSetTimeout(  
    HCLIENT hClient,  
    INT nTimeout  
);
```

The **DnsSetTimeout** function sets the number of seconds that the client will wait for a response from a nameserver. The timeout value is used each time a server in the client's nameserver table is queried. When used in conjunction with the **DnsSetRetryCount** function, it determines the total amount of time the client will spend attempting to resolve a query.

Parameters

hClient

Handle to the client session.

nTimeout

The number of seconds until the client times out waiting for a response from a nameserver.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is DNS_ERROR. To get extended error information, call **DnsGetLastError**.

Remarks

The timeout value determines the amount of time the client will wait for a response from each query, the effective amount of time the client will wait increases with each nameserver and the total number of retries specified. For example, with two nameservers registered with the client, with a default of 4 retries per nameserver and a timeout value of 10 seconds, would cause the client to wait a total of 80 seconds until it returns an error indicating that it was unable to resolve the query.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csdnsv10.lib

See Also

[DnsGetRetryCount](#), [DnsGetTimeout](#), [DnsSetRetryCount](#)

DnsUninitialize Function

```
VOID WINAPI DnsUninitialize();
```

The **DnsUninitialize** function terminates the use of the library.

Parameters

There are no parameters.

Return Value

None.

Remarks

An application is required to perform a successful **DnsInitialize** call before it can call any of the other the library functions. When it has completed the use of library, the application must call **DnsUninitialize** to allow the library to free any resources allocated on behalf of the process. Any pending blocking or asynchronous calls in this process are canceled without posting any notification messages, and all sockets that were opened by the process are closed.

There must be a call to **DnsUninitialize** for every successful call to **DnsInitialize** made by a process. In a multithreaded environment, operations for all threads in the client are terminated.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csdnsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[DnsInitialize](#), [DnsCloseHandle](#), [DnsCreateHandle](#)

DnsUnregisterServer Function

```
INT WINAPI DnsUnregisterServer(  
    HCLIENT hClient,  
    INT nServer  
);
```

The **DnsUnregisterServer** function removes the specified nameserver information from the client. Unregistering a server prevents the client from using that server to satisfy subsequent DNS queries.

Parameters

hClient

Handle to the client session.

nServer

The index into the client's nameserver table. This index is the same value that is passed to the **DnsRegisterServer** function when the nameserver is registered.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is DNS_ERROR. To get extended error information, call **DnsGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csdnsv10.lib

Unicode: Implemented as Unicode and ANSI versions.

Domain Name Service Data Structures

- HOSTENT
- INITDATA
- INTERNET_ADDRESS

Copyright © 2023 Catalyst Development Corporation. All rights reserved.

HOSTENT Structure

This structure is used by the [DnsGetHostByAddress](#) and [DnsGetHostByName](#) functions to return information about a specified host. The application must never attempt to modify this structure or to free any of its components.

Only one copy of this structure is allocated per thread, so the application should copy any information it needs before issuing any other function calls. This is the same data structure used by the Windows Sockets API.

```
typedef struct _HOSTENT
{
    char *   h_name;
    char **  h_aliases;
    short    h_addrtype;
    short    h_length;
    char **  h_addr_list;
} HOSTENT, *LPHOSTENT;
```

Members

h_name

The fully qualified domain name (FQDN) that caused the nameserver server to return a reply.

h_aliases

A NULL-terminated array of alternate names.

h_addrtype

The type of address being returned.

h_length

The length, in bytes, of each address.

h_addr_list

A NULL-terminated list of addresses for the host. Addresses are returned in network byte order. The macro **h_addr** is defined to be **h_addr_list[0]** for compatibility with older software.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header: Include winsock.h.

INITDATA Structure

This structure contains information about the SocketTools library when the initialization function returns.

```
typedef struct _INITDATA
{
    DWORD        dwSize;
    DWORD        dwVersionMajor;
    DWORD        dwVersionMinor;
    DWORD        dwVersionBuild;
    DWORD        dwOptions;
    DWORD_PTR    dwReserved1;
    DWORD_PTR    dwReserved2;
    TCHAR        szDescription[128];
} INITDATA, *LPINITDATA;
```

Members

dwSize

Size of this structure. This structure member must be set to the size of the structure prior to calling the initialization function. Failure to do so will cause the function to fail.

dwVersionMajor

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the major version number for the library.

dwVersionMinor

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the minor version number for the library.

dwVersionBuild

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the build number for the library.

dwOptions

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

dwReserved1

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

dwReserved2

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

szDescription

A null terminated string which describes the library.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Unicode: Implemented as Unicode and ANSI versions.

INTERNET_ADDRESS Structure

This structure represents a numeric IPv4 or IPv6 address in network byte order.

```
typedef struct _INTERNET_ADDRESS
{
    INT    ipFamily;
    BYTE   ipNumber[16];
} INTERNET_ADDRESS, *LPINTERNET_ADDRESS;
```

Members

ipFamily

An integer which identifies the type of IP address. It will be one of the following values:

Constant	Description
INET_ADDRESS_UNKNOWN	The address has not been specified or the bytes in the <i>ipNumber</i> array does not represent a valid address. Functions which populate this structure will use this value to indicate that the address cannot be determined.
INET_ADDRESS_IPV4	Specifies that the address is in IPv4 format. The first four bytes of the <i>ipNumber</i> array are significant and contains the IP address. The remaining bytes are not significant and an application should not depend on them having any particular value, including zero.
INET_ADDRESS_IPV6	Specifies that the address is in IPv6 format. All bytes in the <i>ipNumber</i> array are significant. Note that it is possible for an IPv6 address to actually represent an IPv4 address. This is indicated by the first 10 bytes of the address being zero.

ipNumber

A byte array which contains the numeric form of the IP address. This array is large enough to store both IPv4 (32 bit) and IPv6 (128 bit) addresses. The values are stored in network byte order.

Remarks

The **INTERNET_ADDRESS** structure is used by some functions to represent an Internet address in a binary format that is compatible with both IPv4 and IPv6 addresses. Applications that use this structure should consider it to be opaque, and should not modify the contents of the structure directly.

For compatibility with legacy applications that expect an IP address to be 32 bits and stored in an unsigned integer, you can copy the first four bytes of the *ipNumber* array using the **CopyMemory** function or equivalent. Note that if this is done, your application should always check the *ipFamily* member first to make sure that it is actually an IPv4 address.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Domain Name Service Constants

Value	Constant	Description
0	DNS_RECORD_NONE	No record type
1	DNS_RECORD_ADDRESS	Host address
2	DNS_RECORD_NS	Authoritative nameserver
5	DNS_RECORD_CNAME	Canonical name (alias)
6	DNS_RECORD_SOA	Start of Authority
11	DNS_RECORD_WKS	Well known services
12	DNS_RECORD_PTR	Domain name
13	DNS_RECORD_HINFO	Host information
14	DNS_RECORD_MINFO	Mailbox information
15	DNS_RECORD_MX	Mail exchange host
16	DNS_RECORD_TXT	Text strings
29	DNS_RECORD_LOC	Location information
100	DNS_RECORD_UINFO	User information
101	DNS_RECORD_UID	User ID
102	DNS_RECORD_GID	Group ID

Encoding and Compression Library

Encode and decode files using standard algorithms such as base64, uuencode and quoted-printable. The library can also be used to compress and expand files, as well as encrypt or decrypt file data using AES encryption.

Reference

- [Functions](#)

Library Information

File Name	CSNCDV10.DLL
Version	10.0.1468.2518
LibID	15999BB0-0394-4284-9E69-2DC698118E2F
Import Library	CSNCDV10.LIB
Dependencies	None
Standards	RFC 1738, RFC 1951, RFC 2045

Overview

The Encoding and Compression library provides functions for encoding and decoding binary files, typically attachments to email messages. The process of encoding converts the contents of a binary file to printable 7-bit ASCII text. Decoding reverses the process, converting a previously encoded text file back into a binary file.

There are two primary types of encoding methods used with various Internet applications: base64 and uuencode. The base64 algorithm is most commonly used with email attachments, and is often referred to as MIME encoding since this is the encoding method specified in the MIME standards document. The uuencode algorithm (so called because the programs to perform the encoding were called uuencode and uudecode) is often used when attaching binary files to Usenet newsgroup posts. The library also supports an alternate encoding format called yEnc which is also widely used to attach files to Usenet posts.

In addition to encoding and decoding data files, this library includes functions to compress and expand data, as well as encrypt and decrypt files using 256-bit AES encryption.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). If you are using Visual C++ 6.0 it is required that you have Service Pack 6 (SP6) installed. You should install all updates for your development tools and have the current Windows SDK installed. The minimum recommended version of Visual Studio is Visual Studio 2010.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are using Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. It is recommended that you install the current service pack and all critical updates available for your version of the operating system.

This product includes both 32-bit and 64-bit libraries. Native 64-bit CPU support requires the 64-bit version of Windows 7 or later versions of the Windows operating system.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

Encoding and Compression Functions

Function	Description
AesDecryptBuffer	Decrypt a buffer previously encrypted using the AesEncryptBuffer function
AesDecryptFile	Decrypt a file previously encrypted using the <code>strong>AesEncryptFile</code> function
AesDecryptString	Decrypt a string previously encrypted using the AesEncryptString function
AesEncryptBuffer	Encrypt a memory buffer using 256-bit AES encryption
AesEncryptFile	Encrypt the contents of a file using 256-bit AES encryption
AesEncryptString	Encrypt a null-terminated string using 256-bit AES encryption
CompressBuffer	Compress the contents of the specified buffer
CompressFile	Compress the contents of the specified file
CompressFileEx	Compress the contents of the specified file with additional options
DecodeBuffer	Decode an encoded string, storing the result in the specified buffer
DecodeFile	Decode the contents of a file using the specified decoding method
EncodeBuffer	Encode the contents of a buffer using the specified encoding method
EncodeFile	Encode the contents of a file using the specified encoding method
ExpandBuffer	Expand the contents of a previously compressed buffer
ExpandFile	Expand the contents of a previously compressed file
ExpandFileEx	Expand the contents of a previously compressed file with additional options
GetMessageDigest	Compute a message digest for a buffer, string or data file
IsUnicodeText	Determine if a text buffer contains valid Unicode characters
UnicodeDecodeText	Decode UTF-8 encoded text and return a localized string
UnicodeEncodeText	Encode a text buffer and return a UTF-8 encoded string

AesDecryptBuffer Function

```
BOOL WINAPI AesDecryptBuffer(  
    LPCTSTR lpszPassword,  
    LPVOID lpvInputBuffer,  
    DWORD dwInputSize  
    LPVOID lpvOutputBuffer,  
    LPDWORD lpdwOutputSize  
);
```

The **AesDecryptBuffer** function decrypts the contents of a memory buffer.

Parameters

lpszPassword

A pointer to a null terminated string of characters that will be used to generate the decryption key. This parameter may be NULL or a zero-length string, in which case a default internal hash value is used to decrypt the data. Password strings that exceed 215 characters will be truncated.

lpvInputBuffer

A pointer to the buffer which contains the data to be decrypted.

dwInputSize

The number of bytes in the input buffer. This value must be greater than zero.

lpvOutputBuffer

A pointer to the buffer which will contain the decrypted data when the function returns. This memory must be allocated by the application and be large enough to contain all of the decrypted data. If the output buffer is not large enough, the function will fail. This parameter cannot be NULL.

lpdwOutputSize

A pointer to the number of bytes that may be copied into the output buffer. This parameter must be initialized to a non-zero value. When the function returns, the actual number of bytes of decrypted data is returned in this parameter. This parameter cannot be NULL.

Return Value

A non-zero value is returned if the data was successfully decrypted. A zero value indicates that the data could not be decrypted. To get extended error information, call **GetLastError**.

Remarks

The **AesDecryptBuffer** function will decrypt a block of memory using a 256-bit AES (Advanced Encryption Standard) algorithm and returns a copy of the decrypted data to the caller. The password (or passphrase) provided by the caller is used to generate a SHA-256 hash value which is used as part of the decryption process. The *lpszPassword* value must be identical to the value used to encrypt the data using the **AesEncryptBuffer** function.

Due to how the SHA-256 hash is generated, this function cannot be used to decrypt data that was encrypted using another third-party library. It can only be used to decrypt data that was previously encrypted using **AesEncryptBuffer**.

If you wish to decrypt the contents of a file, use the **AesDecryptFile** function.

This function uses the Microsoft CryptoAPI and the RSA AES cryptographic provider. This provider may not be available in some languages, countries or regions. The availability of this provider may also be constrained by cryptography export restrictions imposed by the United States or other

countries. If the required cryptographic provider is not available, the function will fail.

Example

```
BOOL bIsDecrypted = FALSE;
DWORD dwOutputSize = MAX_BUFFER_SIZE;
BYTE *lpOutputBuffer = (BYTE *)LocalAlloc(LPTR, dwOutputSize);

if (lpOutputBuffer != NULL)
{
    bIsDecrypted = AesDecryptBuffer(lpszPassword,
                                   lpInputBuffer,
                                   dwInputSize,
                                   lpOutputBuffer,
                                   &dwOutputSize);
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csncdv10.lib

Unicode: Implemented as Unicode and ANSI versions.

AesDecryptFile Function

```
BOOL WINAPI AesDecryptFile(  
    LPCTSTR lpszPassword,  
    LPCTSTR lpszInputFile,  
    LPCTSTR lpszOutputFile  
);
```

The **AesDecryptFile** function decrypts the contents of a file.

Parameters

lpszPassword

A pointer to a null terminated string of characters that will be used to generate the decryption key. This parameter may be NULL or a zero-length string, in which case a default internal hash value is used to decrypt the data. Password strings that exceed 215 characters will be truncated.

lpszInputFile

A pointer to a null terminated string which specifies the name of the file to be decrypted. The file must exist, and it must be a regular file that can be opened for reading by the current process. An error will be returned if a character device, such as CON: is specified as the file name.

lpszOutputFile

A pointer to a null terminated string which specifies the name of the file that will contain the decrypted data. If the file exists, it will be overwritten. It must be a regular file that can be opened for writing by the current process. An error will be returned if a character device, such as CON: is specified as the file name.

Return Value

A non-zero value is returned if the string was successfully encrypted. A zero value indicates that the string could not be encrypted. To get extended error information, call **GetLastError**.

Remarks

The **AesDecryptFile** function will decrypt the contents of a file using a 256-bit AES (Advanced Encryption Standard) algorithm and stores the decrypted data in the specified output file. The password (or passphrase) provided by the caller is used to generate a SHA-256 hash value which is used as part of the decryption process. The *lpszPassword* value must be identical to the value used to encrypt the data using the **AesEncryptFile** function.

Due to how the SHA-256 hash is generated, this function cannot be used to decrypt files that were encrypted using another third-party library. It can only be used to decrypt data that was previously encrypted using **AesEncryptFile**.

A temporary file is created during the decryption process and the output file is created or overwritten only if the input file could be successfully decrypted. If the decryption fails, no output file will be created.

If you wish to decrypt the contents of a memory buffer or string, use the **AesDecryptBuffer** or **AesDecryptString** functions.

This function uses the Microsoft CryptoAPI and the RSA AES cryptographic provider. This provider may not be available in some languages, countries or regions. The availability of this provider may also be constrained by cryptography export restrictions imposed by the United States or other countries. If the required cryptographic provider is not available, the function will fail.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csncdv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[AesDecryptBuffer](#), [AesDecryptString](#), [AesEncryptFile](#)

AesDecryptString Function

```
BOOL WINAPI AesDecryptString(  
    LPCTSTR lpszPassword,  
    LPCTSTR lpszInputString,  
    LPCTSTR lpszOutputString,  
    LONG nMaxLength  
);
```

The **AesDecryptString** function decrypts the contents of a string.

Parameters

lpszPassword

A pointer to a null terminated string of characters that will be used to generate the decryption key. This parameter may be NULL or a zero-length string, in which case a default internal hash value is used to decrypt the data. Password strings that exceed 215 characters will be truncated.

lpszInputString

A pointer to a null terminated string which contains the data to be decrypted. The encrypted input data must be base64 encoded and identical to the encrypted string returned by the **AesEncryptString** function. If this parameter is NULL or points to an empty string the function will fail.

lpszOutputString

A pointer to the buffer which will contain the decrypted string data. This parameter cannot be NULL.

nMaxLength

The maximum number of characters that can be copied to the output string buffer. The output buffer must be large enough to store the complete decrypted string and is terminated with a null character. This value must be greater than zero. If the output string buffer is not large enough, the function will fail.

Return Value

A non-zero value is returned if the string was successfully encrypted. A zero value indicates that the string could not be decrypted. To get extended error information, call **GetLastError**.

