SocketTools10

.NET Edition

Developer's Guide and Technical Reference

Version 10.0.1468.2518

Introduction

The SocketTools .NET Edition is a collection of managed code classes that simplify the task of developing TCP/IP networking applications in Visual Studio .NET using any of the available programming languages such as Visual Basic and C#. The .NET Edition is ideal for the developer who requires the flexibility, ease of use and rapid development features of a component without the complexities of working with the native socket class or in-depth knowledge of how the various Internet protocols are implemented. The SocketTools .NET Edition consists of fourteen core networking classes which can be used to develop applications that meet a wide range of needs. SocketTools covers it all, including uploading and downloading files, sending and retrieving email, remote command execution, terminal emulation, and much more.

The SocketTools .NET Edition includes support for the industry standard Transport Security Layer (TLS) and Secure Shell (SSH) protocols which are used to ensure that data exchanged between the local system and a server is secure and encrypted. The .NET Edition implements the major secure protocols such as HTTPS, FTPS, SFTP, SMTPS, POP3S, IMAPS and more. Your data is protected with TLS 1.2 using 256-bit encryption and full support for client certificates. SocketTools also includes an FTP and HTTP server component, as well as a general purpose TCP server component that can be used to create custom server applications. There's no need for you to understand the details of certificate management, data encryption or how the security protocols work. All it takes is a few lines of code to enable the security features, and SocketTools handles the rest.

For developers who have used the ActiveX version of SocketTools, you'll immediately find yourself in familiar territory. The SocketTools .NET class interface has properties, methods and events that are very similar to the control that you've used in languages like Visual Basic 6.0. It is important to keep in mind that SocketTools .NET is a managed code class, not a wrapper around the ActiveX control, so there will be some inherent differences. However, whenever possible the class interface was designed to make the transition from the ActiveX control as easy as possible.

The following are just some of the features in the SocketTools 10 .NET Edition:

- Support for Windows 10, Visual Studio 2019 and .NET 5.0
- Managed code class written in C# that can be used with any .NET language
- An interface that is very similar to the components in the SocketTools ActiveX Edition
- Support for both synchronous and asynchronous network connections
- Includes components that can be used to create custom client and server applications
- Provides cloud-based application storage and geographical IP location services
- Support for the standard TLS 1.2 protocol with 256-bit AES encryption
- Support for both implicit and explicit TLS connections
- Support for the SSH protocol and integrated support for SFTP as part of the FTP class
- Support for standard and secure proxy servers using FTP and HTTP
- Support for using client and server certificates in PKCS12 format
- Thread-safe implementation with full support for multithreaded applications
- An extensive Developer's Guide and online Technical Reference
- Easy redistribution for any number of applications and end users

Developer's Guide

To help you get started using SocketTools, the Developer's Guide covers a variety of programming topics related to SocketTools, as well an overview of each of the controls included in the product. Even if you have experience working with previous versions of SocketTools, we recommend that you review the Developer's Guide. If you are using a language other than Visual Basic, you'll also find some very helpful information about how to make the most of SocketTools in other programming languages such as Visual C#.NET and Visual C++.

Technical Reference

The Technical Reference provides extensive documentation on all of the functions in each of the SocketTools controls. It's here that you'll find information on the various properties, methods and events provided by the component. If it is your first time using a particular class, we recommend that you first read the overview of that class in the Developer's Guide.

Licensing Information

The SocketTools .NET Edition License Agreement provides you with a single developer license and the right to redistribute the class libraries (assemblies) included with this product without any additional royalties or runtime licensing fees.

Evaluation Licenses

When you install SocketTools, you are given the option of entering a serial number or proceeding with the installation without a serial number. If you install SocketTools without a serial number, an evaluation development license will be created which is valid for a period of thirty (30) days from the date of installation. The product is fully functional during this evaluation period; however the SocketTools components may not be redistributed to third-parties. After the evaluation period has ended, you must either purchase a development license or remove SocketTools from your computer system.

Runtime Licensing

When you install SocketTools with a serial number, a runtime license key will be automatically generated for you and stored in a file named SocketToolsLicense.cs in the Include folder where you've installed the product. There are similarly named files for other languages, such as SocketToolsLicense.vb. These files define the SocketTools runtime licensing key which must be passed to the Initialize method in the classes that you are using. More information about that utility is provided below.

The runtime license key is a null terminated string that is unique to your licensed copy of SocketTools. The runtime license key is not the same as your serial number and should only be embedded in your compiled application. If you provide source code for your product, you cannot include the runtime key with the source code. The same runtime license key should be used for all of the .NET assemblies.

If you install SocketTools with an evaluation license, then the runtime license key will be defined as an empty string. This will allow the assemblies to function on a system with a valid evaluation license, but they will not function on any other system. You must purchase a license and generate a runtime license key before redistributing an application which uses one or more of the SocketTools assemblies.

License Manager

Included with your copy of SocketTools is a License Manager utility. This program enables you to see what components have been installed and registered on your system, as well as display information about your SocketTools license. If you need to create a new runtime license key, you can use this utility to do so. Select **License** | **Header File** from the menu and choose the type of file that you wish to create. For more information about how the License Manager can be used, please refer to the online help file that is included with the utility.

Product Evaluation

If you install SocketTools without registering a serial number, the product will be installed with an evaluation license that is valid for a period of thirty (30) days. During this trial period, the SocketTools controls are fully functional and can be used on the development system where the product was installed. If you need to extend the evaluation period, please contact the Catalyst Development sales office by email at sales@sockettools.com or by telephone at 1-760-228-9653, Monday through Friday during normal business hours.

Redistribution Restrictions

When using an evaluation copy of SocketTools, you cannot redistribute the controls to another system. If you build an application using an evaluation license, it will function correctly on the development system but will fail with an error on any system that does not have a license. Once you have purchased a development license, you should recompile your application before redistributing it to an end-user. If you need to test your application on another system during the evaluation period, you must install an evaluation copy of SocketTools on that system.

Runtime Licensing

When you purchase a development license, a runtime license key will be generated for you which will be included in your applications. Normally this runtime key is managed automatically when the control is placed on a form or referenced in a project. However, there are situations in which the key must be explicitly passed to the control's Initialize method. In all cases, if the product is installed as an evaluation copy, the runtime license key will be defined as an empty string. If you have previously installed an evaluation copy of SocketTools and then purchased a license, you can create the runtime license key using the License Manager utility.

SocketTools Upgrade Information

This section will help you upgrade an application written using a previous version of the SocketTools .NET Edition. In most cases, the modifications required will be minimal and may only require updating your project references and recompiling the program. However, it is recommended that you review this entire guide so that you understand what changes were made and how those changes can be implemented in your software.

Supported Platforms

SocketTools 10 is supported on Windows 7, Windows Server 2008 R2 and later versions. Earlier versions of the operating system, including Windows 2000, Windows XP and Windows Vista are no longer supported by Microsoft and are not recommended for use with SocketTools.

Developers who are redistributing applications which target Windows 10 or Windows Server 2019 should upgrade to ensure compatibility with the platform and current development tools. Secure connections on Windows XP and Windows Vista has been deprecated because those platforms do not support TLS 1.2 and most services will no longer accept connections from a client using SSL 3.0 or TLS 1.0.

Development Tools

The SocketTools .NET components may be used with Visual Studio 2010 and later versions. If you are developing using Visual Studio 2010, use the .NET 4.0 assemblies. For Visual Studio 2012 and later versions, you can use the .NET 4.5 assemblies. If you are targeting a later version of the Framework, such as .NET 4.7.2 or .NET 4.8, you should reference the .NET 4.5 assemblies, which are compatible with those versions. The .NET 5.0 Framework is supported with Visual Studio 2019.

If you are developing on Windows 7 or Windows 8.1, it is recommended that you use Visual Studio 2010 or a later version. Earlier versions of Visual Studio may require that you use those development tools with elevated privileges.

If you are developing on Windows 10, it is recommended you use Visual Studio 2017 or later versions. SocketTools 10 includes assemblies which target the .NET 4.5 Framework as well as .NET 5.0.

Upgrading From SocketTools 9.5

If you are upgrading from version 9.5, applications will be source code compatible with the SocketTools 10 .NET classes. In most cases, all you will need to do is install the current version, update your project references and recompile your application. While the assembly modules retain the same name, the platform specific 32-bit and 64-bit interop libraries have changed to **SocketTools10.Interop.dll**. This allows applications created using SocketTools 10 to co-exist with applications created using earlier versions of SocketTools.

Your runtime license key has changed for SocketTools 10, which will require you to define the new key in your application when calling the class **Initialize** method. As with previous versions of SocketTools, you can use the License Manager utility to generate a file which contains the runtime key you should use. The SocketTools 9 and earlier runtime license keys are not valid for the version 10 classes and an error will be returned if an invalid runtime key is specified.

With SocketTools 10, secure connections will use TLS 1.2. By default, the .NET components will not support connections to servers which use older, less secure versions of TLS or any version of SSL. They will also no longer use weaker cipher suites that incorporate insecure algorithms, such as RC4 or MD5. For applications that require secure connections, it is recommended you use the current build of Windows 10 or Windows Server with all security updates applied.

It is possible to force the class to use earlier versions of TLS for backwards compatibility with older servers. This is done by explicitly setting the **SecureProtocol** property to specify the protocol version required.

However, this is not generally recommended because using an older version of TLS (or any version of SSL) may cause servers to immediately reject the connection attempt.

Upgrading From SocketTools 8.0

If you are upgrading from SocketTools 8.0 and earlier versions, most applications will be source code compatible and not require significant changes to existing code. However, it should be noted that the path to the common assembly folder has changed and earlier versions of SocketTools did not provide assemblies which targeted the .NET 4.5 or later framework versions. The SocketTools 10 assemblies are now installed in the folder **C:\Program Files (x86)\Common Files\SocketTools\10.0\Assemblies** for each version of the .NET Framework which is supported.

The runtime license key has changed for SocketTools 10, which will require you to define the new key in your application when calling the class **Initialize** method. As with previous versions of SocketTools, you can use the License Manager utility to generate a file which contains the runtime key you should use. The earlier runtime license keys are not valid for the version 10 classes and an error will be returned if an invalid runtime key is specified.

Interop Libraries

The platform specific interop libraries have been updated for SocketTools 10 and must be installed when deploying your application. For more information, refer to the Redistribution section.

File Name	Description
SocketTools10.Interop.dll	The SocketTools runtime library. This library is shared by all of the SocketTools and SocketTools class libraries. This library should not be referenced directly in the project, but must be included in the application installation package. It is recommended you install this file in the appropriate Windows system folder.
SocketTools10.TraceLog.dll	A debugging library used to generate log files which record the low-level networking functions called and the data exchanged. This library only needs to be distributed if the debugging features of the class are used. This library should not be referenced directly in the project, but should be included in the application installation package. It is recommended that you install this file in the appropriate Windows system folder.

Component Redistribution

The SocketTools license permits the use of the .NET assemblies to build application software and redistribute that software to end-users. There are no restrictions on the number of products in which the classes may be used. However, if it has been installed with an evaluation license, any products built using SocketTools cannot be redistributed to another system until a licensed copy of the toolkit has been purchased.

Supported Platforms

SocketTools .NET is supported on Windows 32-bit and 64-bit desktop and server platforms. The minimum required desktop platform is Windows 7 with Service Pack 1 (SP1) installed. The minimum required server platform is Windows Server 2008 R2 with Service Pack 1 (SP1) installed. It is recommended that the current service pack be installed for the operating system, along with the latest Windows updates available from Microsoft. Some features may require Windows 8.1 or later versions of the platform. When this is the case, it will be noted in the documentation.

Windows 2000, Windows XP and Windows Vista are no longer supported by Microsoft. SocketTools is designed for Windows 7 as the minimum operating system version and may not work correctly on earlier versions of Windows.

SocketTools .NET includes assemblies which target .NET Core 2.1 LTS (Long Term Support) and .NET Core 3.1. You can use these assemblies with .NET Core and .NET Standard projects, however it is important to note that SocketTools is only supported on Windows desktop and server platforms. It is not currently supported for other architectures. If your project is targeting .NET Core 2.1 LTS you will have access to all of the SocketTools assemblies except for the SocketTools.Terminal class which is a graphical control. The required support for graphical controls was added in .NET Core 3.0 and is supported with with the .NET Core 3.1 assemblies.

This version of SocketTools includes support for .NET 5.0, which is effectively a merge of .NET 4.8 and .NET Core 3.1 into a single framework. Microsoft released .NET 5.0 in November 2020 and is included with the latest release of Visual Studio 2019.

Supported Development Tools

SocketTools .NET includes assemblies that can be used with Visual Studio with support for .NET Framework version 2.0 through version 5.0. Other .NET development tools such as Embarcadero RAD Studio and SharpDevelop are also supported. It is recommended that you install all service packs and updates that are available. Development is only supported on Windows platforms and is not currently supported on the Mono implementation of the Common Language Runtime.

Component Files

For those applications created using SocketTools .NET, the appropriate class libraries (assemblies) must be distributed along with the application. The following component files can be included with your application:

Assembly File Name	Description
SocketTools.DnsClient.dll	The Domain Name Services component which provides domain name services for the application. This assembly is added as a reference in the project.
SocketTools.FileEncoder.dll	The File Encoding and Decoding component which provides functions to encode, compress and encrypt files. This assembly is added as a reference in the project.

SocketTools.FileTransfer.dll	The FileTransfer assembly which provides a common interface to the File Transfer Protocol and Hypertext Transfer Protocol. This assembly should be added as a reference in the project.
SocketTools.FtpClient.dll	The File Transfer Protocol client component which enables an application to upload and download files, as well as manage files on the server. This assembly is added as a reference in the project.
SocketTools.FtpServer.dll	The File Transfer Protocol server component which enables an application to accept connections from standard FTP clients which can transfer and manage files on the system. This assembly is added as a reference in the project.
SocketTools.HttpClient.dll	The Hypertext Transfer Protocol client component which enables an application to transfer files and query a web server. This assembly is added as a reference in the project.
SocketTools.HttpServer.dll	The Hypertext Transfer Protocol server component which enables an application to accept connections from HTTP clients, such as web browsers. This assembly is added as a reference in the project.
SocketTools.IcmpClient.dll	The Internet Control Message Protocol component which provides ping and traceroute functionality for an application. This assembly is added as a reference in the project.
SocketTools.ImapClient.dll	The Internet Message Access Protocol component which enables an application to retrieve mail messages from a server and manage one or more mailboxes remotely. This assembly is added as a reference in the project.
SocketTools.InternetDialer.dll	The Remote Access Services component which enables an application to establish a dial-up networking connection using PPP or SLIP. This assembly is added as a reference in the project.
SocketTools.InternetMail.dll	The InternetMail assembly which provides a client interface to the Post Office Protocol, Internet Message Access Protocol and Simple Mail Transfer Protocol. This assembly should be added as a reference in the project.
SocketTools.InternetServer.dll	The Internet Server component which provides the framework for implementing an event-driven multithreaded server application. This assembly is added as a reference in the project.
SocketTools.MailMessage.dll	The Mail Message component which enables an application to create, store and parse email messages. This assembly is added as a reference in the project.
SocketTools.NetworkTime.dll	The Network Time Services component which enables an application to query a time server to determine the current time. This assembly is added as a reference in the project.

SocketTools.NewsFeed.dll	The Syndicated News Feed component which enables an application to load and parse a news feed, either from the local system or a server. This assembly is added as a reference in the project.
SocketTools.NntpClient.dll	The Network News Transfer Protocol component which enables an application to download and process messages from a news server. This assembly is added as a reference in the project.
SocketTools.PopClient.dll	The Post Office Protocol component which enables an application to retrieve messages from a mail server. This assembly is added as a reference in the project.
SocketTools.RshClient.dll	The Remote Command Shell component which enables an application to execute commands on a server, returning the output of the command to the program. This assembly is added as a reference in the project.
SocketTools.SmtpClient.dll	The Simple Mail Transfer Protocol component which enables an application to submit an email message for delivery to a mail server. This assembly is added as a reference in the project.
SocketTools.SocketWrench.dll	The SocketWrench (Windows Sockets) component which provides a general purpose networking interface, allowing applications to connect to other systems and exchange data using the TCP/IP protocol. This assembly is added as a reference in the project.
SocketTools.SshClient.dll	The Secure Shell component which enables an application to establish a secure, encrypted connection with a server providing either an interactive terminal session or the ability to execute commands remotely. This assembly is added as a reference in the project.
SocketTools.TelnetClient.dll	The Telnet Protocol component which enables an application to connect to a server, providing an interactive terminal session. This assembly is added as a reference in the project.
SocketTools.Terminal.dll	The Terminal Emulation component which provides VT-100 and VT-220 terminal emulation services for an application, typically used for interactive sessions with a TELNET or SSH server. This control is added as a visual component to the application.
SocketTools.TextMessage.dll	The TextMessage component which enables an application to send SMS text messages through an SMTP gateway service. This assembly is added as a reference in the project.
SocketTools.WebLocation.dll	The WebLocation component provides information about the physical location of the current computer system based on its external IP address. This assembly is added as a reference in the project.

SocketTools.WebStorage.dll	The WebStorage component provides private cloud storage for uploading and downloading shared data files which are available to your application. This is primarily intended for use by developers to store configuration information and other data generated by the application. This assembly is added as a reference in the project.
SocketTools.WhoisClient.dll	The Whois Protocol component which enables an application to query a server for registration information about a specific domain name. This assembly is added as a reference in the project.
SocketTools10.Interop.dll	The SocketTools runtime library. This library is shared by all of the SocketTools and SocketTools class libraries. This library should not be referenced directly in the project, but must be included in the application installation package. It is recommended you install this file in the appropriate Windows system folder.
SocketTools10.TraceLog.dll	A debugging library used to generate log files which record the low-level networking functions called and the data exchanged. This library only needs to be distributed if the debugging features of the class are used. This library should not be referenced directly in the project, but should be included in the application installation package. It is recommended that you install this file in the appropriate Windows system folder.

Version Information

The SocketTools components have embedded information which provides version information to an installation utility. This information, called the version resource, specifies the assembly's version number among other things. If you are using a third-party or in-house installation program, it is extremely important that the program knows how to use this information. You should never overwrite a newer (higher) version of the SocketTools assembly with an older (lower) version or build number.

Installation Directory

It is recommended that you install the SocketTools assemblies in the same directory as the application executable on the target system. It is not recommended that you install the assemblies in the Global Assembly Cache (GAC) or in the Windows system folder. The assemblies are built to target both the x86 and x64 platforms and can be used on either type of system. The SocketTools10.Interop.dll runtime library is platform specific and it is recommended that you install it in the Windows system folder. This is a shared library that is used by all of the SocketTools assemblies and should not be referenced directly in your project.

If you are deploying your application to a system running the 32-bit version of Windows, you should install the 32-bit version of the SocketTools10.Interop.dll library in the \Windows\System32 folder. If you are deploying your application to a system running the 64-bit version of Windows, you should install the 32-bit version of the runtime library in the \Windows\Syswow64 folder, and the 64-bit version of the library in the \Windows\System32 folder. If you are using the **Trace** related properties in your application, you should also include SocketTools10.TraceLog.dll library in your installation package and install it in the same folder as the runtime library.

The installer should always perform version checking to ensure that it is not overwriting a newer version of the runtime library with an older version. If your installer package creates a 32-bit executable and you're deploying a 64-bit application, the installer must be capable of detecting that it is running on a 64-bit system and can disable filesystem redirection to ensure that the 64-bit libraries are installed in the correct location. Consult the documentation for your installer to determine if it is 64-bit compatible.

Windows Install Packages

To help simplify deployment, SocketTools includes MSI (Windows Installer) packages you can use to install the SocketTools .NET interop libraries on end-user systems. These packages are found in the **Redist** folder where you've installed SocketTools.

Package Name	Description
cstools10_interop_x86.msi	SocketTools 10 .NET redistributable libraries for 32-bit applications. This installer is what developers should use if they are targeting the x86 platform and want their software to run on both 32-bit and 64-bit versions of Windows.
cstools10_interop_x64.msi	SocketTools 10 .NET redistributable libraries for 64-bit applications. This installer should only be used if 64-bit development tools were used to build the application, and can only be installed on 64-bit versions of Windows.

If you're redistributing a 32-bit application, then all you need is the x86 installer package. If you're redistributing a 64-bit application, then you need the x64 installer package. If your application is built to target both platforms (Any CPU), then you will need both x86 and x64 packages. The installer packages will make sure the interop libraries are installed in the correct shared Windows folders and will perform the appropriate version checking.

If you have your own installer for your software, then you can redistribute those MSI packages with your installation and use the **msiexec** command to perform the installation. For example, this would install and register the 32-bit .NET interop libraries with no UI displayed:

```
msiexec /qn /I cstools10_interop_x86.msi
```

For the complete list of command line options for **msiexec**, refer to the Windows Dev Center documentation.

Strong Name Signing

The SocketTools assemblies are given what is known as a "strong name", which means they have been signed with a cryptographic public/private key pair which ensures that the assembly has not been tampered with. However, if you are redistributing an updated version of the assembly, it requires that you also recompile your application and include it in the distribution. Unlike standard Windows dynamic link libraries, you cannot simply redistribute the assembly by itself because a strong-name signed assembly requires that the signature of the assembly, which includes the version number, match exactly what the application was built with. This is a feature in .NET designed to ensure that the application is using the correct version of the assembly.

Technical Support

Catalyst Development is committed to providing quality technical support for our products and we offer several different support options designed to meet the needs of our customers. Technical support by email is available for installation, development and redistribution issues related to the purchased product. There are also paid support options available for customers who require additional assistance.

Standard Support

Registered developers have access to a variety of free technical support resources and we always encourage developers to review our online documentation and knowledge base to determine if the question has already been answered.

Frequently Asked Questions

A collection of answers to the most frequently asked questions about a product. General questions about features, functionality and platform compatibility are answered here. The product FAQ is also recommended reading for any developer who is evaluating our software.

Knowledge Base

A searchable online database of solutions to hundreds of common technical questions and problems. The articles provide detailed information, including background information, workarounds and the availability of updates to resolve the problem. This is the first place that most developers should check to determine if the question or problem that they're having has already been addressed.

Online Documentation

A comprehensive collection of online help, tutorials and whitepapers for our products. Our online help is useful to evaluators who are interested in learning about how our components work and for developers who would like access to the most current reference material.

Release Notes

Information about the latest changes, improvements and corrections made to the current version SocketTools. The release notes can reflect changes that affect all SocketTools editions, as well as updates to a component in a specific edition. If you are upgrading from a previous release, it's recommended that you review the release notes.

Priority Support

For developers who require additional support, Priority Support offers a guaranteed, priority response to technical support issues on the same business day. Corrections which require a source code change and/or documentation change to resolve a problem will be made available as a hotfix at no additional charge, and whenever there is a new product update or hotfix, you will be automatically notified by email.

Premium Support

For developers who have critical support needs, an annual Premium Support agreement offers both telephone and email support, and a guaranteed four hour response time during business hours. This support option also includes all of the benefits of priority support, including hotfixes, source code analysis and assistance with example code. In addition, Premium Support also includes free upgrades if a new version of the product is released while your support agreement is active, ensuring that you're always working with the latest version.

License Agreement

This License Agreement is a legal agreement between you, either as an individual or a single entity ("Developer"), and Catalyst Development Corporation ("Catalyst") for the software product identified as "SocketTools .NET Edition" ("Software" or "Software Product"). The Software Product includes executable programs, redistributable modules, controls, and dynamic link libraries ("Components" or "Software Components"), electronic documentation, and may include associated media and printed materials.

Installing this Software Product on to a hard disk or any other storage device of a computer, or loading any of the Components into the memory of any computer, constitutes use of the Software and shall acknowledge your acceptance of the terms and conditions of this License Agreement and your agreement to bound thereby.

1. GRANT OF LICENSE

Catalyst Development grants you as an individual, a personal, non-exclusive, non-transferable license to install the Software Product using an authorized serial number. If you are an entity, Catalyst grants you the right to appoint an individual within your organization to use and administer the Software Product subject to the same restrictions enforced on individual users. You may not network the Software or otherwise use it on more than one workstation or computer at the same time. Contact Catalyst for more information regarding multi-developer site licensing.

You may install the Software Product on one or more workstations or computers expressly for the purposes of evaluating the performance of the Software for a period of no more than thirty (30) days. If continued use of the Software is desired after the evaluation period has expired, then the Software Product must be purchased and/or registered with Catalyst Development for each computer or workstation. The Software Product must be removed from all unregistered workstations or computers after the evaluation period has expired.

2. COPYRIGHT

Except for the licenses granted by this agreement, all right, title, and interest in and to the Software Product (including, but not limited to, all copyrights in any executable programs, modules, controls, libraries, electronic documentation, text and example programs), any printed materials and copies of the Software Product are owned by Catalyst Development. The Software Product is protected by copyright laws and international treaty provisions. Therefore you must treat the Software Product like any other copyrighted material except that you may (i) make one copy of the Software solely for backup or archival purposes, or (ii) transfer the Software to a single hard disk, provided you keep the original solely for backup or archival purposes. You may not copy any printed materials that may accompany the Software Product. All rights not specifically granted in this Agreement, including Federal and International Copyrights, are reserved by Catalyst Development.

3. REDISTRIBUTION

(a) In addition to the rights granted in section 1, you are granted the right to use and modify those portions of the Software designated as "example code" for the sole purposes of designing, developing, and testing your software product, and to reproduce and distribute the example code, along with any modifications thereof, only in object code form, provided that you comply with section 3(c).

(b) In addition to the rights granted in section 1, you are granted a non-exclusive, royalty-free right to reproduce and distribute the object code version of any portion of the Software Product, along with any modifications thereof, in accordance with the above stated conditions.

(c) If you redistribute the sample code or redistributable components, you agree to: (i) distribute the redistributables in object code only, in conjunction with and as a part of a software application product developed by you which adds significant and primary functionality to the Software; (ii) not use Catalyst Development's name, logo, or trademarks to market your software application product; (iii) include a valid copyright notice on your software product ; (iv) indemnify, hold harmless, and defend Catalyst Development from and against any claims or lawsuits, including attorney's fees, that arise or result from the use or distribution of your software application product; (v) not permit further distribution of the redistributables by your end user.

4. UPGRADES

If this copy of the Software is an upgrade from an earlier version of the Software, you must possess a valid full license to a copy of an earlier version of the Software to install and/or use this upgrade copy. You may continue to use each earlier version copy of the Software to which this upgrade copy relates on your computer after you receive this upgrade copy, provided that, (i) the upgrade copy and the earlier version copy are installed and/or used on the same computer only and the earlier version copy is not installed and/or used on any other computer; (ii) you comply with the terms and conditions of the earlier version's end user license agreement with respect to the installation and/or use of such earlier version copy; (iii) the earlier version copy or any copies thereof on any computer are not transferred to another computer unless all copies of this upgrade copy on such computer are also transferred to such other computer; and (iv) you acknowledge and agree that any obligation Catalyst may have to support and/or offer support for the earlier version of the Software may be ended upon availability of the upgrade.

5. LICENSE RESTRICTIONS

You may not rent, lease or transfer the Software. You may not reverse engineer, decompile or disassemble the Software, except to the extent applicable law expressly prohibits the foregoing restriction. You may not alter the contents of a hard drive or computer system to enable the use of the evaluation version of the Software for an aggregate period in excess of the evaluation period for one license. Without prejudice to any other rights, Catalyst Development may terminate this License Agreement if you fail to comply with the terms and conditions of the agreement. In such event, you must destroy all copies of the Software Product.

6. CONFIDENTIALITY

(a) The Software contains information or material which is proprietary to Catalyst Development ("Confidential Information"), which is not generally known other than by Catalyst, and which you may obtain knowledge of through, or as a result of the relationship established hereunder with Catalyst. Without limiting the generality of the foregoing, Confidential Information includes, but is not limited to, the following types of information, and other information of a similar nature (whether or not reduced to writing or still in development): designs, concepts, ideas, inventions, specifications, techniques, discoveries, models, data, object code, documentation, diagrams, flow charts, research, development, methodology, processes, procedures, know-how, new product or new technology information, strategies and development plans (including prospective trade names or trademarks).

(b) Such Confidential Information has been developed and obtained by Catalyst by the investment of significant time, effort and expense, and provides Catalyst with a significant competitive advantage in its business.

(c) You agree that you shall not make use of the Confidential Information for your own benefit or for the benefit of any person or entity other than Catalyst, except for the expressed purposes described in this section, in accordance with the provisions of this Agreement, and not for any other purpose.

(d) You agree to hold in confidence, and not to disclose or reveal to any person or entity, the Software, other related documentation, your product Serial Number or any other Confidential Information concerning the Software other than to such persons as Catalyst shall have specifically agreed in writing to utilize the Software for the furtherance of the expressed purposes described in this section, in accordance with the provisions of this Agreement, and not for any other purpose.

(e) You acknowledge the purpose of this section is to protect Catalyst Development's ability to limit the use of the data and the Software generally to licensees, and to prevent use of Confidential Information concerning the Software by other developers or vendors of software.

7. CONTINUATION OF SERVICE

Some features of the Software may require the use of remote servers under the control of Catalyst Development to provide specific services. Catalyst makes no warranty as to the availability of these services and reserves the right to discontinue these services at any time and without warning. These services may only be accessed using the Application Programming Interfaces (API) provided by the Software Product and access is limited to licensees and evaluation users of the Software.

We may suspend or terminate your access to these services without liability if (i) we reasonably believe that the services are being used (or have been or will be used) in violation of the Agreement, (ii) we reasonably believe that suspending or terminating your access is necessary to protect our network or our other customers, or (iii) the suspension or termination is required by law. We will give you reasonable advance notice of suspension or termination under this section and a chance to cure the grounds on which the suspension or termination is based, unless we determine, in our reasonable commercial judgment, that an immediate suspension or termination is necessary to protect Catalyst or its other customers from imminent and significant operational or security risk.

8. LIMITED WARRANTY

If within thirty days of your purchase of this software product, you become dissatisfied with the Software for any reason, you may return the software to Catalyst Development (or your dealer, if you did not purchase it directly from Catalyst) for a refund of your purchase price. To return the Software, you must contact Catalyst Development and obtain a Return Material Authorization (RMA) number. Catalyst will not accept returns of opened or installed software without an RMA number. Returns may be subject to the deduction from your purchase price of a restocking fee and all shipping costs.

CATALYST PROVIDES NO REMEDIES OR WARRANTIES, WHETHER EXPRESS OR IMPLIED, FOR ANY SAMPLE APPLICATION CODE, TRIAL VERSION AND THE NOT FOR RESALE VERSION OF THE SOFTWARE. ANY SAMPLE APPLICATION CODE, TRIAL VERSION AND THE NOT FOR RESALE VERSION OF THE SOFTWARE ARE PROVIDED "AS IS".

CATALYST DISCLAIMS ALL OTHER WARRANTIES, EITHER EXPRESS OR IMPLIED, INCLUDING BUT NOT LIMITED TO IMPLIED WARRANTY OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE, WITH RESPECT TO THE SOFTWARE, THE ACCOMPANYING WRITTEN MATERIALS, AND ANY ACCOMPANYING HARDWARE.

9. LIMITATION OF LIABILITY

IN NO EVENT SHALL CATALYST OR ITS SUPPLIERS BE LIABLE FOR ANY DAMAGES WHATSOEVER (INCLUDING, WITH LIMITATION, INCIDENTAL, CONSEQUENTIAL, SPECIAL, OR EXEMPLARY DAMAGES OR LOST PROFITS, BUSINESS INTERRUPTION, OR OTHER PECUNIARY LOSS) ARISING OUT OF THE USE OR INABILITY OF THIS CATALYST PRODUCT, EVEN IF CATALYST HAS BEEN ADVISED OF SUCH DAMAGES.