Remarks

The **AesDecryptString** function will decrypt a string using a 256-bit AES (Advanced Encryption Standard) algorithm and returns a copy of the decrypted string to the caller. The password (or passphrase) provided by the caller is used to generate a SHA-256 hash value which is used as part of the decryption process. The *lpszPassword* value must be identical to the value used to encrypt the data using the **AesEncryptString** function.

Due to how the SHA-256 hash is generated, this function cannot be used to decrypt strings that were encrypted using another third-party library. It can only be used to decrypt strings that were previously encrypted using **AesEncryptString**.

If you wish to decrypt the contents of a file, use the **AesDecryptFile** function.

This function uses the Microsoft CryptoAPI and the RSA AES cryptographic provider. This provider may not be available in some languages, countries or regions. The availability of this provider may also be constrained by cryptography export restrictions imposed by the United States or other countries. If the required cryptographic provider is not available, the function will fail.

Example

```
BOOL bIsDecrypted = FALSE;
LPCTSTR lpszPassword = _T("NFr-E{Ki3_1w0iV+LI@z}");
TCHAR szDecryptedText[MAX_STRING_LENGTH];

bIsDecrypted = AesDecryptString(lpszPassword,
                               szEncryptedText,
                               szDecryptedText,
                               MAX_STRING_LENGTH);

if (bIsDecrypted)
{
    _tprintf(_T("The decrypted string is \"%s\"\n"), szDecryptedText);
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csncdv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[AesDecryptBuffer](#), [AesDecryptFile](#), [AesEncryptString](#)

AesEncryptBuffer Function

```
BOOL WINAPI AesEncryptBuffer(  
    LPCTSTR lpszPassword,  
    LPVOID lpvInputBuffer,  
    DWORD dwInputSize  
    LPVOID lpvOutputBuffer,  
    LPDWORD lpdwOutputSize  
);
```

The **AesEncryptBuffer** function encrypts the contents of a memory buffer.

Parameters

lpszPassword

A pointer to a null terminated string of characters that will be used to generate the encryption key. Passwords are case sensitive and must match exactly when decrypting data that was previously encrypted using this function. This parameter may be NULL or a zero-length string, in which case a default internal hash value is used. Password strings that exceed 215 characters will be truncated.

lpvInputBuffer

A pointer to the buffer which contains the data to be encrypted.

dwInputSize

The number of bytes in the input buffer. This value must be greater than zero.

lpvOutputBuffer

A pointer to the buffer which will contain the encrypted data when the function returns. This memory must be allocated by the application and be large enough to contain all of the encrypted data. The amount encrypted data returned will always be larger than the amount of data specified by *dwInputSize*. If the output buffer is not large enough, the function will fail. This parameter cannot be NULL.

lpdwOutputSize

A pointer to the number of bytes that may be copied into the output buffer. This parameter must be initialized to a non-zero value. When the function returns, the actual number of bytes of encrypted data is returned in this parameter. This parameter cannot be NULL.

Return Value

A non-zero value is returned if the data was successfully encrypted. A zero value indicates that the data could not be encrypted. To get extended error information, call **GetLastError**.

Remarks

The **AesEncryptBuffer** function will encrypt a block of memory using a 256-bit AES (Advanced Encryption Standard) algorithm and returns a copy of the encrypted data to the caller. The password (or passphrase) provided by the caller is used to generate a SHA-256 hash value which is used as part of the encryption process. The identical password is required to decrypt the data using the **AesDecryptBuffer** function.

It is recommended that most applications specify a password value. If the *lpszPassword* parameter is NULL or specifies a zero-length string, a default internal hash value is used. This means that any other application which uses a NULL password value will be able to decrypt the data. If the Unicode version of this function is called, the *lpszPassword* value will be encoded using UTF-8

prior to the hash value being generated.

Due to how the SHA-256 hash is generated, the encrypted data cannot be decrypted using another third-party library with the same password value. It can only be decrypted using the **AesDecryptBuffer** function.

The amount of encrypted data returned by this function will always be somewhat larger than original unencrypted data. If your application dynamically allocates a block of memory to store the encrypted data, provide a maximum buffer size that is at least several hundred bytes larger than the unencrypted data. If the output buffer provided is not large enough, the function will fail and the **GetLastError** function will return ERROR_INSUFFICIENT_BUFFER.

The encrypted data returned by this function can contain embedded nulls and should be typically handled as unsigned char (byte) values. If you wish to encrypt strings and store the encrypted values, use the **AesEncryptString** function. It will perform the same 256-bit AES encryption, but return the encrypted data as a base64 encoded string rather than binary data.

If your application is also using the **CompressBuffer** function to compress the data, it is recommended that you call **CompressBuffer** before calling **AesEncryptBuffer**. You will typically achieve a better compression rate on unencrypted data than attempting to compress data which has been encrypted with this function.

If you wish to encrypt the contents of a file, use the **AesEncryptFile** function.

This function uses the Microsoft CryptoAPI and the RSA AES cryptographic provider. This provider may not be available in some languages, countries or regions. The availability of this provider may also be constrained by cryptography export restrictions imposed by the United States or other countries. If the required cryptographic provider is not available, the function will fail.

Example

```
BOOL bIsEncrypted = FALSE;
DWORD dwOutputSize = MAX_BUFFER_SIZE;
BYTE *lpOutputBuffer = (BYTE *)LocalAlloc(LPTR, dwOutputSize);

if (lpOutputBuffer != NULL)
{
    bIsEncrypted = AesEncryptBuffer(lpszPassword,
                                   lpInputBuffer,
                                   dwInputSize,
                                   lpOutputBuffer,
                                   &dwOutputSize);
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csncdv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[AesDecryptBuffer](#), [AesEncryptFile](#), [AesEncryptString](#), [CompressBuffer](#)

AesEncryptFile Function

```
BOOL WINAPI AesEncryptFile(  
    LPCTSTR lpszPassword,  
    LPCTSTR lpszInputFile,  
    LPCTSTR lpszOutputFile  
);
```

The **AesEncryptFile** function encrypts the contents of a file.

Parameters

lpszPassword

A pointer to a null terminated string of characters that will be used to generate the encryption key. Passwords are case sensitive and must match exactly when decrypting data that was previously encrypted using this function. This parameter may be NULL or a zero-length string, in which case a default internal hash value is used. Password strings that exceed 215 characters will be truncated.

lpszInputFile

A pointer to a null terminated string which specifies the name of the file to be encrypted. The file must exist, and it must be a regular file that can be opened for reading by the current process. An error will be returned if a character device, such as CON: is specified as the file name.

lpszOutputFile

A pointer to a null terminated string which specifies the name of the file that will contain the encrypted data. If the file exists, it will be overwritten. It must be a regular file that can be opened for writing by the current process. An error will be returned if a character device, such as CON: is specified as the file name.

Return Value

A non-zero value is returned if the string was successfully encrypted. A zero value indicates that the string could not be encrypted. To get extended error information, call **GetLastError**.

Remarks

The **AesEncryptFile** function will encrypt the contents of a file using a 256-bit AES (Advanced Encryption Standard) algorithm and stores the encrypted data in the specified output file. The password (or passphrase) provided by the caller is used to generate a SHA-256 hash value which is used as part of the encryption process. The identical password is required to decrypt the data using the **AesDecryptFile** function.

It is recommended that most applications specify a password value. If the *lpszPassword* parameter is NULL or specifies a zero-length string, a default internal hash value is used. This means that any other application which uses a NULL password value will be able to decrypt the data. If the Unicode version of this function is called, the *lpszPassword* value will be encoded using UTF-8 prior to the hash value being generated.

Due to how the SHA-256 hash is generated, the encrypted data cannot be decrypted using another third-party library with the same password value. It can only be decrypted using the **AesDecryptFile** function.

A temporary file is created during the encryption process and the output file is created or overwritten only if the input file could be successfully encrypted. If the encryption fails, no output

file will be created.

The input file contents will always be processed as a binary data stream. If you use this function to encrypt a text file, the output file will contain binary characters, not printable text. If you wish to transfer or store the encrypted data as text, it should be encoded using the **EncodeFile** function after calling **AesEncryptFile**.

If your application is also using the **CompressFile** function to compress the data, it is recommended that you call **CompressFile** before calling **AesEncryptFile**. You will typically achieve a better compression rate on unencrypted data than attempting to compress data which has been encrypted with this function.

If you wish to encrypt the contents of a memory buffer or string, use the **AesEncryptBuffer** or **AesEncryptString** functions.

This function uses the Microsoft CryptoAPI and the RSA AES cryptographic provider. This provider may not be available in some languages, countries or regions. The availability of this provider may also be constrained by cryptography export restrictions imposed by the United States or other countries. If the required cryptographic provider is not available, the function will fail.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csncdv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[AesDecryptFile](#), [AesEncryptBuffer](#), [AesEncryptString](#), [CompressFile](#), [EncodeFile](#)

AesEncryptString Function

```
BOOL WINAPI AesEncryptString(  
    LPCTSTR lpszPassword,  
    LPCTSTR lpszInputString,  
    LONG nInputLength  
    LPCTSTR lpszOutputString,  
    LONG nMaxLength  
);
```

The **AesEncryptString** function encrypts the contents of a string.

Parameters

lpszPassword

A pointer to a null terminated string of characters that will be used to generate the encryption key. Passwords are case sensitive and must match exactly when decrypting data that was previously encrypted using this function. This parameter may be NULL or a zero-length string, in which case a default internal hash value is used. Password strings that exceed 215 characters will be truncated.

lpszInputString

A pointer to a null terminated string which contains the text to be encrypted. If the Unicode version of this function is called, the string is automatically UTF-8 encoded prior to being encrypted.

nInputLength

The number of characters in the input string which will be encrypted. If this value is -1, the length of the input string is determined automatically by counting the number of characters up to the terminating null byte. Note that with Unicode strings, this value must represent the number of characters in the string, not the number of bytes allocated for the string.

lpszOutputString

A pointer to the buffer which will contain a base64 encoded encrypted string when the function returns. This memory must be allocated by the application and be large enough to contain all of the encrypted data. The amount encrypted data returned will always be larger than the amount of data specified by *nInputLength*. If the output string buffer is not large enough, the function will fail. This parameter cannot be NULL.

nMaxLength

The maximum number of characters that can be copied to the output string buffer. The output buffer must be large enough to store the complete encrypted string which is encoded using base64 and terminated with a null character. This value must be greater than zero. If the output string buffer is not large enough, the function will fail.

Return Value

A non-zero value is returned if the string was successfully encrypted. A zero value indicates that the string could not be encrypted. To get extended error information, call **GetLastError**.

Remarks

The **AesEncryptString** function will encrypt a string using a 256-bit AES (Advanced Encryption Standard) algorithm and returns a copy of the encrypted data as a base64 encoded string to the caller. The password (or passphrase) provided by the caller is used to generate a SHA-256 hash value which is used as part of the encryption process. The identical password is required to

decrypt the data using the **AesDecryptString** function.

It is recommended that most applications specify a password value. If the *lpzPassword* parameter is NULL or specifies a zero-length string, a default internal hash value is used. This means that any other application which uses a NULL password value will be able to decrypt the data. If the Unicode version of this function is called, the *lpzPassword* value will be encoded using UTF-8 prior to the hash value being generated.

Due to how the SHA-256 hash is generated, the encrypted data cannot be decrypted using another third-party library with the same password value. It can only be decrypted using the **AesDecryptString** function.

The amount of encrypted data returned by this function will always be larger than original unencrypted data. If your application dynamically allocates a block of memory to store the encrypted string, provide a maximum output string size that is at least several hundred bytes larger than the unencrypted data. If the output string is not large enough, the function will fail and the **GetLastError** function will return ERROR_INSUFFICIENT_BUFFER.

The string provided to this function cannot contain embedded nulls and should not be used to encrypt binary data. If you wish to encrypt binary data, use the **AesEncryptBuffer** function. It will perform the same 256-bit AES encryption and return the encrypted data into a buffer provided by the caller.

If you wish to encrypt the contents of a file, use the **AesEncryptFile** function.

This function uses the Microsoft CryptoAPI and the RSA AES cryptographic provider. This provider may not be available in some languages, countries or regions. The availability of this provider may also be constrained by cryptography export restrictions imposed by the United States or other countries. If the required cryptographic provider is not available, the function will fail.

Example

```
BOOL bIsEncrypted = FALSE;
LPCTSTR lpzPassword = _T("NFr-E{Ki3_1w0iV+LI@z}");
LPCTSTR lpzPlainText = _T("The quick brown fox jumped over the lazy dog.");
TCHAR szEncryptedText[MAX_STRING_LENGTH];

bIsEncrypted = AesEncryptString(lpzPassword,
                               lpzPlainText,
                               -1,
                               szEncryptedText,
                               MAX_STRING_LENGTH);

if (bIsEncrypted)
{
    _tprintf(_T("The encrypted string is \"%s\"\n"), szEncryptedText);
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csncdv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[AesDecryptString](#), [AesEncryptBuffer](#), [AesEncryptFile](#)

CompressBuffer Function

```
BOOL WINAPI CompressBuffer(  
    LPVOID lpvInputBuffer,  
    DWORD cbInputBuffer  
    LPVOID lpvOutputBuffer,  
    LPDWORD lpcbOutputBuffer  
);
```

The **CompressBuffer** function compresses the contents of the specified buffer.

Parameters

lpvInputBuffer

A pointer to the buffer which contains the data to be compressed.

cbInputBuffer

The number of bytes in the input buffer. This value must be greater than zero.

lpvOutputBuffer

A pointer to the buffer which will contain the compressed data. This parameter may be NULL, which can be used to determine the size of the of the resulting compressed data prior to allocating memory for it.

lpcbOutputBuffer

A pointer to the number of bytes that may be copied into the output buffer. If the *lpvOutputBuffer* parameter is not NULL, this must be initialized to a non-zero value. When the function returns, the actual number of bytes of compressed data is returned in this parameter.

Return Value

A non-zero value is returned if the data was successfully compressed. A zero value indicates that the data could not be compressed.

Remarks

The compression ratio achieved by the **CompressBuffer** function depends on the type of data that is being compressed. The compressed data can be expanded to its original contents by calling the **ExpandBuffer** function.

Example

```
cbOutputBuffer = 0;  
bResult = CompressBuffer(lpInputBuffer,  
                        cbInputBuffer,  
                        NULL,  
                        &cbOutputBuffer);  
  
if (bResult)  
{  
    lpOutputBuffer = (LPBYTE)LocalAlloc(LPTR, cbOutputBuffer);  
    bResult = CompressBuffer(lpInputBuffer,  
                            cbInputBuffer,  
                            lpOutputBuffer,  
                            &cbOutputBuffer);  
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csncdv10.lib

Unicode: Implemented as Unicode and ANSI versions.

CompressFile Function

```
BOOL WINAPI CompressFile(  
    LPCTSTR lpszInputFile,  
    LPCTSTR lpszOutputFile  
);
```

The **CompressFile** function compresses the contents of the specified file.

Parameters

lpszInputFile

A pointer to a string which specifies the name of the file to be compressed. The file must exist, and it must be a regular file that can be opened for reading by the current process. An error will be returned if a character device, such as CON:, is specified as the file name.

lpszOutputFile

The name of the file that is to contain the compressed file data. If the file exists, it must be a regular file that can be opened for writing by the current process and will be overwritten. If the file does not exist, it will be created. An error will be returned if a character device, such as CON:, is specified as the file name.

Return Value

A non-zero value is returned if the file was successfully compressed. A zero value indicates that the input file could not be read or that the output file could not be created.

Remarks

The compression ratio achieved by the **CompressFile** function depends on the type of file that is being compressed. The compressed file is not stored in an archive format that is recognized by third-party applications such as PKZip or WinZip.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csncdv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[CompressFileEx](#), [DecodeFile](#), [EncodeFile](#), [ExpandFile](#), [ExpandFileEx](#)

CompressFileEx Function

```
BOOL WINAPI CompressFileEx(  
    LPCTSTR lpszInputFile,  
    LPCTSTR lpszOutputFile,  
    DWORD dwCompressionType,  
    DWORD dwCompressionLevel,  
    LPVOID lpvHeaderBlock,  
    DWORD dwHeaderLength  
);
```

The **CompressFileEx** function compresses the contents of the specified file.

Parameters

lpszInputFile

A pointer to a string which specifies the name of the file to be compressed. The file must exist, and it must be a regular file that can be opened for reading by the current process. An error will be returned if a character device, such as CON: is specified as the file name.

lpszOutputFile

The name of the file that is to contain the compressed file data. If the file exists, it must be a regular file that can be opened for writing by the current process and will be overwritten. If the file does not exist, it will be created. An error will be returned if a character device, such as CON: is specified as the file name.

dwCompressionType

A numeric value which determines the algorithm that will be used to compress the data. One of the following values may be specified. By default, the Deflate algorithm is used.