APART FROM THE FOREGOING LIMITED WARRANTY, THE SOFTWARE PROGRAMS ARE PROVIDED "AS-IS", WITHOUT WARRANTY OF ANY KIND, EITHER EXPRESSED OR IMPLIED. THE ENTIRE RISK AS TO THE PERFORMANCE OF THE PROGRAMS IS WITH THE PURCHASER. CATALYST DOES NOT WARRANT THAT THE OPERATION OF THE PROGRAMS WILL BE UNINTERRUPTED OR ERROR-FREE. CATALYST ASSUMES NO RESPONSIBILITY OR LIABILITY OF ANY KIND FOR ERRORS IN THE PROGRAMS OR DOCUMENTATION, OF/FOR THE CONSEQUENCES OF ANY SUCH ERRORS. THE LAWS OF THE STATE OF CALIFORNIA GOVERN THIS AGREEMENT.

10. GOVERNMENT-RESTRICTED RIGHTS

United States Government Restricted Rights. The Software and related documentation are provided with RESTRICTED RIGHTS. Use, duplication, or disclosure by the Government is subject to the restrictions set forth in subparagraph (c)(1)(ii) of the Rights in Technical Data and Computer Software clause at DFARS 252.227-7013 or subparagraphs (c)(1) and (2) of the Commercial Computer Software - Restricted Rights at 48 CFR 52.227-19, as applicable. Manufacturer for such purposes is Catalyst Development Corporation, 56925 Yucca Trail #254, Yucca Valley, CA 92284

11. EXPORT CONTROLS

You agree to comply with all relevant regulations, including but not limited to those, of the United States Department of Commerce and with the United States Export Administration Act to insure that the Software is not exported in violation of United States law. You acknowledge that the Software is subject to export regulations and agree that you will not export, re-export, import or transfer the software in violation of any United States or other applicable laws, whether directly or indirectly, and you will not assist or facilitate others in doing so. You acknowledge that you have the responsibility to obtain any export classifications and licenses as may be required to comply with such laws.

12. PROHIBITED DESTINATIONS

The exportation, re-exportation, sale or supply of Catalyst products, software components or documentation, directly or indirectly, from the United States or by a United States citizen wherever located, to Cuba, Iran, North Korea, Sudan, Syria, or any other country to which the United States has embargoed goods, is strictly prohibited without prior authorization by the United States Government. You represent and warrant that neither the United States Bureau of Export Administration nor any other federal agency has suspended, revoked or denied your export privileges. Catalyst products, software components or documentation may not be exported or re-exported to anyone on the United States Treasury Department's list of Specially Designated Nationals or the United States Department of Commerce Denied Person's List or Entity List.

13. GOVERNING LAW

This License is governed by the laws of the State of California, without reference to conflict of laws principles. Any controversy or claim arising out of or relating to this contract, or the breach thereof, shall be settled by arbitration administered by the American Arbitration Association (“AAA”) under its Commercial Arbitration Rules, and judgment on the award rendered by the arbitrator(s) may be entered in any court having jurisdiction thereof. The arbitrator shall be a retired judge or attorney with at least 15 years commercial law experience and shall be selected either by mutual agreement of the parties or by AAA’s selection process. The parties shall be entitled to take discovery in accordance with the provisions of the California Code of Civil Procedure, including but not limited to CCP §1283.05. The arbitration shall be held in San Bernardino, California and in rendering the award the arbitrator must apply the substantive law of the State of California.

14. GENERAL PROVISIONS

This License Agreement contains the complete agreement between the parties with respect to the subject matter hereof, and supersedes all prior or contemporaneous agreements or understandings, whether oral or written. You agree that any varying or additional terms contained in any purchase order or other written notification or document issued by you in relation to the Software licensed hereunder shall be of no effect. The failure or delay of Catalyst to exercise any of its rights under this Agreement or upon any breach of this Agreement shall not be deemed a waiver of those rights or of the breach.

If any provision of this agreement shall be held by a court of competent jurisdiction to be contrary to law, that provision will be enforced to the maximum extent permissible, and the remaining provisions of this agreement will remain in full force and effect.

SocketTools and other trademarks contained in the Software are trademarks or registered trademarks of Catalyst Development Corporation in the United States and/or other countries. Third party trademarks, trade names, product names and logos may be the trademarks or registered trademarks of their respective owners. You may not remove or alter any trademark, trade names, product names, logo, copyright or other proprietary notices, legends, symbols or labels in the Software.

Copyright Information

Features Overview

The SocketTools .NET components can be used with any Visual Studio .NET programming language. SocketTools includes assemblies which can target every version of the .NET Framework, from version 1.1 through version 4.8.

Features of the SocketTools .NET Edition include:

- The SocketTools classes provide a simple interface that is easy to use and understand. There are no complicated methods or data structures to use, and most methods are overloaded to provide reasonable defaults appropriate for most applications. Most complex operations can be performed with only a few lines of code.
- There are no external dependencies on third party libraries or components. The SocketTools classes are managed code classes and are not "wrappers" around ActiveX controls or COM libraries.
- The class interfaces were designed to be as similar as possible to the COM version of the components, reducing the learning curve for developers who are already familiar with SocketTools and reducing the amount of time required to port an application to the .NET platform.
- A comprehensive design which supports both high-level operations as well as lower-level methods at the protocol level. For example, the File Transfer Protocol component has methods such as PutFile and GetFile which allow an application to easily upload and download files in a single method call. It also includes lower-level methods like OpenFile to open a file on the server and access it in a fashion similar to traditional file I/O operations.
- Support for both synchronous (blocking) and asynchronous (non-blocking) operation depending on the needs of the application. Asynchronous operation is supported by an event-driven model where the application is notified of networking events by events generated by the component. Event notification can be enabled, disabled and resumed completely under the control of the application, giving developers complete freedom in controlling their behavior of their software. Synchronous operation is also fully supported, enabling developers to easily write programs using a procedural programming style without the inherent complexity of an event-driven model.
- A thread-safe implementation that allows the classes to be easily used in a multithreaded application. SocketTools handles any internal synchronization required, ensuring that multiple, simultaneous operations can be performed safely and efficiently without extensive coding on the part of the developer.
- The SocketTools .NET Edition enables applications to take advantage of security features, including support for TLS 1.2 and AES 256-bit encryption without requiring any knowledge of data encryption or certificate validation. The components use the Windows CryptoAPI to provide security services, which means that there are no third-party security libraries that must be installed by your users. Taking advantage of the security features in the SocketTools .NET Edition is as simple as setting a few properties before connecting to the server. The protocol negotiation, data encryption and decryption is handled transparently by the control. From the perspective of the application developer, it is just as if it were a standard connection to the server.

The SocketTools .NET Edition includes everything professional software developers need to create complex programs, enabling developers to focus on their core application technology rather than the details of how a particular application protocol is implemented or understanding the specifics of network programming.

Getting Started

SocketTools is a large collection of components that can be used to create a variety of applications, so deciding what protocols and controls you'll need to use will be the first step. SocketTools covers several general categories, and there is some cross-over between the components in terms of functionality. We'll cover the most common programming needs and discuss what protocols should be used. Note that this section doesn't cover all of the controls in SocketTools, and more specific information for each component is available within the technical reference documentation.

One thing you'll discover as you start to use SocketTools is that the interface was intentionally designed to be consistent between many of the controls. For example, both the File Transfer Protocol and Hypertext Transfer Protocol controls can be used to upload and download files, and the properties, methods and events for both of those controls are very similar. Once you've become comfortable working with one of the controls, you'll find it very easy to use the other, related controls.

File Transfers

- File Transfer Protocol
- Hypertext Transfer Protocol

One of the most common requirements for an application is the ability to upload and download files, either over the Internet or between systems on a local intranet. There are two core protocols which are used for file transfers, the File Transfer Protocol (FTP) and the Hypertext Transfer Protocol (HTTP). The decision as to which protocol to use largely depends on whether or not the program must also perform any type of file management on the server. Because many of the methods in the FTP and HTTP components are similar, you may wish to use both and simply give your users an option as to which protocol they prefer to use.

If your program needs to upload files or manage the files on the server, we recommend that you use FTP. In addition to uploading and downloading files, FTP can be used to rename or delete files, create directories, list the files in a directory and perform a variety of other functions. On the other hand, if you primarily need to just download files, HTTP can be a better choice. The protocol is simpler and you're less likely to encounter some of the issues that can arise when using FTP from behind a firewall.

It is also an option to use FTP to upload and manage files and HTTP to download files within the same program. The important thing to keep in mind is that if you want to use HTTP and need to upload files, you must make sure that the server has been configured for it. Most web servers do not support the ability to upload files by default; it requires the administrator to specifically enable that functionality.

World Wide Web

- Hypertext Transfer Protocol

If you need to access documents or execute scripts on a web server, you'll want to use the Hypertext Transfer Protocol (HTTP) control. You can use the control to download files and post data to scripts. The control also supports the ability to upload files, either using the PUT command or by using the POST command, which is the same method used when selecting a file to upload using a form. The control can also be used to execute custom commands, allowing your application to take advantage of features like WebDAV, a distributed authoring extension to HTTP.

Electronic Mail

- Domain Name Services Protocol
- Internet Message Access Protocol

- Mail Message Class
- Post Office Protocol
- Simple Mail Transfer Protocol

There are a number of SocketTools components which can be used by an application that needs to send email messages or retrieve them from a user's mailbox. The email related controls can be broken into three groups, those that deal primarily with managing and retrieving messages for a user, those which are used to send messages and those which can be used for either purpose.

The two principal protocols used to manage a user's email are the Post Office Protocol (POP3) and the Internet Message Access Protocol (IMAP). POP3 is the protocol that the majority of Internet Service Providers (ISP) use to give their customers access to their messages. It is primarily designed to enable an application to download the messages from the mail server and store them on the local system. Once all of the messages have been downloaded, they are deleted from the server. The user's mailbox is essentially treated as a temporary storage area.

On the other hand, IMAP is designed to allow the application to manage the messages on the server. You can create new mailboxes, move messages between mailboxes and search for messages. Because IMAP can be used to access specific parts of a message, it's not necessary to download the entire message if you just want to read a specific part of it. In terms of the SocketTools controls, it's useful to think of the properties, methods and events in the IMAP control as a superset of those in the POP3 control. You'll find that methods used for accessing messages are very similar, but the IMAP component contains additional methods for managing mailboxes and performing operations that are specific to that protocol, such as the ability to search for messages.

To send an email message to someone, the protocol that you'll use is the Simple Mail Transfer Protocol (SMTP). The SocketTools control supports the standard implementation of this protocol, along with many of the extensions that have been added since its original design. Extended SMTP (ESMTP) provides features such as authentication, delivery status notification, secure connections using SSL/TLS and so on. Another component that you may use is the Domain Name Services (DNS) control, which your application can use to determine what servers are responsible for accepting mail for a particular user.

Common to both sending and receiving email messages is the need to be able to create and process those messages. An email message has a specific structure which is defined by a number of standards, collectively called the Multipurpose Internet Mail Extensions (MIME). The SocketTools Mail Message control can be used to create messages in the format, as well as parse existing messages so that you application can access the specific information that it needs. For example, you can use this component to attach files to a message as well as extract a specific file attachment from a message and store it on the local system.

Terminal Sessions

- Rlogin Protocol
- Telnet Protocol
- Terminal Emulation

If you need to establish an interactive terminal session with a server, there are two protocols that you can use. The most common is the Telnet Protocol; however, there is also the Rlogin protocol which is part of the Remote Command control. Either of these protocols are typically used in conjunction with the Terminal Emulation control, which provides ANSI and DEC VT-220 terminal emulation functionality. Used together, the user can login and interact with the server in the same way that they would use a console or character based terminal.

Newsgroups

- File Encoding Class
- Mail Message Class
- Network News Transfer Protocol

If you need to access newsgroups, the Network News Transfer Protocol will enable you to connect, list, retrieve and post articles. Because news articles have a format that is very similar to email messages, the Mail Message control can be used to parse articles that you've downloaded or create new articles to be posted. If you need to attach a file to the article that you're posting, the File Encoding control can be used to encode the file using the yEnc encoding algorithm, which has become the de facto standard on USENET.

General Concepts

This section of the developer's guide will cover the core networking protocols along with the general concepts related to Internet programming. Although it is not necessary to understand the lower level details of network programming in order to use SocketTools, it is useful to be familiar with the basic concepts and terminology.

- Windows Sockets
- Networking Protocols
- Application Protocols
- Domain Names
- Service Ports
- Client-Server Applications
- Client Sessions
- Secure Networking
- Digital Certificates

Windows Sockets

The Windows Sockets application program interface (API) specification was created by a group of companies, including Microsoft, in an effort to standardize the TCP/IP suite of protocols for the Windows operating system. Prior to Windows Sockets, each vendor developed their own proprietary libraries, and although they all had similar functionality, the differences were significant enough to cause problems for the software developers that used them. The biggest limitation was that, upon choosing to develop against a specific vendor's library, the developer was "locked" into that particular implementation. A program written against one vendor's product would not work with another's. Windows Sockets was offered as a solution, leaving developers and their end-users free to choose any vendor's implementation with the assurance that the product will continue to work.

There are two general approaches that you can take when creating a program that uses Windows Sockets. One is to code directly against the API, which requires learning how to make direct API calls to the system and how the Interop features of the .NET framework function. The other is to use a component (class library) like SocketTools which provides a higher-level interface by setting properties, calling methods and responding to events. This can provide a more natural programming interface, and it allows you to avoid much of the error-prone drudgery commonly associated with sockets programming. By simply referencing SocketTools in a project, setting some properties, calling a few methods and responding to events, you can quickly and easily write an Internet-enabled application.

SocketTools .NET provides a comprehensive interface to the networking subsystem that is powerful and flexible enough to build virtually any kind of application, yet doesn't have a steep learning curve for those developers who aren't experienced network programmers. In general, we believe that you'll be able to use SocketTools to write software for the Internet faster and easier than the native socket class that's part of the .NET framework.

Networking Protocols

Throughout the Developer's Guide, you will see the word "protocols" mentioned. There are two general types of protocols that will be discussed. The first type of protocol will be referred to as networking protocols. They are lower level protocols which define how data is exchanged between two systems. The two networking protocols that will be discussed are the User Datagram Protocol (UDP) and the Transmission Control Protocol (TCP).

There are also application protocols, which use the networking protocols to communicate. Application protocols deal with a specific type of functionality. For example, the File Transfer Protocol (FTP) is used to upload and download files, while the Simple Mail Transfer Protocol (SMTP) is used to send email messages. Conceptually, you can think of the networking protocols as defining the rules for how programs can communicate with one another over the Internet. The application protocols operate at a higher level, defining the rules for how a specific kind of task can be carried out, such as transferring a file from one computer to another.

- Transmission Control Protocol
- User Datagram Protocol

Transmission Control Protocol

When two computers wish to exchange information over a network, there are several components that must be in place before the data can actually be sent and received. Of course, the physical hardware must exist, which is typically either a network interface card (NIC) or a serial communications port for dial-up networking connections. Beyond this physical connection, however, computers also need to use a protocol which defines the parameters of the communication between them. In short, a protocol defines the "rules of the road" that each computer must follow so that all of the systems in the network can exchange data. One of the most popular protocols in use today is TCP/IP, which stands for Transmission Control Protocol/Internet Protocol.

By convention, TCP/IP is used to refer to a suite of protocols, all based on the Internet Protocol (IP). Unlike a single local network, where every system is directly connected to each other, an internet is a collection of networks, combined into a single, virtual network. The Internet Protocol provides the means by which any system on any network can communicate with another as easily as if they were on the same physical network. Each system, commonly referred to as a host, is assigned a numeric value which can be used to identify it over the network. These numeric values are known as IP addresses, and are usually represented as a string value that contains a series of numbers.

There are two versions of TCP/IP and two different IP address formats based on which version of the protocol is being used. For Internet Protocol v4 (IPv4), addresses are 32 bits wide and are represented by a sequence of four 8-bit numbers separated by periods. This is called dot-notation and looks something like **192.168.19.64**. This is the address format that many developers are familiar with because IPv4 continues to be the most commonly used version of the protocol. Internet Protocol v6 (IPv6) is the next generation of IP and it supports a much larger address space as well as a number of other features. IPv6 addresses are 128 bits wide and represented by a sequence of hexadecimal values separated by colons. As expected, this format is much longer than the simple dot-notation used by IPv4 address. A typical IPv6 address will look something like **fd7c:2f6a:4f4f:ba34::a32**, although there are certain shorthand notations that can be used. SocketTools supports both IPv4 and IPv6, and can automatically determine which version of the protocol should be used based on the address. Because IPv4 is still widely used, if given a choice between using IPv4 or IPv6, the SocketTools components will choose IPv4 for backwards compatibility whenever possible. However, an application can choose to exclusively use IPv6 if required.

When a system sends data over the network using the Internet Protocol, it is sent in discrete units called datagrams, also commonly referred to as packets. A datagram consists of a header followed by application-defined data. The header contains the addressing information which is used to deliver the datagram to its destination, much like an envelope is used to address and contain postal mail. And like postal mail, there is no guarantee that a datagram will actually arrive at its destination. In fact, datagrams may be lost, duplicated or delivered out of order during their travels over the network. Needless to say, this kind of unreliability can cause a lot of problems for software developers. What's really needed is a reliable, straightforward way to exchange data without having to worry about lost packets or jumbled data.

To fill this need, the Transmission Control Protocol (TCP) was developed. Built on top of IP, TCP offers a reliable, full-duplex byte stream which may be read and written to in a fashion similar to reading and writing a file. The advantages to this are obvious: the application programmer doesn't need to write code to handle dropped or out-of-order datagrams, and instead can focus on the application itself. And because the data is presented as a stream of bytes, existing code can be easily adopted and modified to use TCP.

TCP is known as a connection-oriented protocol. In other words, before two programs can begin to exchange data they must establish a "connection" with each other. This is done with a three-way handshake in which both sides exchange packets and establish the initial packet sequence numbers (the sequence number is important because, as mentioned above, datagrams can arrive out of order; this number is used to ensure that data is received in the order that it was sent). When establishing a connection, one program must assume the role of the client, and the other the server. The client is responsible for initiating the connection, while the server's responsibility is to wait, listen and respond to incoming connections. Once the connection has been established, both sides may send and receive data until the connection is closed.

User Datagram Protocol

Unlike TCP, the User Datagram Protocol (UDP) does not present data as a stream of bytes, nor does it require that you establish a connection with another program in order to exchange information. Data is exchanged in discrete units called datagrams, which are similar to IP datagrams. In fact, the only features that UDP offers over raw IP datagrams are port numbers and an optional checksum.

UDP is sometimes referred to as an unreliable protocol because when a program sends a UDP datagram over the network, there is no way for it to know that it actually arrived at its destination. This means that the sender and receiver must typically implement their own application protocol on top of UDP. Much of the work that TCP does transparently (such as generating checksums, acknowledging the receipt of packets, retransmitting lost packets and so on) must be performed by the application itself.

With the limitations of UDP, you might wonder why it's used at all. UDP has the advantage over TCP in two critical areas: speed and packet overhead. Because TCP is a reliable protocol, it goes through great lengths to ensure that data arrives at its destination intact, and as a result it exchanges a fairly high number of packets over the network. UDP doesn't have this overhead, and is considerably faster than TCP. In those situations where speed is paramount, or the number of packets sent over the network must be kept to a minimum, UDP is an appropriate protocol to use.

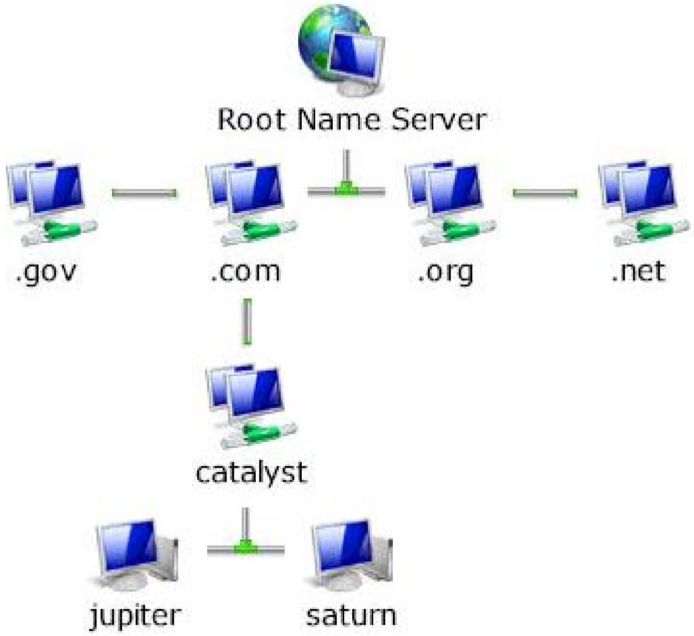
Application Protocols

The Internet application protocols are defined in standards documents called RFCs (Request For Comments) which are maintained by the Internet Engineering Task Force. The following protocols standards are implemented by the SocketTools components:

Document	Description
RFC 792	Internet Control Message Protocol
RFC 822	Standard for the Format of ARPA Internet Text Messages
RFC 854	Telnet Protocol Specification
RFC 868	Time Protocol
RFC 954	Nicname/Whois Protocol
RFC 959	File Transfer Protocol (FTP)
RFC 977	Network News Transfer Protocol
RFC 1034	Domain Name Services
RFC 1055	Serial Line IP (SLIP)
RFC 1282	Rlogin
RFC 1288	Finger User Information Protocol
RFC 1579	Firewall-Friendly FTP
RFC 1661	The Point-to-Point Protocol (PPP)
RFC 1738	Uniform Resource Locators
RFC 1869	SMTP Service Extensions
RFC 1939	Post Office Protocol Version 3
RFC 1945	Hypertext Transfer Protocol 1.0
RFC 1951	Deflate Compressed Data Format Specification
RFC 2045	Multipurpose Internet Mail Extensions (Part One)
RFC 2046	Multipurpose Internet Mail Extensions (Part Two)
RFC 2047	Multipurpose Internet Mail Extensions (Part Three)
RFC 2048	Multipurpose Internet Mail Extensions (Part Four)
RFC 2228	FTP Security Extensions
RFC 2616	Hypertext Transfer Protocol 1.1
RFC 2821	Simple Mail Transfer Protocol (SMTP)
RFC 2980	Common NNTP Extensions
RFC 3501	Internet Message Access Protocol Version 4

Domain Name System

An application must have several pieces of information to exchange data with a program running on another system. The first is the Internet Protocol (IP) address of the computer system on which the other program is running. Although this address is internally represented by a numeric value (either 32 or 127 bits wide), it is typically identified by a logical name called a host name or fully qualified domain name. Host names are divided into several parts separated by periods, called domains. The structure is hierarchical, with the top-level domains defining the type of organization that network belongs to, and sub-domains further identifying the specific network. Everyone who has used a web browser is familiar with host names such as **www.microsoft.com**.



In this figure, the top-level domains are "gov" (government agencies), "com" (commercial organizations), "edu" (educational institutions) and "net" (Internet service providers). The fully qualified domain name is specified by naming the host and each parent sub-domain above it, separating them with periods. For example, the fully qualified domain name for the "jupiter" host would be "jupiter.sockettools.com". In other words, the system "jupiter" is part of the "catalyst" domain (a company's local network) which in turn is part of the "com" domain (a domain used by all commercial enterprises).

To use a host name instead of an IP address to identify a specific system or network, there must be some correlation between the two. This is accomplished by one of two means: a local host table or a name server. A host table is a text file that lists the IP address of a host, followed by the names by which it is known. A name server is a system which can be presented with a host name and will return that host's IP address. This approach is advantageous because the host information for the entire network is maintained in one centralized location, rather than being scattered over every system on the network.

The standard protocol used to convert a host name into an IP address is called the Domain Name Service (DNS) protocol. All of the SocketTools networking libraries have the ability to automatically convert between host names and IP addresses, and in most cases they can be used interchangeably. For example, those methods which require that you specify the name of a server to connect to, you can use either its host name or its IP address. In addition, SocketTools has a control that specifically supports the Domain Name Service protocol, enabling your application to send specialized queries to the name server. Later in the Developer's Guide there will be information about how DNS can be used in a number of different types of applications.

Service Ports

In addition to the IP address of the server, an application also needs to know how to address the specific program that it wishes to communicate with. This is accomplished by specifying a service port, a number between 1 and 65535 that uniquely identifies an application running on the system. A port can be referred to by its number, or by a name that is associated with that number. Like hostnames, service names are usually matched to port numbers through a local file, commonly called services. This file lists the logical service name, followed by the port number and protocol used by the server.

A number of standard service names are used by Internet-based applications and these are referred to as Well Known Services (WKS). These services are defined by a standards document and include common application protocols used for transferring files, accessing documents on a webserver or sending and receiving email messages. In most cases, when connecting to a service using the SocketTools libraries, they will default to the appropriate port number for that server. For example, the File Transfer Protocol control has default port values for standard and secure connections. Specifying a different port number is only necessary if you know that the server has been configured to use a non-standard port number.

It is important to remember that a service name or port number is a way to address an application running on a server. Because a particular service name is used, it doesn't guarantee that the service is available, just as dialing a telephone number doesn't guarantee that there is someone at home to answer the call.

Client-Server Applications

Programs written to use TCP are developed using the client-server model. As mentioned previously, when two programs wish to use TCP to exchange data, one of the programs must assume the role of the client, while the other must assume the role of the server. The client application initiates what is called an active open. It creates a socket and actively attempts to connect to a server program. On the other hand, the server application creates a socket and passively listens for incoming connections from clients, performing what is called a passive open. When the client initiates a connection, the server is notified that some process is attempting to connect with it. By accepting the connection, the server completes what is called a virtual circuit, a logical communications pathway between the two programs. It's important to note that the act of accepting a connection creates a new socket; the original socket remains unchanged so that it can continue to be used to listen for additional connections. When the server no longer wishes to listen for connections, it closes the original passive socket.

To review, there are five significant steps that a program which uses TCP must take to establish and complete a connection. The server side would follow these steps:

1. Create a socket.
2. Listen for incoming connections from clients.
3. Accept the client connection.
4. Send and receive information.
5. Close the socket when finished, terminating the conversation.

In the case of the client, these steps are followed:

1. Create a socket.
2. Specify the address and service port of the server program.
3. Establish the connection with the server.
4. Send and receive information.
5. Close the socket when finished, terminating the conversation.
6. Only steps two and three are different, depending on if it's a client or server application.

Client Sessions

One of the first issues that you'll encounter when developing your applications is the difference between blocking and non-blocking client sessions. Whenever you perform some network operation, it may not be able to complete immediately and return control back to your program. For example, a read on a socket cannot complete until some data has been sent by the server. If there is no data waiting to be read, one of two things can happen: the function can wait until some data has been written on the socket, or it can return immediately with an error that indicates that there is no data to be read.

The first case is called a synchronous or blocking session. In other words, the program is "blocked" until the request for data has been satisfied. When the server does write some data on the socket, the read operation will complete and execution of the program will resume. The second case is called an asynchronous or non-blocking session, and requires that the application recognize the error condition and handle the situation appropriately. Programs that use non-blocking sockets typically use one of two methods when sending and receiving data. The first method, called polling, is when the program periodically attempts to read or write data from the socket (typically using a timer). The second, and preferred method, is to use what is called asynchronous notification. This means that the program is notified whenever a socket event takes place, and in turn can respond to that event. For example, if the remote program writes some data to the socket, an event is generated so that program knows it can read the data from the socket at that point.

With Visual Studio .NET, it is recommended that most applications using blocking (synchronous) sessions. However, it should be noted that blocking sockets can introduce some special problems in single-threaded applications. The blocking function will allow the application to continue processing messages from the operating system. Because messages are being processed, this means that the program can be re-entered at a different point with the blocked operation suspended on the program's stack. For example, consider a program that attempts to read some data from the socket when a button is pressed. Because no data has been written yet, it blocks and the program begins processing system messages. The user then presses a different button, which causes code to be executed, which in turn attempts to read data from the socket, and so on.

To resolve the general problems with blocking sockets, the Windows Sockets standard states that there may only be one outstanding blocked call per thread of execution. This means that applications that are re-entered will encounter errors whenever they try to take some action while a blocking function is already in progress. It is recommended that worker threads be created to manage each client session, with each thread owning a specific instance of the class being used. This resolves the potential conflict between multiple blocking sessions in the same thread, and will improve the performance of the application overall.

The only time that non-blocking (asynchronous) sessions are recommended are with single-threaded applications with a user interface that the user must interact with as the network operation is being performed. It should be noted that there is additional overhead involved with asynchronous sessions which can negatively impact the overall performance of the application. When possible, a multithreaded solution using worker threads to handle the client session in the background is preferred.

In summary, there are three general approaches that can be taken when building an application with the control in regard to blocking or non-blocking sockets:

- Use a blocking (synchronous) session. In this mode, the program will not resume execution until the socket operation has completed. This is the recommended approach, offering better performance and simplified debugging.
- Use a non-blocking (asynchronous) session, which allows your application to respond to events. For example, when the remote system writes data to the socket, an OnRead event is generated for the control. This approach should only be used with single-threaded applications with a user interface. There is additional overhead for processing network messages and debugging can be more complex.

- Use a non-blocking (asynchronous) session and poll the socket for data using properties such as IsReadable and IsWritable. This approach incurs additional overhead and it is recommended that you create worker threads to handle a blocking client session rather than poll for data.

If you decide to use a non-blocking session in your application, it's important to keep in mind that you must check the return value from every read and write operation, since it is possible that you may not be able to send or receive all of the specified data. Frequently, developers encounter problems when they write a program that assumes a given number of bytes can always be written to, or read from, the socket. In many cases, the program works as expected when developed and tested on a local area network, but fails unpredictably when the program is released to a user that has a slower network connection (such as a serial dial-up connection to the Internet). By always checking the return values of these operations, you insure that your program will work correctly, regardless of the speed or configuration of the network.

Secure Networking

Security and privacy is a concern for everyone who uses the Internet, and the ability to provide secure transactions over the Internet has become one of the key requirements for many business applications. SocketTools .NET has the ability to establish secure, encrypted connections with servers using one of several standard security protocols. Although most of the technical issues such as data encryption are handled internally by the component itself, a general understanding of the standard security protocols is useful when designing your own applications.

When you establish a connection to a server over the Internet (for example, a web server), the data that you exchange is typically routed over dozens of computer systems until it reaches its destination. Any one of these systems may monitor and log the data that it forwards, and there is no way for either the sender or receiver of that data to know if this has been done. Exchanging information over the Internet could be likened to talking with someone in a public restaurant. Anyone can choose to listen to what you're saying, and unless they introduce themselves, you have no idea who they are or if they've even heard what you said.

To ensure that private information can be securely exchanged over the Internet, two basic requirements must be met: there must be a way to send that information so that only the sender and the receiver can understand what is being exchanged, and there must be a way for them to determine that they each are in fact who they claim to be. The solution to the first problem is to use encryption, where a key is used to encrypt and decrypt the data using a mathematical formula. The second problem is addressed by using digital certificates. These certificates are issued by a certificate authority (CA), which is a trusted third-party organization who verifies the individual or company which is issued a certificate are who they claim to be. These two concepts, encryption and digital certificates, are combined to provide the means to send and receive secure information over the Internet.

The Secure Sockets Layer (SSL) protocol was originally developed by Netscape as a way to exchange information securely over the Internet, and is no longer widely used. Improvements to SSL have resulted in the Transport Layer Security (TLS) protocol, and it has become the the standard for secure communications over the Internet. Both of these protocols are designed to allow a private exchange of encrypted data between the sender and receiver, making it unreadable by an intermediate system. Using the restaurant analogy, it would be as if two people were speaking in a language that only they could understand. Although someone sitting at the next table could listen in on the conversation, they wouldn't have any idea what was actually being said.

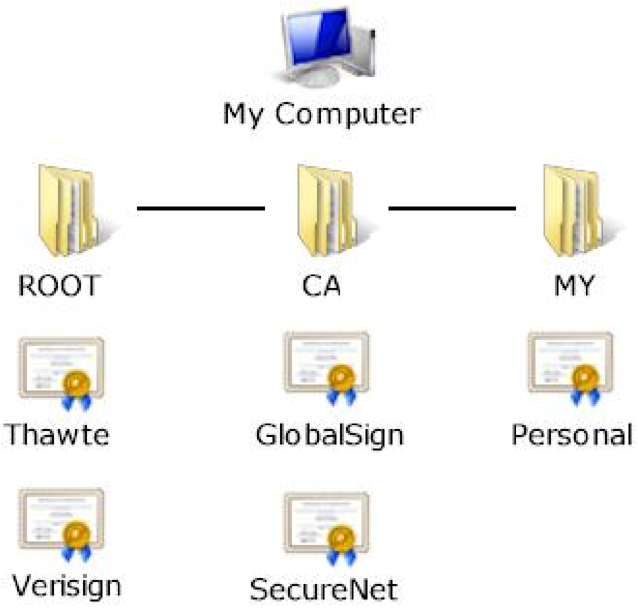
A secure connection, for example between a web browser and a server, begins with what is called the handshake phase where the client and server identify themselves. When the client first connects with the server it sends a block of data to the server and the server responds with its digital certificate, along with its public key and information about what type of encryption it would like to use. Next, the client generates a master key and sends this key to the server, which authenticates it. Once the client and server have completed this exchange, keys are generated which are used to encrypt and decrypt the data that is exchanged. With the handshake completed, a secure connection between the client and server is established. SocketTools handles the handshake phase of the secure connection automatically and does not require any additional programming. If a secure connection cannot be established, an error is returned and the network connection is closed.

After the handshake phase has completed, the client may choose to examine the digital certificate that has been returned by the server. The information contained in the certificate includes the date that it was issued, the date that it expires, information about the organization who issued the certificate (called the issuer) and to whom the certificate was issued (called the subject of the certificate). The client may also validate the status of the certificate, determining if it was issued by a trusted certificate authority and was returned by the same company or individual it was issued to. There may be certain cases where the client determines that there's a problem with the certificate (for example, if the certificate's common name does not match the domain name of the server), but chooses to continue communicating with the server. Note that the connection with the server will still be secure in this case. In other cases, for example if the certificate has expired, the client may choose to terminate the connection and warn the user.

Digital Certificates

With secure connections, digital certificates are used to exchange public keys for data encryption and to provide identification information. This information typically includes the organization that was issued the certificate, its physical location and so on. The certificate itself is used to validate that the public key actually belongs to the entity it was issued to. The certificate also includes information about the Certification Authority (CA) who issued the certificate. The CA is responsible for validating the information provided by that organization, and then digitally signing the certificate. This establishes a relationship between the two so that when others validate the certificate, they know that it has been issued by a trusted third-party. For example, let's say that a company wants to implement a secure site so people can order products online. They would provide information about their company (organizational contacts, financial information and so on) to a trusted third party organization such as Verisign or Thawte. That organization would then verify that the information they provided was complete and correct, and then would issue a signed certificate to them, which they install on their server. When a user connects to their server and checks the certificate, they see that it was issued by a trusted Certification Authority. In essence, the user is saying that because they trust the Certificate Authority, and the Certificate Authority trusts the company to whom the certificate was issued, they will trust the company as well.

To establish this relationship between the Certification Authority and the organization a certificate is issued to, there needs to be a root certificate which has been signed by the same trusted organization. This serves as the beginning of the certification path that is used to validate signed certificates. Using the above example, on the user's system there is a root certificate for Verisign, signed by Verisign. Root certificates are maintained in the local system's certificate store which is essentially a database of digital certificates. This database is structured so that different types of certificates can be organized in one central location on the system, and a standard interface is provided to enumerate and validate these certificates. Certificates are associated with a store name, allowing them to be easily categorized. For example, root certificates are stored under the name "Root", while a user's personal certificates (along with their private keys) are stored under the name "My".



When the Windows operating system is installed, there is a certificate store that contains the root certificates for the major Certification Authorities. However, there are situations where additional certificates may need to be added to the system. To facilitate this, there is a tool called CertMgr.exe which allows a user to install certificates, as well as export or remove certificates from the certificate store. When managing your system's certificate store, you should take the same care that you do when making changes to the system registry. Inadvertently removing a certificate could result in errors when attempting to access secure systems.

In general, the one situation where certificate management becomes important is when you want to develop your own secure server. This is because your server needs to have a signed certificate to send to the client in order to establish the secure connection. For general-purpose commercial applications, this generally means you would need to obtain a certificate that has been signed by a Certification Authority such as Verisign or Thawte. This certificate would then be installed in the certificate store on the server. However, for development purposes it may be inconvenient to purchase a certificate. There also may be situations in which an organization wishes to function as its own Certification Authority and issue certificates themselves. This allows the organization to control how certificates are managed and can be ideal for secure applications that are designed for the corporate intranet. A utility for creating self-signed root certificates and server certificates is included with SocketTools.

SocketTools Development

The SocketTools .NET Edition provides a comprehensive collection of managed code classes for performing a variety of Internet related programming tasks. Although the number of properties, methods and events may appear daunting, once you begin using SocketTools in your own applications you'll find that the various controls are designed to work together in a cohesive fashion. After you've familiarized yourself with one control, the others will become much simpler to use.

Throughout the Developer's Guide there are some general concepts and terminology used that are essential to understanding how SocketTools works. Each of these concepts is explored in detail, however a general, broad overview can also be useful when you are just getting started.

Protocols

A protocol, in terms of how the word is used in SocketTools, refers to the rules for how programs communicate with one another over a network. There are low level networking protocols such as TCP and UDP, as well as high level application protocols like FTP and HTTP. It can be helpful to think of a protocol as a sort of language; for two programs to communicate with each other, they must agree upon a protocol and understand how it is implemented.

Connections

The process of establishing a connection enables one program to communicate with another. Connection requests are made by client applications, and accepted by server applications. When the server accepts the connection request, the connection is completed. When you use the Connect method to successfully establish a connection to a server, a client session is created. SocketTools uses a one-to-one relationship between an instance of a control and a client session. By creating multiple instances of a control, an application can create multiple client/server sessions if necessary.

Sessions

A session refers to an active connection between a client and server program. This term is typically used interchangeably with connection; however in some cases a single session may involve multiple network connections. For example, the File Transfer Protocol control establishes one connection, called the command channel, when the client initially connects to the server. However, when a file is being uploaded or downloaded, a second connection called the data channel is created just for that transfer. When the transfer completes, the second connection is terminated while the original command channel connection remains active. Even though there are multiple connections being made, SocketTools considers it to be a single client session. An active session is referenced by the instance of the control that was used to create the session. When the session is no longer needed, the control's Disconnect method will terminate the connection to the server and release the resources allocated for that session. After that point, the session is no longer valid and subsequent function calls using the control cannot be made until another connection is established.

Authentication

Many servers require that clients authenticate themselves by providing user names and passwords. Different application protocols implement several different types of authentication, and some protocols may support more than one authentication method. SocketTools provides one of two general types of authentication methods, depending on the protocol. For protocols which require the client to authenticate itself, the controls will provide a Login method. For protocols where authentication is optional, the controls will provide an Authenticate method. Refer to the technical reference for the specific protocol to determine if authentication is required.

Events

Developers who use programming languages such as Visual Basic will find the concept of events and event handling to be very familiar. In general terms, the SocketTools documentation uses "event" to refer to a mechanism where the control notifies the application that an operation has completed, some action has taken place or a change in status has occurred. One example of an event is a connection event, which is generated whenever an asynchronous network connection is completed by the client. Another example is a progress event, which is generated periodically by the control to inform the client of its progress as it sends or receives data. To determine what events are available in a specific control, refer to the documentation. More specific information about event handling is provided later in this guide.

Application Design

The SocketTools .NET Edition is designed to be flexible enough to address the needs of developers who have very basic needs, as well as those who have more complex requirements. As a result, the properties and methods for a control can be broken down into two general categories: a high level interface to perform common tasks, and a lower level interface which provides more control at the expense of being somewhat more complicated and requiring more coding. For example, consider the Hypertext Transfer Protocol (HTTP) control which has a variety of high level methods such as GetFile, PostData and so on. Using these methods, your application can perform the most common tasks for that protocol with a minimum of coding. You don't need to even understand the basics of how the protocol works, or what the control is doing. The high level methods allow you to program against the control as though it is a "black box", where you can provide the input and process the output without concerning yourself with the details of what's going on behind the scenes.

However, in some cases it's necessary for an application to have more direct control over how the control operates or to take advantage of features that aren't explicitly supported by one of the higher level methods. As an example, the HTTP control also has methods like Command, which enable you to send custom commands to a web server. Normally, for operations like retrieving a file or posting data to a script, this isn't necessary. But if your application needs to use WebDAV, a set of extensions to the HTTP protocol to support distributed web authoring, then the lower level methods like Command enable you to do this.

If you are generally new to Internet programming or are just getting started with SocketTools, we recommend that you begin familiarizing yourself with the higher level methods using a basic synchronous (blocking) connection in a single-threaded application. Once you become more familiar with how the control works, then you can move on to more complex applications which leverage the lower level methods, taking advantage of asynchronous networking connections and so on.

One of the common pitfalls that developers can encounter with a large toolkit like SocketTools is the inclination to over-design the application from the start, and then become frustrated because they don't yet have a clear picture of how all the pieces fit together. Start out with a basic design and then as you become more familiar with how the SocketTools controls work, expand on it.

Program Structure

Applications which use the SocketTools classes will tend to have a similar structure, regardless of the specific protocol or programming language. While the details vary based on the control being used, the implementation can be broken down into several general steps:

- Initializing the class instance
- Connecting to the server
- Authenticating the client
- Performing one or more operations
- Disconnecting from the server
- Uninitializing the class instance

Initialization prepares an instance of the class to be used by your program, and is the first step that must be performed before you can use any other methods. Next, a connection is established with the server using the information provided by your program. For example, most of the connection methods require that you provide a host name, port number, a timeout period for synchronous operations and any additional options.

If the protocol requires that you authenticate the client in order to use the service, your application needs to provide this information. Once the client has been authenticated, it can then perform one or more operations, such as downloading a file, sending an email message and so on.

After you have finished, you disconnect from the server. Finally, before your program terminates, you uninitialize the class instance which causes it to perform any necessary housekeeping prior to releasing any system resources which were allocated on behalf of your program.

Class Initialization

When you begin developing your application using SocketTools .NET, the first thing that must happen is the class instance must be initialized. The initialization method serves two purposes. It loads the networking libraries required to establish a connection and it validates the runtime license key that you provide. The runtime license key is a string of characters which identifies your license to use and redistribute SocketTools. It is unique to your product serial number and must be used when redistributing your application to an end-user.

Creating an instance of the class with your runtime license key can be accomplished in one of two ways, depending on personal preferences and the design of your application. The simplest approach, and one familiar to developers who have used the SocketTools ActiveX control, is to explicitly call the Initialize method in your code. The other more advanced approach is to define the RuntimeLicense attribute for the assembly that is referencing the class. This attribute is set in the AssemblyInfo.vb or AssemblyInfo.cs module that is part of the project. For more information on specific usage, refer to the Technical Reference.

Developers who are evaluating SocketTools will not have a runtime license key and must pass an empty string to the **Initialize** method. This will enable that instance of the class to load on the development system during the evaluation period, but will prevent component from being redistributed to an end-user until a license has been purchased.

If you install the product with a serial number, the runtime license key will be automatically created for you during the installation process. If you have installed an evaluation copy of SocketTools and then purchased a license, the license key can be created using the License Manager utility that was included with the product. Simply select the License | Header File menu option and select the programming language that you are using.

The runtime license key is normally stored in the Include folder where you installed SocketTools and is defined in a file named SocketToolsLicense which can be included with your application. For example, C# programmers would use the SocketToolsLicense.cs header file while Visual Basic programmers would use the SocketToolsLicense.vb module. The Visual Basic module would define the runtime license key as:

```
'
' SocketTools 10.0
' Copyright 2023 Catalyst Development Corporation
' All rights reserved
'
' This file is licensed to you pursuant to the terms of the
' product license agreement included with the original software
' and is protected by copyright law and international treaties.
'
Public Const SocketToolsLicenseKey As String = ""
```

This could either be included with your Visual Basic.NET application or you could simply copy the string into your application. The class could then be initialized like this:

```
'
' Initialize the control using the specified runtime license key;
' if the key is not specified, the development license will be used
'
If Socket.Initialize(SocketToolsLicenseKey) = False Then
    MsgBox("Unable to initialize SocketTools component")
End If
```

A return value of **true** indicates that the class was initialized successfully. A return value of **false** indicates that the class could not be initialized with the specified runtime license key. The **LastError** property will contain the error code that indicates the exact cause of the error.

An application is only required to call the Initialize method once, but it must be called for each instance of the class that is created. It is safe to call the initialization method more than once, but for each time that it is called, you must call the Uninitialize method for that class before your program terminates. In other words, if you called Initialize at the beginning of your program, you must call Uninitialize before your program ends. The Uninitialize method performs any necessary housekeeping operations, such as returning memory allocated for the class back to the operating system. If there are any open connections at the time that the Uninitialize method is called, they will be aborted. After the class has been uninitialized, you must call the Initialize method again before setting any properties or calling any methods in that instance of the class.

Secure Connections

The SocketTools .NET Edition supports the ability to create secure connections using the standard SSL and TLS protocols. In most cases, it is as simple as setting the **Secure** property to **true** or specifying an additional option when the **Connect** method is called. In some cases, certain Internet application protocols have additional requirements in terms of how the secure connection is established . Secure connections may either be implicit or explicit, depending on the protocol. An implicit secure connection is one where the client and server begin negotiating the security options as soon as the connection is established. In most cases, a server which accepts secure implicit connections listens on a port number that is different from the default port it uses for standard, non-secure connections. An example of this is the Hypertext Transfer Protocol (HTTP) which accepts standard connections on port 80 and secure connections on port 443. When a client connects to port 443, the server automatically assumes that the client wants a secure connection.

On the other hand, an explicit connection requires that the client explicitly specify to the server that it wants a secure connection. Typically this is done by the client sending a command to the server that causes the server to begin negotiating with the client to establish a secure session. An example of this is the File Transfer Protocol (FTP), where the client can use the AUTH command to tell the server that it wants a secure connection. Servers may also support both explicit and implicit secure connections, based on which port the client connects to. SocketTools supports both implicit and explicit secure connections. If the **Secure** property is set to **true** prior to calling the **Connect** method, then an implicit secure connection is established. Setting the **Secure** property to **true** after a connection has been established will cause SocketTools to begin negotiating a secure connection at that time.

In addition to establishing a secure connection, you may also be required to provide additional authentication information to the server in form a client certificate. For example, a server may require that the client provide a certificate in addition to or instead of a username and password. To support this, your application must specify the security credentials for the client prior to establishing a connection. For more information, refer to the **CertificateStore** and **CertificateName** properties in the Technical Reference.

Network Input/Output

Each of the SocketTools networking classes provides methods for exchanging data between your application and the server. At the lowest level, this is done by calling the Write method for sending data and the Read method for receiving data. In most cases, these methods exchange data as a stream of bytes without any regard for the actual content. It is important to note that if the data being read or written is binary, it is recommended that applications pass byte arrays, not strings, to the Read and Write methods if possible.

When working at this very low level, it is important to understand how data is exchanged over the network. Many developers are inclined to think of the data that is sent or received in terms of discrete blocks, or packets. The expectation is that if they send a certain number of bytes of data in a single write, the server will receive that number of bytes in a single read. However, this is not how TCP works, and by extension, not how the SocketTools libraries work with regards to this kind of low level network I/O. The Transmission Control Protocol (TCP) is called a stream-oriented protocol because data is exchanged between the client and server as a stream of bytes. While TCP will guarantee that the data will arrive intact, with the bytes received in the same order that they were written, there is no guarantee that the amount of data received in a single read operation on the socket will match the amount of data written by the server.

For example, consider a server that sends data to a client in four separate operations, each containing 1024 bytes of data. While it is convenient to think of these as discrete blocks of data, TCP considers it to be a stream of 4096 bytes. The client may receive that data in a single read on the socket, returning all 4096 bytes. Alternatively, it may read the socket, and only receive the first 1460 bytes; subsequent reads may return another 1460 bytes, followed by the remaining 1176 bytes. Applications which make assumptions about the amount of data they can read or write in a single operation may work in some environments, such as on a local network, but fail on slower connections.

A general rule to use when designing an application using TCP is to consider how the program would handle the situation where reading n bytes of data only returns a single byte. If the application can correctly handle this kind of extreme case, then it should function correctly even under adverse network conditions.

In some situations it may be desirable to design the application to exchange information as discrete messages or blocks of data. While this isn't directly supported by TCP, it can be implemented on top of the data stream. There are several methods that can be used to accomplish this, depending on the requirements of the application:

1. Exchange the data as fixed length structures. This is the simplest approach, and has very little or no overhead. The client and server can either use predefined values, or negotiate the size of the data structures when the connection is established.
2. Prefix variable-length data structures with the number of bytes being sent. The length value could be expressed either as a native integer value, or as a fixed-length string that is converted to a numeric value by the application. This allows the receiver to read this fixed length value, and then use that value to determine how many additional bytes must be read to obtain the complete message or data structure.
3. Prefix the data with a unique byte or byte sequence that would normally not be found in the data stream. This would be followed by the data itself, with a complete message received when another unique byte sequence is encountered. Alternatively, a unique byte sequence could be used to terminate a message. This is the approach that many Internet application protocols use, such as FTP, SMTP and POP3. Commands are sent as one or more printable characters, terminated with a carriage-return (CR) and linefeed (LF) byte sequence that tells the server that a complete command has been received.
4. A combination of the above methods, using unique byte sequences, the message length

and even additional information such as a CRC-32 checksum or MD5 hash to validate the integrity of the data. This would effectively create an "envelope" around the data being exchanged, and additional checks could be made to ensure that the data has been received and processed correctly.

Regardless of the method used, for best performance it is recommended that the application buffer the data received and then process the data out of that buffer. When using asynchronous (non-blocking) connections, the application should read all of the data available on the socket, typically in a loop which adds the data to the buffer and exiting the loop when there is no more data available at that time.

It is important to keep in mind that all of this is only required if you decide to use the lower level methods in the SocketTools controls. The higher level methods automatically handle the lower level network I/O for you. For example, the GetData method in the File Transfer Protocol control will retrieve a file from the server and return the entire contents to your application in a single method call. When using the high level methods, the details of how the data is read and processed is handled by the control and no additional coding is required on your part.

Event Handling

Event notification provides a mechanism for SocketTools to inform the application of a change in the status of the current session. Events are generally divided into two general categories, asynchronous network events and status events.

Asynchronous network events occur when a non-blocking connection is established and a network event occurs, such as a connection completing or data arriving from the server. Status events are used to indicate a change in status, such as a blocking operation being canceled or the progress of an operation such as reading a stream of bytes from the socket and storing it in a file. Note that asynchronous network events require that the **Blocking** property be set to **false**. The following events can be generated when SocketTools is in non-blocking mode:

OnConnect

This event is generated whenever a connection to a server has completed. Unlike a blocking connection, when the component is in non-blocking mode, a successful call to the **Connect** method does not indicate that you are actually connected to the host. Instead, it means that the connection process has been started. Your application will not actually be connected until the **OnConnect** event fires.

OnDisconnect

This event is generated whenever the server closes its socket and terminates the connection with your application. Note that this event will not fire when you disconnect from the host by calling the **Disconnect** method; it only fires when the server closes its connection to you. It is also important to keep in mind that although the server has disconnected from you, there still may be data buffered on your local system, waiting to be read. If you are performing any low-level network I/O, your program should continue to call the **Read** method until it returns a value of zero, indicating that all of the available data has been read.

OnRead

This event is generated whenever the server sends data to your application. Once this event has fired, it will not be triggered again until you read at least one byte of data that has been sent to you. It is recommended that you attempt to read and buffer all of the data that is available to be read in the socket. When the **Read** method returns a value less than or equal to zero, you should exit the event handler.

OnWrite

This event is generated whenever there is enough memory available in the local send buffers to accommodate some data. It is generated immediately after a connection has completed, which tells your application that it may begin sending data to the server. It will also be generated if a call to the **Write** method fails with the error that it would cause the thread to block. In this case, when the socket is able to accept more data, the **OnWrite** event will fire.

An important consideration when it comes to event handling is that all asynchronous network events are level triggered. This means that once an event is fired, it will not be fired again until some action is taken by the application to handle the event. This is most commonly found with **OnRead** events, which are generated when the server sends data to your application, signaling to you that there is data available to be read. Even though the server may continue sending you more data, another **OnRead** event will not be generated until you read at least one byte of the data that has been sent to you. This is done to prevent the application from being flooded with event notifications. However, failure to handle an event can cause event notification to appear to stall. It is recommended that you do not do excessive processing in an event handler that would cause the thread to block or enter a message loop. This can have a significant negative effect on performance and can lead to unexpected behavior on the part of your application. Instead, it's recommended that you buffer the data that you receive and then process that data after exiting the event handler.

Status related events are different because they do not depend on the value of the **Blocking** property, and are not directly related to asynchronous network operations. The most typical status event is the **OnProgress** event, which is used to provide information to the application about the status of a blocking operation, such as downloading a file from the server using the **GetFile** method. The possible status events are:

OnCancel

This event is used by the class to indicate that a blocking network operation has been canceled by a call to the **Cancel** method. It is important to note that when the **Cancel** method is called, the blocking socket operation will not immediately fail. An internal flag is set which causes the blocking operation to exit with an error. This means that the application cannot cancel an operation and immediately perform some other blocking function. Instead it must allow the calling stack to unwind, returning back to the blocking operation before making any further function calls. The **OnCancel** event handler should only be used for notification purposes or updating the internal state of the application. It is not recommended that you perform any network operations inside this event handler.

OnError

This event is used by the class to indicate an error has occurred. This event is only generated when a method is called, never as the result of setting a property value. The **OnError** event handler should only be used for notification purposes or updating the internal state of the application. It is not recommended that you perform any network operations inside this event handler.

OnProgress

This event is used by the class to inform the application of the progress of a blocking operation, such as a file transfer. Note that in some cases, the class may not be able to determine the total amount of data to be transferred, which would prevent a percentage from being calculated. In this case, because the server is unable to specify the total size of the resource, the class will not be able to calculate a percentage. Instead, it will simply inform the program of the amount of data copied to the local host up to that point.

OnTimeout

This event is used by the class to indicate a blocking operation has timed-out. A timeout period is specified by setting the **Timeout** property to a value greater than zero. The **OnTimeout** event handler should only be used for notification purposes or updating the internal state of the application. It is not recommended that you perform any network operations inside this event handler.

Status events are typically used to update a user interface. For example, the **OnProgress** event may be used to update a **ProgressBar** control, or a warning message may be displayed if an **OnError** event occurs.

Error Handling

Error conditions can occur in one of two general circumstances, either when setting a property in the control or when calling a method. If the error occurs when setting a property, an exception will be generated which must be caught and handled by the application. Failure to do this will typically result in the program displaying an error message and then terminating. For example, in Visual Basic.NET, the Try..Catch statements can be used to establish an error handler.

Methods are a bit different in that errors can be handled in one of two ways. By default, when a method is called it will return a value that indicates success or failure. For those methods that return boolean values, a value of **true** indicates success and a value of **false** indicates failure. For methods that return numeric values, such as the **Read** and **Write** methods, a return value of zero or greater indicates success, and a return value of -1 indicates failure.

If you prefer to handle exceptions, rather than check return values for each method call, SocketTools has a property called **ThrowError**. If this property is set to **true**, when a method fails it will throw an exception that must be caught by the application. In that case, if an error occurs without there being an exception handler in place, the application will typically terminate. The **ErrorCode** property of the exception class will specify the error that generated the exception. Refer to the Technical Reference for more information about the exception class specific to the class library being used.

To determine the error code for the last error generated by that instance of the class, use the **LastError** property. To display a description of the error to the user, the **LastErrorString** property will can be used. This returns a string that describes the error which corresponds to the value of the **LastError** property. It is permitted to set the **LastError** property to a value of zero in order to clear the last error code. It is important to note that the last error code only has meaning if the previous method call indicates the operation has failed. If the previous operation was successful, the value of the last error code will be undefined and should not be used.

Debugging Facilities

The SocketTools .NET class includes a built-in facility for generating debugging output in the form of a log file that provides information about the internal functions that it is using and the data that is being exchanged between the client and server. This is commonly referred to in the documentation as generating a trace log or enabling function logging.

To provide logging functionality for your application, you must redistribute the **SocketTools10.TraceLog.dll** library along with the the class library. This library is what performs the actual logging and must be placed in the same folder where your application is installed. Note that you cannot add this library as a reference to your project. It is used internally by SocketTools and cannot be used directly by your program.

To create a trace log, your application must set the **TraceFile** property to the name of a file, the **TraceFlags** property to the level of logging desired and then set the **Trace** property to **true**. The default level of logging, zero, specifies that general information about the function calls being made will be logged. The most detailed logging is provided by specifying a level of four. In that case, all data exchanged between your application and the server is logged. This provides the most information, however it also generates the largest log files. To disable logging, set the **Trace** property to false.

There are two important things that you need to consider when enabling trace logging. The first is that the log file is always appended to, never overwritten by the control. This means that the files can grow to be very large, particularly with trace that includes all of the data sent and received by your application. You can use the standard file I/O functions in your language to manage the log file or even write your own data out to the file. Each time the file is written to, SocketTools will open the file, append the logging data and then close the file; it will never keep the file open between operations. This is important because if your application terminates abnormally, it ensures all of the logging data has been written and there are no open file handles being held by that instance of the class. However, this does incur additional overhead and can impact the performance of your application. When possible, it is recommended that you enable logging around the code that you feel may be part of the problem you're trying to resolve, and then disable logging when it is no longer required. Simply enabling logging at the beginning of your application can result in unnecessarily large log files.

If your application uses multiple instances of the class, it is only necessary to enable logging in one of them. Once enabled, all network operations in the current thread will be logged, regardless of which instance has enabled logging.

SocketTools Class Overview

The SocketTools .NET Edition includes components that implement fourteen standard Internet application protocols, as well as components which provide support for general TCP/IP networking services, encoding and compressing files, processing email messages and ANSI terminal emulation. The following classes are included in the SocketTools .NET Edition:

SocketTools.DnsClient Class
The Domain Name Service (DNS) protocol is what applications use to resolve domain names into Internet addresses, as well as provide other information about a domain, such as the name of the mail servers which are responsible for receiving email for users in that domain. This class enables an application to query one or more nameservers directly, without depending on the configuration of the client system.

SocketTools.FileEncoder Class
The File Encoding class provides methods for encoding and decoding binary files, typically attachments to email messages. The process of encoding converts the contents of a binary file to printable text. Decoding reverses the process, converting a previously encoded text file back into a binary file. The class supports a number of different encoding methods, including support for the base64, uucode, quoted-printable and yEnc algorithms. The class can also be used to compress and expand data in a user-supplied buffer or in a file.

SocketTools.FtpClient Class
The File Transfer Protocol (FTP) class provides methods for uploading and downloading files from a server, as well as a variety of remote file management methods. In addition to file transfers, an application can create, rename and delete files and directories, list files and search for files using wildcards. The class provides both high level methods, such as the ability to transfer multiple files in a single method call, as well as access to lower level remote file I/O methods.

SocketTools.FtpServer Class
The File Transfer Server class provides an interface for implementing an embedded, lightweight server that can be used to exchange files with a client using the standard File Transfer Protocol. The server can accept connections from any third-party application or a program developed using the SocketTools.FtpClient class. The server supports active and passive mode file transfers, has compatibility options for NAT router and firewall support, and provides support for secure file transfers using explicit SSL/TLS sessions. Secure connections require that a valid SSL certificate be installed on the system.

SocketTools.HttpClient Class
The Hypertext Transfer Protocol (HTTP) class provides an interface for accessing documents and other types of files on a server. In some ways it is similar to the File Transfer Protocol in that it can be used to upload and download files; however, the protocol has expanded to also support remote file management, script execution and distributed authoring over the World Wide Web. The SocketTools Hypertext Transfer Protocol class implements version 0.9, 1.0 and 1.1 of the protocol, including features such as support for proxy servers, persistent connections, user-defined header fields and chunked data.

SocketTools.HttpServer Class
The Hypertext Transfer Server class provides an interface for implementing an embedded, lightweight server that can be used to provide access to documents and other resources using the Hypertext Transfer Protocol. The server can accept connections from any standard web browser, third-party applications or programs developed using the SocketTools.HttpClient class. The server includes support for CGI scripting, virtual hosting, client authentication and the creation of virtual directories and files. The server also supports secure connections using SSL/TLS. Secure connections require that a valid SSL certificate be installed on the system.

SocketTools.IcmpClient Class
The Internet Control Message Protocol (ICMP) is commonly used to determine if a server is reachable and

how packets of data are routed to that system. Users are most familiar with this protocol as it is implemented in the ping and tracert command line utilities. The ping command is used to check if a system is reachable and the amount of time that it takes for a packet of data to make a round trip from the local system, to the server and then back again. The tracert command is used to trace the route that a packet of data takes from the local system to the server, and can be used to identify potential problems with overall throughput and latency. The class can be used to build in this type of functionality in your own applications, giving you the ability to send and receive ICMP echo datagrams in order to perform your own analysis.

SocketTools.ImapClient Class

The Internet Message Access Protocol (IMAP) is an application protocol which is used to access a user's email messages which are stored on a mail server. However, unlike the Post Office Protocol (POP) where messages are downloaded and processed on the local system, the messages on an IMAP server are retained on the server and processed remotely. This is ideal for users who need access to a centralized store of messages or have limited bandwidth. For example, traveling salesmen who have notebook computers or mobile users on a wireless network would be ideal candidates for using IMAP. The SocketTools IMAP class implements the current standard for this protocol, and provides methods to retrieve messages, or just certain parts of a message, create and manage mailboxes, search for specific messages based on certain criteria and so on. The interface is designed as a superset of the Post Office Protocol interface, so developers who are used to working with the POP3 class will find the IMAP class very easy to integrate into an existing application.

SocketTools.InternetServer Class

The Internet Server ActiveX control provides a simplified interface for creating event-driven, multithreaded server applications using the TCP/IP protocol. The control interface is similar to the SocketWrench ActiveX control, however it is designed specifically to make it easier to implement a server application without requiring the need to manage multiple socket controls. In addition, the Internet Server control supports secure communications using the Secure Sockets Layer (SSL) and Transport Layer Security (TLS) protocols.

SocketTools.MailMessage Class

The Mail Message class provides an interface for composing and processing email messages and newsgroup articles which are structured according to the Multipurpose Internet Mail Extensions (MIME) standard. Using this class, an application can easily create complex messages which include multiple alternative content types, such as plain text and styled HTML text, file attachments and customized headers. It is not required that the developer understand the complex MIME standard; a single method call can be used to create multipart message, complete with a styled HTML text body and support for international character sets. The Mail Message class can be easily integrated with the other mail related protocol libraries, making it extremely easy to create and process MIME formatted messages.