Value	Constant	Description
1	COMPRESSION_TYPE_DEFLATE	A compression algorithm that combines LZ77 algorithm for creating common substrings and Huffman coding to process the different frequencies of byte sequences in the data stream. Deflate is widely used by compression software.
2	COMPRESSION_TYPE_BURROWSWHEELER	A compression algorithm that rearranges blocks of data in sorted order and then uses Huffman coding to process different frequencies of data within the block. Burrows-Wheeler compression provides a better compression ratio

	than the Deflate algorithm, however it requires more resources to perform the compression.
--	--

dwCompressionLevel

A numeric value which specifies the compression level to use. A value of zero specifies that the default compression level appropriate for the selected algorithm should be used, balancing resource usage and the compression ratio of the data. A value of 1 specifies that the compression should be performed using minimal memory resources, at the expense of the compression ratio. The maximum value of 9 specifies that the algorithm should use more memory to achieve the maximum compression ratio. It is recommended that most applications use the default value of zero.

lpvHeaderBlock

A pointer to a block of uncompressed data that is written to the beginning of the output file. If this parameter is NULL and the *dwHeaderLength* parameter is not zero, a null buffer of the specified size is written to the file.

dwHeaderLength

The length of the data buffer to be written to beginning of the output file. If this value is zero, the *lpvHeaderBlock* parameter is ignored and no header block is written.

Return Value

A non-zero value is returned if the file was successfully compressed. A zero value indicates that the input file could not be read or that the output file could not be created.

Remarks

The compression ratio achieved by the **CompressFile** function depends on the type of file that is being compressed. The compressed file is not stored in an archive format that is recognized by third-party applications such as PKZip or WinZip.

The *lpvHeaderBlock* and *dwHeaderLength* parameters can be used to write application-defined data to the beginning of the file, commonly called a header block. Typically this is a fixed-length structure which provides information to the application about the compressed file.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csncdv10.lib

Unicode: Implemented as Unicode and ANSI versions.

DecodeBuffer Function

```
LONG WINAPI DecodeBuffer(  
    LPCTSTR lpszInput,  
    LPBYTE lpOutput,  
    LONG cbOutput,  
    DWORD dwOptions  
);
```

The **DecodeBuffer** function decodes an encoded string, and stores the result in the specified buffer.

Parameters

lpszInput

A pointer to a string which contains the base64 encoded text.

lpOutput

A pointer to a byte array buffer which is used to store the decoded data. It is recommended that the buffer be as large as the length of the encoded string.

cbOutput

A long integer which specifies the maximum number of bytes which may be stored in the buffer.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
DATA_DECODE_BASE64	Decode a string that was created using the base64 encoding algorithm. This is the encoding method that is used by most modern email client software. Note that this option cannot be combined with other decoding methods.
DATA_DECODE_QUOTED	Decode a string that was created using the quoted-printable encoding algorithm. Note that this option cannot be combined with the other decoding methods.
DATA_DECODE_URL	Decode a string that was created using the URL encoding algorithm. Note that this option cannot be combined with the other decoding methods.
DATA_DECODE_UTF7	Decode a string that was created using the UTF-7 encoding algorithm. Note that this option cannot be combined with the other decoding methods.
DATA_DECODE_UTF8	Decode a string that was created using the UTF-8 encoding algorithm. Note that this option cannot be combined with the other decoding methods.
DATA_DECODE_COMPRESSED	The data was compressed prior to being encoded, and should be expanded after the decoding has completed successfully. This option is ignored if the

encoding type is not base64. This should only be used if it was specified when the data was encoded.

Return Value

If the function succeeds, it will return the number of bytes decoded and stored in the buffer. If the function fails, it will return -1. Failure typically indicates that the encoded string was corrupted or the buffer is not large enough to store the decoded data.

Remarks

The **DecodeBuffer** function is used to decode a block of data that was previously encoded with the **EncodeBuffer** function. To decode the contents of a file, it is recommended that you use the **DecodeFile** function instead.

If you specify either UTF-7 or UTF-8 encoding, the *lpOutput* parameter must point to a Unicode string and the *cbOutput* parameter must specify the maximum number of characters, not bytes, that can be copied into the string. The return value will be the number of Unicode characters, not bytes, that were copied into the output buffer. The conversion is always performed using the default system code page.

It is recommended that you use the **UnicodeEncodeText** function to convert a string to UTF-8 encoded text, and the **UnicodeDecodeText** function to convert UTF-8 encoded text to a UTF-16 or localized multi-byte string.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csncdv10.lib

Unicode: Implemented as Unicode and ANSI versions.

DecodeFile Function

```
BOOL WINAPI DecodeFile(  
    LPCTSTR lpszInputFile,  
    LPCTSTR lpszOutputFile,  
    DWORD dwOptions,  
    DWORD dwReserved  
);
```

The **DecodeFile** function opens and decodes an encoded file, storing the contents in the specified file.

Parameters

lpszInputFile

A pointer to a string which specifies the name of the file to be decoded. The file must exist, and it must be a regular file that can be opened for reading by the current process. An error will be returned if a character device, such as CON: is specified as the file name.

lpszOutputFile

The name of the file that is to contain the decoded file data. If the file exists, it must be a regular file that can be opened for writing by the current process and will be overwritten. If the file does not exist, it will be created. An error will be returned if a character device, such as CON: is specified as the file name.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
FILE_DECODE_BASE64	Use the base64 algorithm for decoding the file. This is the encoding method that is used by most modern email client software. Note that this option cannot be combined with other decoding methods.
FILE_DECODE_QUOTED	Use the quoted-printable algorithm for decoding the file. Note that this option cannot be combined with the other decoding methods.
FILE_DECODE_UUCODE	Use the uuencode algorithm for decoding the file. This is a common encoding method used in UNIX systems and older email client software. Note that this option cannot be combined with other decoding methods.
FILE_DECODE_YENCODE	Use the yEnc algorithm for decoding the file. Note that this option cannot be combined with other decoding methods.
FILE_DECODE_COMPRESSED	The file was compressed prior to being encoded, and should be expanded after the decoding has completed successfully. This option should only be used if it was specified when the file was encoded.

dwReserved

This parameter is reserved and should always be set to zero.

Return Value

A non-zero value is returned if the file was successfully decoded. A zero value indicates that the file does not exist, the encoded file was damaged or the output file could not be created.

Remarks

The **DecodeFile** function decodes files that were previously encoded through a call to the **EncodeFile** function or by a third-party application such as an email client. The option to expand a previously compressed file requires that the function be able to create a temporary file on the local system in the directory specified by the TEMP environment variable. This function can only expand a file that was previously compressed with the **EncodeFile** or **CompressFile** functions.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csncdv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

EncodeBuffer Function

```
LONG WINAPI EncodeBuffer(  
    LPBYTE lpInput,  
    LONG cbInput,  
    LPTSTR lpszOutput,  
    LONG cchOutput,  
    DWORD dwOptions  
);
```

The **EncodeBuffer** function encodes the contents of the specified byte array, converting the data into printable text.

Parameters

lpInput

A pointer to a buffer that contains the data to be encoded.

cbInput

A long integer which specifies the number of characters in the buffer which should be encoded.

lpszOutput

A pointer to a string that will be used to store the encoded text. The length of the string must be at least 33% larger than the number of bytes being encoded, and will be terminated with a null byte.

cchOutput

The maximum number of characters that may be stored in the string buffer. If this value is too small to store the encoded text, the function will fail.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
DATA_ENCODE_BASE64	Use the base64 algorithm for encoding the data. This is the encoding method that is used by most modern email client software. Note that this option cannot be combined with other encoding methods.
DATA_ENCODE_QUOTED	Use the quoted-printable algorithm for encoding the data. Most printable characters are left as-is, with control characters and 8-bit characters encoded as their hexadecimal value. Note that this option cannot be combined with the other encoding methods.
DATA_ENCODE_URL	Use the URL encoding algorithm for encoding the data. Letters and numbers are left as-is, with control characters, most punctuation and 8-bit characters encoded as their hexadecimal value. Note that this option cannot be combined with the other encoding methods.
DATA_ENCODE_UTF7	Encode the data using the Unicode Transformation Format. This converts Unicode text into 7-bit

	characters. Note that this option cannot be combined with the other encoding methods.
DATA_ENCODE_UTF8	Encode the data using the Unicode Transformation Format. This converts Unicode text into 8-bit characters. Note that this option cannot be combined with the other encoding methods.
DATA_ENCODE_COMPRESSED	The data should be compressed before it is encoded. To restore the original data, it must be expanded after it has been decoded. This option is ignored if the encoding type is not base64.
DATA_ENCODE_LINEBREAK	The encoded data should be broken into multiple lines of text if the resulting string is longer than 72 characters. This option is ignored if the encoding type is not base64 or quoted-printable. This option should be specified if the encoded data is going to be included in an email message.

Return Value

If the function succeeds, it will return the number of bytes encoded and stored in the string. If the function fails, it will return -1. Failure typically indicates that the buffer is not large enough to store the encoded data.

Remarks

The **EncodeBuffer** function is used to encode a block of data and store it in the specified string buffer as printable text. To encode the contents of a file it is recommended that you use the **EncodeFile** function instead.

A common use of this function is to use the Base64 algorithm to obscure a plain text string. This technique is used by some Internet application protocols when passing authentication information over a standard connection. Although it is not a secure method of encrypting data, it does prevent a casual observer from reading the encoded text.

If you specify either UTF-7 or UTF-8 encoding, the *lpInput* parameter must point to a Unicode string and the *cbInput* parameter must specify the number of characters, not bytes, that are to be encoded. The conversion is always performed using the default system code page.

It is recommended that you use the **UnicodeEncodeText** function to convert a string to UTF-8 encoded text, and the **UnicodeDecodeText** function to convert UTF-8 encoded text to a UTF-16 or localized multi-byte string.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csncdv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

EncodeFile Function

```
BOOL WINAPI EncodeFile(  
    LPCTSTR lpszInputFile,  
    LPCTSTR lpszOutputFile,  
    DWORD dwOptions,  
    DWORD dwReserved  
);
```

The **EncodeFile** function opens and encodes a file, storing the contents as printable text in the specified file.

Parameters

lpszInputFile

A pointer to a string which specifies the name of the file to be encoded. The file must exist, and it must be a regular file that can be opened for reading by the current process. An error will be returned if a character device, such as CON: is specified as the file name.

lpszOutputFile

The name of the file that is to contain the encoded file data. If the file exists, it must be a regular file that can be opened for writing by the current process and will be overwritten. If the file does not exist, it will be created. An error will be returned if a character device, such as CON: is specified as the file name.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
FILE_ENCODE_BASE64	Use the base64 algorithm for encoding the file. This is the encoding method that is used by most modern email client software. Note that this option cannot be combined with the other encoding methods.
FILE_ENCODE_UUCODE	Use the uuencode algorithm for encoding the file. This is a common encoding method used UNIX systems and older email client software. Note that this option cannot be combined with the other encoding methods.
FILE_ENCODE_QUOTED	Use the quoted-printable algorithm for encoding the file. Note that this option cannot be combined with the other encoding methods.
FILE_ENCODE_YENCODE	Use the yEnc algorithm for encoding the file. This is an encoding method that is commonly used when posting files to Usenet newsgroups. Note that this option cannot be combined with other encoding methods.
FILE_ENCODE_COMPRESSED	The file should be compressed before it is encoded. To restore the original contents of the file, it must be expanded after it has been decoded.

dwReserved

This parameter is reserved and should always be set to zero.

Return Value

A non-zero value is returned if the file was successfully encoded. A zero value indicates that the input file does not exist or the output file could not be created.

Remarks

The **EncodeFile** function converts binary data files to a format that contains only printable ASCII characters. The option to compress the file requires that the function be able to create a temporary file on the local system in the directory specified by the TEMP environment variables. A compressed file must be expanded with the **DecodeFile** or **ExpandFile** functions. The compressed file is not stored in an archive format that is recognized by third-party applications such as PKZip or WinZip.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csncdv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[CompressFile](#), [DecodeFile](#), [ExpandFile](#), [GetMessageDigest](#)

ExpandBuffer Function

```
BOOL WINAPI ExpandBuffer(  
    LPVOID lpvInputBuffer,  
    DWORD cbInputBuffer  
    LPVOID lpvOutputBuffer,  
    LPDWORD lpcbOutputBuffer  
);
```

The **ExpandBuffer** function expands the contents of the previously compressed buffer.

Parameters

lpvInputBuffer

A pointer to the buffer which contains the compressed data.

cbInputBuffer

The number of bytes in the input buffer. This value must be greater than zero.

lpvOutputBuffer

A pointer to the buffer which will contain the expanded data. This parameter may be NULL, which can be used to determine the size of the of the resulting expanded data prior to allocating memory for it.

lpcbOutputBuffer

A pointer to the number of bytes that may be copied into the output buffer. If the *lpvOutputBuffer* parameter is not NULL, this must be initialized to a non-zero value. When the function returns, the actual number of bytes of expanded data is returned in this parameter.

Return Value

A non-zero value is returned if the data was successfully expanded. A zero value indicates that the data could not be expanded. Failure typically indicates that the compressed data was not in a recognized format.

Remarks

The compressed data buffer passed to the **ExpandBuffer** function must have been compressed by either the **CompressBuffer** or **CompressFile** functions. Data read from files that were compressed using third-party utilities such as WinZip will not be recognized by this function.

Example

```
cbOutputBuffer = 0;  
bResult = ExpandBuffer(lpInputBuffer,  
                        cbInputBuffer,  
                        NULL,  
                        &cbOutputBuffer);  
  
if (bResult)  
{  
    lpOutputBuffer = (LPBYTE)LocalAlloc(LPTR, cbOutputBuffer);  
    bResult = ExpandBuffer(lpInputBuffer,  
                           cbInputBuffer,  
                           lpOutputBuffer,  
                           &cbOutputBuffer);  
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csncdv10.lib

Unicode: Implemented as Unicode and ANSI versions.

ExpandFile Function

```
BOOL WINAPI ExpandFile(  
    LPCTSTR lpszInputFile,  
    LPCTSTR lpszOutputFile  
);
```

The **ExpandFile** function expands the contents of a previously compressed file.

Parameters

lpszInputFile

A pointer to a string which specifies the name of the file to be compressed. The file must exist, and it must be a regular file that can be opened for reading by the current process. An error will be returned if a character device, such as CON:, is specified as the file name.

lpszOutputFile

The name of the file that is to contain the expanded file data. If the file exists, it must be a regular file that can be opened for writing by the current process and will be overwritten. If the file does not exist, it will be created. An error will be returned if a character device, such as CON:, is specified as the file name.

Return Value

A non-zero value is returned if the file was successfully expanded. A zero value indicates that the input file could not be read or that the output file could not be created.

Remarks

The **ExpandFile** function can only expand files that were previously compressed using the **CompressFile** function. It cannot expand the contents of a file stored in an archive format used by third-party applications such as PKZip or WinZip.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csncdv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[CompressFile](#), [DecodeFile](#), [EncodeFile](#)

ExpandFileEx Function

```
BOOL WINAPI ExpandFileEx(  
    LPCTSTR lpszInputFile,  
    LPCTSTR lpszOutputFile,  
    DWORD dwCompressionType,  
    LPVOID lpvHeaderBlock,  
    DWORD dwHeaderLength  
);
```

The **ExpandFileEx** function expands the contents of the previously compressed file.

Parameters

lpszInputFile

A pointer to a string which specifies the name of the file which contains the compressed data. The file must exist, and it must be a regular file that can be opened for reading by the current process. An error will be returned if a character device, such as CON: is specified as the file name.

lpszOutputFile

The name of the file that is to contain the expanded data. If the file exists, it must be a regular file that can be opened for writing by the current process and will be overwritten. If the file does not exist, it will be created. An error will be returned if a character device, such as CON: is specified as the file name.

dwCompressionType

A numeric value which determines the algorithm that was used to compress the data. One of the following values may be specified. By default, the Deflate algorithm is used.

Value	Constant	Description
1	COMPRESSION_TYPE_DEFLATE	A compression algorithm that combines LZ77 algorithm for creating common substrings and Huffman coding to process the different frequencies of byte sequences in the data stream. Deflate is widely used by compression software.
2	COMPRESSION_TYPE_BURROWSWHEELER	A compression algorithm that rearranges blocks of data in sorted order and then uses Huffman coding to process different frequencies of data within the block. Burrows-Wheeler compression provides a better compression ratio

		than the Deflate algorithm, however it requires more resources to perform the compression.
--	--	--

lpvHeaderBlock

A pointer to a buffer which will contain uncompressed data that is read from the beginning of the input file. If this parameter is NULL then no header block is read from the file.

dwHeaderLength

The length of the data buffer to be read from the beginning of the input file. If this value is zero, the *lpvHeaderBlock* parameter is ignored and no header block is read from the file.

Return Value

A non-zero value is returned if the file was successfully expanded. A zero value indicates that the input file could not be read or that the output file could not be created.

Remarks

The **ExpandFileEx** function can only expand files that were previously compressed using the **CompressFile** or **CompressFileEx** functions. It cannot expand the contents of a file stored in an archive format used by third-party applications such as PKZip or WinZip.

The *lpvHeaderBlock* and *dwHeaderLength* parameters can be used to be read application-defined data from the beginning of the file, commonly called a header block. Typically this is a fixed-length structure which provides information to the application about the compressed file.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csncdv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[CompressBuffer](#), [CompressFile](#), [DecodeFile](#), [EncodeFile](#), [ExpandBuffer](#), [ExpandFile](#)

GetMessageDigest Function

```
BOOL WINAPI GetMessageDigest(  
    LPVOID lpvBuffer,  
    DWORD cbBuffer,  
    DWORD dwDigestOptions,  
    LPTSTR lpszDigest,  
    INT nMaxLength  
);
```

The **GetMessageDigest** function computes a message digest for a buffer, string or data file.

Parameters

lpvBuffer

A pointer to the data that will be processed by the message digest algorithm. This parameter may be NULL, in which case the standard null hash value will be returned. Depending on the options specified, this may point to a block of memory, a null-terminated string or the name of a data file.

cbBuffer

The number of bytes of data that will be processed by the message digest algorithm. If this value is zero, then the standard null hash value will be returned. If the *lpvBuffer* parameter is NULL, this value must be zero. If this value is -1 then *lpvBuffer* is considered to be a pointer to a null-terminated string.

dwDigestOptions

A numeric value which specifies the algorithm that will be used to generate the message digest, and may be combined with other option flags. The algorithm may be one of the following values:

Value	Constant	Description
0	MESSAGE_DIGEST_DEFAULT	Use the default message digest algorithm, which is the same as specifying MESSAGE_DIGEST_SHA256
1	MESSAGE_DIGEST_MD5	Use the MD5 algorithm which generates a 128-bit hash value that is returned as as 32 digit hexadecimal string. This algorithm is typically used as a checksum to verify data integrity, however it is not considered cryptographically secure and hash collision is possible.
2	MESSAGE_DIGEST_SHA1	Use the SHA1 algorithm which generates a 160-bit hash value that is returned as a 40 digit hexadecimal string. This algorithm is typically used as a checksum to verify data integrity, however it is not considered cryptographically secure.
3	MESSAGE_DIGEST_SHA256	Use the SHA-256 algorithm which generates a 256-bit hash value that is returned as a 64 digit hexadecimal string. This algorithm is used for data integrity validation and various

		cryptographic uses, such as password storage and document signing.
4	MESSAGE_DIGEST_SHA384	Use the SHA-384 algorithm which generates a 384-bit hash value that is returned as a 96 digit hexadecimal string. This is a truncated version of the SHA-512 algorithm that uses different initial values.
5	MESSAGE_DIGEST_SHA512	Use the SHA-512 algorithm which generates a 512-bit hash value that is returned as a 128 digit hexadecimal string. This algorithm is used for data integrity validation and various cryptographic uses, such as password storage and document signing.

The following values may be combined with the algorithm ID to specify options that determine how the message digest is computed and returned to the caller:

Value	Constant	Description
0x10000	MESSAGE_DIGEST_MEMORY	The <i>lpvBuffer</i> parameter is a pointer to a block of memory and the <i>cbBuffer</i> parameter specifies how many bytes in the buffer should be used to compute the message digest. This is the default behavior if no other options are specified and the <i>cbBuffer</i> parameter is not -1.
0x20000	MESSAGE_DIGEST_STRING	The <i>lpvBuffer</i> parameter is a pointer to a null-terminated string and the <i>cbBuffer</i> parameter specifies how many characters in the string should be used to compute the message digest. If the <i>cbBuffer</i> parameter is -1 then all characters up to the terminating null byte will be used.
0x40000	MESSAGE_DIGEST_DATAFILE	The <i>lpvBuffer</i> parameter is a pointer to a null-terminated string that specifies the name of a data file, and the entire contents of the file will be used to compute the message digest. The <i>cbBuffer</i> parameter is ignored.
0x80000	MESSAGE_DIGEST_BASE64	The message digest will be returned in <i>lpzDigest</i> as a base64 encoded value rather than a string of hexadecimal digits. This can be useful for services that use HMAC message digests and require the hash to be in base64 format.

lpzDigest

A pointer to a string that will contain the message digest computed using the contents of the specified buffer. The digest value will consist of upper-case hexadecimal numbers, with the length varying based on the algorithm selected. The string buffer must be large enough to

accommodate the entire message digest, including the terminating null character. This parameter cannot be NULL.

nMaxLength

The maximum number of characters that may be copied into the *lpzDigest* string buffer, including the terminating null character. This value cannot be zero, and must be large enough to accommodate the complete message digest string value. It is recommended that the string buffer be at least MAX_DIGEST_STRING characters in size.

Return Value

A non-zero value is returned if the message digest was computed and returned in the string buffer provided by the caller. A zero value indicates that the digest could not be computed, or the string buffer provided by the caller was not large enough to contain the message digest value.

Remarks

The **GetMessageDigest** function accepts an arbitrary block of data, a null-terminated string or a data file and computes a fixed-length value (hash) that can be used to uniquely identify that content. These algorithms are designed to be one-way functions that are deterministic, have a low probability of collision and are difficult or infeasible to reverse. It should be noted that the MD5 and SHA1 algorithms are no longer considered cryptographically secure, however they are still widely used for data integrity validation to protect against accidental or unintended changes.

If the MESSAGE_DIGEST_STRING option is specified and the Unicode version of this function is called, the string will be automatically converted from UTF-16 to UTF-8 encoding, and the UTF-8 encoded text will be used to generate the message digest. If you need to generate a message digest using the UTF-16 encoded version of the string, use the MESSAGE_DIGEST_MEMORY option instead. Keep in mind that UTF-16 encoding represents each character with two bytes, so the buffer length should be twice the number of characters in the Unicode string.

If the MESSAGE_DIGEST_DATAFILE option is specified, the file contents will be processed as binary data with no special consideration given for the various end-of-line conventions used in text files, or any Unicode byte order marks (BOMs) in the file. It is permissible for the file to be empty (zero length), in which case the default null-hash value will be returned based on the algorithm selected by the caller.

The current thread will block while the message digest is being computed. If a large amount of data is being processed, this may cause the application to become non-responsive. In that case, it is recommended that you create a background worker thread and call this function from that worker thread, rather than from the main UI thread.

The length of the message digest string returned by this function will always be the same for a given algorithm, regardless of the size of the data buffer. For example, the length of the message digest for the SHA-256 algorithm will always be 64 characters long. Each byte of the message digest is represented by two upper-case hexadecimal numbers.

It is permitted to provide a NULL or zero-length data buffer to this function, in which case the standard null-hash value will be returned. The same null-hash value will also be returned for a zero-length string or an empty file.

Example

```
// Get a SHA-256 message digest for a string value
LPCTSTR lpzValue = _T("The quick brown fox jumps over the lazy dog");
TCHAR szDigest[MAX_DIGEST_STRING];
BOOL bSuccess;
```

```
bSuccess = GetMessageDigest(  
    lpszValue,  
    (DWORD)-1L,  
    MESSAGE_DIGEST_SHA256 | MESSAGE_DIGEST_STRING,  
    szDigest,  
    MAX_DIGEST_STRING);  
  
// Get an MD5 message digest for the contents of a data file  
LPCTSTR lpszFileName = _T("testfile.zip");  
  
bSuccess = GetMessageDigest(  
    lpszFileName,  
    0,  
    MESSAGE_DIGEST_MD5 | MESSAGE_DIGEST_DATAFILE,  
    szDigest,  
    MAX_DIGEST_STRING);
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csncdv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

IsUnicodeText Function

```
BOOL WINAPI IsUnicodeText(  
    LPCTSTR lpString,  
    INT nLength  
);
```

The **IsUnicodeText** function checks if a string contains valid Unicode characters.

Parameters

lpString

A pointer to a null terminated string. This parameter cannot be NULL.

nLength

An integer value which specifies the number of characters to check. If this value is -1, the length of the string is determined by counting the number of characters up to the terminating null character. This parameter cannot be zero.

Return Value

A non-zero value is returned if the string contains valid Unicode characters. A zero value indicates the string contains characters that are not valid Unicode, or the string does not contain any Unicode characters.

Remarks

There are two versions of this function, **IsUnicodeTextA** which checks a multi-byte string to ensure that it contains valid UTF-8 encoded text, and **IsUnicodeTextW** which checks a wide string to ensure it contains valid UTF-16 text.

If the value of the *nLength* parameter is larger than the number of characters in the string, the function will not check beyond the terminating null character. If the length of the string is unknown, specify a length of -1 and the function will check the entire contents of the string up to the terminating null character.

If there is a byte order mark (BOM) sequence at the beginning of the string, this will be recognized by the function. A string that contains a valid BOM sequence with no corresponding text will be successfully validated by this function.

This function does not perform checks to ensure the string contains printable characters. It only validates that the Unicode string is structurally valid. The **IsUnicodeTextA** function will check to make sure there are no invalid UTF-8 encodings. The **IsUnicodeTextW** function will check to make sure the UTF-16 string does not contain any unpaired surrogates.

This function does not preserve state information and cannot be used to check the validity of a stream of text or binary data. It should only be used to validate complete Unicode strings that are terminated with a null character.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csncdv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

UnicodeDecodeText Function

```
INT WINAPI UnicodeDecodeText(  
    UINT nCodePage,  
    LPCSTR lpUtf8Text,  
    INT nLength,  
    LPTSTR lpString,  
    INT nMaxLength  
);
```

The **UnicodeDecodeText** function decodes UTF-8 encoded text and returns the contents in a string buffer.

Parameters

nCodePage

A value that specifies the code page used when decoding the text. This parameter can be set to the value of any code page that is available in the operating system. It is recommended that you use CP_ACP which specifies the system default ANSI code page. This parameter is only used when decoding UTF-8 encoded text to a multi-byte string.

lpUtf8Text

A pointer to a null terminated string that contains the UTF-8 encoded text to be decoded. This parameter must always specify a pointer to an 8-bit character string, regardless if the project is configured to use the Unicode or Multi-Byte character set. This parameter cannot be NULL.

nLength

The number of bytes in the UTF-8 encoded string to be decoded. If this parameter is -1, the length of the UTF-8 encoded text is determined by counting the number of characters up to the terminating null character.

lpString

A pointer to a string buffer that will contain the decoded UTF-8 text when the function returns. The string buffer must be large enough to contain all of the encoded text, and cannot be a NULL a pointer.

nMaxLength

The maximum number of characters that can be copied into the string buffer. The contents of the *lpString* buffer will always be null terminated, and the maximum size must be large enough to include the null character. This value must be greater than zero.

Return Value

If the UTF-8 encoded text is successfully decoded, the return value is the number of characters copied to the string buffer. If the text cannot be decoded, or the string buffer is not large enough to store all of the decoded text, the function will return zero. To get extended error information, call **GetLastError**.

Remarks

There are two versions of this function, **UnicodeDecodeTextA** which returns a localized multi-byte string and **UnicodeDecodeTextW** which converts the UTF-8 encoded text to UTF-16 text. Your project configuration typically determines which version of this function is used by default.

If the value of the *nLength* parameter is larger than the number of UTF-8 characters, the function will not check beyond the terminating null character. If the length of the *lpUtf8Text* string is

unknown, specify a length of -1 and the function will decode the entire contents of the string up to the terminating null character.

When calling **UnicodeDecodeTextA** to convert UTF-8 encoded text to a localized multi-byte string, it is recommended that you specify CP_ACP (zero) as the code page value unless you know it contains Unicode characters that cannot be represented using the default ANSI code page. Using CP_ACP will ensure the UTF-8 text is decoded using the current locale and language settings.

When calling **UnicodeDecodeTextW** to convert UTF-8 encoded text to UTF-16 text, the code page parameter is ignored and should always be a value of zero.

This function performs a strict check on the UTF-8 encoded text and will fail if the encoding is malformed, or in the case of being converted to a multi-byte string, if it cannot be decoded using the specified code page. It will not simply replace invalid character sequences with a default character.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csncdv10.lib

Unicode: Implemented as Unicode and ANSI versions.

UnicodeEncodeText Function

```
INT WINAPI UnicodeEncodeText(  
    UINT nCodePage,  
    LPCTSTR lpString,  
    INT nLength,  
    LPSTR lpUtf8Text,  
    INT nMaxLength  
);
```

The **UnicodeEncodeText** function encodes a string and returns UTF-8 encoded text.

Parameters

nCodePage

A value that specifies the code page used when encoding the text. This parameter can be set to the value of any code page that is available in the operating system. It is recommended that you use CP_ACP which specifies the system default ANSI code page. This parameter is only used when encoding a multi-byte string.

lpString

A pointer to a null terminated string that contains the text to be encoded. This parameter cannot be NULL.

nLength

The number of characters in the string to be encoded. If this parameter is -1, the length of the string is determined by counting the number of characters up to the terminating null character.

lpUtf8Text

A pointer to a character buffer which will contain the UTF-8 encoded text when the function returns. This parameter must always specify a pointer to an 8-bit character string, regardless if the project is configured to use the Unicode or Multi-Byte character set. This parameter cannot be NULL.

nMaxLength

The maximum number of bytes that can be copied into the UTF-8 text buffer. The contents of the *lpUtf8Text* buffer will always be null terminated, and the maximum size must be large enough to include the null byte. This value must be greater than zero.

Return Value

If the string is successfully encoded, the return value is the number of characters copied to the output buffer. If the text cannot be encoded, or the output buffer is not large enough to store all of the encoded text, the function will return zero. To get extended error information, call **GetLastError**.

Remarks

There are two versions of this function, **UnicodeEncodeTextA** which converts a multi-byte string to UTF-8 encoded text, and **UnicodeEncodeTextW** which converts a UTF-16 string to a UTF-8 string. Your project configuration typically determines which version of this function is used by default.

If the value of the *nLength* parameter is larger than the number of characters in *lpString*, the function will not check beyond the terminating null character. If the length of *lpString* is unknown, specify a length of -1 and the function will encode the entire contents of the string up to the

terminating null character.

When calling **UnicodeEncodeTextA** to convert a multi-byte string to UTF-8 encoding, it is recommended that you specify CP_ACP (zero) as the code page value unless you know it contains ANSI characters from a different code page. Using CP_ACP will ensure the string is encoded using the current locale and language settings.

This function performs a strict check on the multi-byte input string and will fail if it contains a malformed multi-byte sequence or characters that cannot be converted to UTF-8 using the specified code page. It will not simply replace invalid character sequences with a default character.

When calling **UnicodeEncodeTextW** to convert UTF-16 text to UTF-8 encoded text, the code page parameter is ignored and should always be a value of zero. The text will be normalized prior to being converted to UTF-8 using canonical composition, where decomposed characters are combined to create their canonical precomposed equivalent.

Requirements

Library Information

File Name	CSFTPV10.DLL
Version	10.0.1468.2518
LibID	C01B14F0-7091-429D-A690-B99D635CB8AB
Import Library	CSFTPV10.LIB
Dependencies	None
Standards	RFC 959, RFC 1579, RFC 2228

Overview

The File Transfer Protocol (FTP) library provides a comprehensive API which supports both high level operations, such as uploading or downloading files, as well as a collection of lower-level file I/O functions. In addition to file transfers, an application can create, rename and delete files and directories, search for files using wildcards and perform other common file management functions.

Files can be stored on the local file system or in memory, depending on the needs of your application and multiple file transfers be performed using a single function call. The library can also be used to manage files on the server and supports many of the common protocol extensions that can be used to access the remote file system. It understands a number of different directory listing formats, including those typically used with UNIX and Linux based systems, Windows server platforms, NetWare servers and VMS systems.

This library supports active and passive mode file transfers, firewall compatibility options, proxy servers and secure file transfers using the standard SSL/TLS and SFTP protocols. Secure file transfers support implicit and explicit SSL sessions, client certificates and up to 256-bit AES encryption.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). If you are using Visual C++ 6.0 it is required that you have Service Pack 6 (SP6) installed. You should install all updates for your development tools and have the current Windows SDK installed. The minimum recommended version of Visual Studio is Visual Studio 2010.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are using Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. It is recommended that you install the current service pack and all critical updates available for your version of the operating system.