SocketTools.NntpClient Class

The Network News Transfer Protocol (NNTP) is used with servers that provide news services. This is similar in functionality to bulletin boards or message boards, where topics are organized hierarchically into groups, called newsgroups. Users can browse and search for messages, called news articles, which have been posted by other users. On many servers, they can also post their own articles which can be read by others. The largest collection of public newsgroups available is called USENET, a world-wide distributed discussion system. In addition, there are a large number of smaller news servers. For example, Microsoft operates a news server which functions as a forum for technical questions and announcements. The class provides a comprehensive interface for accessing newsgroups, retrieving articles and posting new articles. In combination with the Mail Message class to process the news articles, SocketTools can be used to integrate newsgroup access with an existing email application, or you can implement your own full-featured newsgroup client.

SocketTools.NetworkTime Class

The NetworkTime class provides an interface for synchronizing the local system's time and date with that of a server. The class enables developers to query a server for the current time and then update the system clock if desired.

SocketTools.PopClient Class

The Post Office Protocol (POP) provides access to a user's new email messages on a mail server. Methods are provided for listing available messages and then retrieving those messages, storing them either in files or in memory. Once a user's messages have been downloaded to the local system, they are typically removed from the server. This is the most popular email protocol used by Internet Service Providers (ISPs) and the class provides a complete interface for managing a user's mailbox. This class is typically used in conjunction with the Mail Message class, which is used to process the messages that are retrieved from the server.

SocketTools.InternetDialer Class

The Remote Access Services (RAS) class enables an application to connect to an Internet Service Provider (ISP) using a standard Dial-Up Networking connection. Using this class, the application can discover what dial-up devices are available, what dial-up networking entries, known as "connectoids", are available on the local system and allows the program to manage those connections. Existing connections can be monitored, new connections created and a single class can be used to manage multiple dial-up connections if the system has more than one modem. While Windows can be configured to simply autodial a service provider whenever a network connection is needed, this component gives your application complete control over the process of connecting to a service provider, monitoring that connection and then terminating that connection if needed.

SocketTools.RshClient Class

The Remote Command protocol is used to execute a command on a server and return the output of that command to the client. The class provides an interface to this protocol, enabling applications to remotely execute a command and process the output. This is most commonly used with UNIX based servers, although there are implementations of remote command servers for the Windows operating system. The class supports both the rcmd and rshell remote execution protocols and provides methods which can be used to search the data stream for specific sequences of characters. This makes it extremely easy to write Windows applications which serve as light-weight client interfaces to commands being executed on a UNIX server or another Windows system. The class can also be used to establish a remote terminal session using the rlogin protocol, which is similar to how the Telnet protocol methods.

SocketTools.SshClient Class

The Secure Shell (SSH) protocol is used to establish a secure connection with a server which provides a virtual terminal session for a user. Its functionality is similar to how character based consoles and serial terminals work, enabling a user to login to the server, execute commands and interact with applications running on the server. The SSH control provides an interface for establishing the connection and handling the standard I/O functions needed by the program. The control also provides methods that enable a program to easily scan the data stream for specific sequences of characters, making it very simple to write light-weight client interfaces to applications running on the server.

SocketTools.SmtpClient Class

The Simple Mail Transfer Protocol (SMTP) enables applications to deliver email messages to one or more recipients. The class provides an interface for addressing and delivering messages, and extended features such as user authentication and delivery status notification. Unlike Microsoft's Messaging API (MAPI) or Collaboration Data Objects (CDO), there is no requirement to have certain third-party email applications installed or specific types of servers installed on the local system. The class can be used to deliver mail through a wide variety of systems, from standard UNIX based mail servers to Windows systems running Exchange or Lotus Notes and Domino. Using this class, messages can be delivered directly to the recipient, or they can be routed through a relay server, such as an Internet Service Provider's mail system. The Mail Message class can be integrated with this class in order to provide an extremely simple, yet flexible interface for composing and delivering mail messages.

SocketTools.SocketWrench Class

The SocketWrench class provides a higher-level interface to the Windows Sockets API, designed to be suitable for programming languages other than C and C++. In addition, SocketWrench supports secure communications using the Secure Sockets Layer (SSL) and Transport Layer Security (TLS) protocols.

SocketTools.TelnetClient Class

The Telnet protocol is used to establish a connection with a server which provides a virtual terminal session for a user. Its functionality is similar to how character based consoles and serial terminals work, enabling a user to login to the server, execute commands and interact with applications running on the server. The class provides an interface for establishing the connection, negotiating certain options (such as whether characters will be echoed back to the client) and handling the standard I/O functions needed by the program. The class also provides methods that enable a program to easily scan the data stream for specific sequences of characters, making it very simple to write light-weight client interfaces to applications running on the server. This class can be combined with the Terminal Emulation control to provide complete terminal emulation services for a standard ANSI or DEC-VT220 terminal.

SocketTools.Terminal Class

The Terminal Emulation control provides a comprehensive interface for emulating an ANSI or DEC-VT220 character terminal, with full support for all standard escape and control sequences, color mapping and other advanced features. The class methods provide both a high level interface for parsing escape sequences and updating a display, as well as lower level primitives for directly managing the virtual display, such as controlling the individual display cells, moving the cursor position and specifying display attributes. This control can be used in conjunction with the Remote Command or Telnet Protocol class to provide terminal emulation services for an application, or it can be used independently. For example, this control could also be used to provide emulation services for a program that provides serial modem connections to a server.

SocketTools.WebLocation Class

The WebLocation class provides your application with geographical information about the physical location of the computer system based on its external IP address. This can enable developers to know where their application is being used, and provide convenience functionality such as automatically completing a form based on the location of the user.

SocketTools.WebStorage Class

The WebStorage class provides private cloud storage for uploading and downloading shared data files which are available to your application. This is primarily intended for use by developers to store configuration information and other data generated by the application. For example, you may want to store certain application settings, and the next time a user or organization installs your software, those settings can be downloaded and restore.

SocketTools.WhoisClient Class

The Whois protocol provides a mechanism for requesting information about an Internet domain name. When a domain name is registered, the organization that registers the domain must provide certain contact information along with technical information such as the primary name servers for that domain. The Whois protocol enables an application to query a server which provides that registration information. The class provides an interface for requesting that information and returning it to the program so that it can be displayed or processed.

Domain Name Services

The Domain Name Service (DNS) protocol is what applications use to resolve domain names into Internet addresses, as well as provide other information about a domain, such as the name of the mail servers which are responsible for receiving email for users in that domain. All of the SocketTools components provide basic domain name resolution functionality, but the Domain Name Services class gives an application direct control over what servers are queried, the amount of time spent waiting for a response and the type of information that is returned.

Initialization

Initialize

Initialize an instance of the class, loading the networking library and validating the development license. This method must be called before any properties are changed or any other methods in this class are called by the application.

Reset

Reset the internal state of the class and re-initialize the component to use the default nameserver configuration for the local host. This can be useful if your application wishes to discard any settings made by a user and return to using the local system configuration.

Uninitialize

Unload the networking library and release any resources that have been allocated for the class instance. This method is automatically invoked when the class instance is disposed or goes out of scope.

Host Tables

When resolving a host name or IP address, the class will first search the local system's host table, a file that is used to map host names to addresses. The hosts file is found in C:\Windows\system32\drivers\etc\hosts. Note that the file does not have an extension.

HostFile

Return the full path of the file that contains the default host table for the local system. This can be useful if you wish to temporarily switch between the default host file and another host file specific to your application.

Host Name Resolution

The class can be used to resolve host names into IP addresses, as well as perform reverse DNS lookups converting IP addresses into the host names that are assigned to them. The class will search the local system's host table first, and then perform a nameserver query if required.

HostAddress

A property which returns the IP address of the host name specified in the HostName property. Setting this property to an IP address will cause the class to perform a reverse DNS lookup to attempt to determine the name of the host that was assigned that address. If successful, the host name for the specified IP address can be determined by reading the value of the HostName property.

HostName

A property which returns the name of the host associated with the IP address specified in the HostAddress property. Setting this property to a host name will cause the class to perform a DNS lookup to determine the IP address of that host. If successful, the IP address for the host can be determined by reading the value of the HostAddress property.

Resolve

A method which resolves a host name into an IP address, returned as a string in dotted notation. The class first checks the system's local host table, and if the name is not found there, it will perform a nameserver query for the A (address) record for that host.

Query
Perform a general nameserver query for a specific record type. This method can be used to perform queries for the common record types such as A and PTR records, as well as for other record types such as TXT (text) records. Refer to the Technical Reference for more information about the specific types of records that can be returned.

Mail Exchange Records

When a system needs to deliver a mail message to someone, it needs to determine what server is responsible for accepting mail for that user. This is done by looking up the mail exchange (MX) record for the domain. For example, if a message was addressed to joe@example.com, to determine the name of the mail server that would accept mail for that recipient, you would perform an MX record query against the domain example.com. A domain may have more than one mail server, in which case multiple MX records will be returned.

MailExchange
A property array which returns the mail exchanges for the domain specified in the HostName property. This is a zero-based array, with the maximum number of entries returned by the MailExchanges property

Advanced Properties

In addition to providing host name and IP address resolution, the class can be used to perform advanced queries for other types of records.

HostInfo
Return additional information about the specified host name. If the name server has been configured to provide host information for the domain, this method will return that data. Typically it is used to indicate what hardware and operating system the host uses.

HostServices
Return information about the UDP and TCP based services that the host provides. If defined, this will return a list of service names such as "ftp" and "http". Note that your application should not depend on this information to be a definitive list of what services a server provides.

NameServer
A property array which can be used to return the current nameservers that are configured for the local host, or the values can be changed to specify new nameservers. The maximum number of nameservers that can be configured for each instance of the class is four.

File Encoding

A common requirement for applications which use Internet protocols is the need to encode binary files, as well as compress data to reduce the bandwidth and time required to send or receive the data. Encoding a binary file converts the contents of the file into printable characters which can be safely transferred over the Internet using protocols that only support a subset of 7-bit ASCII characters. This is commonly a restriction for email, since many mail servers still are not capable of correctly processing messages which contain control characters, 8-bit data or multi-byte character sequences found in International text. To address this problem, the sender encodes and sends the data as part of a message; the recipient then extracts and decodes the data, with the end result being the same as the original, without any potential corruption by the mail servers which store and/or forward the message. The File Encoding class supports several encoding and decoding methods, including standard base64 encoding, quoted-printable encoding and uuencoding. For applications which access USENET newsgroup, the class also supports the newer yEnc encoding method which has become a popular method for attaching binary files to a message.

In addition to encoding and decoding files, the File Encoding class also can be used to compress files, reducing their overall size. Two compression algorithms are supported, the standard deflate algorithm which is commonly used in Zip files, and an algorithm based on the Burrows-Wheeler Transform (BWT) which can offer improved compression over the deflate algorithm for some types of files. The developer has control over the type of compression performed, as well as details such as the level of compression which determines how much memory and CPU time is allocated to compress the data. Developers can even create their own custom compression formats by creating an application-specific header block, typically represented by a structure or user-defined type that can be used to provide information to the program.

Note that if you are interested in using this class for purposes of attaching files to an email message, it is not necessary that you use these methods. The Mail Message class has the ability to automatically encode and decode file attachments without requiring that you use the methods in this control. However, the File Encoding class is useful if you need the ability to encode and/or compress for other applications.

Encoding Types

There are several different encoding types available, with the default being the standard MIME encoding called Base64. The following encoding methods are supported by the class:

Base64
Base64 encoding works by representing three bytes of data as four printable characters. Each of the three bytes is converted into four six-bit numbers, and each six-bit number is converted to one of 64 printable characters (which is where the encoding method gets its name). Base64 is the default encoding method used by the control and is the standard encoding used for MIME formatted email messages as well as many other applications.

Quoted-Printable
Quoted-printable encoding is primarily used in email messages, and is best used when the data being encoded is text which consists primarily of printable characters. Only characters with the high-bit set or a certain subset of printable characters are actually encoded by representing them as their hexadecimal value. All other printable characters are passed through unmodified.

Uucode
One of the original encoding methods used for email, it gets its name from two UNIX command-line utilities called uuencode and uudecode, which were used to encode and decode files. Like Base64, uuencoding converts three bytes of data into four six-bit numbers, and then a value of 32 is added to ensure that it is printable. Uuencoding also adds some additional characters which are used to ensure the integrity of the encoded data. This encoding method is still used when posting files to USENET

newsgroups, but has largely been replaced by Base64 when attaching files to email messages.

yEnc
yEnc is a relatively new encoding method that was created specifically for binary newsgroups on USENET. Because USENET doesn't have the same limitations as email systems in terms of what kind of characters can be safely used, yEnc only encodes null characters and certain control characters; the remaining 8-bit data is passed through as is which can significantly reduce the overall size of the encoded data. yEnc also uses checksums to ensure the integrity of the data and is designed so that a large file can be split across multiple messages and then recreated.

Data Encoding

Encoding a binary file converts the contents of the file into printable characters which can be safely transferred over the Internet using protocols that only support a subset of 7-bit ASCII characters. This is commonly a restriction for email, since many mail servers still are not capable of correctly processing messages which contain control characters, 8-bit data or multi-byte character sequences found in International text. To address this problem, the sender encodes and sends the data as part of a message; the recipient then extracts and decodes the data, with the end result being the same as the original, without any potential corruption by the mail servers which store and/or forward the message.

EncodeFile
This method encodes a file using the specified encoding method, storing the encoded data in a new file. An option also allows you to automatically compress the data prior to encoding it in order to reduce the overall size of the encoded file.

DecodeFile
This method decodes a previously encoded file using the specified encoding method, restoring the original contents. If the encoded data was compressed, this method can also be used to automatically expand the data after it has been decoded.

Data Compression

In addition to encoding and decoding data, the control can be used to compress data in order to reduce its size. The compression methods may be used separately, or may be used as part of the process of encoding a file.

CompressFile
This method reduces the size of a file using the standard Deflate algorithm. This is the same algorithm that is commonly used in Zip archives. Note however, that this does not create a Zip file, it simply uses the same compression method.

ExpandFile
This method restores the original contents of a file that was previously compressed using the CompressFile method. Note that this method is not designed to extract files from a Zip archive or expand data compressed using a different algorithm.

Note that there are advanced options for compressing files, such as the ability to specify the compression type and level. Please refer to the Technical Reference for more information.

File Transfer Protocol

The File Transfer Protocol (FTP) is the most common application protocol used to upload and download files. In addition to basic file transfer capabilities, FTP also supports common file and directory management functions on the server, such as renaming and deleting files or creating new directories. The SocketTools .NET Edition also supports secure file transfers using SSH (SFTP) and SSL/TLS (FTPS) by simply specifying an option when establishing the connection.

Initialization

Initialize
Initialize an instance of the class, loading the networking library and validating the development license. This method must be called before any properties are changed or any other methods in this class are called by the application.

Connect
Connect to the server, using either a host name or IP address. The method has several options related to security as well as the general operation of the class. One important option is **FtpOptions.optionPassive**, which instructs the class to use passive mode file transfers. If the local system is behind a firewall or a route which uses Network Address Translation (NAT), it is often necessary to use this option. It is also possible to enable passive mode transfers by simply setting the Passive property prior to calling this method.

Login
Authenticate the client session, providing the server with a user name, password and optionally an account name. It is also possible to use an anonymous (unauthenticated) session by providing empty strings as the username and password. If the **UserName** and **Password** properties are set prior to connecting, the user will automatically be logged in. This method is only necessary if the application needs to access the server using different user accounts during the same session.

Disconnect
Disconnect from the server and release the memory allocated for that client session. After this method is called, the client session is no longer valid.

Reset
Reset the internal state of the component. This can be useful if your application wishes to discard any settings made by a user and return that instance of the class to its default state.

Uninitialize
Unload the networking library and release any resources that have been allocated for the class instance. This method is automatically invoked when the class instance is disposed or goes out of scope.

File Transfers

The class provides several methods which can be used to transfer files between the local and server. This group of methods are high level, meaning that it is not necessary to actually write the code to read and/or write the file data. The class automatically handles the lower level file I/O and notifies your application of the status of the transfer by periodically generating progress events.

GetData
This method transfers a file from the server to the local system, storing the file data in memory. This can be useful if your application needs to perform some operation based on the contents of the file, but does not need to store the file locally. The file data can returned in a string or byte array.

GetFile
This method transfers a file from the server and stores it in a file on the local system. This method is similar to how the GET command works for the command-line FTP client in Windows.

GetMultipleFiles

This method transfers multiple files from the server and stores them in a directory on the local system. A wildcard may be specified so that only files which a certain name or those that match a particular file extension are downloaded. This method is similar to how the MGET command works for the command-line FTP client in Windows.

PutData
This method creates a file on the server containing the data that you provide. This can be useful if your application wants to upload dynamically created content without having to create a temporary file on the local system. The data may be specified either as a string, or as the contents of a byte array.

PutFile
This method uploads a file from the local system to the server. This method is similar to how the PUT command works for the command-line FTP client in Windows.

PutMultipleFiles
This method transfers multiple files from the local system to a directory on the server. A wildcard may be specified so that only files with a certain name or those that match a particular file extension are uploaded. This method is similar to how the MPUT command works for the command-line FTP client in Windows.

File Management

In addition to performing file transfers, the File Transfer Protocol class can also perform many of the same kinds of file management methods on the server as you would on the local system.

DeleteFile
Delete a file from the server. This operation requires that the current user have the appropriate permissions to delete the file.

GetFileStatus
Return status information about the file in the form of a structure. This typically specifies the ownership, access permissions, size and modification time for the file. It is similar to opening a directory on the server and reading information about the file, but with less overhead.

GetFileSize
Return the size of a file on the server without actually downloading the contents of the file.

GetFileTime
Return the modification time for the specified file on the server. This can be used by you application to determine if the file has been changed since the time that you last uploaded or downloaded the contents.

RenameFile
Change the name of a file or move a file to a different directory. This operation requires that the current user have the appropriate permissions to rename the file. If the file is being moved to another directory, the user must have permission to access that directory.

SetFileTime
Update the modification time for a file on the server. This method requires that the current user have the appropriate permissions to change the last modification timestamp for the file. Note that this is not supported on all servers and in some cases may be restricted to specific accounts.

GetFilePermissions
Return the access permissions for a file on the server. This can be used to determine if a file can be read, modified and/or deleted by the current user. For users who are familiar with UNIX file permissions, it is the same type which is used by the class.

SetFilePermissions
Change the access permissions for a file. This method is supported on most UNIX based servers, as well as any other server that supports the site-specific CHMOD command.

Directory Management

The class also provides a set of methods which can be used to access and manage directories or folders, including the ability to list and search for files, create new directories and remove empty directories from the server.

ChangeDirectory
Change the current working directory on the server. This is similar to how the CD command is used from the command-line to change the current directory in Windows. If a path is not specified in the file name, the current working directory is where files will be uploaded to and downloaded from.

MakeDirectory
Create a new directory on the server. This requires that the current user have the appropriate access permissions in order to create the directory.

OpenDirectory
Open the specified directory on the server. This is the first step in returning a list of files in the directory. After the directory has been opened, information about the files it contains can be returned to the application. The directory path may also include wildcards to only return information about a certain subset of files based on the file name or extension.

GetFirstFile and GetNextFile
Return information about the next file in the directory that has been opened. This method is called repeatedly until it indicates that all of the files have been returned.

RemoveDirectory
Remove an empty directory from the server. This operation requires that the current user have the appropriate permissions to delete the directory. For safety, it is required that the directory does not contain any files or subdirectories or the operation will fail.

File Transfer Server

The File Transfer Server class provides an interface for implementing an embedded, lightweight server that can be used to exchange files with a client using the standard File Transfer Protocol. The server can accept connections from any third-party application or a program developed using SocketTools. The application specifies an initial server configuration by setting the relevant properties and can implement event handlers to monitor the activities of the clients that have connected to the server. The class automatically handles the standard FTP commands and requires minimal coding on the part of the application that is hosting the control. However, the application may also use event mechanism to filter specific commands or to extend the protocol by providing custom implementations of existing commands or add entirely new commands.

An important consideration when using this class is that events are raised in the context of the thread that manages the client session. The .NET Framework does not allow one thread to modify a control that was created in the main user interface thread, which means that you cannot update user interface controls directly from within the event handlers. If you want to change any property values or call methods in a control, you need to create a delegate and marshal the call to the user interface thread to using the control's Invoke method.

Initialization

Initialize
Initialize an instance of the class, loading the networking library and validating the development license. This method must be called before any properties are changed or any other methods in this class are called by the application.

Start
This method starts the server, creating the background thread and listening for incoming client connections on the specified port number. You can specify the local address, port number, backlog queue size and the maximum number of clients that can establish a connection with the server.

Restart
This method will terminate all active client connections, close the listening socket and re-create a new listening socket bound to the same address and port number.

Suspend
This method instructs the server to temporarily suspend accepting new client connections. Existing connections are unaffected, and any incoming client connections are rejected until the server is resumed. It is not recommended that you leave a server in a suspended state for an extended period of time.

Resume
This function instructs the server to resume accepting client connections after it was suspended. Any pending client connections are accepted after the server has resumed normal operation.

Throttle
This method is used to control the maximum number of clients that may connect to the server, the maximum number of clients that can connect from a single IP address and the rate at which the server will accept client connections. By default, there are no limits on the number of active client sessions and connections are accepted immediately. This method can be useful in preventing denial-of-service attacks where the the attacker attempts to flood the server with connection attempts.

Stop
This method will terminate all active client connections, close the listening socket and terminate the background thread that manages the server. Any incoming client connections will be refused, and all resources allocated for the server will be released.

Uninitialize

Unload the networking library and release any resources that have been allocated for the class instance. This method is automatically invoked when the class instance is disposed or goes out of scope.

Events

The application is informed of all client activity through event notifications. These events will tell your program when a client has connected, issued a command, uploaded or downloaded a file or disconnects from the server. Through the event mechanism it's also possible to implement your own custom commands.

OnConnect

This event occurs when the client first establishes a connection with the server. At this point, the client is in an unauthenticated state and may only issue a limited subset of commands before it submits user credentials for authentication. This event provides your application with the unique client ID that identifies the session and the remote IP address that the client has connected from.

OnAuthenticate

This event occurs when the client has submitted user credentials for authentication. The class supports several mechanisms for user authentication, including automatic local user authentication, the creation of one or more virtual users or custom authentication by implementing an event handler for this event. It is not necessary to implement a handler for this event if you choose to create virtual user accounts for your server instance because the server will automatically handle authentication for those users.

OnCommand

This event occurs for each command sent by the client, prior to the command being processed by the server. This event can be used by your application to monitor the commands that are being issued, or may create an event handler that filters certain commands or implements support for custom commands by processing the command in your own code.

OnResult

This event occurs after each command has been processed by the server. This event can be used by your application to monitor those commands which were successful and those which failed. For example, your application could use this event to track the actions of a client and terminate the session if the client is issuing a large number of commands that fail.

OnDownload

This notification event occurs after a file has been successfully downloaded by a client. It can be used for logging and monitoring purposes or to update your user interface with relevant information about the current client activity.

OnUpload

This notification event occurs after a file has been successfully uploaded by a client.

OnDisconnect

This event occurs after a client has disconnected from the server and the thread that manages the client session has released all of the resources allocated for that client.

Local Host Information

Several properties are provided to return information about the local host, including its fully qualified domain name and the IP addresses that are configured on the system.

ServerName

Return the fully qualified domain name of the local host, if it has been configured. If the system has not been configured with a domain name, then the machine name is returned instead.

ExternalAddress

Return the IP address assigned to the router that connects the local host to the Internet. This is typically used by an application executing on a system in a local network that uses a router which performs

Network Address Translation (NAT).

AdapterAddress
This property array returns the IP addresses that are associated with the local network or remote dial-up network adapters configured on the system. The AdapterCount property can be used to determine the number of adapters that are available.

Hypertext Transfer Protocol

The Hypertext Transfer Protocol (HTTP) is the most prevalent application protocol used on the Internet today. It was originally used for document retrieval, and has grown into a complex protocol which supports file uploading, script execution, file management and distributed web authoring through extensions such as WebDAV. The SocketTools Hypertext Transfer Protocol control implements version 0.9, 1.0 and 1.1 of the protocol, including features such as support for proxy servers, persistent connections, user-defined header fields and chunked data.

File Transfers

Similar to the interface used with the File Transfer Protocol control, you can use HTTP to upload and download files. In addition to the standard method for downloading files, the control supports two methods for uploading files, using either the PUT or the POST command. When downloading a file from the server, you can either store the contents in a local file, or you can copy the data into a memory buffer that you allocate. Similarly, when uploading files, you can either specify a local file to upload, or you can provide a memory buffer that contains the file data to send to the server. High level methods such as PutFile and GetFile can be used to transfer files in a single method call. There are also methods such as OpenFile and CreateFile which provide lower level file I/O interfaces.

Script Execution

Another common use for HTTP is to execute scripts on the web server. The application can pass additional data to the script, which is similar in concept to how arguments are passed to a command that is entered from the command prompt. This uses the standard POST command, and the resulting output from the script is returned back to the application where it can be displayed or processed. An application can use the Command method to execute the script and then process the output in code, or can use the higher level method PostData which will execute the script and return the output from that script in a single method call.

Uniform Resource Locators

Anyone who has used a web browser is familiar with the Uniform Resource Locator (URL); it is the value that is entered as the address of a website. URLs have a specific format which provides information about the server, the port number and the name of the resource that is being accessed:

```
http://[username : [password] @] remotehost [:remoteport] / resource [?
parameters]
```

The first part of the URL identifies the protocol, also known as the scheme, which will be used. With web servers, this will be either http or https for secure connections. If a username and password is required for authentication, then this will be included in the URL before the name of the server. Next, there is the name of the server to connect to, optionally followed by a port number. If no port number is given, then the default port for the protocol will be used. This is followed by the resource, which is usually a path to a file or script on the server. Parameters to the resource may also be specified, called the query string, which are typically used as arguments to a script that is executed on the server.

Understanding how a URL is constructed will help in understanding how the different methods in the control work together. For example, the server name and port number portion of the URL are the values passed to the Connect method to establish the connection. The user name and password values are assigned to the UserName and Password properties to authenticate the client session. And the resource name is passed to the GetData or GetFile methods to transfer it to the local system.

Initialization

Initialize

Initialize an instance of the class, loading the networking library and validating the development license. This method must be called before any properties are changed or any other methods in this class are called by the application.

Connect
Connect to the server, using either a host name or IP address. This method creates the client session and must be called before your application attempts to request a resource from the server.

Disconnect
Disconnect from the server and release the memory allocated for that client session. After this method is called, the client session is no longer valid.

Reset
Reset the internal state of the component. This can be useful if your application wishes to discard any settings made by a user and return that instance of the class to its default state.

Uninitialize
Unload the networking library and release any resources that have been allocated for the class instance. This method is automatically invoked when the class instance is disposed or goes out of scope.

File Transfers

Using an interface similar to the File Transfer Protocol control, this control provides several methods which can be used to transfer files between the local and server. This group of methods is high level, meaning that it is not necessary to actually write the code to read and/or write the file data. The control automatically handles the lower level file I/O and notifies your application of the status of the transfer by periodically generating progress events.

GetData
This method transfers a file from the server to the local system, storing the file data in memory. This can be useful if your application needs to perform some operation based on the contents of the file, but does not need to store the file locally.

GetFile
This method transfers a file from the server and stores it in a file on the local system.

PutData
This method creates a file on the server containing the data that you provide. This can be useful if your application wants to upload dynamically created content without having to create a temporary file on the local system.

PutFile
This method uploads a file from the local system to the server using the PUT command. Not all servers support this command, and some may require that the client authenticate prior to calling this method.

PostFile
This method uploads a file from the local system to the server using the POST command. This enables your application to upload a file in the same way that a user would when using a form in a web browser.

File Management

The control can also perform some basic file management methods as well as send custom commands to the server. Some web servers also provide more advanced document management methods using WebDAV, an extension to HTTP for distributed document authoring.

GetFileSize
Return the size of a file on the server without actually downloading the contents of the file. It is important to note that most servers will only return file size information for actual documents stored on the server, not for dynamically created content generated by scripts or web pages which use server-side includes.

GetFileTime
Return the modification time for the specified file on the server. This can be used by your application to determine if the file has been changed since the time that you last uploaded or downloaded the contents.

DeleteFile

Remove a file from the server. This operation requires that the current user have the appropriate permissions to delete the file. Not all servers support the use of this command, and it would typically require that the client authenticate prior to calling this method.

Command

This method enables the client to send any command directly to the server. This is commonly used to issue custom commands to servers that are configured to use extensions to the standard protocol.

Script Execution

The control also provides methods to execute scripts on the web server and return the output from those scripts back to your application. Your program can pass additional data to the script, typically either as a query string or as form data, which is similar in concept to how arguments are passed to a command that is entered from the command prompt.

GetData

In addition to being used to simply return the contents of a file, this method can also be used to execute a script on the server and return the output of that script to your program. Arguments to the script can be specified by passing them as a query string. For example, consider the following resource name:

```
/cgi-bin/test.cgi?data1=value1&data2=value2
```

This would specify that the script /cgi-bin/test.cgi will be executed, and two arguments will be passed to that script: data1=value and data2=value2. The ampersand is used to separate the arguments, and they are grouped as pairs of values separated by an equal sign. Note that the actual format and value of the query string depends on how the script is written.

PostData

An alternative method of providing information to a script is to post data to the script. Instead of the data being part of the resource name itself, posted data is sent separately and is provided as input to the script. This is the same method that is typically used when a user clicks the Submit button on a web-based form. This method requires the name of the script and the address of a buffer that contains the data that will be posted. The resulting output from the script is returned to the caller in the same way that the GetData method works.

Hypertext Transfer Server

The Hypertext Transfer Server class provides an interface for implementing an embedded, lightweight server that can be used to provide access to documents and other resources using the Hypertext Transfer Protocol. The application specifies an initial server configuration and then responds to events that are generated when the client sends a request to the server. An application may implement only minimal handlers for most events, in which case the default actions are performed for most standard HTTP commands. However, an application may also use the event mechanism to filter specific commands or to extend the protocol by providing custom implementations of existing commands or add entirely new commands.

An important consideration when using this class is that events are raised in the context of the thread that manages the client session. The .NET Framework does not allow one thread to modify a control that was created in the main user interface thread, which means that you cannot update user interface controls directly from within the event handlers. If you want to change any property values or call methods in a control, you need to create a delegate and marshal the call to the user interface thread to using the control's Invoke method.

Initialization

Initialize

Initialize an instance of the class, loading the networking library and validating the development license. This method must be called before any properties are changed or any other methods in this class are called by the application.

Start

This method starts the server, creating the background thread and listening for incoming client connections on the specified port number. You can specify the local address, port number, backlog queue size and the maximum number of clients that can establish a connection with the server.

Restart

This method will terminate all active client connections, close the listening socket and re-create a new listening socket bound to the same address and port number.

Suspend

This method instructs the server to temporarily suspend accepting new client connections. Existing connections are unaffected, and any incoming client connections are rejected until the server is resumed. It is not recommended that you leave a server in a suspended state for an extended period of time.

Resume

This function instructs the server to resume accepting client connections after it was suspended. Any pending client connections are accepted after the server has resumed normal operation.

Throttle

This method is used to control the maximum number of clients that may connect to the server, the maximum number of clients that can connect from a single IP address and the rate at which the server will accept client connections. By default, there are no limits on the number of active client sessions and connections are accepted immediately. This method can be useful in preventing denial-of-service attacks where the the attacker attempts to flood the server with connection attempts.

Stop

This method will terminate all active client connections, close the listening socket and terminate the background thread that manages the server. Any incoming client connections will be refused, and all resources allocated for the server will be released.

Uninitialize

Unload the networking library and release any resources that have been allocated for the class instance.

This method is automatically invoked when the class instance is disposed or goes out of scope.

Events

The application is informed of all client activity through event notifications. These events will tell your program when a client has connected, issued a command, uploaded or downloaded a file or disconnects from the server. Through the event mechanism it's also possible to implement your own custom commands.

OnConnect
This event occurs when the client first establishes a connection with the server. This event provides your application with the unique client ID that identifies the session and the remote IP address that the client has connected from.

OnAuthenticate
This event occurs when the client has submitted user credentials for authentication. The class supports several mechanisms for user authentication, including automatic local user authentication, the creation of one or more virtual users or custom authentication by implementing an event handler for this event. It is not necessary to implement a handler for this event if you choose to create virtual user accounts for your server instance because the server will automatically handle authentication for those users.

OnCommand
This event occurs for each command sent by the client, prior to the command being processed by the server. This event can be used by your application to monitor the commands that are being issued, or may create an event handler that filters certain commands or implements support for custom commands by processing the command in your own code.

OnResult
This event occurs after each command has been processed by the server. This event can be used by your application to monitor those commands which were successful and those which failed. For example, your application could use this event to track the actions of a client and terminate the session if the client is issuing a large number of commands that fail.

OnDownload
This notification event occurs after a file has been successfully downloaded by a client. It can be used for logging and monitoring purposes or to update your user interface with relevant information about the current client activity.

OnUpload
This notification event occurs after a file has been successfully uploaded by a client.

OnDisconnect
This event occurs after a client has disconnected from the server and the thread that manages the client session has released all of the resources allocated for that client.

Local Host Information

Several properties are provided to return information about the local host, including its fully qualified domain name and the IP addresses that are configured on the system.

ServerName
Return the fully qualified domain name of the local host, if it has been configured. If the system has not been configured with a domain name, then the machine name is returned instead.

ExternalAddress
Return the IP address assigned to the router that connects the local host to the Internet. This is typically used by an application executing on a system in a local network that uses a router which performs Network Address Translation (NAT).

AdapterAddress

This property array returns the IP addresses that are associated with the local network or remote dial-up network adapters configured on the system. The AdapterCount property can be used to determine the number of adapters that are available.

Internet Control Message Protocol

The Internet Control Message Protocol (ICMP) class enables your application to send and receive ICMP echo datagrams. These are a special type of IP datagram which can be used to determine if a server is reachable, as well as determine the amount of time it takes for data to be exchanged with the local system. The ICMP class can also be used to trace the route that data takes from the local system to a server, which can be useful in determining why a connection to a particular system may be experiencing higher latency than normal.

Overview

Initialize
Initialize an instance of the class, loading the networking library and validating the development license. This method must be called before any properties are changed or any other methods in this class are called by the application.

Reset
Reset the internal state of the component. This can be useful if your application wishes to discard any settings made by a user and return that instance of the class to its default state.

Uninitialize
Unload the networking library and release any resources that have been allocated for the class instance. This method is automatically invoked when the class instance is disposed or goes out of scope.

Ping and TraceRoute

To determine if a server is reachable, your application can send ICMP echo datagrams. You can also map the route between the local system and the server by sending a series of echo datagrams to each intermediate host. This is what the ping.exe and tracert.exe command line utilities do, and you can emulate that functionality in your own applications.

Echo
This is the simplest method you can use to send ICMP echo datagrams. Specify the server, the size of the ICMP datagram you want to send and the number of times you want to send it. The method will return if the operation was successful along with information such as the average number of milliseconds it took for the datagram to be returned by the server.

TraceRoute
This method will map the route that data packets take from your local system to a server. Whenever you send data over the Internet, that data is routed from one computer system to another until it reaches its destination. This method returns statistical information about each system that the data is routed through, and the latency between that system and the local host. For each intermediate host in the route to the destination server, the OnTrace event will fire.

OnTrace
This event is generated when the TraceRoute method is called. The event will fire for each intermediate host in the route from the local system and the server.

Remote Access Services

The Remote Access Services (RAS) InternetDialer class enables an application to connect to an Internet Service Provider (ISP) using a standard Dial-Up Networking connection. Using this class, the application can discover what dial-up devices are available, what dial-up networking entries, known as "connectoids", are available on the local system and allows the program to manage those connections. Existing connections can be monitored, new connections created and a single instance of the class can be used to manage multiple dial-up connections if the system has more than one modem. While Windows can be configured to simply autodial a service provider whenever a network connection is needed, this component gives your application complete control over the process of connecting to a service provider, monitoring that connection and then terminating that connection if needed.

Initialization

Initialize

Initialize an instance of the class, validating the development license. This method must be called before any properties are changed or any other methods in this class are called by the application.

Connect

Establish a connection to the dial-up networking server. Once the connection has been established, the class will authenticate the session and the local system will have a network connection to the service provider.

Disconnect

Disconnect from the server and release any resources that have been allocated for the dial-up networking session. After this method is called, the session is no longer valid.

Uninitialize

Release any resources that have been allocated for the class instance. This method is automatically invoked when the class instance is disposed or goes out of scope.

Connection Properties

The class properties are used to set or return information about the current dial-up networking connection. To load a dial-up networking connection, called a connectoid or phonebook entry, use the LoadEntry method. There are a large number of properties, however the most significant of those properties are as follows:

DeviceName

This property specifies the name of the device that is used to establish the dial-up networking connection. In most cases this is the name of an analog modem using a serial communications port, connected to a standard telephone line. If your application needs to enumerate the available dial-up networking devices, refer to the DeviceCount, DeviceEntry and DeviceType properties.

DynamicAddress

This property determines if the dial-up networking connection uses a dynamically assigned IP address returned by the server, or a specific IP address configured on the local host. In most cases, this property should be set to True, unless otherwise specified by your service provider.

DynamicNameservers

This property determines if the dial-up networking connection uses dynamically assigned nameservers, used to resolve domain names into IP addresses. In most cases, this property should be set to True. If your service provider requires that you explicitly specify the nameservers to use, then set this property to False and set the NameServer property array to the address of the nameserver(s) to use.

EntryName

This property specifies the name of the connectoid for the current dial-up networking connection. If no connection is active and no connectoid has been loaded, then this property will return an empty string.

InternetAddress
This property returns the IP address assigned to the current dial-up networking session, if a connection has been established. It can also be used to explicitly specify an IP address if the DynamicAddress property is set to False.

NameServer
This is a property array which specifies the IP addresses of the nameservers that are to be used for the current dial-up networking session. If a connection has been established, this property array will return the addresses of those nameservers that have been assigned to you. If the DynamicNameserver property is set to False, this property array can also be used to explicitly specify the nameservers to be used by the dial-up networking connection.

Password
This property specifies the password used to authenticate the dial-up networking connection.

PhoneNumber
This property specifies the telephone number for the dial-up networking connection. You should also check the value of the CountryCode property, which will tell your application if area code dialing rules are being used. If the CountryCode property is set to zero, then no area code dialing rules are in effect and the telephone number is dialed as-is. Otherwise you should check the value of the AreaCode property if you need to determine the area code being used for the connection.

UserName
This property specifies the username used to authenticate the dial-up networking connection

Managing Connectoids

A connectoid contains the information needed to establish a connection, and is represented as the icon in the Network Connections for the local system. Connectoids are referenced by name and typically are named after the service provider, such as "EarthLink" or "Verizon". In addition to simply connecting to a dial-up networking server, the class also enables your application to create, edit and delete these connectoids. Note that in the class documentation, connectoids are also referred to as "entry names" or "phonebook entries".

CreateEntry
This method displays a dialog box that allows the user to specify the information needed to create a new connectoid. This is similar to the dialog that is displayed whenever the user chooses to create a new Dial-Up Networking connection. Note that if you want to create a connectoid without showing a dialog to the user, use the SaveEntry method instead.

DeleteEntry
This method deletes an existing dial-up networking connection. Exercise caution when using this method; once a connectoid has been deleted, there is no way to recover it.

LoadEntry
This method loads an existing connectoid, and updates the properties to reflect the connectoid's settings. Changing one or more of those properties and then calling the SaveEntry method is how you can modify an existing connectoid.

RenameEntry
This method renames an existing connectoid.

SaveEntry
This method modifies or creates a new connectoid based on the current properties of the class instance. If the connectoid already exists, it is modified, otherwise a new connectoid is created. Unlike the CreateEntry method, this method will not display any dialogs, so it is the responsibility of the application to provide a user interface if needed.

Internet Message Access Protocol

The Internet Message Access Protocol (IMAP) is an application protocol which is used to access a user's email messages which are stored on a mail server. However, unlike the Post Office Protocol (POP) where messages are downloaded and processed on the local system, the messages on an IMAP server are retained on the server and processed remotely. This is ideal for users who need access to a centralized store of messages or have limited bandwidth. The SocketTools IMAP class implements the current standard for this protocol, and provides methods to retrieve messages, create and manage mailboxes, and search for specific messages based on some user-defined search criteria.

Initialization

Initialize
Initialize an instance of the class, loading the networking library and validating the development license. This method must be called before any properties are changed or any other methods in this class are called by the application.

Connect
Establish a connection to the IMAP server. Once the connection has been established, the other methods in the class may be used to access the messages on the server.

Disconnect
Disconnect from the server and release the memory allocated for that client session. After this method is called, the client session is no longer valid.

Reset
Reset the internal state of the component. This can be useful if your application wishes to discard any settings made by a user and return that instance of the class to its default state.

Uninitialize
Unload the networking library and release any resources that have been allocated for the class instance. This method is automatically invoked when the class instance is disposed or goes out of scope.

Managing Mailboxes

One of the primary differences between the IMAP and POP3 protocol is that IMAP is designed to manage messages on the mail server, rather than downloading all of the messages and storing them on the local system. To support this, IMAP allows the client to maintain multiple mailboxes on the server, which are similar in concept to message folders used by mail client software. A mailbox can contain messages, and in some cases a mailbox can contain other mailboxes, forming a hierarchy of mailboxes and messages, similar to directories and files in a filesystem. A special mailbox named INBOX contains new messages for the user, and additional mailboxes can be created, renamed and deleted as needed. The following are the most important methods for managing mailboxes:

CheckMailbox
Check the mailbox for any new messages which may have arrived. Because messages are managed on the server, it is possible for new mail to arrive during the client session.

CreateMailbox
Create a new mailbox on the server with the specified name.

DeleteMailbox
Delete a mailbox from the server. Most servers will only permit a mailbox to be deleted if it does not contain any mailboxes itself. Unlike deleting a message, which can be undeleted, deleting a mailbox is permanent.

ExamineMailbox
Once the session has been established and authenticated, a mailbox should be selected. This enables the

client to manage the messages in that mailbox. This method selects the specified mailbox in read-only mode so that messages can be read, but not modified. To select the mailbox in read-write mode, use the SelectMailbox method.

RenameMailbox
Renames an existing mailbox. One of the interesting uses of this method is the ability to rename the special INBOX mailbox. Instead of actually renaming it, it moves all of the messages to the new mailbox and empties the INBOX.

SelectMailbox
Once the session has been established and authenticated, a mailbox should be selected. Selecting a mailbox enables the client to manage the messages in that mailbox. This method selects the specified mailbox in read-write mode so that changes can be made to the mailbox.

UnselectMailbox
This method unselects the currently selected mailbox, and allows the caller to specify if messages marked for deletion should be expunged (removed) from the mailbox or reset back to an undeleted state.

Managing Messages

There are methods in the IMAP class for managing messages which enables the application to create, delete and move messages. To use these methods, a mailbox must be selected, either by setting the MailboxName property or calling the SelectMailbox method. Methods which modify the mailbox require that it be opened in read-write mode. Messages are identified by a number, starting with one for the first message in the mailbox.

CopyMessage
Copy a message to a specific mailbox.

DeleteMessage
Mark the specified message for deletion. Unlike the POP3 protocol, when a message is deleted on an IMAP server it can still be accessed. The message will not actually be removed from the mailbox unless the mailbox is expunged, unselected or the client disconnects from the server.

UndeleteMessage
Remove the deletion flag from the specified message.

Viewing Messages

One of the more powerful features of the IMAP protocol is the ability to precisely select what kinds of message data you wish to retrieve from the server. It is possible to retrieve only specific headers, or specific sections of a multipart message. Because IMAP understands MIME formatted messages, it is possible to only retrieve the textual portion of a message without having to download any attachments that may have come with it.

GetHeader
This method returns the value for a specified header field in the message. Using this method, it is not necessary to download and parse the message header.

GetHeaders
This method retrieves the complete headers for the specified message and stores it in a string or byte array provided by the caller.

GetMessage
The GetMessage method retrieves the specified message and stores it in a string or byte array provided by the caller; you can specify the type of message data that you want, a specific part of a multipart message and the amount of data that you want. For example, it is possible to request that only the first 1500 bytes of the body of the 3rd part of a multipart message should be returned.

OpenMessage

The OpenMessage method is a lower level method which opens a message for reading from the server. The application would then call Read to read the contents of the message, followed by CloseMessage when all the message data has been read. Also see the GetMessage method, which will return the contents of a message into a string or byte array.

Downloading Messages

In some cases, it may be preferable to download a complete message from the server to the local system. This can be easily done with a single method call.

StoreMessage
This method downloads a complete message and stores it as a text file on the local system.

Internet Server

The Internet Server class provides an interface which is similar to the SocketWrench control, but is specifically designed to simplify the development of a server application. The class provides a collection of methods which can be used to easily create an event-driven server application. The server runs on a separate thread in the background, automatically managing the individual client sessions as servers connect and disconnect from the server. Events are used to notify the application when the client establishes a connection with the server, sends data to the server or disconnects. Methods such as Read and Write are used to exchange data with the clients.

An important consideration when using the Internet Server class is that events are raised in the context of the thread that manages the client session. The .NET Framework does not allow one thread to modify a control that was created in the main user interface thread, which means that you cannot update user interface controls directly from within the event handlers. If you want to change any property values or call methods in a control, you need to create a delegate and marshal the call to the user interface thread to using the control's Invoke method.

Initialization

Initialize

Initialize an instance of the class, loading the networking library and validating the development license. This method must be called before any properties are changed or any other methods in this class are called by the application.

Start

This method starts the server, creating the background thread and listening for incoming client connections on the specified port number. You can specify the local address, port number, backlog queue size and the maximum number of clients that can establish a connection with the server.

Restart

This method will terminate all active client connections, close the listening socket and re-create a new listening socket bound to the same address and port number.

Suspend

This method instructs the server to temporarily suspend accepting new client connections. Existing connections are unaffected, and any incoming client connections are queued until the server is resumed. It is not recommended that you leave a server in a suspended state for an extended period of time. Once the connection backlog queue has filled, any subsequent client connections will be automatically rejected.

Resume

This function instructs the server to resume accepting client connections after it was suspended. Any pending client connections are accepted after the server has resumed normal operation.

Throttle

This method is used to control the maximum number of clients that may connect to the server, the maximum number of clients that can connect from a single IP address and the rate at which the server will accept client connections. By default, there are no limits on the number of active client sessions and connections are accepted immediately. This method can be useful in preventing denial-of-service attacks where the the attacker attempts to flood the server with connection attempts.

Lock

This method enables the application to lock the server so that only the current thread may interact with the server and the client sessions. This will cause all other client threads to go to sleep, waiting for the server to be unlocked. This should only be used when the server application needs to ensure that no other client threads are performing a network operation. If the server is left in a locked state for an extended period of time, it will cause the server to become non-responsive. If the application has started multiple servers, only one server can be locked at any one time.

Unlock
This method unlocks a server that has been previously locked. The threads which manage the client sessions will awaken and resume normal execution.

Stop
This method will terminate all active client connections, close the listening socket and terminate the background thread that manages the server. Any incoming client connections will be refused, and all resources allocated for the server will be released.

Uninitialize
Unload the networking library and release any resources that have been allocated for the class instance. This method is automatically invoked when the class instance is disposed or goes out of scope.

Input and Output

When a TCP connection is established, data is sent and received as a stream of bytes. The following methods can be used to send and receive data over the socket:

Read
This method reads data from the client and copy it to the string buffer or byte array provided by the caller. If the client closes its connection, this method will return zero after all the data has been read. If the method is successful, it will return the actual number of bytes read. This method should always be used when reading binary data from the client into a byte array.

ReadLine
Read a line of text from the client, up to an end-of-line character sequence or when the client closes the connection. This method is useful when the client and server are exchanging textual data, as is common with most command/response application protocols.

Write
This method sends data to the client. If the method succeeds, the return value is the number of bytes actually written. This method should always be used when sending binary data to the client.

WriteLine
Write a line of text to the socket, terminating it with an end-of-line character sequence. This method is useful when the client and server are exchanging textual data, as is common with most command/response application protocols.

Broadcast
Broadcasts data to each of the clients that are connected to the server. This can be useful when the application needs to send the same data to each active client session, such as broadcasting a shutdown message when the server is about to be terminated.

IsReadable
This property is used to determine if there is data available to be read from the socket. If the property returns a value of True, the Read method will return without causing the application to block. If the property returns False, there is no data available to read from the socket.

IsWritable
This property is used to determine if data can be written to the socket. In most cases this will return True, unless the internal socket buffers are full.

Local Host Information

Several properties are provided to return information about the local host, including its fully qualified domain name and the IP addresses that are configured on the system.

ServerName
Return the fully qualified domain name of the local host, if it has been configured. If the system has not

been configured with a domain name, then the machine name is returned instead.

ExternalAddress
Return the IP address assigned to the router that connects the local host to the Internet. This is typically used by an application executing on a system in a local network that uses a router which performs Network Address Translation (NAT).

AdapterAddress
This property array returns the IP addresses that are associated with the local network or remote dial-up network adapters configured on the system. The AdapterCount property can be used to determine the number of adapters that are available.

Mail Message

The Mail Message class can be used to create and process messages in the format defined by the Multipurpose Internet Mail Extensions (MIME) standard. When a message is parsed, it is broken into parts, each consisting of two sections. The first part is called the header section and it describes the format of the data and how it should be represented to the user. The second section is the data itself. A typical mail message without file attachments has one part, with the body of the message being the data. Messages with attachments have multiple parts, each with a header describing the type of data. The class can be then used to extract the data from a multipart message and save it to a file on the local system, delete the part from the message, or add additional parts to the message, such as attaching a file.

The class can also be used to create new multipart messages with alternative content, such a message with both plain text and styled HTML text. Once a message has been created, files can be attached to the message and the application can make any other changes that are needed. The class provides complete access to all headers and content in a multipart message, including the ability to create your own custom headers and make modifications to specific sections.

Initialization

Initialize
Initialize an instance of the class, validating the development license. This method must be called before any properties are changed or any other methods in this class are called by the application.

ComposeMessage
Compose a new message using the specified header field values and content. Using this method, you can create a message with the From, To, Cc and Subject headers already defined, along with any text for the message. You can also optionally provide both plain and styled HTML text versions of the message and the method will automatically create a multipart message.

ClearMessage
Releases the memory allocated for the current message, including any file attachments, and creates a new, empty message.

Uninitialize
Release any resources that have been allocated for the class instance. This method is automatically invoked when the class instance is disposed or goes out of scope.

Message Headers

Each message has one or more headers fields which provide information about the contents of the message. For example, the "From" header field specifies the email address of the person who sent the message. There are a fairly large number of header fields defined by the MIME standard, and applications can also create their own custom headers if they wish. The class gives the application complete access to the header fields in a message. Headers can be examined, modified, created or removed from the message as needed.

GetHeader
This method copies the value of a header field into a string buffer that you provide. To return the value of the common header fields such as "From", "To" and "Subject", you should specify a message part of zero by setting the MessagePart property.

GetFirstHeader
This method returns the value of the first header defined in the current message part, copying it into the string buffer that you provide. This is used in conjunction with the GetNextHeader method to enumerate all of the headers that have been defined.

GetNextHeader

This method returns the value of the next header defined in the current message part. It should be called in a loop until it returns a value of zero (False) which indicates that the last message header has been returned.

SetHeader
Set a message header field to the specified value in the current message part. If the value is an empty string, the message header will be deleted from the message.

DeleteHeader
Delete the specified message header from the current message part.

Message Contents

The content or body of a message contains the text that will be read or processed by the recipient. It may be a simple, plain text message or it may be more complex, such as a combination of plain and styled HTML text or the data for a file attachment. The class provides complete access to the contents of the message, enabling the application to modify, extract, replace or delete specific sections of the message.

Message
This property returns the current message, including the headers and all message parts, as a string. Setting this property will cause the current message to be cleared and replaced by the new value. The string contents must follow the standard specifications for a message. If the property is set to an empty string, the current message is cleared.

Text
This property returns the body of the current message part. Setting this property replaces the entire message body with the new text.

Multipart Messages

Most typical messages contain a single part, which consists of the message headers followed by the contents of the message. However, when files are attached to a message or alternative content types such as HTML are used, a more complex multipart message is required. With a multipart message, the contents of the message are split into logical sections with each section containing a specific part of the message. For example, when a file is attached to a message, one part of the message contains the text to be read by the recipient and another part contains the data for the file.

The first of a multipart message is called part 0, and contains the main header block. This is what defines the headers that you are most familiar with, such as "From", "To" and "Subject". The body of this message part is typically a plain text message that indicates that this is a multipart message. This is done for the benefit of older mail clients that cannot parse MIME messages correctly. Next part, part 1, typically contains the actual body of the message that would be displayed by the mail client. Additional parts may contain file attachments and other information. In the case of a multipart message that contains both plain and styled HTML text versions of a message, part 1 is typically the plain text version of the message while part 2 contains the HTML version. The mail client can then make a decision based on its own configuration as to which version of the message it displays.

Part
This property returns the current message part index. All messages have at least one part, which consists of one or more header fields, followed by the body of the message. The default part, part 0, refers to the main message header and body. If the message contains multiple parts (as with a message that contains one or more attached files), this property can be set to refer to that specific part of the message.

PartCount
This property returns the number of parts in the current message. All messages have at least one part, referenced as part 0. Multipart messages will consist of additional parts which may be accessed by setting the Part property.

CreatePart

Create a new, empty message part. If the message was not originally a multipart message, it will be restructured into one. Otherwise, the new part is simply added to the end of the message. This method will cause the current message part to change to the new part that was just created.

DeletePart
Delete the message part from the message. If the message part is in the middle of the message, it will cause the subsequent parts of the message to be reordered. You should not delete part zero to delete a message; use the DeleteMessage method instead.

Importing and Exporting Messages

The class can be used to import existing messages from a text file and export messages to a text file. Once the message has been parsed, the application can examine or modify specific parts of the message. The following methods are provided to import and export the contents of a message:

ImportMessage
The simplest method of importing a message, this method reads the contents of the specified file and imports it into the current message. Note that the current message contents will be overwritten with the imported message.

ExportMessage
This method exports the current message to a file. When using this method, only certain headers are exported and they may be reordered. To force all headers to be included in the message or to preserve the order of the headers, set the Options property.

File Attachments

In addition to simple text messages, one or more files can be attached to a message. The process of attaching a file involves creating a multipart message, encoding the contents of the file and then including that encoded data in the message. The following methods are provided to manage files attached to the message, as well as attach files to an existing message:

Attachment
A property which returns the name of a file attachment in the current message part. This property serves two purposes, to determine if the current message part contains a file attachment, and if so, what file name should be used when extracting that attachment.

AttachFile
This method attaches the contents of the file to the message. The file will be attached using the specified encoding algorithm and will become the current message part. If the message is not a multipart message, it will be converted to one; if it already is a multipart message, the attachment will be added to the end of the message.

AttachData
This method works in similar fashion to AttachFile, except that instead of the contents of a file, the data in a memory buffer will be attached to the message. If the message is not a multipart message, it will be converted to one; if it already is a multipart message, the attachment will be added to the end of the message.

AttachImage
This method attaches an inline image file to the message. It is similar to the AttachFile method, except that the image is designed to be referenced as an embedded graphic in an HTML message. This method will automatically set the correct header values for an inline image attachment, and enables the developer to specify a content ID which is used in the HTML message.

ExtractFile
Extract the file attachment in the current message part, storing the contents in a file. The attachment will automatically be decoded if necessary. This method also recognizes uuencoded attachments that are embedded directly in the body of the message, rather than using the standard MIME format.

Mail Addresses

The Mail Message class also has methods which are designed to make it easier to work with email addresses. Addresses are typically in the format of "user@domain.com" however additional information can be included with the address, such as the user's name or other comments that aren't part of the address itself. The class can parse these addresses for you, returning them in a format that is suitable for use with other protocols such as the SMTP class.

ParseAddress

Parse an email address that may include an address without a domain name or comments in the address, such as the user's name. For example, the From header field may return an address like "Joe Smith <joe@example.com>"; this method would parse the address and return "joe@example.com", the actual address for the user.

Recipient

It is common for certain headers to contain multiple addresses separated by a comma. These addresses may also include comments such as the user's name. This property array returns a list of valid addresses defined in the current message. For example, the To header field may contain "Tom Jones <tom@example.com>, Jerry Lewis <jerry@example.com>"; this property array would return "tom@example.com" and "jerry@example.com" as the two addresses listed. The total number of addresses that are available is returned by the Recipients property.

Message Storage

The Mail Message class has a collection of methods which makes it simple for an application to store a group of messages together in a single file, search for and retrieve specific message. The collection of messages is referred to as a "message store" and messages may either be stored in a plaintext format or in a compressed binary format.

OpenStore

This method is used to open an existing message store or creates a new storage file. If a storage file has been opened previously, it will be closed and the new storage file will be opened. The storage files may either be plaintext, or stored in a compressed format. It also supports opening storage files in the UNIX mbox format.

StoreSize

This property returns the total number of messages that currently in the message store, including deleted messages. Each message is referred to by an integer which is its index into the storage file.

StoreIndex

This property specifies the current message index into the storage file. Messages are identified by an integer value that starts at one for the first message and increments for each additional message in the storage file. If no message store has been opened, this property will return a value of zero. Changing the value of this property changes the current message index for the message store.

FindMessage

An application can search the message store for messages that match any header value. Searches can be complete or partial, and may be case-sensitive or case-insensitive. For example, this method can be used to enumerate all of the messages in the storage file that were sent by a specific user or match a specific subject.

ReadStore

This method reads a message from the storage file and replaces the current message. If the application modifies the message, it can replace the message in the storage file or discard the changes.

WriteStore

This method writes the current message to the message store. Note that the message store must be opened for write access, and the message will always be appended to the storage file. The StoreIndex property is updated with the index value for the new message.

DeleteMessage
This method flags a message for deletion from the message store. Once a message has been flagged for deletion, it may no longer be accessed by the application. When the storage file is closed, the contents of the deleted message will be removed from the file.

ReplaceMessage
This method replaces an existing message in the storage file, overwriting it with the current message. Unlike many of the other methods which do not permit the application to reference a deleted message, this method can be used to replace a previously deleted message.

CloseStore
The message store must be closed when the application has finished accessing it. This method updates the storage file with any changes, purges all deleted messages and closes the storage file. If the storage file is locked for exclusive access, this method will release that lock, allowing another process to open the file

Network News Transfer Protocol

The Network News Transfer Protocol (NNTP) class enables applications to access a news server, list the available newsgroups, retrieve articles and post new articles. It is common for this class to be used in conjunction with the Mail Message class to construct the articles, since a news article uses the same general format as an email message.

Initialization

Initialize
Initialize an instance of the class, loading the networking library and validating the development license. This method must be called before any properties are changed or any other methods in this class are called by the application.

Connect
Establish a connection to the server. Once the connection has been established, the other methods in the class may be used to access the messages on the server.

Disconnect
Disconnect from the server and release the memory allocated for that client session. After this method is called, the client session is no longer valid.

Reset
Reset the internal state of the component. This can be useful if your application wishes to discard any settings made by a user and return that instance of the class to its default state.

Uninitialize
Unload the networking library and release any resources that have been allocated for the class instance. This method is automatically invoked when the class instance is disposed or goes out of scope.

Newsgroups

News articles are posted in hierarchical groups, similar to how files are stored in folders. Each level in the newsgroup hierarchy is separated by a period, so newsgroup names look like microsoft.public.vc. This is Microsoft's newsgroup for articles about Visual C++ programming. Additional subgroups are used to further narrow the topic; for example, there's the microsoft.public.vc.3rdparty newsgroup for third party tools and components for Visual C++, and the microsoft.public.vc.atl newsgroup which discusses issues related to the Active Template Library. The NNTP class provides the following methods for accessing newsgroups on the server:

GetFirstGroup
This method returns the first available newsgroup on the server. This method is used in conjunction with the GetNextGroup method to enumerate all of the available newsgroups. An overloaded implementation of this method also enables you to specify a date value, where only those newsgroups created on or after that date are returned. This is useful for updating a locally stored list of newsgroups without downloading the complete list of newsgroups each time the client connects to the server.

GetNextGroup
This method returns the next available newsgroup on the server and is used in conjunction with the GetFirstGroup method.

SelectGroup
This method is used to select a newsgroup as the current group. Once selected, the application has access to the articles in that newsgroup.

News Articles

News articles are the messages posted to one or more newsgroups. Articles are referenced by their article number, which is a value assigned by the news server. These articles have a structure that is the same as an email message, with some slightly different headers. Because of this, you can use the Mail Message interface to parse articles that you retrieve, as well as create new articles to post to the server. The following methods are used to access and create news articles:

GetFirstArticle
This method returns information about the first available article in the currently selected newsgroup. This method is used in conjunction with the GetNextArticle method to enumerate all of the available articles in a newsgroup. An overloaded implementation of this method also enables you to specify a starting and ending article number, which enables you to only list those articles within a specific range.

GetNextArticle
This method returns the next available article and is used in conjunction with the GetFirstArticle method.

GetArticle
Retrieve an article from the server, storing the contents in a string buffer or byte array. This can be used to process the contents of an article without the overhead of storing it in a file on the local system.

StoreArticle
Retrieve an article from the server and store it in a file on the local system.

PostArticle
This method posts an article to one or more newsgroups on the server. A newsgroup article is similar to an email message, and the MIME interface may be used to create the article headers and body. One important difference is that the message must contain a header named "Newsgroups" with the value set to the newsgroup or newsgroups that the article should be posted to; multiple newsgroups should be separated by commas. If this header is not defined, the posting will be rejected by the server and the method will return an error. You should also be aware that some servers limit the number of newsgroups that a message can be posted to. When an article is posted to more than one newsgroup at a time, this is called cross-posting. Current convention says that an article should not be cross-posted to more than five newsgroups at a time. Also keep in mind that multiposting (posting the same article to different newsgroups separately) is generally discouraged and should never be done on USENET.

Attaching Files

It is possible to attach files to newsgroup articles; however it should only be done if it is considered appropriate for the group. Many newsgroups have their own acceptable use policies which determine whether or not file attachments, particularly large binary files, are acceptable. If the newsgroup accepts attachments, you can use one of several methods for posting files. It is recommended that you use the File Encoding interface to handle the actual encoding of the data.

Uuencode
A uuencoded file attachment is included directly in the body of the message. Because the MIME interface creates a multipart message even when uuencoding is specified, the File Encoding interface should be used to encode the data and then it should be included in the main body of the message.

Base64
A Base64 file attachment has the same structure as what is used by email messages. This requires that a multipart message be created, with the encoded data attached as a part of the message. You can use the MIME class to create this kind of message. Note that not all third-party newsreaders correctly handle multipart messages.

yEnc
The newest encoding method used on USENET is called yEnc. Similar to uuencoded attachments, the file data is part of the body of the message. The File Encoding class should be used to encode the data and then it should be included in the main body of the message. More information about yEnc encoding can be found at www.yenc.org

Network Time Protocol

The Time protocol control enables an application to retrieve the current time from a server, and optionally synchronize the local system time using that value. The first step that your application must take is to initialize the control. After the control has been initialized, the application can request the current time from a system and update the local system clock if necessary.