This product includes both 32-bit and 64-bit libraries. Native 64-bit CPU support requires the 64-bit version of Windows 7 or later versions of the Windows operating system.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

File Transfer Protocol Functions

Function	Description
FtpAllocate	Allocate the specified number of bytes on the server
FtpAsyncConnect	Connect asynchronously to the specified server
FtpAsyncFileList	Return an unparsed list of files in the specified directory
FtpAsyncGetData	Copy the contents of a remote file to a local buffer
FtpAsyncGetFile	Copy a file from the server to the local system
FtpAsyncGetFileEx	Copy a file from the server to the local system, supporting files larger than 4GB
FtpAsyncProxyConnect	Connect asynchronously to the specified proxy server
FtpAsyncPutData	Create a file on the server using the contents of a local buffer
FtpAsyncPutFile	Copy a file from the local system to the server
FtpAsyncPutFileEx	Copy a file from the local system to the server, supporting files larger than 4GB
FtpAttachThread	Attach the specified client handle to another thread
FtpCancel	Cancel the current blocking operation
FtpChangeDirectory	Change the current working directory on the server
FtpChangeDirectoryUp	Change the current working directory on the server
FtpCloseDirectory	Close the open directory on the server
FtpCloseFile	Close the current file on the server
FtpCommand	Send a command to the server
FtpConnect	Establish a client connection with a server
FtpConnectUrl	Establish a client connection using the specified URL
FtpCreateDirectory	Create the specified directory on the server
FtpCreateSecurityCredentials	Create a new security credentials structure
FtpDeleteFile	Delete a file from the server
FtpDeleteSecurityCredentials	Delete a previously created security credentials structure
FtpDisableEvents	Disable event notification
FtpDisableTrace	Disable logging of socket function calls to the trace log
FtpDisconnect	Disconnect the client session from the server
FtpDownloadFile	Download a file from the server to the local system
FtpEnableEvents	Enable event notification
FtpEnableFeature	Enable the specified feature in the client
FtpEnableTrace	Enable logging of socket function calls to a file

FtpEndOfFile	Determine if the end-of-file has been reached
FtpEnumFiles	Return a list of files in a directory on the server
FtpEnumFilesEx	Return a list of files in a directory on the server, supporting files larger than 4GB
FtpEnumTasks	Return a list of asynchronous tasks
FtpEventProc	Callback function that processes events generated by the client
FtpFreezeEvents	Suspend and resume event handling by the client
FtpGetActivePorts	Return the range of local port numbers used for active transfers
FtpGetBufferSize	Return the size of an internal buffer used during data transfers
FtpGetChannelMode	Return the mode for the specified communication channel
FtpGetClientQuota	Return quota information for the current client session
FtpGetData	Copy the contents of a remote file to a local buffer
FtpGetDirectory	Get the current working directory on the server
FtpGetDirectoryFormat	Get the format which is used by the server to list files
FtpGetErrorString	Return a description for the specified error code
FtpGetFeatures	Return the features available to the client
FtpGetFile	Copy a file from the server to the local system
FtpGetFileEx	Copy a file from the server to the local system, supporting files larger than 4GB
FtpGetFileList	Return an unparsed list of files in the specified directory
FtpGetFileNameEncoding	Return the character encoding used when sending a file name to the server
FtpGetFilePermissions	Return the access permissions for the specified file
FtpGetFileSize	Return the size of a file on the server
FtpGetFileStatus	Return file status information from the server
FtpGetFileStatusEx	Return file status information from the server, supporting files larger than 4GB
FtpGetFileTime	Return the modification time for the specified file on the server
FtpGetFileType	Return the default file type for the current session
FtpGetFirstFile	Return the first file from the file list returned by the server
FtpGetFirstFileEx	Return the first file from the file list returned by the server, supporting files larger than 4GB
FtpGetLastError	Return the last error code
FtpGetMultipleFiles	Copy multiple files from the server to the local system
FtpGetNextFile	Return the next file from the file list returned by the server
FtpGetNextFileEx	Return the next file from the file list returned by the server, supporting files larger than 4GB

FtpGetPriority	Return the current priority for file transfers
FtpGetProxyType	Return the proxy type selected by the client
FtpGetResultCode	Return the result code from the previous command
FtpGetResultString	Return the result string from the previous command
FtpGetSecurityInformation	Return security information about the current client connection
FtpGetServerInformation	Get system information about the server
FtpGetServerStatus	Return system status of server
FtpGetServerTimeZone	Return the timezone offset in seconds for the current server
FtpGetServerType	Return the type of operating system the server is running on
FtpGetStatus	Return the current client status
FtpGetTaskError	Return the last error code for the specified asynchronous task
FtpGetTaskId	Return the unique task identifier associated with the specified client session
FtpGetText	Download the contents of a text file to a string buffer
FtpGetTimeout	Return the number of seconds until an operation times out
FtpGetTransferStatus	Return current file transfer statistics
FtpGetTransferStatusEx	Return current file transfer statistics, supporting files larger than 4GB
FtpInitialize	Initialize the library and validate the specified runtime license key
FtpIsBlocking	Determine if the current operation is blocked
FtpIsConnected	Determine if the client is connected to the server
FtpIsReadable	Determine if the client can read data from the data channel
FtpIsWritable	Determine if the client can write data to the data channel
FtpLogin	Login to the server
FtpLogout	Logout from the server
FtpMountStructure	Mount a structure (filesystem) on the server
FtpOpenDirectory	Open the specified directory for reading
FtpOpenFile	Open the specified file for reading or writing
FtpProxyConnect	Establish a connection with a proxy server
FtpPutData	Create a file on the server using the contents of a local buffer
FtpPutFile	Copy a file from the local system to the server
FtpPutFileEx	Copy a file from the local system to the server, supporting files larger than 4GB
FtpPutMultipleFiles	Copy multiple files from the local system to the server
FtpPutText	Create a text file on the server from the contents of a string buffer
FtpRead	Read data from the server

FtpRegisterEvent	Register an event handler for the specified event
FtpRegisterFileType	Associate a file name extension with a specific file type
FtpRemoveDirectory	Remove a directory from the server
FtpRenameFile	Rename a file on the server
FtpReset	Reset the client connection
FtpSetActivePorts	Set the range of local port numbers used for active transfers
FtpSetBufferSize	Set the size of an internal buffer used during data transfers
FtpSetChannelMode	Change the security mode for the specified channel
FtpSetDirectoryFormat	Set the format which is used by the server to list files
FtpSetFeatures	Set the features which can be used by the client
FtpSetFileMode	Set the current file mode
FtpSetFileNameEncoding	Set the character encoding type used when sending a file name to the server
FtpSetFilePermissions	Set the access permissions for the specified file
FtpSetFileStructure	Set the current file data structure
FtpSetFileTime	Set the modification time for the specified file on the server
FtpSetFileType	Set the default file type for the current session
FtpSetLastError	Set the last error code
FtpSetPassiveMode	Set the server in passive mode
FtpSetPriority	Set the priority for file transfers
FtpSetTimeout	Set the number of seconds until an operation times out
FtpTaskAbort	Abort the specified asynchronous task
FtpTaskDone	Determine if an asynchronous task has completed
FtpTaskResume	Resume execution of an asynchronous task
FtpTaskSuspend	Suspend execution of an asynchronous task
FtpTaskWait	Wait for an asynchronous task to complete
FtpUninitialize	Terminate use of the library by the calling process
FtpUploadFile	Upload a file from the local system to the server
FtpValidateUrl	Check the contents of a string to ensure it represents a valid URL
FtpVerifyFile	Compare the contents of a local file against a file stored on the server
FtpWrite	Write data to the server

FtpAllocate Function

```
INT WINAPI FtpAllocate(  
    HCLIENT hClient,  
    DWORD dwFileLength,  
    DWORD dwRecSize  
);
```

The **FtpAllocate** function instructs the server to reserve sufficient storage to accommodate the new file being transferred.

Parameters

hClient

Handle to the client session.

dwFileLength

The number of bytes to allocate storage for on the server.

dwRecSize

The maximum record or page size for the file. A value of zero indicates that the file does not have a record or page structure, and the parameter is ignored.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

This function should be called immediately before the **FtpOpenFile** function.

This function is ignored by those servers which do not require that the maximum size of the file be declared beforehand. The most common FTP servers running under UNIX and Windows do not require that file space be pre-allocated.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftpv10.lib

See Also

FtpAsyncConnect Function

```
HCLIENT WINAPI FtpAsyncConnect(  
    LPCTSTR lpszRemoteHost,  
    UINT nRemotePort,  
    LPCTSTR lpszUserName,  
    LPCTSTR lpszPassword,  
    UINT nTimeout,  
    DWORD dwOptions,  
    LPSECURITYCREDENTIALS LpCredentials,  
    HWND hEventWnd,  
    UINT uEventMsg  
);
```

The **FtpAsyncConnect** function establishes a connection with the specified server.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

The application should create a background worker thread and establish a connection by calling **FtpConnect** within that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each client session.

Parameters

lpszRemoteHost

A pointer to the name of the server to connect to; this may be a fully-qualified domain name or an IP address.

nRemotePort

The port number the server is listening on. A value of zero specifies that the default port number should be used. For standard connections, the default port number is 21. For secure connections, the default port number is 990. If the secure port number is specified, an implicit SSL/TLS connection will be established by default.

lpszUserName

Points to a string that specifies the user name to be used to authenticate the current client session. If this parameter is NULL or an empty string, then the login is considered to be anonymous. Note that anonymous logins are not supported for secure connections using the SSH protocol.

lpszPassword

Points to a string that specifies the password to be used to authenticate the current client session. This parameter may be NULL or an empty string if no password is required for the specified user, or if no username has been specified.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
FTP_OPTION_PASSIVE	<p>This option specifies the client should attempt to establish the data connection with the server. When the client uploads or downloads a file, normally the server establishes a second connection back to the client which is used to transfer the file data.</p> <p>However, if the local system is behind a firewall or a NAT router, the server may not be able to create the data connection and the transfer will fail. By specifying this option, it forces the client to establish an outbound data connection with the server. It is recommended that applications use passive mode whenever possible.</p>
FTP_OPTION_FIREWALL	<p>This option specifies the client should always use the host IP address to establish the data connection with the server, not the address returned by the server in response to the PASV command. This option may be necessary if the server is behind a router that performs Network Address Translation (NAT) and it returns an unreachable IP address for the data connection. If this option is specified, it will also enable passive mode data transfers.</p>
FTP_OPTION_NOAUTH	<p>This option specifies the server does not require authentication, or that it requires an alternate authentication method. When this option is used, the client connection is flagged as authenticated as soon as the connection to the server has been established. Note that using this option to bypass authentication may result in subsequent errors when attempting to retrieve a directory listing or transfer a file. It is recommended that you consult the technical reference documentation for the server to determine its specific authentication requirements.</p>
FTP_OPTION_KEEPALIVE	<p>This option specifies the client should attempt to keep the connection with the server active for an extended period of time. It is important to note that regardless of this option, the server may still choose to disconnect client sessions that are holding the command channel open but are not performing file transfers.</p>
FTP_OPTION_NOAUTHRSA	<p>This option specifies that RSA authentication should not be used with SSH-1 connections. This option is ignored with SSH-2 connections and should only be specified if required by the server. This option has no effect on standard or secure connections using SSL.</p>

FTP_OPTION_NOPWDNUL	This option specifies the user password cannot be terminated with a null character. This option is ignored with SSH-2 connections and should only be specified if required by the server. This option has no effect on standard or secure connections using SSL.
FTP_OPTION_NOREKEY	This option specifies the client should never attempt a repeat key exchange with the server. Some SSH servers do not support rekeying the session, and this can cause the client to become non-responsive or abort the connection after being connected for an hour. This option has no effect on standard or secure connections using SSL.
FTP_OPTION_COMPATSID	This compatibility option changes how the session ID is handled during public key authentication with older SSH servers. This option should only be specified when connecting to servers that use OpenSSH 2.2.0 or earlier versions. This option has no effect on standard or secure connections using SSL.
FTP_OPTION_COMPATHMAC	This compatibility option changes how the HMAC authentication codes are generated. This option should only be specified when connecting to servers that use OpenSSH 2.2.0 or earlier versions. This option has no effect on standard or secure connections using SSL.
FTP_OPTION_VIRTUALHOST	This option specifies the server supports virtual hosting, where multiple domains are hosted by a server using the same external IP address. If this option is enabled, the client will send the HOST command to the server upon establishing a connection.
FTP_OPTION_VERIFY	This option specifies that file transfers should be automatically verified after the transfer has completed. If the server supports the XMD5 command, the transfer will be verified by calculating an MD5 hash of the file contents. If the server does not support the XMD5 command, but does support the XCRC command, the transfer will be verified by calculating a CRC32 checksum of the file contents. If neither the XMD5 or XCRC commands are supported, the transfer is verified by comparing the size of the file. Automatic file verification is only performed for binary mode transfers because of the end-of-line conversion that may occur when text files are uploaded or downloaded.
FTP_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server

	certificate will not be validated and the connection will always be permitted. This option only affects connections using either the SSL or TLS protocols.
FTP_OPTION_SECURE	This option specifies the client should attempt to establish a secure connection with the server. This option is the same as specifying FTP_OPTION_SECURE_IMPLICIT which immediately performs the SSL/TLS protocol negotiation when the connection is established.
FTP_OPTION_SECURE_IMPLICIT	This option specifies the client should attempt to immediately establish secure SSL/TLS connection with the server. This option is typically used when connecting to a server on port 990, which is the default port number used for FTPS.
FTP_OPTION_SECURE_EXPLICIT	This option specifies the client should establish a standard connection to the server and then use the AUTH command to negotiate an explicit secure connection. This option is typically used when connecting to the server on ports other than 990.
FTP_OPTION_SECURE_SHELL	This option specifies the client should use the Secure Shell (SSH) protocol to establish the connection. This option will automatically be selected if the connection is established using port 22, the default port for SSH.
FTP_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
FTP_OPTION_TUNNEL	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established. This option also forces all connections to be outbound and enables the firewall compatibility features in the client.
FTP_OPTION_KEEPALIVE_DATA	This option specifies the client should attempt to keep the control connection active during a file transfer. Normally, when a data transfer is in progress, no additional commands are issued on the control channel until the transfer completes. Specifying this option automatically enables the FTP_OPTION_KEEPALIVE option and forces the client to continue to issue NOOP commands during the file transfer. This option only applies to FTP and

	FTPS connections and has no effect on connections using SFTP (SSH).
FTP_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
FTP_OPTION_FREETHREAD	This option specifies the handle returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the handle is synchronized across multiple threads.
FTP_OPTION_HIRES_TIMER	This option specifies the elapsed time for data transfers should be returned in milliseconds instead of seconds. This will return more accurate transfer times for smaller files being uploaded or downloaded using fast network connections.
FTP_OPTION_TLS_REUSE	This option specifies that TLS session reuse should be enabled for secure connections. This option is only supported on Windows 8.1 or Windows Server 2012 R2 and later platforms, and it should only be used when explicitly required by the server. This option is not compatible with servers built using OpenSSL 1.0.2 and earlier versions which do not provide Extended Master Secret (EMS) support as outlined in RFC7627.

lpCredentials

A pointer to a [SECURITYCREDENTIALS](#) structure. This parameter should be NULL if the connection is not secure or when client credentials are not required. Most servers do not require a client certificate to establish a secure connection. However, if the server does require a client certificate, the structure members *dwSize*, *lpzCertStore* and *lpzCertName* must be defined. Undefined structure members must be initialized to a value of zero or NULL and the *dwSize* member must be initialized to the size of the **SECURITYCREDENTIALS** structure.

hEventWnd

The handle to the event notification window. This window receives messages which notify the client of various asynchronous network events that occur.

uEventMsg

The message identifier that is used when an asynchronous network event occurs. This value should be greater than WM_USER as defined in the Windows header files.

Return Value

If the function succeeds, the return value is a handle to a client session. If the function fails, the return value is INVALID_CLIENT. To get extended error information, call **FtpGetLastError**.

Remarks

When a message is posted to the notification window, the low word of the *lParam* parameter contains the event identifier. The high word of *lParam* contains the low word of the error code, if an error has occurred. The *wParam* parameter contains the client handle. One or more of the following event identifiers may be sent:

Constant	Description
FTP_EVENT_CONNECT	The control connection to the server has completed. The high word of the <i>lParam</i> parameter should be checked, since this notification message will be posted if an error has occurred.
FTP_EVENT_DISCONNECT	The server has closed the control connection to the client. The client should read any remaining data and disconnect.
FTP_EVENT_OPENFILE	The data connection to the server has completed. The high word of the <i>lParam</i> parameter should be checked, since this notification message will be posted if an error has occurred.
FTP_EVENT_CLOSEFILE	The server has closed the data connection to the client. The client should read any remaining data and close the data channel.
FTP_EVENT_READFILE	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
FTP_EVENT_WRITEFILE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
FTP_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
FTP_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and reconnect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.
FTP_EVENT_COMMAND	A command has been issued by the client and the server response has been received and processed. This event can be used to log the result codes and messages returned by the server in response to actions taken by the client.
FTP_EVENT_PROGRESS	The client is in the process of sending or receiving a file on the data channel. This event is called periodically during a transfer so that the client can update any user interface components such as a status control or progress bar.
FTP_EVENT_GETFILE	This event is generated when a file download has completed. If multiple files are being downloaded, this event will be generated for each file.

FTP_EVENT_PUTFILE	This event is generated when a file upload has completed. If multiple files are being uploaded, this event will be generated for each file.
-------------------	---

To cancel asynchronous notification and return the client to a blocking mode, use the **FtpDisableEvents** function.

If the FTP_OPTION_KEEPALIVE option is specified, a background worker thread will be created to monitor the command channel and periodically send NOOP commands to the server if no commands have been sent recently. This can prevent the server from terminating the client connection during idle periods where no commands are being issued. However, it is important to keep in mind that many servers can be configured to also limit the total amount of time a client can be connected to the server, as well as the amount of time permitted between file transfers. If the server does not respond to the NOOP command, this option will be automatically disabled for the remainder of the client session.

If the FTP_OPTION_SECURE_EXPLICIT option is specified, the client will establish a standard connection to the server and send the AUTH TLS command to the server. If the server does not accept this command, it will then send the AUTH SSL command. If both commands are rejected by the server, an explicit SSL session cannot be established. By default, both the command and data channels will be encrypted when a secure connection is established. To change this, use the **FtpSetChannelMode** function.

The *dwOptions* argument can be used to specify the threading model that is used by the library when a connection is established. By default, the handle is initially attached to the thread that created it. From that point on, until the it is released, only the owner may call functions using that handle. The ownership of the handle may be transferred from one thread to another using the **FtpAttachThread** function.

Specifying the FTP_OPTION_FREETHREAD option enables any thread to call any function using the handle, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the handle is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same handle.

Example

```
// The Ipswitch WS_FTP server accepts the AUTH command to establish
// an explicit SSL session on the default FTP port
hClient = FtpAsyncConnect(lpszRemoteHost,
                        FTP_PORT_DEFAULT,
                        FTP_TIMEOUT,
                        FTP_OPTION_SECURE_EXPLICIT,
                        NULL,
                        hEventWnd,
                        uEventMsg);

// When the GlobalSCAPE Secure FTP server is configured in implicit
// authorization mode, it negotiates a secure session as soon as the
// connection is established and does not require a command
hClient = FtpAsyncConnect(lpszRemoteHost,
                        FTP_PORT_SECURE,
                        FTP_TIMEOUT,
                        FTP_OPTION_SECURE_IMPLICIT,
```

```
NULL,  
hEventWnd,  
uEventMsg);
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csftpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

FtpAsyncFileList Function

```
UINT WINAPI FtpAsyncFileList(  
    HCLIENT hClient,  
    LPCTSTR lpszDirectory,  
    DWORD dwOptions,  
    LPTSTR lpszBuffer,  
    INT nMaxLength,  
    FTPEVENTPROC lpEventProc,  
    DWORD_PTR dwParam  
);
```

Return an unparsed list of files in the specified directory.

Parameters

hClient

Handle to the client session.

lpszDirectory

A pointer to a string that specifies the name of a directory and/or a wildcard file mask. The format of the directory name must match the file naming conventions of the server. If this parameter is NULL or points to an empty string, the current working directory will be used.

dwOptions

An unsigned integer that specifies one or more options. This parameter may be any one of the following values:

Constant	Description
FTP_LIST_DEFAULT	This option specifies the server should return a complete listing of files in the specified directory with as much detail as possible. This typically means that the file size, date, ownership and access rights will be returned to the client. Information about the files are returned in lines of text, with each line terminated by carriage return and linefeed (CRLF) characters. The exact format of the data returned is specific to the server operating system.
FTP_LIST_NAMEONLY	This option specifies the server should only return a list of file names, with no additional information about the file. Each file name is terminated by carriage return and linefeed (CRLF) characters.

lpszBuffer

A pointer to a string buffer that will contain the list of files when the function returns. This buffer should be large enough to store the complete file listing and a terminating null character. If the buffer is smaller than the total amount of data returned by the server, the data will be truncated. This parameter cannot be NULL.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer, including the terminating null character.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **FtpEventProc** callback function. This parameter may be NULL if you do not wish to implement an event handler.

dwParam

A user-defined integer value that is passed to the callback function. This parameter is ignored if the *lpEventProc* parameter is NULL.

Return Value

If the function succeeds, the return value is non-zero integer value that specifies a unique asynchronous task identifier. If the function fails, the return value is zero. To get extended error information, call the **FtpGetLastError** function.

Remarks

The **FtpAsyncFileList** function returns a list of files in the specified directory, copying the data to a string buffer. This function is similar to the **FtpGetFileList** function, however it retrieves the list of files asynchronously using a background worker thread and does not block the current working thread. This enables the application to continue to perform other operations while the file listing is being returned by the server.

Because this function works asynchronously, it is important that the memory allocated for the buffer is not released before the asynchronous task completes. If you provide a buffer that is allocated on the stack, such as with the example listed below, then you must ensure that your code does not return from the function while the directory listing is being retrieved. In the example, this is achieved by calling the **FtpTaskWait** function. You can also perform other operation and poll the status of the task by calling the **FtpTaskDone** function. If you wish to return from the calling function immediately, then you must dynamically allocate memory for the *lpzBuffer* parameter on the heap and free that memory after the task has completed and the data is no longer needed.

If the address of an event handler is provided to this function, it is guaranteed that the handler will be invoked with the FTP_EVENT_CONNECT event after the connection has been established, and the FTP_EVENT_DISCONNECT event after the directory listing has completed. This enables your application to know when the directory listing is about to begin, and immediately before the worker thread is terminated. The worker thread creates a secondary connection to the server with its own session handle. This ensures that the asynchronous operation will not interfere with the current client session. Your application can interact with this background worker thread using the client handle that is passed to the event handler.

This function can be particularly useful when the client is connected to a server that returns file listings in a format that is not recognized by the library. The application can retrieve the unparsed file listing from the server and parse the contents. Note that if you specify the FTP_LIST_NAMEONLY option, the data will only contain a list of file names and there will be no way for the application to know if they represent a regular file or a subdirectory.

This function is supported for both FTP and SFTP (SSH) connections, however the format of the data may differ depending on which protocol is used. Most UNIX based FTP servers will not list files and subdirectories that begin with a period, however most SFTP servers will return a list of all files, even those that begin with a period.

Example

```
TCHAR szFileList[MAXFILELISTSIZE];  
UINT nTaskId;
```

```
nTaskId = FtpAsyncFileList(hClient,
                           NULL,
                           FTP_LIST_DEFAULT,
                           szFileList,
                           MAXFILELISTSIZE,
                           NULL, 0);

if (nTaskId == 0)
{
    _tprintf(_T("Unable to list files (error 0x%08lx)\n"), FtpGetLastError());
    return;
}
else
{
    DWORD dwError = NO_ERROR;
    DWORD dwElapsed = 0;

    FtpTaskWait(nTaskId, INFINITE, &dwElapsed, &dwError);
    _tprintf(_T("Asynchronous file listing returned in %lu milliseconds\n"),
dwElapsed);
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csftpv10.lib

FtpAsyncGetData Function

```
UINT WINAPI FtpAsyncGetData(  
    HCLIENT hClient,  
    LPCTSTR lpszRemoteFile,  
    LPVOID lpvBuffer,  
    LPDWORD lpdwLength,  
    DWORD dwReserved,  
    FTPEVENTPROC lpEventProc,  
    DWORD_PTR dwParam  
);
```

Copies the contents of a file on the server to the specified buffer.

Parameters

hClient

Handle to the client session.

lpszRemoteFile

A pointer to a string that specifies the file on the server that will be transferred to the local system. The file naming conventions must be that of the host operating system.

lpvBuffer

A pointer to a byte buffer which will contain the data transferred from the server, or a pointer to a global memory handle which will reference the data when the function returns.

lpdwLength

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the *lpvBuffer* parameter. If the *lpvBuffer* parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the actual length of the file that was downloaded.

dwReserved

A reserved parameter. This value should always be zero.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **FtpEventProc** callback function. This parameter may be NULL if you do not wish to implement an event handler.

dwParam

A user-defined integer value that is passed to the callback function. This parameter is ignored if the *lpEventProc* parameter is NULL.

Return Value

If the function succeeds, the return value is non-zero integer value that specifies a unique asynchronous task identifier. If the function fails, the return value is zero. To get extended error information, call the **FtpGetLastError** function. The application should treat the task ID as an opaque value and never make an assumption about the sequence in which IDs are assigned to a background task.

Remarks

The **FtpAsyncGetData** function is used to download the contents of a remote file into a local

buffer. This function is similar to the **FtpGetData** function, however it retrieves the contents of the file using a background worker thread and does not block the current working thread. This enables the application to continue to perform other operations while the file is being copied to the local system.

Because this function works asynchronously, it is important that the memory allocated for the buffer is not released before the asynchronous task completes. If you provide a buffer that is allocated on the stack, such as with the example listed below, then you must ensure that your code does not return from the function while the data is being downloaded. In the example, this is achieved by calling the **FtpTaskWait** function. You can also perform other operation and poll the status of the task by calling the **FtpTaskDone** function. If you wish to return from the calling function immediately, then you must dynamically allocate memory for the *lpvBuffer* and *lpdwLength* parameters on the heap and free that memory after the task has completed and the data is no longer needed.

If the address of an event handler is provided to this function, it is guaranteed that the handler will be invoked with the FTP_EVENT_CONNECT event after the connection has been established, and the FTP_EVENT_DISCONNECT event after the transfer has completed. This enables your application to know when the data transfer is about to begin, and immediately before the worker thread is terminated. The worker thread creates a secondary connection to the server with its own session handle. This ensures that the asynchronous operation will not interfere with the current client session. Your application can interact with this background worker thread using the client handle that is passed to the event handler.

The *lpvBuffer* parameter may be specified in one of two ways, depending on the needs of the application. It can either be a pre-allocated buffer large enough to store the contents of the file or it can specify the address of a global memory handle that will contain the data. If it points to a pre-allocated buffer, the *lpdwLength* parameter must be initialized to the maximum number of bytes that can be copied into the buffer. If specifies the address of a global memory handle, then *lpdwLength* must be initialized to a value of zero. See the example code below.

Example

```
HGLOBAL hglobalBuffer = NULL;
DWORD dwLength = 0;
UINT nTaskId;

// Return the file data into block of global memory allocated by
// the GlobalAlloc function; the handle to this memory will be
// returned in the hglobalBuffer parameter

nTaskId = FtpAsyncGetData(hClient,
                        lpzFileName,
                        &hglobalBuffer,
                        &dwLength,
                        0, NULL, 0);

if (nTaskId != 0)
{
    DWORD dwError = NO_ERROR;
    DWORD dwElapsed = 0;

    // Wait for the transfer to complete
    FtpTaskWait(nTaskId, INFINITE, &dwElapsed, &dwError);

    // Lock the global memory handle, returning a pointer to the
```

```
// contents of the file data
lpBuffer = (LPBYTE)GlobalLock(hgblBuffer);

// After the data has been used, the handle must be unlocked
// and freed, otherwise a memory leak will occur
GlobalUnlock(hgblBuffer);
GlobalFree(hgblBuffer);
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csftpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

FtpAsyncGetFile Function

```
UINT WINAPI FtpAsyncGetFile(  
    HCLIENT hClient,  
    LPCTSTR lpszLocalFile,  
    LPCTSTR lpszRemoteFile,  
    DWORD dwOptions,  
    DWORD dwOffset,  
    FTPEVENTPROC lpEventProc,  
    DWORD_PTR dwParam  
);
```

Downloads the specified file from the server to the local system.

Parameters

hClient

Handle to the client session.

lpszLocalFile

A pointer to a string that specifies the file on the local system that will be created, overwritten or appended to. The file pathing and name conventions must be that of the local host.

lpszRemoteFile

A pointer to a string that specifies the file on the server that will be transferred to the local system. The file naming conventions must be that of the host operating system.

dwOptions

An unsigned integer that specifies one or more options. This parameter may be any one of the following values:

Constant	Description
FTP_TRANSFER_DEFAULT	This option specifies the default transfer mode should be used. If the local file exists, it will be overwritten with the contents of the downloaded file.
FTP_TRANSFER_APPEND	This option specifies that if the local file exists, the contents of file on the server is appended to the local file. If the local file does not exist, it is created.

dwOffset

A byte offset which specifies where the file transfer should begin. The default value of zero specifies that the file transfer should start at the beginning of the file. A value greater than zero is typically used to restart a transfer that has not completed successfully. Note that specifying a non-zero offset requires that the server support the REST command to restart transfers.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **FtpEventProc** callback function. This parameter may be NULL if you do not wish to implement an event handler.

dwParam

A user-defined integer value that is passed to the callback function. This parameter is ignored if the *lpEventProc* parameter is NULL.

Return Value

If the function succeeds, the return value is non-zero integer value that specifies a unique asynchronous task identifier. If the function fails, the return value is zero. To get extended error information, call the **FtpGetLastError** function. The application should treat the task ID as an opaque value and never make an assumption about the sequence in which IDs are assigned to a background task.

Remarks

The **FtpAsyncGetFile** function is used to download the contents of a remote file to a file on the local system. This function is similar to the **FtpGetFile** function, however it retrieves the file using a background worker thread and does not block the current working thread. This enables the application to continue to perform other operations while the file is being transferred to the local system.

If the address of an event handler is provided to this function, it is guaranteed that the handler will be invoked with the `FTP_EVENT_CONNECT` event after the connection has been established, and the `FTP_EVENT_DISCONNECT` event after the transfer has completed. This enables your application to know when the file transfer is about to begin, and immediately before the worker thread is terminated. During the file transfer, the callback function will be invoked periodically with the `FTP_EVENT_PROGRESS` event. The client session handle is passed to the event handler, allowing you to call functions such as **FtpGetTransferStatus** to determine the amount of data that has been copied.

To determine when the transfer has completed without implementing an event handler, periodically call the **FtpTaskDone** function. If you wish to block the current thread and wait for the transfer to complete, call the **FtpTaskWait** function. To stop a background file transfer that is in progress, call the **FtpTaskAbort** function. This will signal the background worker thread to cancel the transfer and terminate the session.

This function can be called multiple times to download multiple files in the background; however, most servers limit the number of simultaneous connections that can originate from a single IP address. It is recommended that you only perform two simultaneous background transfers from the same server at any one time. The application should not make any assumptions about the order in which multiple background transfers may complete or how they are sequenced. For example, it should never be assumed that a background task with a lower task ID will complete before a task with a higher ID value.

Example

```
UINT nTaskId;

// Begin a file transfer in the background

nTaskId = FtpAsyncGetFile(hClient,
                        lpszLocalFile,
                        lpszRemoteFile,
                        FTP_TRANSFER_DEFAULT,
                        0,
                        NULL,
                        0);

if (nTaskId != 0)
{
    DWORD dwError = NO_ERROR;
    DWORD dwElapsed = 0;
```

```
// Wait for the transfer to complete
FtpTaskWait(nTaskId, INFINITE, &dwElapsed, &dwError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools10.h

Import Library: csftpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

FtpAsyncGetFileEx Function

```
UINT WINAPI FtpAsyncGetFileEx(  
    HCLIENT hClient,  
    LPCTSTR lpszLocalFile,  
    LPCTSTR lpszRemoteFile,  
    DWORD dwOptions,  
    ULARGE_INTEGER uiOffset,  
    FTPEVENTPROC lpEventProc,  
    DWORD_PTR dwParam  
);
```

Downloads the specified file from the server to the local system. This version of the function is designed to support files that are larger than 4GB.