Overview

Initialize
Initialize an instance of the class, loading the networking library and validating the development license. This method must be called before any properties are changed or any other methods in this class are called by the application.

GetTime
Return the current time from a server. The time and date retrieved from the server will be returned as a string formatted according to the user's current locale. If the date could not be retrieved, an empty string will be returned.

SetTime
Update the local system time with the value returned by GetTime. This method requires that the current user have the appropriate permissions to modify the system time or the method will fail.

Reset
Reset the internal state of the component. This can be useful if your application wishes to discard any settings made by a user and return that instance of the class to its default state.

Uninitialize
Unload the networking library and release any resources that have been allocated for the class instance. This method is automatically invoked when the class instance is disposed or goes out of scope.

Time Conversion

The class also provides a method which can be used to convert between the local date and time and UTC date and time for the value returned by the server.

ConvertTime
This method enables the application to easily convert between the network time value (which is expressed as a long integer specifying the number of seconds elapsed since midnight, January 1, 1900) and the System.DateTime class.

Post Office Protocol

The Post Office Protocol (POP3) class enables an application to retrieve a user's mail messages and store them on the local system. The control provides support for all of the standard functionality such as listing and downloading messages, as well as extended features such as the ability to retrieve only the headers for a message or just specific header values. The class also has methods for changing the user's password and sending messages if they are supported by the server.

Initialization

Initialize
Initialize an instance of the class, loading the networking library and validating the development license. This method must be called before any properties are changed or any other methods in this class are called by the application.

Connect
Establish a connection to the server. Once the connection has been established, the other methods in the class may be used to access the messages on the server.

Disconnect
Disconnect from the server and release the memory allocated for that client session. After this method is called, the client session is no longer valid.

Reset
Reset the internal state of the component. This can be useful if your application wishes to discard any settings made by a user and return that instance of the class to its default state.

Uninitialize
Unload the networking library and release any resources that have been allocated for the class instance. This method is automatically invoked when the class instance is disposed or goes out of scope.

Managing Messages

There are methods in the POP3 control for managing messages which enables the application to list, delete and retrieve messages stored on the server. Messages are identified by a number, starting with one for the first message in the mailbox. The most typical operation for a POP3 client is to retrieve each message, store it on the local system and then delete the message from the server. Any processing that is done on the message would then be done on the local copy.

Message
This property sets or returns the message number for the currently selected mailbox. Message numbers range from 1 through the number of messages available on the server, as returned by the MessageCount property.

MessageCount, LastMessage
A property which returns the number of messages available for retrieval. There are two values the application should use. One is the number of currently available messages and the other is the last valid message number. As messages are deleted from the server, the total number of available messages will decrease; however, the last available message number will remain constant.

MessageSize
This property returns the size of the message in bytes. One thing to be aware of when using this method is that some servers will only return approximate message sizes. In addition, because of the difference between the end-of-line characters on UNIX and Windows systems, the size reported by the server may not be the actual size of the message when stored on the local system. Therefore, the application should not depend on this value as an absolute. For example, it should not use this value to determine the maximum number of bytes to read from the server; instead, it should read until the server indicates that

the end of the message has been reached.

GetMessage
This method is used to retrieve a message from the server and copy it into a local string or byte array buffer. This method will cause the current thread to block until the message transfer completes, a timeout occurs or the transfer is canceled.

StoreMessage
This method downloads a complete message and stores it as a text file on the local system.

DeleteMessage
Mark the message for deletion. When the connection with the server is closed, the message will be removed from the user's inbox. An important difference between the POP3 and IMAP protocols is that when a message is marked as deleted on a POP3 server, that message can no longer be accessed. An attempt to retrieve a message after it has been marked for deletion will result in an error. The only way to undelete a message once it has been deleted is to terminate the connection with the server by calling the Reset method instead of calling the Disconnect method.

Message Headers

The class also includes methods which enable the application to access the headers for a message. This can be useful if the program doesn't want to incur the overhead of downloading the entire message contents.

GetHeader
This method returns the value for a specified header field in the message. Using this method, it is not necessary to download and parse the message header.

GetHeaders
This method retrieves the complete headers for the specified message and stores it in a string or byte array provided by the caller.

MessageUID
This property returns the unique ID (UID) that the server has associated with the message. The UID can be used by an application to track whether or not it has previously viewed the message. Unlike the message number, which can change between client sessions, the message UID is guaranteed to be the same value across sessions until the message is deleted.

Downloading Messages

In some cases, it may be preferable to download a complete message from the server to the local system. This can be easily done with a single method call.

StoreMessage
This method downloads a complete message and stores it as a text file on the local system.

Remote Command Protocol

The Remote Command protocol enables an application to execute commands on a server, with the output of the command returned to the client. The SocketTools control actually implements three related protocols: rexec, rshell and rlogin. The choice of protocols is determined by the port that is selected when a connection is established.

Initialization

Initialize
Initialize an instance of the class, loading the networking library and validating the development license. This method must be called before any properties are changed or any other methods in this class are called by the application.

Reset
Reset the internal state of the component. This can be useful if your application wishes to discard any settings made by a user and return that instance of the class to its default state.

Uninitialize
Unload the networking library and release any resources that have been allocated for the class instance. This method is automatically invoked when the class instance is disposed or goes out of scope.

Executing Commands

When executing commands remotely, there are two similar protocols that can be used. The **rexec** protocol enables a client application to execute a command on a server. Output from the command is returned to the client and the connection is closed when the command terminates. The client connects on port 512 and must provide a user name and password to authenticate the session.

The **rshell** protocol is similar to rexec in that it enables a client to execute a command on a server. Output from the command is returned to the client and the connection is closed when the command terminates. The client connects on port 514 and must provide a user name. The primary difference between the rexec and rshell protocols is that rshell does not require a password. Instead, it uses what is called "host equivalence" to determine if the client is permitted to execute commands as that user. On a UNIX based operating system, host equivalence is controlled by the /etc/hosts.equiv and the .rhosts file in the user's home directory. These files list the host names and user names which are permitted to execute commands using the rshell protocol. Consult your operating system manual pages for more information about how to configure host equivalence.

An important consideration when deciding whether to use rexec or rshell is how the server is configured and the type of command being executed. If there is no entry for the local host in the server's host equivalence tables, then the rexec command should be used instead of rshell.

When using rexec or rshell, it is important to keep in mind that although the command is executed with the privileges of the specified user, that user is not actually logged in. The user's login script is not executed and the program will not inherit the user's normal environment as it would during an interactive session. If you are connecting to a UNIX system, you should not attempt to execute programs which try to put standard input into raw mode; an example of this would be the vi editor. If you are connecting to a Windows system, you should not execute a program which uses a graphical interface. Only programs which read standard input and write to standard output are suitable for use with rexec or rshell.

Execute
Execute the specified command on the server. The rshell or rexec protocol is selected based on the port number that is specified. Output from the command will be returned to the client to be read. When the command terminates, the connection to the server will be closed.

Read

Read the output generated by the command. Your application would typically call this method in a loop until all of the data has been read or an error occurs.

Search
Search for a specific sequence of characters in the output returned by the server. The method returns when the sequence is encountered or when a timeout occurs. The data captured up to the point where the character sequence was matched is returned to the caller for processing.

Remote Login

The **rlogin** protocol is similar to Telnet in that it provides an interactive terminal session. The connection is closed when the user logs out or the shell process on the server is terminated. The client connects on port 513 and must provide a user name and terminal type. If there is an entry in the host equivalence tables for the user and local host, then the client will be automatically logged in and provided with a shell prompt. If there is no host equivalence, the client will be prompted for a password. The terminal emulation control can be used to provide ANSI or DEC VT-220 emulation services if needed.

Login
Establish an interactive login session which is similar to how the Telnet protocol works. If there is no host equivalence with the local host, you will be prompted for a password. Output from the session will be returned to the client, and when the client logs out the connection will be closed.

Read
Reads any output that has been generated by the program executing on the server. Once a connection has been established, users are typically given a command line prompt where they can enter commands to be executed on the server. If the server closes the connection, the Read method will indicate that with an error result and the client can disconnect from the server at that point.

Search
Search for a specific sequence of characters in the output returned by the server. The method returns when the sequence is encountered or when a timeout occurs. The data captured up to the point where the character sequence was matched is returned to the caller for processing.

Write
Send data to the server which will be received as input to the program. In most cases, the server will automatically echo back any characters written as data to be read by the client.

Secure Shell Protocol

The Secure Shell (SSH) protocol enables an application to establish a secure, interactive terminal session with a server, or execute commands remotely on the server, with the output of the command returned to the client. The SocketTools .NET class supports both version 1.0 and 2.0 of the protocol.

Initialization

Initialize

Initialize an instance of the class, loading the networking library and validating the development license. This method must be called before any properties are changed or any other methods in this class are called by the application.

Connect

Establish a connection to the server. Once the connection has been established, the other methods in the class may be used to exchange data with the server.

Disconnect

Disconnect from the server and release the memory allocated for that client session. After this method is called, the client session is no longer valid.

Reset

Reset the internal state of the component. This can be useful if your application wishes to discard any settings made by a user and return that instance of the class to its default state.

Uninitialize

Unload the networking library and release any resources that have been allocated for the class instance. This method is automatically invoked when the class instance is disposed or goes out of scope.

Input and Output

Once connected to the server, any output generated by the command shell or a program executed on the server will be sent as data for the client to read. Any input to the program is sent by the client and received and processed by the server. The following methods are used:

Read

Reads any output that has been generated by the program executing on the server. If the server closes the connection, this method will return zero after all the data has been read. If the method is successful, it will return the actual number of bytes read.

ReadLine

The ReadLine method reads data from the server up to the specified number of bytes or until an end-of-line character sequence is encountered. Unlike the Read method which reads arbitrary bytes of data, this function is specifically designed to return a single line of text data in a string variable.

Peek

The Peek method can be used to examine the data that is available to be read from the internal receive buffer. If there is no data in the receive buffer at that time, a value of zero is returned. The Peek method will never cause the client to block, and so may be safely used with asynchronous connections.

Write

Send data to the server which will be received as input to the program. If the method succeeds, the return value is the number of bytes actually written. This method should always be used when sending binary data to the server.

WriteLine

The WriteLine method sends a line of text to the server and terminates the line with a carriage-return and linefeed control character sequence. Unlike the Write method which writes arbitrary bytes of data to the socket, this method is specifically designed to write a single line of text data from a string.

Command Processing

The SSH protocol can be used to connect to a server, log in and execute one or more commands, process the output from those commands and display it to an end-user using a graphical interface. The user never sees or interacts with the actual terminal session. The class interface provides methods which can simplify this kind of application, reducing the amount of code needed to process the data stream returned by the server.

Execute

This method executes a command on a server and copies the output to a user-specified buffer, with the exit code for the remote program as the method's return value. This is a convenience method that enables you to execute a remote command in a single call, without having to write the code to establish the connection and read the output.

Search

This method is used to search for a specific character or sequence of characters in the data stream returned by the server. The control will accumulate all of the data received up to the point where the character sequence is encountered. This can be used to capture all of the output from a command, or search for specific results returned by the command as it executes on the server.

Simple Mail Transfer Protocol

The Simple Mail Transfer Protocol (SMTP) class enables applications to deliver email messages to one or more recipients. The class provides an interface for addressing and delivering messages, and extended features such as user authentication and delivery status notification. This class is typically used in conjunction with the MailMessage class to create the messages, and the Domain Name Service class to determine what servers are responsible for accepting mail for a specific user.

Mail Exchanges

When a message is delivered to a user, the application must determine what mail server is responsible for accepting messages for that user. This can be accomplished using the Domain Name Services (DNS) protocol, a protocol that is most commonly used to resolve host names such as www.microsoft.com into Internet addresses. This is typically accomplished by sending a request to a nameserver, a computer system that provides domain name services. In addition to resolving host names, nameservers can also provide information about those servers which are responsible for accepting mail for a given domain. There can be multiple servers which process mail for a domain with each server assigned a priority as part of their mail exchange (MX) record. If there is no mail exchange record for a domain, then the domain name itself is used.

To deliver a message directly to the recipient, you must examine the recipient address and request the list of mail exchanges for that user's domain. Using the DNS class, this is done by reading the MailExchange property array. If the recipient address is joe@example.com, you would want to enumerate the mail exchanges for the example.com domain. This will give you the name of the servers that will accept mail for users in that domain. For example, the property may return the host name mail.example.com as the name of the server which will accept mail for users in the example.com domain. Note that it is possible that one or more of the mail exchanges for a domain may not be in the recipient domain itself. In other words, it is possible that smtp.othercorp.net could be returned as a mail exchange for example.com. This is frequently the case when another organization is forwarding mail for that domain.

Therefore, there are four general steps that you must take when delivering mail directly to the recipient:

1. Parse the address of each recipient in the message. If you are using the MailMessage class, the Recipient and Recipients properties can be helpful in extracting all of the recipient addresses. Everything after the atsign (@) in the address is the domain portion of that address.
2. Perform an MX record lookup using the DNS class by setting the HostName property to the domain name and reading the values returned in the MailExchange property array. This property will return the name of the servers responsible for accepting mail for that user. If there are more than one server, they will be returned in order of their relative priority, with the highest priority server having a lower index value. This means that you should attempt to connect to those servers in the order that they are returned by the property, starting with an index value of zero.
3. Attempt to connect to the first server returned by the MailExchange property array. The connection should be on the default port, and you should not attempt to use any authentication. If the server accepts the connection, then use the SendMessage method to deliver the message. If the connection is rejected or the message is not accepted, attempt to connect to the next mail exchange server until all servers have been tried.
4. If no mail exchange servers were returned by the MailMessage class MailExchange property, or you could not connect to any of them, attempt to connect to the domain specified in the address using the default port. If the connection succeeds, then deliver the message. If you cannot connect or the message is not accepted, then report to the user

that the message could not be delivered.

One last important consideration is that many Internet Service Providers now block outbound connections on port 25 to any mail servers other than their own. If you are unable to establish any connections, either with the error that the connection was refused or it consistently times out, contact your ISP to determine if port 25 is being blocked as an anti-spam measure. If this is the case, it will be required that you relay all messages through their mail servers.

Relay Servers

In some situations it may not be possible to send mail directly to the server that accepts mail for a given domain. The two most common situations are corporate networks which have centralized servers that are responsible for delivering and forwarding messages, or an Internet Service Provider (ISP) which specifically blocks access to all mail servers other than their own. This is usually done as either a security measure or as a means to inhibit users from sending unsolicited commercial email messages. If the standard SMTP port is being blocked, then any connection attempts will either fail immediately with an error that the server is unreachable, or the connections will simply time-out. In either case, a relay server must be specified in order to send email messages.

A relay server is a system which will accept messages addressed to users who may be in a different domain, and will relay those messages to the appropriate server that does accept mail for the domain. Using a relay server is generally easier than sending messages directly to the recipient. In order to send a message through a relay, you need to perform the following steps:

1. Connect to the relay server as you would normally.
2. Authenticate the client to the server. This may or may not be required, depending on how the server is configured. Some servers may be configured to only require authentication if you are connecting from an IP address that is not recognized as part of that system's network, for example, if you are connecting using a different Internet Service Provider. Others may always require authentication. Check with the server administrator if necessary to determine if and when authentication is required.
3. Use the SendMessage method to deliver the message to the recipients through the relay server. If there are multiple recipients, you can use the MailMessage class to enumerate the recipient addresses and then pass them to the SendMessage method.

It is important to note that using a mail server as a relay without the permission of the organization or individual who owns that server may violate Acceptable Use Policies and/or Terms of Service agreements with your service provider. Systems which relay messages from anyone, regardless of whether the message is coming from a recognized domain, are called open relays. Because open relays are often used to send unsolicited email, many administrators block mail that comes from one. It is recommended that users check with their network administrators or Internet service providers to determine if access to external mail servers is restricted and what is the acceptable use policy for relaying messages through their mail servers.

Initialization

Initialize

Initialize an instance of the class, loading the networking library and validating the development license. This method must be called before any properties are changed or any other methods in this class are called by the application.

Connect

Connect to the server, using either a host name or IP address. This method creates the client session and must be called before your application attempts to request a resource from the server.

Authenticate

Authenticate yourself to the server using a username and password. This method should be called immediately after the connection has been established to the server. This is typically required if you are attempting to use the mail server as a relay, asking it to forward the message on to the server that actually accepts email for the recipient. Many Internet Service Providers (ISPs) require that users authenticate prior to sending mail through their servers. You may need to contact the server administrator to determine if authentication is required.

Disconnect
Disconnect from the server and release the memory allocated for that client session. After this method is called, the client session is no longer valid.

Reset
Reset the internal state of the component. This can be useful if your application wishes to discard any settings made by a user and return that instance of the class to its default state.

Uninitialize
Unload the networking library and release any resources that have been allocated for the class instance. This method is automatically invoked when the class instance is disposed or goes out of scope.

Message Delivery

There are two general methods that can be used to deliver messages through the mail server. In most cases, it can be done with a single method call. However, there are some circumstances where it would be more appropriate to perform the transaction in stages. The SMTP class supports both methods.

SendMessage
This is the simplest method for sending an email message through the server. You provide the sender and recipient addresses, along with the message contents and the method will submit the message to the server for delivery.

CreateMessage
This method begins a transaction in which a message is dynamically composed, addressed and delivered in stages. You provide the sender address and message size to this method, and after it returns you begin the next stage, which is addressing the message.

AddRecipient
This method adds a recipient address to the recipient list for the message. This should be called once for each recipient, as well as for any recipients who are to receive "blind copies" of the message. A blind copy is when the message is sent to a recipient, but that recipient's address is not listed in any of the headers of the message; the other recipients will be unaware that the message was delivered to him. Most servers have a limit of approximately 100 recipients per message. It is possible that this method will return an error for a specific recipient address; the address may be malformed or it may not be acceptable for some other reason. This does not mean that the message will be rejected in its entirety, only that the specified recipient is not acceptable.

AppendMessage
This method should be called after all of the recipients have been added. It is used to send the contents of the message to the server. It is also possible to use the lower level Write method to send data directly to the server, however AppendMessage is generally easier to use and can write data from memory, the system clipboard or from a file on disk.

CloseMessage
This method is called after the entire message has been sent to the server. This terminates the transaction and the message is submitted for delivery. Note that it is possible for the server to accept the message up to this point and then reject it at this final step due to some restriction, such as the message being too large.

Windows Sockets (SocketWrench)

The SocketWrench class provides a simplified interface to the Windows Sockets API. It was designed to be easier to use, and to provide properties and methods which eliminate much of the redundant coding common to network programming. SocketWrench also supports creating client and server applications which use the SSL and TLS security protocols without any dependencies on third-party security libraries.

Initialization

Initialize

Initialize an instance of the class, loading the networking library and validating the development license. This method must be called before any properties are changed or any other methods in this class are called by the application.

Connect

Connect to the server, using either a host name or IP address. When an application calls this method, it will be acting as a client. This method creates the socket and must be called before your application attempts to exchange data with a server. For an asynchronous session, set the Blocking property to False.

Listen

Begin listening for incoming client connections. When an application calls this method, it will be acting as a server. Once the Listen method returns, the socket is created and that socket handle is used by the Accept method accept an incoming client connection. For an asynchronous session, set the Blocking property to False.

Accept

Accept a connection from a client. This method should only be called if the application has previously called the Listen method. If there is no client waiting to connect at the time this method is called, it will block until a client connects or the timeout period is reached.

Uninitialize

Unload the networking library and release any resources that have been allocated for the class instance. This method is automatically invoked when the class instance is disposed or goes out of scope.

Input and Output

When a TCP connection is established, data is sent and received as a stream of bytes. The following methods can be used to send and receive data over the socket:

Read

A low-level method used to read data from the socket and copy it to the string buffer or byte array provided by the caller. If the server closes the connection, this method will return zero after all the data has been read. If the method is successful, it will return the actual number of bytes read. This method should always be used when reading binary data from the server into a byte array.

ReadLine

Read a line of text from the socket, up to an end-of-line character sequence or when the server closes the connection. This method is useful when the client and server are exchanging textual data, as is common with most command/response application protocols.

ReadStream

A high-level method used to read a stream of bytes and copy it to a string buffer or byte array provided by the caller. This method can be used to read an arbitrarily large amount of data in a single call.

Write

A low-level method used to write data to the socket. If the method succeeds, the return value is the number of bytes actually written. This method should always be used when sending binary data to the remote host.

WriteLine
Write a line of text to the socket, terminating it with an end-of-line character sequence. This method is useful when the client and server are exchanging textual data, as is common with most command/response application protocols.

WriteStream
A high-level method used to write a stream of bytes to the socket. This method can be used to write an arbitrarily large amount of data to the socket in a single call.

IsReadable
This property is used to determine if there is data available to be read from the socket. If the property returns a value of True, the Read method will return without causing the application to block. If the property returns False, there is no data available to read from the socket.

IsWritable
This property is used to determine if data can be written to the socket. In most cases this will return True, unless the internal socket buffers are full.

Host Name Resolution

The class can be used to resolve host names into IP addresses, as well as perform reverse DNS lookups converting IP addresses into the host names that are assigned to them. The class will search the local system's host table first, and then perform a nameserver query if required.

HostAddress
This property can be used to set the IP address for a server that you wish to communicate with. If the address is valid and matches an entry in the host table, the HostName property will be changed to match the address.

HostName
This property should be set to the name of the server that you wish to communicate with. If the name is found in the host table, the HostAddress property is updated to reflect the IP address of the host. Note that it is legal to assign an IP address to this property, but it is not legal to assign a host name to the HostAddress property.

Local Host Information

Several methods are provided to return information about the local host, including its fully qualified domain name, local IP address and the physical MAC address of the primary network adapter.

LocalName
Return the fully qualified domain name of the local host, if it has been configured. If the system has not been configured with a domain name, then the machine name is returned instead.

LocalAddress
Return the IP address of the local host. If a connection has been established, then the IP address of the network adapter that was used to establish the connection will be returned. This can be particularly useful for multihomed systems that have more than one adapter and the application needs to know which adapter is being used for the connection.

ExternalAddress
Return the IP address assigned to the router that connects the local host to the Internet. This is typically used by an application executing on a system in a local network that uses a router which performs Network Address Translation (NAT).

PhysicalAddress
Return the physical MAC address for the primary network adapter on the local system.

AdapterAddress
This property array returns the IP addresses that are associated with the local network or remote dial-up

network adapters configured on the system. The AdapterCount property can be used to determine the number of adapters that are available.

Telnet Protocol

The Telnet Protocol control enables an application to connect to a Telnet server, which provides an interactive terminal session similar to how character based consoles and terminals work. The user can login, enter commands and interact with applications programmatically or in conjunction with the terminal emulation control.

Initialization

Initialize
Initialize an instance of the class, loading the networking library and validating the development license. This method must be called before any properties are changed or any other methods in this class are called by the application.

Connect
Establish a connection to the server. Once the connection has been established, the other methods in the class may be used to exchange data with the server.

Disconnect
Disconnect from the server and release the memory allocated for that client session. After this method is called, the client session is no longer valid.

Reset
Reset the internal state of the component. This can be useful if your application wishes to discard any settings made by a user and return that instance of the class to its default state.

Uninitialize
Unload the networking library and release any resources that have been allocated for the class instance. This method is automatically invoked when the class instance is disposed or goes out of scope.

Input and Output

Once connected to the Telnet server, any output generated by a program on the server will be sent as data for the client to read. Any input to the program is sent by the client and received and processed by the server. The following methods are used:

Read
Reads any output that has been generated by the program executing on the server. When the client first connects, the server typically executes a login program that requests the users authenticate themselves by entering a user name and password. Once the user has logged in, they are usually given a command line prompt where they can enter commands to be executed on the server. If the server closes the connection, the Read method will indicate that with an error result and the client can disconnect from the server at that point.

Write
Send data to the Telnet server which will be received as input to the program. If the local echo option is enabled, then the client is also responsible for writing the input data to the display device, if there is one. If local echo is not enabled, the server will automatically echo back any characters written as data to be read by the client.

Local Echo

Telnet supports a mode of operation where the it is the responsibility of the client to echo any data sent to the server. This is controlled by the LocalEcho property.

LocalEcho
If this property is set to True, it is the responsibility of the client to echo any data that it is sending to the server. For example, if the character "A" is sent to the server, the application must also send the character

"A" to whatever interface the user is interacting with, such as a terminal emulation window. The default mode is for this option to be disabled, which means that the server will echo back any data that is sent to it.

Command Processing

The Telnet protocol can be used to connect to a server, log in and execute one or more commands, process the output from those commands and display it to an end-user using a graphical interface. The user never sees or interacts with the actual terminal session. The Telnet interface provides methods which can simplify this kind of application, reducing the amount of code needed to process the data stream returned by the server.

Login
This method is used to automatically log a user in, using the specific user name and password. This method is specifically designed for UNIX based servers or Windows servers which emulate the same basic login sequence.

Search
This method is used to search for a specific character or sequence of characters in the data stream returned by the server. The control will accumulate all of the data received up to the point where the character sequence is encountered. This can be used to capture all of the output from a command, or search for specific results returned by the command as it executes on the server.

Terminal Emulation

The Terminal Emulation control provides a virtual terminal interface for emulating an ANSI or DEC VT-220 compatible character-based terminal. It can be used in conjunction with the Telnet interface or the Remote Command interface to display the output of commands executed on a server. It can also be used independently of any other networking control, such as providing emulation services for a serial connection.

Display Management

The control provides a number of properties and methods to manage and update the virtual display. The most commonly used methods are:

BackColor
This property can be used to change the background color displayed by the virtual terminal.

ColorMap
This property array can be used to change the default colors which are used when escape sequences are used to change the foreground or background color of a character cell. In most cases the default color map will be appropriate, but applications can change the RGB values associated with an entry in the color map if needed. For example, the default value for the color gray is at position 8 in the color map index with an RGB value of 192,192,192. If you wanted to use a darker color, you could change the RGB value to 128,128,128

Emulation
This property specifies the type of emulation that will be performed by the control. The control is capable of emulating an ANSI console, a DEC VT-100 and DEC VT-220/320 terminal.

Font
This property sets the font which is used by the control to draw text on the display window. It is recommended that you only used fixed-width fonts such as Terminal or Courier New.

ForeColor
This property can be used to change the foreground color displayed by the virtual terminal.

Write
This is the most commonly used method of writing to the display. This method will automatically parse the data being written for escape sequences and update the display appropriately.

Refresh
Refresh the virtual display, updating the current cursor position and caret. The control will periodically refresh the display automatically based on its own internal state, but the application can call this if it wishes to force the display to refresh at that time.

Reset
This method can be used to reset the display window, the font being used and the size of the display. Note that resetting the display causes the contents of the display to be cleared.

Cursor Control

There are a number of properties and methods which enable an application to have direct control over cursor positioning, clearing the display and so on. In most cases these methods are called automatically by the control as the result of processing the escape sequences found in the data being written to the display. However, an application can choose to manage the display itself. One important thing to keep in mind is that the X,Y positions used by these properties and methods refer to the cursor position in the virtual display and correspond to columns and rows, not pixels.

There is also a slight difference in terminology that you should be aware of when reading the technical reference documentation. In Windows, the term "cursor" is typically used to refer to the mouse pointer, while "caret" is used to refer to the blinking marker that is displayed at the current position in the display. In the documentation for the emulator, the term "cursor" is used in the same way that it is used for character based terminals, as the marker for the current position in the display. Therefore, in terms of the control, you can think of the cursor and the caret as being synonymous.

CursorX
This property returns the current position of the cursor in the display, or can be used to change the current position. The current position is given in columns and indicates where the next text character will be displayed.

CursorY
This property returns the current position of the cursor in the display, or can be used to change the current position. The current position is given in rows and indicates where the next text character will be displayed.

Clear
This method clears the contents of the display. You can clear from the start of the display to the current cursor position, from the current position to the end of the display or the entire display.

DelLine
This method deletes the line at the current cursor position, shifting the remaining lines in the display up.

InsLine
This method inserts a blank line at the current cursor position, shifting the following lines down.

ScrollDown
This method scrolls the display down by one line.

ScrollUp
This method scrolls the display up by one line.

Function Key Mapping

Another aspect of terminal emulation is how function keys and other special keys are handled by the application. The emulation control can be used to convert Windows virtual key codes into the escape sequences that are generated by character based terminals.

KeyMap
This property array allows the application to define character sequences that should be mapped to special keys. When a special key is pressed in the emulation window and there is an entry for it in the key map, the KeyMapped event is fired. For example, if the user presses the F1 key on the keyboard, the control will translate that key code into the three characters escape sequence ESC O P (the ASCII codes 27, 79, 80). That sequence of characters should be sent to the server, which will recognize it as the F1 function key being pressed. It is important to note that the different emulation types have different key mappings. Therefore, the server must be set to recognize the same type of terminal that you are emulating. If you have the emulation set as VT-220 but the server thinks that you are emulating a VT-100, it will not recognize some of the escape sequences correctly.

KeyMapped
This event is generated when the user presses a special key while the emulation window has focus, and that key is mapped to a string using the KeyMap property array. Typically an application will use this event to send the mapped key escape sequence to a server, such as a Telnet server.

Web Location Class

The SocketTools.WebLocation class enables an application to obtain geographical information about the physical location of the computer system based on its external IP address. This can allow developers to know where their application is being used, and provide convenience functionality such as automatically completing a form based on the location of the user.

The connection to the location service is always secure and does not require you subscribe to any third-party services. The accuracy of this information can vary depending on the location, with the most detailed information being available for North America. The country and time zone information for all locations is generally accurate. However, as the location information becomes more precise, details such as city names, postal codes and specific geographic locations (e.g.: longitude and latitude) may have reduced accuracy.

Software which is designed to protect the privacy of users, such as those which route all Internet traffic through proxy servers or VPNs, can significantly impact the accuracy of this information. In this case, the data returned in this structure may reflect the location of the network or proxy server, and not the location of the person using your application. It is recommended you always request permission from the user before acquiring their location, have them confirm the location is correct and provide a mechanism for them to update the information.

Methods

To obtain the location of the local computer system, use the following methods:

Initialize
Initialize an instance of the class, loading the networking library and validating the development license. This method must be called before any properties are changed or any other methods in this class are called by the application.

Update
This method causes the class to update its various properties with information about the current location. The location service is queried to obtain current information about the physical location of the computer system based on its external IP address. The location data is cached and additional queries are only performed if it detects the external IP address for the local system has changed.

Uninitialize
Unload the networking library and release any resources that have been allocated for the class instance. This method is automatically invoked when the class instance is disposed or goes out of scope.

Properties

The following properties provide information about the current location of the local computer:

Property	Description
ASNumber	An integer which is used to uniquely identify a global network (autonomous system) which is connected to the Internet. This value can be used to determine the ownership of a particular network.
CityName	A string which identifies the city at this location. These names will always be in English, regardless of the current system locale. If the city name cannot be determined, this member may contain an empty string.
Coordinates	A string which specifies the location expressed using the Universal Transverse Mercator (UTM) coordinate system with the WGS-84 ellipsoid. These coordinates are commonly used with the Global Positioning System (GPS).
CountryAlpha	A string which contains the ISO 3166-1 alpha-2 code assigned to the country. For example, the alpha-2 code for the United States is "US".

CountryCode	An integer value which identifies the country using the standard UN country code. For example, the numeric country code for the United States is 840.
CountryName	A string which contains the full name of the country in which the external IP address is located, such as "United States". These names will always be in English, regardless of the current system locale.
IPAddress	A string which contains the external IP address for the local system. If the system has been assigned multiple IP addresses, it reflects the address of the interface used to establish the connection with the location server.
Latitude	A real number which specifies the latitude of the location in decimal format. A positive value indicates a location which is north of the equator, while a negative value is a location which is south of the equator.
LocalTime	The current date and time at the location, adjusted for its time zone and whether or not it's in daylight savings time.
LocationId	A string which contains contains a string of hexadecimal characters which uniquely identifies the location for this computer system. This value is used internally by the location service, and may also be used by the application for its own purposes.
Longitude	A real number which specifies the longitude of the location in decimal format. A positive value indicates a location which is east of the prime meridian, while a negative value is a location which is west of the prime meridian.
Organization	A string which identifies the organization associated with the local system's external IP address. For residential end-users this is typically the name of their Internet Service provider, however it may also identify a private company.
PostalCode	A string which contains the postal code associated with the location. In the United States, this is a 5-digit numeric code. Local delivery portions of a postal code (such as the ZIP+4 code in the United States) are not included.
RegionCode	An integer which identifies the geographical region. This value corresponds to standard UN M49 region codes.
RegionName	A string which identifies a broad geographical area, such as "North America" or "Southeast Asia".
Subdivision	A string which identifies a geopolitical subdivision within a country. In the United States, this will contain the full name of the state or commonwealth. In Canada, this will contain the name of the province or territory.
SubdivisionCode	A string which is either a two- or three-letter code which identifies a geopolitical subdivision within the country. These codes are defined by the ISO 3166-2 standard. For example, the code for the state of California in the United States is "CA".
Timezone	A string which specifies the full time zone name. These names are defined by the Internet Assigned Numbers Authority (IANA) and have values like "America/Los_Angeles" and "Europe/London".
TzOffset	A integer which specifies the number of seconds east or west of the prime meridian (UTC). A positive value indicates a time zone which is east of the prime meridian and a negative value indicates a time zone which is west of the prime meridian.
TzShortName	A string which specifies the abbreviated time zone code. If daylight savings time is used within the time zone, then this value can change based on whether or not daylight savings is in effect. If a short time zone code cannot be determined, a value such as "UTC+9" may be returned, indicating the number of hours ahead or behind UTC.

Web Storage Class

The SocketTools.WebStorage class provides private cloud storage for uploading and downloading shared data files which are available to your application. This is primarily intended for use by developers to store configuration information and other data generated by the application. For example, you may want to store certain application settings, and the next time a user or organization installs your software, those settings can be downloaded and restored.

The connection to the storage service is always secure, using TLS 1.2 and AES-256 bit encryption. There are no third-party services you need to subscribe to, and there are no additional usernames or passwords for you to manage. Access to the service is associated with an account which is created when you purchase a development license, and the security tokens are bound to the runtime license key used when initializing the API. You also have the option to compress and encrypt your data you store using the FileEncoder class.

Terminology

When you get started with the WebStorage class, you'll notice there is some different terminology which is used. This will provide an overview of that terminology, and compare it to common terms used with traditional protocols like FTP. When accessing an FTP server, you generally deal with ***directories***, ***files***, ***names*** and ***types*** (generally whether the file is binary or text). The storage control has similar concepts, but uses somewhat different terminology.

Application Identifiers

An application identifier (AppId) is a null terminated string which uniquely identifies your application. This string, used in conjunction with your runtime license key, is used to generate an access token. This token is used to access the storage container which contains the data which you've stored.

It is recommended you use a standard format for the AppId which consists of your company name, application name and optionally a version number. Some examples of an AppId string would be:

- MyCompany.MyApplication
- MyCompany.MyApplication.1

It is important to note with these two example IDs, although they are similar, they reference two different applications. Objects stored using the first ID will not be accessible using the second ID. If you want to store objects which should be shared between all versions of the application, it is recommended you use the first form, without the version number. If you want to store objects which should only be accessible to a specific version of your application, then it is recommended you use the second form which includes the version number.

The AppId must only consist of ASCII letters, numbers, the period and underscore character. Whitespace characters and non-ASCII Unicode characters are not permitted. The maximum length of the string is 63 characters. It is not required for your application to create a unique AppId. Each storage account has a default internal AppId named `SocketTools.Storage.Default`. This AppId is used if a NULL pointer or an empty string is specified.

Containers

Storage containers are somewhat analogous to directories or folders in a file system, however they are general purpose and designed to allow you to control how your application accesses the data that's been stored. There are four container types which are defined by the control, and you can think of them as types of boxes or file cabinets which you store your data in.

It is important to keep in mind these containers are available to all users of your application, your program controls who has access to any particular data file. Your users will not be able to "browse" any of the containers unless you specifically provide that capability by implementing it in your own code. There is no public access to any of the data which you upload, and our service does not use an open API accessible by third parties.

The storage containers are identified using the WebStorage.Container enumeration:

`Container.storageGlobal`
The global storage container which is available to all users of your application. Any data stored in this container is available to everyone who uses your software. Unless you have a specific need to limit access to the data to a specific user or group of users, this is the recommended container you use to store data.

`Container.storageDomain`
The domain storage container is limited to users in the same local domain, defined either by the name of the domain or workgroup assigned to the computer system. This can provide a kind of organization wide storage, but it does depend on the domain being unique. For example, if you are using domain storage for your application, and you have multiple customers who have systems part of the default "Workgroup" domain, they would all share the same container. If the domain or workgroup name changes, then data stored in the container would no longer be available.

`Container.storageMachine`
The local machine storage container is associated with the physical computer system your application is running on. The machine is identified by unique characteristics of the system, including the boot volume GUID. Data stored in this container can only be accessed from the application running on that particular system. If the operating system is reinstalled, the machine ID will change and data stored in this container would no longer be available.

`Container.storageUser`
The current user storage container is associated with the current user who is using your application. The user identifier is based on the Windows Security Identifier (SID) assigned to the account when it's created. If the user account is deleted, the data stored in this container will no longer be available to the application. Another user on the same computer system would not be able to access the data in this container.

If you decide to use anything other than global storage, the data your application stores can be orphaned if the system configuration or user account changes. It's recommended you store critical application data and general configuration information using `Container.storageGlobal` and use other non-global storage containers for configuration information which is unique to that system and/or user which is not critical and can be easily recreated. If you're concerned about protecting the data you upload to global storage, you can encrypt it prior to storing it.

Objects

Storage objects are similar to files in a file system. They are discrete blocks of data, associated with a label (name), have attributes and are associated with a particular content type. However, an object does not need to be an actual file on the local system. For example, you could store an object which is a string, a pointer to a structure, or any block of memory. You could also just store a complete file as an object. Unlike files, you cannot perform partial reads of an object or "seek" into certain parts of a stored object. Of course, you can download an object, either in memory or to a local file, and perform whatever operations you require on the data.

Labels

Object labels are similar to file names, and are a way to identify a stored object instead of using its internal object ID. However, there are some important differences. The most significant difference being labels are case-sensitive, unlike Windows file names. An object with the label "AppConfig" is considered to be different than one with the label "appconfig". Labels can contain Unicode characters, but they cannot contain control characters.

You can also use forward slashes or backslash characters in the label, but it's important to note objects are not stored in a hierarchical structure. Your application can store objects using a folder-like structure, but it's not something which is enforced by the API.

Media Type

Each object your application stores is associated with a media type (also called a content type) which identifies the object's data. This uses the standard MIME media type designations, such as "text/plain" or "application/octet-stream". Your application can explicitly specify the media type you want to associate with the object, or you can have the API choose for you, based on the contents of the object and using the label as a hint for what it may contain. For example, if you create an object with the label "AppConfig.xml" and it contains text, then the API will select "text/xml" as the default media type.

Initialization

The first step your application must take is to initialize the control and then open a storage container. The following methods are available for use by your application:

Initialize
nitialize an instance of the class, loading the networking library and validating the development license. This method must be called before any properties are changed or any other methods in this class are called by the application.

Open
Opens a storage container for your application. Subsequent operations, such as storing, retrieving and copying objects will be performed within this container.

Close
Close the storage container and release the resources allocated for the session.

Uninitialize
Unload the networking library and release any resources that have been allocated for the class instance. This method is automatically invoked when the class instance is disposed or goes out of scope.

Data Storage

The control provides methods to upload and download to the storage container. You can store the contents of local files, or you can create objects from memory using strings or byte arrays.

GetData
Download object data and store it in a string or byte array provided by the caller.

GetFile
Download object data and store it in a file on the local system.

PutData
Upload object data in a string or byte array and store it as an object in the current container. This function would typically be used to store binary data, including compressed or encrypted text.

PutFile
Upload the the contents of a local file and store it as an object in the current container.

Data Management

The data management methods allow you to obtain information about stored objects and perform typical operations such as copying, renaming and deleting objects from the container.

FindFirst
Enables your application to search for and enumerate objects in a container based on their label and/or

their media type. This method is used in conjunction with the FindNext method to list all matching objects in a container.

CompareData
Compares the contents of a string or byte array with the data stored in an object. This method can be used to determine if the contents of the buffer have changed since the data was previously stored using the PutData method.

CompareFile
Compares the contents of a local file with the data in a stored object. This method can be used to determine if the contents of a file have changed since it was previously stored using the PutFile method.

Copy
Copies the contents of a stored object to a new container, or duplicating the object within the same container using a different label.

Move
Moves the contents of a stored object to a new container.

Rename
Changes the label associated with a stored object. The new label for the object cannot already exist in the same container. If you want to change the label to one already assigned to an existing object, the object must first be deleted.

Delete
Removes the stored object from the container. This operation is immediate and permanent. Deleted objects cannot be recovered by the application at a later time.

DeleteAll
Deletes all objects which are stored in the current open container. This method resets the container back to its initial state, deleting all object metadata from the database and removing all stored data. This operation is immediate and the objects stored in the container are permanently deleted. They cannot be recovered by your application.

Other Methods

Several additional methods are available, allowing your application register and de-register custom application identifiers and validate object labels.

RegisterId
Register a new application identifier (AppId) to be used to access a storage container. It is not required you create a unique application ID, but it can be helpful to distinguish stored content between different versions of your applications.

UnregisterId
Unregister an application identifier which was previously registered by your application. You should be extremely careful when using this function because it permanently delete all stored objects created using the AppId value. Internally it revokes the access token granted to your application and causes the server to expunge all objects in the container associated with the token.

ValidateId
A method which can be used to validate an application identifier, ensuring it is valid and has been registered.

ValidateLabel
A method which can be used to validate an object label to ensure it does not contain any invalid characters. This would be primarily used by applications which allow a user to specify the label names for the objects being stored.

Whois Protocol

The Whois protocol class provides an interface for requesting information about an Internet domain name. When a domain name is registered, the organization that registers the domain must provide certain contact information along with technical information such as the primary name servers for that domain. The Whois protocol enables an application to query a server that provides that registration information. The Whois class provides an interface for requesting that information and returning it to the program so it can be displayed or processed.

Overview

Initialize

Initialize an instance of the class, loading the networking library and validating the development license. This method must be called before any properties are changed or any other methods in this class are called by the application.

Connect

Connect to the server, using either a host name or IP address. Once the connection has been established, the other methods in the class may be used to retrieve information from the server.

Search

This method submits a search keyword to the server. The keyword may specify a domain name, a user handle or a user mailbox, depending on the search type. Note that not all servers support all search types. For example, many servers no longer support searching for user information based on email addresses.

Read

Read the data returned by the server, storing it in a string variable or byte array that is specified by the caller. This will contain the information about the domain specified when the Search method was called. Note that the data returned will typically be text, however it may not follow the same end-of-line conventions as Windows. For example, if the server is a UNIX or Linux system, the end-of-line may be indicated by a single linefeed, rather than a carriage-return/linefeed pair. Your application will have to account for this if the data is being displayed as-is to a user.

Disconnect

Disconnect from the server and release the memory allocated for that client session. After this method is called, the client session is no longer valid.

Reset

Reset the internal state of the component. This can be useful if your application wishes to discard any settings made by a user and return that instance of the class to its default state.

Uninitialize

Unload the networking library and release any resources that have been allocated for the class instance. This method is automatically invoked when the class instance is disposed or goes out of scope.

SocketTools Namespace

Classes

Class	Description
DnsClient	The **DnsClient** class resolves domain names into Internet addresses and return information about a remote host, such as the servers that are responsible for accepting mail for the domain.
FileEncoder	The **FileEncoder** class encodes and decodes files using standard algorithms such as base64, uuencode and quoted-printable. The class can also be used to compress and expand files, as well as encrypt or decrypt file data using AES encryption.
FtpClient	The **FtpClient** class implements the File Transfer Protocol (FTP) o transfer files between the local system and a remote server. This class supports both high level operations, such as uploading or downloading files, as well as a collection of lower-level file I/O functions. In addition to file transfers, an application can create, rename and delete files and directories, search for files using wildcards and perform other common file management functions. Secure file transfers are supported using TLS 1.2 and SSH 2.0.
FtpServer	The **FtpServer** class implements an embedded, lightweight server that can be used to exchange files with a client using the standard File Transfer Protocol. The server can accept connections from any third-party application or a program developed using the SocketTools.FtpClient class. Secure file transfers are supported using TLS 1.2.
HttpClient	The **HttpClient** class implements the Hypertext Transfer Protocol (HTTP), a lightweight, stateless application protocol used to access resources on web servers, as well as send data to those servers for processing. The class provides direct, low-level access to the server and the commands that are used to retrieve resources (i.e.: documents, images, etc.). The class also provides a simple interface for downloading resources to the local host, similar to how the SocketTools.FtpClient class can be used to download files. This class supports secure connections using TLS 1.2 and authentication using OAuth 2.0 bearer tokens.
HttpServer	The **HttpServer** class implements an embedded, lightweight server that can be used to provide access to documents and other resources using the Hypertext Transfer Protocol (HTTP). The server can accept connections from any standard web browser, third-party applications or programs developed using the SocketTools.HttpClient class. Secure connections are supported using TLS 1.2.
IcmpClient	The **IcmpClient** class implements the Internet Control Message Protocol (ICMP) which can be used to determine if a remote host is reachable and how packets of data are routed to that system. This class can be used to check if a system is reachable and the amount of time that it takes for a packet of data to make a round trip from the local system, to the remote host and then back again. It can also trace the route that a packet of data takes from the local system to the remote host, and can be used to identify potential problems with overall throughput and latency.

ImapClient	The **ImapClient** class implements the Internet Message Access Protocol (IMAP) is an application protocol which is used to access a user's email messages which are stored on a mail server. This class implements the current standard for this protocol, and provides functions to retrieve messages, or just certain parts of a message, create and manage mailboxes, search for specific messages based on certain criteria and so on. This class is typically used in conjunction with the SocketTools.MailMessage class which is used to process the messages that are retrieved from the server. This class supports secure connections using TLS 1.2 and authentication using OAuth 2.0 bearer tokens.
InternetDialer	The **InternetDialer** class provides a way for client applications to connect to the Internet using Microsoft Windows Remote Access Services (RAS). To use this class, the dial-up networking software must be installed on the local system. For access to the Internet, the TCP/IP protocol must be installed and configured. The class may configured to use either the SLIP or PPP protocols, depending on the requirements of the service provider. Refer to your system documentation for information about installing and configuring dial-up networking on your system.
InternetServer	The **InternetServer** class provides a simplified interface for creating event-driven, multithreaded server applications using the TCP/IP protocol. The interface is similar to the SocketTools.SocketWrench class, however it is designed specifically to make it easier to implement a server application without requiring the need to manage multiple socket classes. In addition, the class supports secure connections using TLS 1.2.
MailMessage	The **MailMessage** class provides an interface for composing and processing email messages and newsgroup articles which are structured according to the Multipurpose Internet Mail Extensions (MIME) standard. Using this class, an application can easily create complex messages which include multiple alternative content types, such as plain text and styled HTML text, file attachments and customized headers. This class is typically used in conjunction with the SocketTools.ImapClient and SocketTools.PopClient classes.
NetworkTime	The **NetworkTime** class provides an interface for synchronizing the local system's time and date with that of a server. The time values returned are in in Coordinated Universal Time and be adjusted for the local host's time zone. The class enables developers to query a server for the current time and then update the system clock if desired.
NewsFeed	The **NewsFeed** class provides an interface parsing Really Simple Syndication (RSS) feeds. A news feed is published in XML format, which contains one or more items that includes summary text, hyperlinks to source content and additional metadata that is used to describe the item. News feeds can be used for a variety of purposes, including providing updates for weblogs, news headlines, video and audio content. News feeds can be accessed remotely from a web server, or locally as an XML formatted text file.
NntpClient	The **NntpClient** class implements the Network News Transfer Protocol (NNTP) which is used to download and post news articles. This is similar in functionality to bulletin boards or message boards, where topics are organized hierarchically into groups, called newsgroups. The largest

	collection of public newsgroups available is called USENET, a world-wide distributed discussion system. Secure connections are supported using TLS 1.2.
PopClient	The **PopClient** class provides access to a user's new email messages on a mail server. Methods are provided for listing available messages and then retrieving those messages, storing them either in files or in memory. Once a user's messages have been downloaded to the local system, they are typically removed from the server. This class is typically used in conjunction with the SocketTools.MailMessage class which is used to process the messages that are retrieved from the server. This class supports secure connections using TLS 1.2 and authentication using OAuth 2.0 bearer tokens.
RshClient	The **RshClient** class is used to execute a command on a server and return the output of that command to the client. This is most commonly used with UNIX based servers, although there are implementations of remote command servers for the Windows operating system. The class supports both the **rcmd** and **rshell** remote execution protocols. This class should not be used when connecting to a server over the Internet because the user credentials are not encrypted. For secure remote command execution and interactive terminal sessions, it is recommended you use the SocketTools.SshClient class.
SmtpClient	The **SmtpClient** class enables applications to deliver email messages to one or more recipients. The class provides an interface for addressing and delivering messages, and extended features such as user authentication and delivery status notification. There is no requirement to have certain third-party email applications installed or specific types of servers installed on the local system. This class supports secure connections using TLS 1.2 and authentication using OAuth 2.0 bearer tokens.
SocketWrench	The **SocketWrench** class is a general purpose networking class used to develop Internet and intranet applications using the TCP/IP protocol. With SocketWrench, you can create both client and server applications, as well as send and receive UDP datagrams. SocketWrench also supports secure connections using the Transport Layer Security (TLS) protocols. Enabling the security features of the class is done by setting a single property and does not require another .NET class to implement the encryption.
SshClient	The **SshClient** class is used to establish a secure connection with a server which provides a virtual terminal session for a user. Its functionality is similar to how character based consoles and serial terminals work, enabling a user to login to the server, execute commands and interact with applications running on the server. It also includes methods that enable a program to easily scan the data stream for specific sequences of characters, making it easy to create light-weight client interfaces to applications running on the server. File transfers using SFTP are implemented using the SocketTools.FtpClient class.
TelnetClient	The **TelnetClient** class is used to establish a connection with a server which provides a virtual terminal session for a user. Its functionality is similar to how character based consoles and serial terminals work,

	enabling a user to login to the server, execute commands and interact with applications running on the server. This class supports secure connections using TLS 1.2.
Terminal	The **Terminal** class is a Windows Forms control which provides a comprehensive interface for emulating an ANSI or DEC-VT220 terminal, with full support for all standard escape and control sequences, color mapping and other advanced features. The class provides both a high level interface for parsing escape sequences and updating a display, as well as lower level primitives for directly managing the virtual display, such as controlling the individual display cells, moving the cursor position and specifying display attributes.
TextMessage	The **TextMessage** class enables your application to send Short Message Service (SMS) messages using a service provider gateway. It submits messages to a wireless device on their network using standard email protocols. The clas provides methods that can be used to determine the provider associated with a specific telephone number and send a text message to the device using the provider's mail gateway. It does not require a third-party service to submit text messages, however it cannot be used to receive text messages.
WebLocation	The **WebLocation** class returns information about the location associated with the with the external IP address of the local system. The accuracy of this information can vary depending on the location, with the most detailed information being available for North America. The country and time zone information for all locations is generally accurate. However, as the location information becomes more precise, details such as city names, postal codes and specific geographic locations (e.g.: longitude and latitude) may have reduced accuracy.
WebStorage	The **WebStorage** class enables an application to securely store and manage private application data on a server. This class uses SocketTools Web Services and will only function if there is an active Internet connection and the local system is capable of establishing a secure connection to our servers.
WhoisClient	The **WhoisClient** class provides an interface for requesting registration information for an Internet domain name. When a domain name is registered, the organization that registers the domain must provide certain contact information along with technical information such as the primary name servers for that domain. The class provides an interface for requesting that information and returning it to the program so that it can be displayed or processed.

DnsClient Class

Implements the Domain Name Services protocol.

For a list of all members of this type, see DnsClient Members.

System.Object
  SocketTools.DnsClient

[Visual Basic]

```
Public Class DnsClient
    Implements IDisposable
```

[C#]

```
public class DnsClient : IDisposable
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

The DnsClient class implements the Domain Name Services (DNS) protocol, which is used to resolve domain names into Internet addresses as well as provide other information about a domain. All of the SocketTools .NET classes provide basic domain name resolution functionality, but the DnsClient class gives an application direct control over what servers are queried, the amount of time spent waiting for a response and the type of information that is returned.

Requirements

Namespace: SocketTools

Assembly: SocketTools.DnsClient (in SocketTools.DnsClient.dll)

DnsClient Members | SocketTools Namespace

DnsClient Members

DnsClient overview

Public Static (Shared) Fields

dnsPortDefault	A constant value which specifies the default port number.
dnsRetries	A constant value which specifies the default number of retries.
dnsTimeout	A constant value which specifies the default timeout period.

Public Instance Constructors

DnsClient Constructor	Initializes a new instance of the DnsClient class.

Public Instance Fields

HostAlias	Returns the aliases for a given host name.
MailExchange	Returns the mail exchange servers for a given domain.
NameServer	Change or return the Internet address for a nameserver

Public Instance Properties

Handle	Returns the internal handle that is used by the class library.
HostAddress	Set or return the Internet address for the remote host.
HostAliases	Return the number of aliases for the specified host name.
HostFile	Set or return the name of an alternate host file.
HostInfo	Returns information about the host operating system.
HostName	Set or return the name of the remote host.
HostProtocol	Set the protocol to return service information for the specified host.
HostServices	Return the well-known services available for the specified host.
IsInitialized	Determine if the component has been initialized.
LastError	Set or return the last error that occurred.
LastErrorString	Return a description of the last error that occurred.
LocalAddress	Return the Internet address for the local system.
LocalDomain	Set or return the domain name for the local

	system.
LocalName	Return the host name for the local system.
MailExchanges	Return the number of mail exchange records for the specified host.
Options	Gets and sets a value which specifies one or more client options.
RemotePort	Set or return the port number used to establish a connection.
RemoteService	Set or return the name of the service associated with the remote port.
Retry	Set the number of times the control attempts to resolve a hostname.
ServerAddress	Return the address of the nameserver that resolved the query.
ThreadModel	Gets and sets a value which specifies the threading model for the class instance.
ThrowError	Enable or disable exceptions being raised when a method fails.
Timeout	Set or return the amount of time until a blocking operation fails.
Trace	Gets and sets a value which indicates if network function logging is enabled.
TraceFile	Specify the socket function trace output file.
TraceFlags	Set or return the network function tracing flags.
Version	Gets a value which returns the current version of the DnsClient class library.

Public Instance Methods

AttachThread	Attach an instance of the class to the current thread
Cancel	Cancels the current blocking network operation.
Dispose	Overloaded. Releases all resources used by DnsClient.
Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from Object)	Gets the Type of the current instance.
Initialize	Overloaded. Initializes the component with the specified runtime license key.
MatchHost	Overloaded. Match a host name against one more

	strings that may contain wildcards.
Query	Perform a general nameserver query for a specific type of record.
Reset	Reset the internal state of the component.
Resolve	Resolve a hostname to an Internet address.
ToString (inherited from Object)	Returns a String that represents the current Object.
Uninitialize	Uninitialize the component and unload the networking library.

Public Instance Events

OnCancel	Occurs when a blocking network operation is canceled using the Cancel method.
OnError	Occurs when a method fails.
OnTimeout	Occurs when a blocking network operation exceeds the timeout period specified by the Timeout property.

Protected Instance Methods

Dispose	Overloaded. Releases the unmanaged resources allocated by the DnsClient class and optionally releases the managed resources.
Finalize	Destroys an instance of the class, releasing the resources allocated for the client session and unloading the networking library.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

Public Sub New()
```

[C#]

```
public DnsClient();
```

Example

The following example demonstrates creating an instance of the **DnsClient** class object and resolving a hostname into an Internet address using the **Resolve** method.

```
Dim dnsClient As SocketTools.DnsClient
Dim strHostName As String
Dim strHostAddress As String

dnsClient = New SocketTools.DnsClient
strHostName = TextBox1.Text.Trim()

If dnsClient.Resolve(strHostName, strHostAddress) Then
    StatusBar1.Text = "The Internet address for " + strHostName + " is " +
strHostAddress
Else
    StatusBar1.Text = "The Internet address for " + strHostName + " could not be
resolved"
End If
```

DnsClient Class | SocketTools Namespace

DnsClient Fields

The fields of the **DnsClient** class are listed below. For a complete list of **DnsClient** class members, see the DnsClient Members topic.

Public Static (Shared) Fields

dnsPortDefault	A constant value which specifies the default port number.
dnsRetries	A constant value which specifies the default number of retries.
dnsTimeout	A constant value which specifies the default timeout period.

Public Instance Fields

HostAlias	Returns the aliases for a given host name.
MailExchange	Returns the mail exchange servers for a given domain.
NameServer	Change or return the Internet address for a nameserver

See Also

DnsClient Class | SocketTools Namespace

DnsClient.HostAlias Field

Returns the aliases for a given host name.

[Visual Basic]
```
Public ReadOnly HostAlias As HostAliasArray
```

[C#]
```
public readonly HostAliasArray HostAlias;
```

Remarks

The **HostAlias** array returns the aliases assigned to the host specified by the **HostAddress** or **HostName** properties. If the host address or name can be resolved, the first element in the **HostAlias** array always refers to the host's fully qualified domain name.

The end of the alias list is indicated when the property returns an empty string. The array is zero based, meaning that the first index value is zero.

Example

```
Dim nIndex As Integer

ListBox1.Items.Clear()
dnsClient.HostName = strHostName

For nIndex = 0 To dnsClient.HostAliases - 1
    ListBox1.Items.Add(dnsClient.HostAlias(nIndex))
Next
```

See Also

DnsClient Class | SocketTools Namespace | HostAliasArray Class | HostAliases Property

DnsClient.MailExchange Field

Returns the mail exchange servers for a given domain.

[Visual Basic]

```
Public ReadOnly MailExchange As MailExchangeArray
```

[C#]

```
public readonly MailExchangeArray MailExchange;
```

Remarks

The **MailExchange** array returns the host name of the systems designated as the mail exchanges for the current domain. The mail exchange hosts are returned sorted in priority order, with the higher priority mail servers being listed first. The array is zero based, which means that the first index value is zero. The **HostName** property must be set to the domain name that you want to obtain the mail exchange records for.

This array is commonly used to determine which system is responsible for forwarding mail within a domain. For example, if a mail message is addressed to the user `someone@example.com`, you can determine the name of the server or servers responsible for accepting mail for that user by setting the value of the HostName property to `example.com` and then checking the **MailExchange** array. Note that it is possible that a domain will not have any mail exchange (MX) records, in which case you should attempt to to connect directly to a mail server running on the host specified in the domain name portion of the address.

Example

The following example populates a ListBox control with the host names of those servers responsible for accepting email for the specified domain:

```
Dim nIndex As Integer

ListBox1.Items.Clear()
dnsClient.HostName = strHostName

For nIndex = 0 To dnsClient.MailExchanges - 1
    ListBox1.Items.Add(dnsClient.MailExchange(nIndex))
Next
```

See Also

DnsClient Class | SocketTools Namespace | MailExchangeArray Class | MailExchanges Property

DnsClient.NameServer Field

Change or return the Internet address for a nameserver

[Visual Basic]

```
Public ReadOnly NameServer As NameServerArray
```

[C#]

```
public readonly NameServerArray NameServer;
```

Remarks

The **NameServer** array is used to specify one or more nameservers used to resolve hostnames and addresses. The address value must be an IP address in dot notation.

The index specifies which nameserver to set or return a value for. There may be up to four nameservers defined for any single instance of the component.

See Also

DnsClient Class | SocketTools Namespace

DnsClient Properties

The properties of the **DnsClient** class are listed below. For a complete list of **DnsClient** class members, see the DnsClient Members topic.

Public Instance Properties

Handle	Returns the internal handle that is used by the class library.
HostAddress	Set or return the Internet address for the remote host.
HostAliases	Return the number of aliases for the specified host name.
HostFile	Set or return the name of an alternate host file.
HostInfo	Returns information about the host operating system.
HostName	Set or return the name of the remote host.
HostProtocol	Set the protocol to return service information for the specified host.
HostServices	Return the well-known services available for the specified host.
IsInitialized	Determine if the component has been initialized.
LastError	Set or return the last error that occurred.
LastErrorString	Return a description of the last error that occurred.
LocalAddress	Return the Internet address for the local system.
LocalDomain	Set or return the domain name for the local system.
LocalName	Return the host name for the local system.
MailExchanges	Return the number of mail exchange records for the specified host.
Options	Gets and sets a value which specifies one or more client options.
RemotePort	Set or return the port number used to establish a connection.
RemoteService	Set or return the name of the service associated with the remote port.
Retry	Set the number of times the control attempts to resolve a hostname.
ServerAddress	Return the address of the nameserver that resolved the query.
ThreadModel	Gets and sets a value which specifies the threading model for the class instance.

ThrowError	Enable or disable exceptions being raised when a method fails.
Timeout	Set or return the amount of time until a blocking operation fails.
Trace	Gets and sets a value which indicates if network function logging is enabled.
TraceFile	Specify the socket function trace output file.
TraceFlags	Set or return the network function tracing flags.
Version	Gets a value which returns the current version of the DnsClient class library.

See Also

DnsClient Class | SocketTools Namespace

DnsClient.Handle Property

Returns the internal handle that is used by the class library.

[Visual Basic]

```
Public ReadOnly Property Handle As Integer
```

[C#]

```
public int Handle {get;}
```

Property Value

An integer value that specifies the client session handle. A return value of -1 indicates that no handle has been allocated for the class library.

See Also

DnsClient Class | SocketTools Namespace

DnsClient.HostAddress Property

Set or return the Internet address for the remote host.

[Visual Basic]
```
Public Property HostAddress As String
```

[C#]
```
public string HostAddress {get; set;}
```

Property Value

A string value which specifies the Internet address in dot notation.

Remarks

Setting the **HostAddress** property causes the control to submit a reverse query to the nameservers that you have specified. If a reverse entry is found for the IP address, the **HostName** property is changed to that host name.

Note that reverse domain name records (PTR records) may not be defined for a system and the application must not depend on this information being available.

See Also

DnsClient Class | SocketTools Namespace | HostName Property

DnsClient.HostAliases Property

Return the number of aliases for the specified host name.

[Visual Basic]

```
Public ReadOnly Property HostAliases As Integer
```

[C#]

```
public int HostAliases {get;}
```

Property Value

An integer value which specifies the number of host aliases.

Remarks

The **HostAliases** property returns the number of aliases for the host specified by the HostName property. If the specified host name cannot be resolved, this property will return a value of zero.

This property is typically used in conjunction with the **HostAlias** array.

Example

```
Dim nIndex As Integer

ListBox1.Items.Clear()
dnsClient.HostName = strHostName

For nIndex = 0 To dnsClient.HostAliases - 1
    ListBox1.Items.Add(dnsClient.HostAlias(nIndex))
Next
```

See Also

DnsClient Class | SocketTools Namespace | HostAlias Field

DnsClient.HostFile Property

Set or return the name of an alternate host file.

[Visual Basic]

```
Public Property HostFile As String
```

[C#]

```
public string HostFile {get; set;}
```

Property Value

A string which specifies a file name.

Remarks

The **HostFile** property is used to specify the name of an alternate file for resolving hostnames and IP addresses. The host file is used as a database that maps an IP address to one or more hostnames, and is used when setting the **HostName** or **HostAddress** properties and establishing a connection with a remote host. The file is a plain text file, with each line in the file specifying a record, and each field separated by spaces or tabs. The format of the file must be as follows:

```
address hostname [hostalias ...]
```

For example, one typical entry maps the name "localhost" to the local loopback IP address. This would be entered as:

```
127.0.0.1 localhost
```

The hash character (#) may be used to specify a comment in the file, and all characters after it are ignored up to the end of the line. Blank lines are ignored, as are any lines which do not follow the required format.

Setting this property loads the file into memory allocated for the current thread. If the contents of the file have changed after the method has been called, those changes will not be reflected when resolving hostnames or addresses. To reload the host file from disk, set the property again with the same file name. To remove the alternate host file from memory, specify an empty string as the file name.

If a host file has been specified, it is processed before the default host file when resolving a hostname into an IP address, or an IP address into a hostname. If the host name or address is not found, or no host file has been specified, a nameserver lookup is performed.

See Also

DnsClient Class | SocketTools Namespace

DnsClient.HostInfo Property

Returns information about the host operating system.

[Visual Basic]

```
Public ReadOnly Property HostInfo As String
```

[C#]

```
public string HostInfo {get;}
```

Property Value

A string which specifies the host operating system.

Remarks

The **HostInfo** property returns a string that includes the machine type and operating system for the host. This information corresponds to it's HINFO record in the database.

See Also

DnsClient Class | SocketTools Namespace

DnsClient.HostName Property

Set or return the name of the remote host.

[Visual Basic]

```
Public Property HostName As String
```

[C#]

```
public string HostName {get; set;}
```

Property Value

A string which specifies the host name.

Remarks

The **HostName** property should be set to the name of the remote system that you wish to obtain information on. Setting this property causes a query to be submitted to the nameservers that you have specified. If the host name can be resolved, the **HostAddress** property is set to the IP address of the host, in dot-notation.

See Also

DnsClient Class | SocketTools Namespace

DnsClient.HostProtocol Property

Set the protocol to return service information for the specified host.

[Visual Basic]

```
Public Property HostProtocol As ProtocolType
```

[C#]

```
public DnsClient.ProtocolType HostProtocol {get; set;}
```

Property Value

A ProtocolType enumeration type.

Remarks

The **HostProtocol** property determines the protocol for which service information is returned.

See Also

DnsClient Class | SocketTools Namespace | ProtocolType Enumeration

DnsClient.HostServices Property

Return the well-known services available for the specified host.

[Visual Basic]
```
Public ReadOnly Property HostServices As String
```

[C#]
```
public string HostServices {get;}
```

Property Value

A string that specifies the available services.

Remarks

The **HostServices** property returns a string that contains a list of well-known services for the specified host. This corresponds to the WKS entry in the nameserver's database. The services returned depend on the protocol specified in the **HostProtocol** property.

See Also

DnsClient Class | SocketTools Namespace

DnsClient.IsInitialized Property

Determine if the component has been initialized.

[Visual Basic]

```
Public ReadOnly Property IsInitialized As Boolean
```

[C#]

```
public bool IsInitialized {get;}
```

Property Value

A boolean value which specifies if the component has been initialized.

Remarks

The **IsInitialized** property will return true if the object has been successfully initialized by the caller.

When an instance of the object is created, the class constructor will attempt to initialize itself using the runtime license key specified using the **RuntimeLicense** attribute. If no runtime license key has been specified, then the caller must explicitly initialize the object using the **Initialize** method.

See Also

DnsClient Class | SocketTools Namespace | Initialize Method | RuntimeLicense Attribute

DnsClient.LastError Property

Set or return the last error that occurred.

[Visual Basic]

```
Public Property LastError As ErrorCode
```

[C#]

```
public DnsClient.ErrorCode LastError {get; set;}
```

Property Value

An ErrorCode enumeration type.

Remarks

The **LastError** property can be read to determine the last error that occurred for this control. If a value is assigned to this property, it must either be zero to clear the error or a valid error code for the control.

See Also

DnsClient Class | SocketTools Namespace | ErrorCode Enumeration | LastErrorString Property

DnsClient.LastErrorString Property

Return a description of the last error that occurred.

[Visual Basic]

```
Public ReadOnly Property LastErrorString As String
```

[C#]

```
public string LastErrorString {get;}
```

Property Value

A string which describes the last error.

Remarks

The **LastErrorString** property returns a description of the last error that occurred. This can be used to display a meaningful error message to a user, rather than just the numeric value returned by the **LastError** property.

See Also

DnsClient Class | SocketTools Namespace | LastError Property

DnsClient.LocalAddress Property

Return the Internet address for the local system.

[Visual Basic]
```
Public ReadOnly Property LocalAddress As String
```

[C#]
```
public string LocalAddress {get;}
```

Property Value

A string which specifies an Internet address.

Remarks

The **LocalAddress** property returns the local system's Internet address in dot notation.

See Also

DnsClient Class | SocketTools Namespace | HostAddress Property | LocalName Property

DnsClient.LocalDomain Property

Set or return the domain name for the local system.

[Visual Basic]
```
Public Property LocalDomain As String
```

[C#]
```
public string LocalDomain {get; set;}
```

Property Value

A string that specifies the local domain name.

Remarks

The **LocalDomain** property is used to set the domain name for the local host. The local domain name is used when the name assigned to **HostName** property does not specify a domain (in other words, does not have a dot in the name). In that case, the value of the **LocalDomain** property is appended to the hostname.

If a domain name has been specified for the local system, the **LocalDomain** property is set to that value by default.

See Also

DnsClient Class | SocketTools Namespace | HostAddress Property | HostName Property

DnsClient.LocalName Property

Return the host name for the local system.

[Visual Basic]
```
Public ReadOnly Property LocalName As String
```

[C#]
```
public string LocalName {get;}
```

Property Value

A string which specifies the local host name.

Remarks

The **LocalName** property returns the name of the local host. The name that is returned depends on the configuration of the TCP/IP software.

See Also

DnsClient Class | SocketTools Namespace | HostName Property | LocalAddress Property

DnsClient.MailExchanges Property

Return the number of mail exchange records for the specified host.

[Visual Basic]

```
Public ReadOnly Property MailExchanges As Integer
```

[C#]

```
public int MailExchanges {get;}
```

Property Value

An integer value. A value of zero specifies that there are no mail exchange records for the host.

Remarks

The **MailExchanges** property returns the number of mail exchange (MX) records for the current host specified by the **HostName** property. This property can be used in conjunction with the **MailExchange** array to enumerate the servers responsible for accepting mail for a given domain.

Example

The following example populates a ListBox control with the host names of those servers responsible for accepting email for the specified domain:

```
Dim nIndex As Integer

ListBox1.Items.Clear()
dnsClient.HostName = strHostName

For nIndex = 0 To dnsClient.MailExchanges - 1
    ListBox1.Items.Add(dnsClient.MailExchange(nIndex))
Next
```

See Also

DnsClient Class | SocketTools Namespace | MailExchange Field

DnsClient.RemotePort Property

Set or return the port number used to establish a connection.

[Visual Basic]

```
Public Property RemotePort As Integer
```

[C#]

```
public int RemotePort {get; set;}
```

Property Value

An integer value which specifies the remote port number.

Remarks

The **RemotePort** property is used to set the port number that the control will use to establish a connection with the remote server. If the port number specifies a well-known port, the **RemoteService** property will be updated with that name.

The valid range for port numbers is 1 through 65535, inclusive. Specifying a port number outside of this range can cause an exception to be thrown. In most cases, it is recommended that you specify the default port number for the protocol.

See Also

DnsClient Class | SocketTools Namespace | RemoteService Property

DnsClient.Retry Property

Set the number of times the control attempts to resolve a hostname.

[Visual Basic]

```
Public Property Retry As Integer
```

[C#]

```
public int Retry {get; set;}
```

Property Value

An integer value.

Remarks

The **Retry** property specifies the number of times, per nameserver, that the control attempts to resolve a hostname or address. If attempts to query a nameserver fail, the control waits a period of time and then resubmits the query. As the number of retries increase, the longer the period of time the control waits to receive a response before attempting the query using another nameserver.

The default number of retries is four, with a minimum value of one and a maximum value of eight.

See Also

DnsClient Class | SocketTools Namespace | Timeout Property

DnsClient.ServerAddress Property

Return the address of the nameserver that resolved the query.

[Visual Basic]

```
Public ReadOnly Property ServerAddress As String
```

[C#]

```
public string ServerAddress {get;}
```

Property Value

A string which specifies an Internet address.

Remarks

The **ServerAddress** property returns the Internet address of the nameserver that resolved the previous query.

See Also

DnsClient Class | SocketTools Namespace

DnsClient.ThreadModel Property

Gets and sets a value which specifies the threading model for the class instance.

[Visual Basic]

```
Public Property ThreadModel As ThreadingModel
```

[C#]

```
public DnsClient.ThreadingModel ThreadModel {get; set;}
```

Property Value

Returns one or more ThreadingModel enumeration value which specifies the threading model for the client. The default value for this property is **modelSingleThread**.

Remarks

The **ThreadModel** property specifies the threading model that is used by the class instance when a connection is established. The default value for this property is **modelSingleThread**, which specifies that only the thread that established the connection should be permitted to invoke methods. It is important to note that this threading model does not limit the application to a single thread of execution. When a session is established using the **Connect** method, that session is attached to the thread that created it. From that point on, until the session is terminated, only the owner may invoke methods in that instance of the class. The ownership of the class instance may be transferred from one thread to another using the **AttachThread** method.

Setting this property to **modelFreeThread** disables certain internal safety checks that are performed by the class and may result in unexpected behavior unless you ensure that access to the class instance is synchronized across multiple threads. The application must ensure that no two threads will attempt to invoke a blocking method at the same time. In other words, if one thread invokes a method, the application must ensure that another thread will not attempt to invoke any other method at the same time using the same instance of the class.

See Also

DnsClient Class | SocketTools Namespace | AttachThread Method | ThreadingModel Enumeration | ThreadModel Attribute

DnsClient.ThrowError Property

Enable or disable exceptions being raised when a method fails.

[Visual Basic]

```
Public Property ThrowError As Boolean
```

[C#]

```
public bool ThrowError {get; set;}
```

Remarks

Error handling for method calls can be done in either of two different styles, according to the value of this property.

If the **ThrowError** property is set to false, the application should check the return value of any method that is used, and report errors based upon the documented value of the **LastError** property. It is the responsibility of the application to interpret the error code and act accordingly.

If the **ThrowError** property is set to true, then errors that occur when calling a method will cause an exception to be raised. The application must handle the exception using the error handling facilities in the language being used. For example, in Visual Basic, the Try..Catch..End Try statements can be used.

Note that if an error occurs while a property value is being accessed, an exception will always be raised regardless of the value of this property.

Example

The following examples demonstrate the difference between handling errors when calling the **Resolve** method. In the first example, the **ThrowError** property is set to False, which means that the **Resolve** method will return True or False, depending on whether it succeeds or fails. If it returns False, the **LastError** and **LastErrorString** properties can be used to determine the error.

In the second example, the **ThrowError** property is set to True, which causes the **Resolve** method to throw an exception if an error occurs. This is handled by the Try..Catch..End Try block, and the **DnsClientException** class provides information about the error.

```
dnsClient.ThrowError = False

If dnsClient.Resolve(strHostName, strHostAddress) = False Then
    MsgBox(dnsClient.LastErrorString, MsgBoxStyle.Exclamation)
    Exit Sub
End If

dnsClient.ThrowError = True

Try
    dnsClient.Resolve(strHostName, strHostAddress)
Catch ex As SocketTools.DnsClientException
    MsgBox(ex.Message, MsgBoxStyle.Exclamation)
End Try
```

See Also

DnsClient Class | SocketTools Namespace | DnsClientException Class | LastError Property | LastErrorString Property

DnsClient.Timeout Property

Set or return the amount of time until a blocking operation fails.

[Visual Basic]
```
Public Property Timeout As Integer
```

[C#]
```
public int Timeout {get; set;}
```

Property Value

An integer value which specifies the timeout period in seconds.

Remarks

Setting the **Timeout** property specifies the number of seconds until a blocking operation fails and the method returns to the caller.

Note that the **Timeout** property also determines the amount of time the component will spend attempting to connect to a remote host. If a connection is not established within the given time period, the connection attempt will fail.

See Also

DnsClient Class | SocketTools Namespace | Retry Property

DnsClient.Trace Property

Gets and sets a value which indicates if network function logging is enabled.

[Visual Basic]

```
Public Property Trace As Boolean
```

[C#]

```
public bool Trace {get; set;}
```

Property Value

A boolean value.

Remarks

The **Trace** property is used to enable or disable the logging of Windows Sockets function calls. When enabled, each function call is logged to a file, including the function parameters, return value and error code if applicable. This facility can be enabled and disabled at run time, and the trace log file can be specified by setting the **TraceFile** property. All function calls that are being logged are appended to the trace file, if it exists. If no trace file exists when tracing is enabled, the trace file is created.

The tracing facility is available in all of the networking components, and is enabled or disabled for an entire process. This means that once tracing is enabled for a given object, all of the function calls made by the process using any of the SocketTools components will be logged. For example, if you have an application using both the FTP and POP3 components, and you set the **Trace** property to True on the FTP component, function calls made by both the FTP and POP3 components will be logged. Additionally, enabling a trace is cumulative, and tracing is not stopped until it is disabled for all components used by the process.

If tracing is not enabled, there is no negative impact on performance or throughput. Once enabled, application performance can degrade, especially in those situations in which multiple processes are being traced or the trace file is fairly large. Since trace files can grow very quickly, even with modest applications, it is recommended that you delete the file when it is no longer needed.

Note that only those function calls made by the SocketTools networking components will be logged. Calls made directly to the Windows Sockets API, or calls made by other components, will not be logged.

See Also

DnsClient Class | SocketTools Namespace | TraceFile Property | TraceFlags Property

DnsClient.TraceFile Property

Specify the socket function trace output file.

[Visual Basic]
```
Public Property TraceFile As String
```

[C#]
```
public string TraceFile {get; set;}
```

Property Value

A string which specifies a file name.

Remarks

TraceFile property is used to specify the name of the trace file that is created when network function tracing is enabled. If this property is set to an empty string (the default value), then a file named `SocketTools.log` is created in the system's temporary directory. If no temporary directory exists, then the file is created in the current working directory.

If the file exists, the trace output is appended to the file, otherwise the file is created. Since network function tracing is enabled per-process, the trace file is shared by all instances of the controls being used. If multiple controls have tracing enabled, the **TraceFile** property should be set to the same value for each control. Since trace files can grow very quickly, even with modest applications, it is recommended that you delete the file when it is no longer needed.

The trace logfile has the following format:

```
    TestApp 105020 0000 INF: WSAAsyncSelect(46, 0xcc4, 0x7e9, 0x27)
returned 0
TestApp 105020 0015 WRN: connect(46, 192.0.0.1:1234, 16) returned -1
[10035]
TestApp 111535 0000 ERR: accept(46, NULL, 0x0) returned -1 [10038]
```

The first column contains the name of the process that is being traced. The second column is the local time in hours, minutes and seconds. The third column is the elapsed time in milliseconds since the previous function call. The fourth column identifies if the trace record is reporting information, a warning, or an error. What follows is the name of the function being called, the arguments passed to the function and the function's return value. If a warning or error is reported, the error code is appended to the record (the value is placed inside brackets).

If parameters are passed as integer values, they are recorded in decimal. If the parameter or return value is a pointer (a memory address), it is recorded as a hexadecimal value preceded with "0x". A special type of pointer, called a null pointer, is recorded as NULL. Those functions which expect socket addresses are displayed in the following format:

```
aa.bb.cc.dd:nnnn
```

The first four numbers separated by periods represent the IP address, and the number following the colon represents the port number in host byte order. Note that in the second line of the above example, the control is attempting to connect to a system with the IP address 192.0.0.1 on port 1234.

If the specified logfile cannot be created, or the user does not have permission to modify an existing file, the error is silently ignored and no trace output will be generated.

See Also

DnsClient Class | SocketTools Namespace | Trace Property | TraceFlags Property

DnsClient.TraceFlags Property

Set or return the network function tracing flags.

[Visual Basic]
```
Public Property TraceFlags As TraceOptions
```

[C#]
```
public DnsClient.TraceOptions TraceFlags {get; set;}
```

Property Value

A TraceOptions enumeration type.

Remarks

The **TraceFlags** property is used to specify the type of information written to the trace file when network function tracing is enabled.

Since function logging is enabled per-process, the trace flags are shared by all instances of the components being used. If multiple components have tracing enabled, the **TraceFlags** property should be set to the same value for each component. Changing the trace flags for any one instance of the component will affect the logging performed for all components used by the application.

Warnings are generated when a non-fatal error is returned by a Windows Sockets function. For example, if data is being written through the control and an error indicating that the operation would block is returned, only a warning is logged since the application simply needs to attempt to write the data at a later time

See Also

DnsClient Class | SocketTools Namespace | Trace Property | TraceFile Property | TraceOptions Enumeration

DnsClient.Version Property

Gets a value which returns the current version of the DnsClient class library.

[Visual Basic]

```
Public ReadOnly Property Version As String
```

[C#]

```
public string Version {get;}
```

Property Value

A string which specifies the version of the class library.

Remarks

The **Version** property returns a string which identifies the current version and build of the DnsClient class library. This value can be used by an application for validation and debugging purposes.

See Also

DnsClient Class | SocketTools Namespace

DnsClient Methods

The methods of the **DnsClient** class are listed below. For a complete list of **DnsClient** class members, see the DnsClient Members topic.

Public Instance Methods

AttachThread	Attach an instance of the class to the current thread
Cancel	Cancels the current blocking network operation.
Dispose	Overloaded. Releases all resources used by DnsClient.
Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from Object)	Gets the Type of the current instance.
Initialize	Overloaded. Initializes the component with the specified runtime license key.
MatchHost	Overloaded. Match a host name against one more strings that may contain wildcards.
Query	Perform a general nameserver query for a specific type of record.
Reset	Reset the internal state of the component.
Resolve	Resolve a hostname to an Internet address.
ToString (inherited from Object)	Returns a String that represents the current Object.
Uninitialize	Uninitialize the component and unload the networking library.

Protected Instance Methods

Dispose	Overloaded. Releases the unmanaged resources allocated by the DnsClient class and optionally releases the managed resources.
Finalize	Destroys an instance of the class, releasing the resources allocated for the client session and unloading the networking library.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

DnsClient Class | SocketTools Namespace

DnsClient.Cancel Method

Cancels the current blocking network operation.

[Visual Basic]

```
Public Function Cancel() As Boolean
```

[C#]

```
public bool Cancel();
```

Return Value

A boolean value which specifies if the method was successful or not. A return value of True indicates that the method call completed successfully. A return value of False indicates that the method failed and the application should check the value of the **LastError** property.

Remarks

When the **Cancel** method is called, the blocked method may not immediately return. An internal flag is set which causes the blocking operation to exit with an error. This means that the application cannot cancel an operation and immediately perform some other operation. It must allow the calling stack to unwind, returning control back to the blocking method before calling any other methods.

Note that if the **ThrowError** property is set to True, calling the **Cancel** method will cause the blocked method to raise an exception which must be handled by the application.

DnsClient.Dispose Method

Releases all resources used by DnsClient.

Overload List

Releases all resources used by DnsClient.

public void Dispose();

Releases the unmanaged resources allocated by the DnsClient class and optionally releases the managed resources.

protected virtual void Dispose(bool);

See Also

DnsClient Class | SocketTools Namespace

DnsClient.Dispose Method ()

Releases all resources used by DnsClient.

[Visual Basic]

```
NotOverridable Overloads Public Sub Dispose() _
    Implements IDisposable.Dispose
```

[C#]

```
public void Dispose();
```

Implements

IDisposable.Dispose

Remarks

The **Dispose** method terminates any active connection and explicitly releases the resources allocated for this instance of the class. In some cases, better performance can be achieved if the programmer explicitly releases resources when they are no longer being used. The **Dispose** method provides explicit control over these resources.

Unlike the **Uninitialize** method, once the **Dispose** method has been called, that instance of the class cannot be re-initialized and you should not attempt to access class properties or invoke any methods. Note that this method can be called even if other references to the object are active.

See Also

DnsClient Class | SocketTools Namespace | DnsClient.Dispose Overload List

DnsClient.Dispose Method (Boolean)

Releases the unmanaged resources allocated by the DnsClient class and optionally releases the managed resources.

[Visual Basic]

```
Overridable Overloads Protected Sub Dispose( _
   ByVal disposing As Boolean _
)
```

[C#]

```
protected virtual void Dispose(
   bool disposing
);
```

Parameters

disposing

A boolean value which should be specified as **true** to release both managed and unmanaged resources; **false** to release only unmanaged resources.

Remarks

The **Dispose** method terminates any active connection and explicitly releases the resources allocated for this instance of the class. In some cases, better performance can be achieved if the programmer explicitly releases resources when they are no longer being used. The **Dispose** method provides explicit control over these resources.

Unlike the **Uninitialize** method, once the **Dispose** method has been called, that instance of the class cannot be re-initialized and you should not attempt to access class properties or invoke any methods. Note that this method can be called even if other references to the object are active.

You should call **Dispose** in your derived class when you are finished using the derived class. The **Dispose** method leaves the derived class in an unusable state. After calling **Dispose**, you must release all references to the derived class and the **DnsClient** class so the memory they were occupying can be reclaimed by garbage collection.

See Also

DnsClient Class | SocketTools Namespace | DnsClient.Dispose Overload List

DnsClient.Finalize Method

Destroys an instance of the class, releasing the resources allocated for the client session and unloading the networking library.

[Visual Basic]

```
Overrides Protected Sub Finalize()
```

[C#]

```
protected override void Finalize();
```

See Also

DnsClient Class | SocketTools Namespace

DnsClient.Initialize Method

Initializes the component with the default runtime license key.

Overload List

Initializes the component with the default runtime license key.

public bool Initialize();

Initializes the component with the specified runtime license key.

public bool Initialize(string);

See Also

DnsClient Class | SocketTools Namespace | RuntimeLicenseAttribute Class | Uninitialize Method

DnsClient.Initialize Method ()

Initializes the component with the default runtime license key.

[Visual Basic]
```
Overloads Public Function Initialize() As Boolean
```

[C#]
```
public bool Initialize();
```

Return Value

A boolean value which specifies if the component was initialized successfully with the default runtime license key. A return value of False indicates that the license key is not valid.

Remarks

The Initialize method is used to explicitly initialize the component with the runtime license key that has been specified using the RuntimeLicense attribute. Normally it is not necessary to call this method because the component will automatically be initialized when the class constructor is called. This method should only be called if the **Uninitialize** method was previously called.

The runtime license key for your copy of SocketTools can be generated using the License Manager utility that is included with the product. Note that if you have installed an evaluation license, you will not have a runtime license key and cannot redistribute any applications which use SocketTools components.

See Also

DnsClient Class | SocketTools Namespace | DnsClient.Initialize Overload List | RuntimeLicenseAttribute Class | Uninitialize Method

DnsClient.Initialize Method (String)

Initializes the component with the specified runtime license key.

[Visual Basic]

```
Overloads Public Function Initialize( _
   ByVal licenseKey As String _
) As Boolean
```

[C#]

```
public bool Initialize(
   string licenseKey
);
```

Parameters

licenseKey

A string which specifies the runtime license key.

Return Value

A boolean value which specifies if the component was initialized successfully with the runtime license key. A return value of False indicates that the license key is not valid.

Remarks

The Initialize method is used to explicitly initialize the component with a runtime license key, if one has not been specified using the RuntimeLicense attribute.

The runtime license key for your copy of SocketTools can be generated using the License Manager utility that is included with the product. Note that if you have installed an evaluation license, you will not have a runtime license key and cannot redistribute any applications which use SocketTools components.

DnsClient.MatchHost Method

Match a host name against one more strings that may contain wildcards.

Overload List

Match a host name against one more strings that may contain wildcards.

public bool MatchHost(string,string);

Match a host name against one more strings that may contain wildcards.

public bool MatchHost(string,string,bool);

See Also

DnsClient Class | SocketTools Namespace

DnsClient.MatchHost Method (String, String)

Match a host name against one more strings that may contain wildcards.

```
[Visual Basic]
Overloads Public Function MatchHost( _
   ByVal hostName As String, _
   ByVal hostMask As String _
) As Boolean
```

```
[C#]
public bool MatchHost(
   string hostName,
   string hostMask
);
```

Parameters

hostName

A string which specifies the host name or Internet address to match against the host mask string.

hostMask

A string which specifies one or more values to match against the host name. The asterisk character can be used to match any number of characters in the host name, and the question mark can be used to match any single character. Multiple values may be specified by separating them with a semicolon.

Return Value

A boolean value which specifies if the method was successful or not. A return value of True indicates that the method call completed successfully. A return value of False indicates that the method failed and the application should check the value of the **LastError** property.

Remarks

The **MatchHost** method provides a convenient way for an application to determine if a given host name matches one or more mask strings which may contain wildcard characters. For example, the host name could be "www.microsoft.com" and the host mask string could be "*.microsoft.com". In this example, the function would return True, indicating the host name matched the mask. However, if the mask string was "*.net" then the function would return False, indicating that there was no match. Multiple mask values can be combined by separating them with a semicolon; for example, the mask "*.com;*.org" would match any host name in either the .com or .org top-level domains.

See Also

DnsClient Class | SocketTools Namespace | DnsClient.MatchHost Overload List

DnsClient.MatchHost Method (String, String, Boolean)

Match a host name against one more strings that may contain wildcards.

[Visual Basic]

```
Overloads Public Function MatchHost( _
   ByVal hostName As String, _
   ByVal hostMask As String, _
   ByVal resolve As Boolean _
) As Boolean
```

[C#]

```
public bool MatchHost(
   string hostName,
   string hostMask,
   bool resolve
);
```

Parameters

hostName
A string which specifies the host name or Internet address to match against the host mask string.

hostMask
A string which specifies one or more values to match against the host name. The asterisk character can be used to match any number of characters in the host name, and the question mark can be used to match any single character. Multiple values may be specified by separating them with a semicolon.

resolve
A boolean value which determines if the host name or address should be resolved when matching the host against the mask string. If this parameter is True, two checks against the host mask string will be performed; once for the host name specified and once for its IP address. If this parameter is False, then the match is made only against the host name string provided.

Return Value

A boolean value which specifies if the method was successful or not. A return value of True indicates that the method call completed successfully. A return value of False indicates that the method failed and the application should check the value of the **LastError** property.

Remarks

The **MatchHost** method provides a convenient way for an application to determine if a given host name matches one or more mask strings which may contain wildcard characters. For example, the host name could be "www.microsoft.com" and the host mask string could be "*.microsoft.com". In this example, the function would return True, indicating the host name matched the mask. However, if the mask string was "*.net" then the function would return False, indicating that there was no match. Multiple mask values can be combined by separating them with a semicolon; for example, the mask "*.com;*.org" would match any host name in either the .com or .org top-level domains.

DnsClient Class | SocketTools Namespace | DnsClient.MatchHost Overload List

DnsClient.Query Method

Perform a general nameserver query for a specific type of record.

[Visual Basic]

```
Public Function Query( _
   ByVal hostName As String, _
   ByVal recordType As RecordType, _
   ByRef recordData As String _
) As Boolean
```

[C#]

```
public bool Query(
   string hostName,
   RecordType recordType,
   ref string recordData
);
```

Return Value

A boolean value which specifies if the method was successful or not. A return value of True indicates that the method call completed successfully. A return value of False indicates that the method failed and the application should check the value of the **LastError** property.

Remarks

The **Query** method performs a general nameserver query for a given record based on the name and type. This method will not use a local host file when performing host name or address queries.

To resolve a hostname into an Internet address, it is recommended that you use the **Resolve** method.

Example

The following example queries a nameserver for the TXT record for the specified remote host. If a record is found, its value will be displayed in a message box.

```
Dim strRecord As String

If dnsClient.Query(TextBox1.Text, RecordType.dnsRecordTXT, strRecord) Then
    MsgBox(strRecord, MsgBoxStyle.Information)
End If
```

See Also

DnsClient Class | SocketTools Namespace | HostAddress Property | HostName Property | Resolve Method

DnsClient.Reset Method

Reset the internal state of the component.

[Visual Basic]

```
Public Sub Reset()
```

[C#]

```
public void Reset();
```

Remarks

The **Reset** method resets the internal state of the component and restores property values to their defaults.

See Also

DnsClient Class | SocketTools Namespace

DnsClient.Resolve Method

Resolve a hostname to an Internet address.

[Visual Basic]

```
Public Function Resolve( _
   ByVal hostName As String, _
   ByRef hostAddress As String _
) As Boolean
```

[C#]

```
public bool Resolve(
   string hostName,
   ref string hostAddress
);
```

Parameters

hostName
A string which specifies the hostname to resolve.

hostAddress
A string which will contain the Internet address for the specified hostname when the method returns. If the hostname cannot be resolved, this parameter will be set to an empty string.

Return Value

A boolean value which specifies if the method was successful or not. A return value of True indicates that the method call completed successfully. A return value of False indicates that the method failed and the application should check the value of the **LastError** property.

Remarks

The **Resolve** method is used to convert a host name into an Internet address. Note that unlike the **Query** method, this method will use the local host file when resolving the host name.

See Also

DnsClient Class | SocketTools Namespace

DnsClient.Uninitialize Method

Uninitialize the component and unload the networking library.

[Visual Basic]
```
Public Sub Uninitialize()
```

[C#]
```
public void Uninitialize();
```

Remarks

The Uninitialize method explicitly releases resources allocated by the component. Normally it is not required that the application call this method since it is automatically called by the class destructor. This method should only be used if the **Initialize** method was explicitly called.

DnsClient Class | SocketTools Namespace | Initialize Method

DnsClient Events

The events of the **DnsClient** class are listed below. For a complete list of **DnsClient** class members, see the DnsClient Members topic.

Public Instance Events

⚡ OnCancel	Occurs when a blocking network operation is canceled using the Cancel method.
⚡ OnError	Occurs when a method fails.
⚡ OnTimeout	Occurs when a blocking network operation exceeds the timeout period specified by the Timeout property.

See Also

DnsClient Class | SocketTools Namespace

DnsClient.OnCancel Event

Occurs when a blocking network operation is canceled using the Cancel method.

[Visual Basic]

```
Public Event OnCancel As EventHandler
```

[C#]

```
public event EventHandler OnCancel;
```

Remarks

The event handler receives an argument of type EventArgs.

See Also

DnsClient Class | SocketTools Namespace

DnsClient.OnError Event

Occurs when a method fails.

[Visual Basic]
```
Public Event OnError As OnErrorEventHandler
```

[C#]
```
public event OnErrorEventHandler OnError;
```

Event Data

The event handler receives an argument of type DnsClient.ErrorEventArgs containing data related to this event. The following **DnsClient.ErrorEventArgs** properties provide information specific to this event.

Property	Description
Description	Returns a description of the last error that occurred.
Error	Returns the value of the last error that has occurred.

Remarks

The event handler receives an argument of type ErrorEventArgs containing data related to this event. The following ErrorEventArgs properties provide information specific to this event.

Property	**Description**
Error	Returns the value of the last error that has occurred
Description	Returns a description of the last error that occurred

See Also

DnsClient Class | SocketTools