Parameters

hClient

Handle to the client session.

lpszLocalFile

A pointer to a string that specifies the file on the local system that will be created, overwritten or appended to. The file pathing and name conventions must be that of the local host.

lpszRemoteFile

A pointer to a string that specifies the file on the server that will be transferred to the local system. The file naming conventions must be that of the host operating system.

dwOptions

An unsigned integer that specifies one or more options. This parameter may be any one of the following values:

Constant	Description
FTP_TRANSFER_DEFAULT	This option specifies the default transfer mode should be used. If the local file exists, it will be overwritten with the contents of the downloaded file.
FTP_TRANSFER_APPEND	This option specifies that if the local file exists, the contents of file on the server is appended to the local file. If the local file does not exist, it is created.

uiOffset

A byte offset which specifies where the file transfer should begin. The default value of zero specifies that the file transfer should start at the beginning of the file. A value greater than zero is typically used to restart a transfer that has not completed successfully. Note that specifying a non-zero offset requires that the server support the REST command to restart transfers.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **FtpEventProc** callback function. This parameter may be NULL if you do not wish to implement an event handler.

dwParam

A user-defined integer value that is passed to the callback function. This parameter is ignored if the *lpEventProc* parameter is NULL.

Return Value

If the function succeeds, the return value is non-zero integer value that specifies a unique asynchronous task identifier. If the function fails, the return value is zero. To get extended error information, call the **FtpGetLastError** function. The application should treat the task ID as an opaque value and never make an assumption about the sequence in which IDs are assigned to a background task.

Remarks

The **FtpAsyncGetFileEx** function is used to download the contents of a remote file to a file on the local system. This function is similar to the **FtpGetFileEx** function, however it retrieves the file using a background worker thread and does not block the current working thread. This enables the application to continue to perform other operations while the file is being transferred to the local system.

If the address of an event handler is provided to this function, it is guaranteed that the handler will be invoked with the `FTP_EVENT_CONNECT` event after the connection has been established, and the `FTP_EVENT_DISCONNECT` event after the transfer has completed. This enables your application to know when the file transfer is about to begin, and immediately before the worker thread is terminated. During the file transfer, the callback function will be invoked periodically with the `FTP_EVENT_PROGRESS` event. The client session handle is passed to the event handler, allowing you to call functions such as **FtpGetTransferStatusEx** to determine the amount of data that has been copied.

To determine when the transfer has completed without implementing an event handler, periodically call the **FtpTaskDone** function. If you wish to block the current thread and wait for the transfer to complete, call the **FtpTaskWait** function. To stop a background file transfer that is in progress, call the **FtpTaskAbort** function. This will signal the background worker thread to cancel the transfer and terminate the session.

This function can be called multiple times to download multiple files in the background; however, most servers limit the number of simultaneous connections that can originate from a single IP address. It is recommended that you only perform two simultaneous background transfers from the same server at any one time. The application should not make any assumptions about the order in which multiple background transfers may complete or how they are sequenced. For example, it should never be assumed that a background task with a lower task ID will complete before a task with a higher ID value.

FtpAsyncProxyConnect Function

```
HCLIENT WINAPI FtpAsyncProxyConnect(  
    UINT nProxyType,  
    LPCTSTR LpszProxyHost,  
    UINT nProxyPort,  
    LPCTSTR LpszProxyUser,  
    LPCTSTR LpszProxyPassword,  
    LPCTSTR LpszRemoteHost,  
    UINT nRemotePort,  
    UINT nTimeout,  
    DWORD dwOptions,  
    LPSECURITYCREDENTIALS lpCredentials,  
    HWND hEventWnd,  
    UINT uEventMsg  
);
```

The **FtpAsyncProxyConnect** function establishes a connection with the specified server.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

The application should create a background worker thread and establish a connection by calling **FtpProxyConnect** within that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each client session.

Parameters

nProxyType

An identifier which specifies the type of proxy server that is being connected to. This value must be defined as one of the following values:

Constant	Description
FTP_PROXY_NONE	This value specifies that no proxy server is being used. In this case, the FtpConnect function is called directly, ignoring the proxy parameters.
FTP_PROXY_USER	This value specifies that the client is not logged into the proxy server. The USER command is sent in the format username@ftpsite followed by the password. This is the format used with the Gauntlet proxy server.
FTP_PROXY_LOGIN	This value specifies that the client is logged into the proxy server. The USER command is then sent in the format username@ftpsite followed by the password. This is the format used by the InterLock proxy server.
FTP_PROXY_OPEN	This value specifies that the client is not logged into the proxy server. The OPEN command is sent specifying the host name, followed by the username and password.
FTP_PROXY_SITE	This value specifies that the client is logged into the server. The SITE command is sent, specifying the host name, followed by the

	username and the password.
FTP_PROXY_OTHER	This special proxy type specifies that another, undefined proxy server is being used. The client connects to the proxy host, but does not attempt to authenticate the client. The application is responsible for negotiating with the proxy server, typically using the FtpCommand function to send specific command sequences.

lpszProxyHost

A pointer to the name of the proxy server to connect through; this may be a fully-qualified domain name or an IP address.

lpszProxyPort

The port number the proxy server is listening on; a value of zero specifies that the default port number should be used.

lpszProxyUser

A pointer to the user name used to authenticate the client on the proxy server. Not all proxy servers require this information; it is recommended that you consult the proxy server documentation to determine if a username is required.

lpszProxyPassword

A pointer to the password used to authenticate the client on the proxy server. Not all proxy servers require this information; it is recommended that you consult the proxy server documentation to determine if a password is required.

lpszRemoteHost

A pointer to the name of the server to connect to; this may be a fully-qualified domain name or an IP address.

nRemotePort

The port number the server is listening on; a value of zero specifies that the default port number should be used. For standard connections, the default port number is 21. For secure connections, the default port number is 990. If the secure port number is specified, an implicit SSL/TLS connection will be established by default.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
FTP_OPTION_PASSIVE	This option specifies the client should attempt to establish the data connection with the server. When the client uploads or downloads a file, normally the server establishes a second connection back to the client which is used to transfer the file data. However, if the local system is behind a firewall or a NAT router, the server may not be able to create the data connection and the transfer will fail. By specifying this option, it forces the client to establish

	<p>an outbound data connection with the server. It is recommended that applications use passive mode whenever possible.</p>
FTP_OPTION_FIREWALL	<p>This option specifies the client should always use the host IP address to establish the data connection with the server, not the address returned by the server in response to the PASV command. This option may be necessary if the server is behind a router that performs Network Address Translation (NAT) and it returns an unreachable IP address for the data connection. If this option is specified, it will also enable passive mode data transfers.</p>
FTP_OPTION_NOAUTH	<p>This option specifies the server does not require authentication, or that it requires an alternate authentication method. When this option is used, the client connection is flagged as authenticated as soon as the connection to the server has been established. Note that using this option to bypass authentication may result in subsequent errors when attempting to retrieve a directory listing or transfer a file. It is recommended that you consult the technical reference documentation for the server to determine its specific authentication requirements.</p>
FTP_OPTION_KEEPAIVE	<p>This option specifies the client should attempt to keep the connection with the server active for an extended period of time. It is important to note that regardless of this option, the server may still choose to disconnect client sessions that are holding the command channel open but are not performing file transfers.</p>
FTP_OPTION_VIRTUALHOST	<p>This option specifies the server supports virtual hosting, where multiple domains are hosted by a server using the same external IP address. If this option is enabled, the client will send the HOST command to the server upon establishing a connection.</p>
FTP_OPTION_VERIFY	<p>This option specifies that file transfers should be automatically verified after the transfer has completed. If the server supports the XMD5 command, the transfer will be verified by calculating an MD5 hash of the file contents. If the server does not support the XMD5 command, but does support the XCRC command, the transfer will be verified by calculating a CRC32 checksum of the file contents. If neither the XMD5 or XCRC commands are supported, the transfer is verified by comparing the size of the file. Automatic file verification is only</p>

	performed for binary mode transfers because of the end-of-line conversion that may occur when text files are uploaded or downloaded.
FTP_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using either the SSL or TLS protocols.
FTP_OPTION_SECURE	This option specifies the client should attempt to establish a secure connection with the server. This option is the same as specifying FTP_OPTION_SECURE_IMPLICIT which immediately performs the SSL/TLS protocol negotiation when the connection is established.
FTP_OPTION_SECURE_IMPLICIT	This option specifies the client should attempt to immediately establish secure SSL/TLS connection with the server. This option is typically used when connecting to a server on port 990, which is the default port number used for FTPS.
FTP_OPTION_SECURE_EXPLICIT	This option specifies the client should establish a standard connection to the server and then use the AUTH command to negotiate an explicit secure connection. This option is typically used when connecting to the server on ports other than 990.
FTP_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
FTP_OPTION_TUNNEL	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established. This option also forces all connections to be outbound and enables the firewall compatibility features in the client.
FTP_OPTION_KEEPALIVE_DATA	This option specifies the client should attempt to keep the control connection active during a file transfer. Normally, when a data transfer is in progress, no additional commands are issued on the control channel until the transfer completes. Specifying this option automatically enables the FTP_OPTION_KEEPALIVE option and forces the client to continue to issue NOOP commands during the file transfer. This option only applies to FTP and FTPS connections and has no effect on connections

	using SFTP (SSH).
FTP_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
FTP_OPTION_FREETHREAD	This option specifies the handle returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the handle is synchronized across multiple threads.
FTP_OPTION_HIRES_TIMER	This option specifies the elapsed time for data transfers should be returned in milliseconds instead of seconds. This will return more accurate transfer times for smaller files being uploaded or downloaded using fast network connections.
FTP_OPTION_TLS_REUSE	This option specifies that TLS session reuse should be enabled for secure connections. This option is only supported on Windows 8.1 or Windows Server 2012 R2 and later platforms, and it should only be used when explicitly required by the server. This option is not compatible with servers built using OpenSSL 1.0.2 and earlier versions which do not provide Extended Master Secret (EMS) support as outlined in RFC7627.

lpCredentials

A pointer to a [SECURITYCREDENTIALS](#) structure. This parameter should be NULL if the connection is not secure or when client credentials are not required. Most servers do not require a client certificate to establish a secure connection. However, if the server does require a client certificate, the structure members *dwSize*, *lpzCertStore* and *lpzCertName* must be defined. Undefined structure members must be initialized to a value of zero or NULL and the *dwSize* member must be initialized to the size of the **SECURITYCREDENTIALS** structure.

hEventWnd

The handle to the event notification window. This window receives messages which notify the client of various asynchronous network events that occur.

uEventMsg

The message identifier that is used when an asynchronous network event occurs. This value should be greater than WM_USER as defined in the Windows header files.

Return Value

If the function succeeds, the return value is a handle to a client session. If the function fails, the return value is INVALID_CLIENT. To get extended error information, call **FtpGetLastError**.

Remarks

The username and password that is used to authenticate the client with the proxy server are not the same as those used to login to the target server. Once a connection has been established with the proxy server, the client must call the **FtpLogin** function to actually login to the server and begin a file transfer.

When a message is posted to the notification window, the low word of the *lParam* parameter contains the event identifier. The high word of *lParam* contains the low word of the error code, if an error has occurred. The *wParam* parameter contains the client handle. One or more of the following event identifiers may be sent:

Constant	Description
FTP_EVENT_CONNECT	The control connection to the server has completed. The high word of the <i>lParam</i> parameter should be checked, since this notification message will be posted if an error has occurred.
FTP_EVENT_DISCONNECT	The server has closed the control connection to the client. The client should read any remaining data and disconnect.
FTP_EVENT_OPENFILE	The data connection to the server has completed. The high word of the <i>lParam</i> parameter should be checked, since this notification message will be posted if an error has occurred.
FTP_EVENT_CLOSEFILE	The server has closed the data connection to the client. The client should read any remaining data and close the data channel.
FTP_EVENT_READFILE	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
FTP_EVENT_WRITEFILE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
FTP_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
FTP_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.
FTP_EVENT_COMMAND	A command has been issued by the client and the server response has been received and processed. This event can be used to log the result codes and messages returned by the server in response to actions taken by the client.
FTP_EVENT_PROGRESS	The client is in the process of sending or receiving a file on the data channel. This event is called periodically during a transfer so that the client can update any user interface components such as a

	status control or progress bar.
FTP_EVENT_GETFILE	This event is generated when a file download has completed. If multiple files are being downloaded, this event will be generated for each file.
FTP_EVENT_PUTFILE	This event is generated when a file upload has completed. If multiple files are being uploaded, this event will be generated for each file.

To cancel asynchronous notification and return the client to a blocking mode, use the **FtpDisableEvents** function.

If the FTP_OPTION_KEEPALIVE option is specified, a background worker thread will be created to monitor the command channel and periodically send NOOP commands to the server if no commands have been sent recently. This can prevent the server from terminating the client connection during idle periods where no commands are being issued. However, it is important to keep in mind that many servers can be configured to also limit the total amount of time a client can be connected to the server, as well as the amount of time permitted between file transfers. If the server does not respond to the NOOP command, this option will be automatically disabled for the remainder of the client session.

If the FTP_OPTION_SECURE_EXPLICIT option is specified, the client will establish a standard connection to the server and send the AUTH TLS command to the server. If the server does not accept this command, it will then send the AUTH SSL command. If both commands are rejected by the server, an explicit SSL session cannot be established. By default, both the command and data channels will be encrypted when a secure connection is established. To change this, use the **FtpSetChannelMode** function.

The *dwOptions* argument can be used to specify the threading model that is used by the library when a connection is established. By default, the handle is initially attached to the thread that created it. From that point on, until the it is released, only the owner may call functions using that handle. The ownership of the handle may be transferred from one thread to another using the **FtpAttachThread** function.

Specifying the FTP_OPTION_FREETHREAD option enables any thread to call any function using the handle, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the handle is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same handle.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstoools10.h

Import Library: csftpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

FtpAsyncPutData Function

```
UINT WINAPI FtpAsyncPutData(  
    HCLIENT hClient,  
    LPCTSTR lpszFileName,  
    LPVOID lpvBuffer,  
    DWORD dwLength,  
    DWORD dwReserved,  
    FTPEVENTPROC lpEventProc,  
    DWORD_PTR dwParam  
);
```

Copies the contents of the specified buffer to a file on the server.

Parameters

hClient

Handle to the client session.

lpszFileName

A pointer to a string that specifies the file on the server that will be created, overwritten or appended to. The file naming conventions must be that of the host operating system.

lpvBuffer

A pointer to the data that will be copied to the server and stored in the specified file.

dwLength

The number of bytes to copy from the buffer.

dwReserved

A reserved parameter. This value should always be zero.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **FtpEventProc** callback function. This parameter may be NULL if you do not wish to implement an event handler.

dwParam

A user-defined integer value that is passed to the callback function. This parameter is ignored if the *lpEventProc* parameter is NULL.

Return Value

If the function succeeds, the return value is non-zero integer value that specifies a unique asynchronous task identifier. If the function fails, the return value is zero. To get extended error information, call the **FtpGetLastError** function. The application should treat the task ID as an opaque value and never make an assumption about the sequence in which IDs are assigned to a background task.

Remarks

The **FtpAsyncPutData** function is used to upload the contents of a local buffer to the server. This function is similar to the **FtpPutData** function, however it uses a background worker thread and does not block the current working thread. This enables the application to continue to perform other operations while the data is being sent to the server.

Because this function works asynchronously, it is important that the memory allocated for the buffer is not released before the asynchronous task completes. If you provide a buffer that is

allocated on the stack, ensure that your code does not return from the function while the data is being uploaded. This can be achieved by calling the **FtpTaskWait** function or periodically calling the **FtpTaskDone** function to determine if the transfer has completed. If you wish to return from the calling function immediately, then you must dynamically allocate memory for the *lpvBuffer* parameter on the heap and free that memory after the task has completed and the data is no longer needed.

If the address of an event handler is provided to this function, it is guaranteed that the handler will be invoked with the FTP_EVENT_CONNECT event after the connection has been established, and the FTP_EVENT_DISCONNECT event after the transfer has completed. This enables your application to know when the data transfer is about to begin, and immediately before the worker thread is terminated. The worker thread creates a secondary connection to the server with its own session handle. This ensures that the asynchronous operation will not interfere with the current client session. Your application can interact with this background worker thread using the client handle that is passed to the event handler.

If the *lpvBuffer* parameter is pointing to a Unicode string, it is important to note that the value of the *dwLength* parameter should specify the number of bytes, not the number of characters. When using UTF-16, each character is two bytes long and therefore the length of the buffer is effectively double the length of the string. Because Unicode strings can contain null characters, you must also set the current file type to FILE_TYPE_IMAGE prior to calling this function.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csftpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

[FtpAsyncGetData](#), [FtpAsyncGetFile](#), [FtpAsyncPutFile](#), [FtpEventProc](#), [FtpPutData](#), [FtpTaskWait](#)

FtpAsyncPutFile Function

```
UINT WINAPI FtpAsyncPutFile(  
    HCLIENT hClient,  
    LPCTSTR lpszLocalFile,  
    LPCTSTR lpszRemoteFile,  
    DWORD dwOptions,  
    DWORD dwOffset,  
    FTPEVENTPROC lpEventProc,  
    DWORD_PTR dwParam  
);
```

Uploads the specified file from the local system to the server.

Parameters

hClient

Handle to the client session.

lpszLocalFile

A pointer to a string that specifies the file that will be transferred from the local system. The file pathing and name conventions must be that of the local host.

lpszRemoteFile

A pointer to a string that specifies the file on the server that will be created, overwritten or appended to. The file naming conventions must be that of the host operating system.

dwOptions

An unsigned integer that specifies one or more options. This parameter may be any one of the following values:

Constant	Description
FTP_TRANSFER_DEFAULT	This option specifies the default transfer mode should be used. If the remote file exists, it will be overwritten with the contents of the uploaded file.
FTP_TRANSFER_APPEND	This option specifies that if the remote file exists, the contents of the local file is appended to the remote file. If the remote file does not exist, it is created.

dwOffset

A byte offset which specifies where the file transfer should begin. The default value of zero specifies that the file transfer should start at the beginning of the file. A value greater than zero is typically used to restart a transfer that has not completed successfully. Note that specifying a non-zero offset requires that the server support the REST command to restart transfers.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **FtpEventProc** callback function. This parameter may be NULL if you do not wish to implement an event handler.

dwParam

A user-defined integer value that is passed to the callback function. This parameter is ignored if the *lpEventProc* parameter is NULL.

Return Value

If the function succeeds, the return value is non-zero integer value that specifies a unique asynchronous task identifier. If the function fails, the return value is zero. To get extended error information, call the **FtpGetLastError** function. The application should treat the task ID as an opaque value and never make an assumption about the sequence in which IDs are assigned to a background task.

Remarks

The **FtpAsyncPutFile** function is used to upload the contents of a local file to the server. This function is similar to the **FtpPutFile** function, however it uploads the file using a background worker thread and does not block the current working thread. This enables the application to continue to perform other operations while the file is being transferred to the server.

If the address of an event handler is provided to this function, it is guaranteed that the handler will be invoked with the `FTP_EVENT_CONNECT` event after the connection has been established, and the `FTP_EVENT_DISCONNECT` event after the transfer has completed. This enables your application to know when the file transfer is about to begin, and immediately before the worker thread is terminated. During the file transfer, the callback function will be invoked periodically with the `FTP_EVENT_PROGRESS` event. The client session handle is passed to the event handler, allowing you to call functions such as **FtpGetTransferStatus** to determine the amount of data that has been copied.

To determine when the transfer has completed without implementing an event handler, periodically call the **FtpTaskDone** function. If you wish to block the current thread and wait for the transfer to complete, call the **FtpTaskWait** function. To stop a background file transfer that is in progress, call the **FtpTaskAbort** function. This will signal the background worker thread to cancel the transfer and terminate the session.

This function can be called multiple times to upload multiple files in the background; however, most servers limit the number of simultaneous connections that can originate from a single IP address. It is recommended that you only perform two simultaneous background transfers from the same server at any one time. The application should not make any assumptions about the order in which multiple background transfers may complete or how they are sequenced. For example, it should never be assumed that a background task with a lower task ID will complete before a task with a higher ID value.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csftpv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

FtpAsyncPutFileEx Function

```
UINT WINAPI FtpAsyncPutFileEx(  
    HCLIENT hClient,  
    LPCTSTR lpszLocalFile,  
    LPCTSTR lpszRemoteFile,  
    DWORD dwOptions,  
    ULARGE_INTEGER uiOffset,  
    FTPEVENTPROC lpEventProc,  
    DWORD_PTR dwParam  
);
```

Uploads the specified file from the local system to the server. This version of the function is designed to support files that are larger than 4GB.

Parameters

hClient

Handle to the client session.

lpszLocalFile

A pointer to a string that specifies the file that will be transferred from the local system. The file pathing and name conventions must be that of the local host.

lpszRemoteFile

A pointer to a string that specifies the file on the server that will be created, overwritten or appended to. The file naming conventions must be that of the host operating system.

dwOptions

An unsigned integer that specifies one or more options. This parameter may be any one of the following values:

Constant	Description
FTP_TRANSFER_DEFAULT	This option specifies the default transfer mode should be used. If the remote file exists, it will be overwritten with the contents of the uploaded file.
FTP_TRANSFER_APPEND	This option specifies that if the remote file exists, the contents of the local file is appended to the remote file. If the remote file does not exist, it is created.

uiOffset

A byte offset which specifies where the file transfer should begin. The default value of zero specifies that the file transfer should start at the beginning of the file. A value greater than zero is typically used to restart a transfer that has not completed successfully. Note that specifying a non-zero offset requires that the server support the REST command to restart transfers.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **FtpEventProc** callback function. This parameter may be NULL if you do not wish to implement an event handler.

dwParam

A user-defined integer value that is passed to the callback function. This parameter is ignored if the *lpEventProc* parameter is NULL.

Return Value

If the function succeeds, the return value is non-zero integer value that specifies a unique asynchronous task identifier. If the function fails, the return value is zero. To get extended error information, call the **FtpGetLastError** function. The application should treat the task ID as an opaque value and never make an assumption about the sequence in which IDs are assigned to a background task.

Remarks

The **FtpAsyncPutFileEx** function is used to upload the contents of a local file to the server. This function is similar to the **FtpPutFileEx** function, however it uploads the file using a background worker thread and does not block the current working thread. This enables the application to continue to perform other operations while the file is being transferred to the server.

If the address of an event handler is provided to this function, it is guaranteed that the handler will be invoked with the `FTP_EVENT_CONNECT` event after the connection has been established, and the `FTP_EVENT_DISCONNECT` event after the transfer has completed. This enables your application to know when the file transfer is about to begin, and immediately before the worker thread is terminated. During the file transfer, the callback function will be invoked periodically with the `FTP_EVENT_PROGRESS` event. The client session handle is passed to the event handler, allowing you to call functions such as **FtpGetTransferStatusEx** to determine the amount of data that has been copied.

To determine when the transfer has completed without implementing an event handler, periodically call the **FtpTaskDone** function. If you wish to block the current thread and wait for the transfer to complete, call the **FtpTaskWait** function. To stop a background file transfer that is in progress, call the **FtpTaskAbort** function. This will signal the background worker thread to cancel the transfer and terminate the session.

This function can be called multiple times to upload multiple files in the background; however, most servers limit the number of simultaneous connections that can originate from a single IP address. It is recommended that you only perform two simultaneous background transfers from the same server at any one time. The application should not make any assumptions about the order in which multiple background transfers may complete or how they are sequenced. For example, it should never be assumed that a background task with a lower task ID will complete before a task with a higher ID value.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

FtpAttachThread Function

```
DWORD WINAPI FtpAttachThread(  
    HCLIENT hClient  
    DWORD dwThreadId  
);
```

The **FtpAttachThread** function attaches the specified client handle to another thread.

Parameters

hClient

Handle to the client session.

dwThreadId

The ID of the thread that will become the new owner of the handle. A value of zero specifies that the current thread should become the owner of the client handle.

Return Value

If the function succeeds, the return value is the thread ID of the previous owner. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

When a client handle is created, it is associated with the current thread that created it. Normally, if another thread attempts to perform an operation using that handle, an error is returned since it does not own the handle. This is used to ensure that other threads cannot interfere with an operation being performed by the owner thread. In some cases, it may be desirable for one thread in a client application to create the client handle, and then pass that handle to another worker thread. The **FtpAttachThread** function can be used to change the ownership of the handle to the new worker thread. By preserving the return value from the function, the original owner of the handle can be restored before the worker thread terminates.

This function should be called by the new thread immediately after it has been created, and if the new thread does not release the handle itself, the ownership of the handle should be restored to the parent thread before it terminates. Under no circumstances should **FtpAttachThread** be used to forcibly release a handle allocated by another thread while a blocking operation is in progress. To cancel an operation, use the **FtpCancel** function and then release the handle after the blocking function exits and control is returned to the current thread.

Note that the *dwThreadId* parameter is presumed to be a valid thread ID and no checks are performed to ensure that the thread actually exists. Specifying an invalid thread ID will orphan the handle until the **FtpUninitialize** function is called.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftpv10.lib

See Also

[FtpCancel](#), [FtpAsyncConnect](#), [FtpConnect](#), [FtpDisconnect](#), [FtpUninitialize](#)

FtpCancel Function

```
INT WINAPI FtpCancel(  
    HCLIENT hClient  
);
```

The **FtpCancel** function cancels any outstanding blocking operation in the client, causing the blocking function to fail. The application may then retry the operation or terminate the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

When the **FtpCancel** function is called, the blocking function will not immediately fail. An internal flag is set which causes the blocking operation to exit with an error. This means that the application cannot cancel an operation and immediately perform some other operation. Instead it must allow the calling stack to unwind, returning back to the blocking operation before making any further function calls.

This function may be called during a blocking file transfer.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[FtpIsBlocking](#)

FtpChangeDirectory Function

```
INT WINAPI FtpChangeDirectory(  
    HCLIENT hClient,  
    LPCTSTR lpszDirectory  
);
```

The **FtpChangeDirectory** function changes the current working directory for the client session.

Parameters

hClient

Handle to the client session.

lpszDirectory

Points to a string that specifies the name of the directory. The file pathing and name conventions must be that of the server.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

This function uses the CWD command to change the current working directory. The user must have the appropriate permission to access the specified directory.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

FtpChangeDirectoryUp Function

```
INT WINAPI FtpChangeDirectoryUp(  
    HCLIENT hClient  
);
```

The **FtpChangeDirectoryUp** function changes directory to the parent of the current working directory.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

This function sends the CDUP command to the server. This command is a special case of the CWD command, and is included to simplify transferring between directory trees on those operating systems which have different syntaxes for naming the parent directory. The current user must have the appropriate permission to access the specified directory.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftpv10.lib

Unicode: Implemented as Unicode and ANSI versions.

See Also

[FtpChangeDirectory](#), [FtpCommand](#), [FtpGetDirectory](#), [FtpGetResultCode](#), [FtpGetResultString](#)

FtpCloseDirectory Function

```
INT WINAPI FtpCloseDirectory(  
    HCLIENT hClient  
);
```

The **FtpCloseDirectory** function closes the data socket connection to the server.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

This function must be called after all of the file information from the server has been returned. Because directory information is returned on the data channel, no file transfers can take place while a directory is being read.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstools10.h

Import Library: csftpv10.lib

See Also

[FtpGetDirectoryFormat](#), [FtpGetFileStatus](#), [FtpGetFirstFile](#), [FtpGetNextFile](#), [FtpOpenDirectory](#), [FtpSetDirectoryFormat](#)

FtpCloseFile Function

```
INT WINAPI FtpCloseFile(  
    HCLIENT hClient  
);
```

The **FtpCloseFile** function flushes the internal client buffers and closes the data socket connection to the server.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

If the file is opened for writing, all buffered data is written to the server before the socket is closed. This may cause the client to block until all of the data can be written. The client application should not perform any other action until the function returns.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: cstdlib10.h

Import Library: csftpv10.lib

See Also

[FtpOpenFile](#), [FtpRead](#), [FtpWrite](#)

FtpCommand Function

```
INT WINAPI FtpCommand(  
    HCLIENT hClient,  
    LPCTSTR LpszCommand,  
    LPCTSTR LpszParameter  
);
```

The **FtpCommand** function sends a command to the server and returns the result code back to the caller. This function is typically used for site-specific commands not directly supported by the API.

Parameters

hClient

Handle to the client session.

lpszCommand

The command which will be executed by the server.

lpszParameter

An optional command parameter. If the command requires more than one parameter, then they should be combined into a single string, with a space separating each parameter. If the command does not accept any parameters, this value may be NULL.

Return Value

If the function succeeds, the return value is the result code returned by the server. If the function fails, the return value is `FTP_ERROR`. To get extended error information, call **FtpGetLastError**.

Remarks

This function should only be used when the application needs to send a custom, site-specific command or send a command that is not directly supported by this API. This function should never be used to issue a command that opens a data channel. If the application needs to transform data as it is being sent or received, and cannot use the **FtpGetFile** or **FtpPutFile** functions, then use the **FtpOpenFile** function to open a data channel with the server.

By default, file names which are sent to the server using the **FtpCommand** function are sent as ANSI characters. If the Unicode version of the function is used, the file name will be converted from Unicode to ANSI using the current codepage. If the server supports UTF-8 encoded file names, the **FtpSetFileNameEncoding** function can be used to specify that file names with non-ASCII characters should be sent as UTF-8 encoded values. It is important to note that this option is only available if the server advertises support for UTF-8 and permits that encoding type.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: `cstools10.h`

Import Library: `csftpv10.lib`

Unicode: Implemented as Unicode and ANSI versions.

FtpConnect Function

```
HCLIENT WINAPI FtpConnect(  
    LPCTSTR lpszRemoteHost,  
    UINT nRemotePort,  
    LPCTSTR lpszUserName,  
    LPCTSTR lpszPassword,  
    UINT nTimeout,  
    DWORD dwOptions,  
    LPSECURITYCREDENTIALS LpCredentials  
);
```

The **FtpConnect** function establishes a connection with the server and defines security related options to be used.

Parameters

lpszRemoteHost

A pointer to the name of the server to connect to; this may be a fully-qualified domain name or an IP address.

nRemotePort

The port number the server is listening on; a value of zero specifies that the default port number should be used. For standard connections, the default port number is 21. For secure connections, the default port number is 990.

lpszUserName

Points to a string that specifies the user name to be used to authenticate the current client session. If this parameter is NULL or an empty string, then the login is considered to be anonymous. Note that anonymous logins are not supported for secure connections using the SSH protocol.

lpszPassword

Points to a string that specifies the password to be used to authenticate the current client session. This parameter may be NULL or an empty string if no password is required for the specified user, or if no username has been specified.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Constant	Description
FTP_OPTION_PASSIVE	This option specifies the client should attempt to establish the data connection with the server. When the client uploads or downloads a file, normally the server establishes a second connection back to the client which is used to transfer the file data. However, if the local system is behind a firewall or a NAT router, the server may not be able to create the data connection and the transfer will fail. By

	<p>specifying this option, it forces the client to establish an outbound data connection with the server. It is recommended that applications use passive mode whenever possible.</p>
FTP_OPTION_FIREWALL	<p>This option specifies the client should always use the host IP address to establish the data connection with the server, not the address returned by the server in response to the PASV command. This option may be necessary if the server is behind a router that performs Network Address Translation (NAT) and it returns an unreachable IP address for the data connection. If this option is specified, it will also enable passive mode data transfers.</p>
FTP_OPTION_NOAUTH	<p>This option specifies the server does not require authentication, or that it requires an alternate authentication method. When this option is used, the client connection is flagged as authenticated as soon as the connection to the server has been established. Note that using this option to bypass authentication may result in subsequent errors when attempting to retrieve a directory listing or transfer a file. It is recommended that you consult the technical reference documentation for the server to determine its specific authentication requirements.</p>
FTP_OPTION_KEEPAIVE	<p>This option specifies the client should attempt to keep the connection with the server active for an extended period of time. It is important to note that regardless of this option, the server may still choose to disconnect client sessions that are holding the command channel open but are not performing file transfers.</p>
FTP_OPTION_NOAUTHRSA	<p>This option specifies that RSA authentication should not be used with SSH-1 connections. This option is ignored with SSH-2 connections and should only be specified if required by the server. This option has no effect on standard or secure connections using SSL.</p>
FTP_OPTION_NOPWDNUL	<p>This option specifies the user password cannot be terminated with a null character. This option is ignored with SSH-2 connections and should only be specified if required by the server. This option has no effect on standard or secure connections using SSL.</p>
FTP_OPTION_NOREKEY	<p>This option specifies the client should never attempt a repeat key exchange with the server. Some SSH servers do not support rekeying the session, and</p>

	<p>this can cause the client to become non-responsive or abort the connection after being connected for an hour. This option has no effect on standard or secure connections using SSL.</p>
FTP_OPTION_COMPATSID	<p>This compatibility option changes how the session ID is handled during public key authentication with older SSH servers. This option should only be specified when connecting to servers that use OpenSSH 2.2.0 or earlier versions. This option has no effect on standard or secure connections using SSL.</p>
FTP_OPTION_COMPATHMAC	<p>This compatibility option changes how the HMAC authentication codes are generated. This option should only be specified when connecting to servers that use OpenSSH 2.2.0 or earlier versions. This option has no effect on standard or secure connections using SSL.</p>
FTP_OPTION_VIRTUALHOST	<p>This option specifies the server supports virtual hosting, where multiple domains are hosted by a server using the same external IP address. If this option is enabled, the client will send the HOST command to the server upon establishing a connection.</p>
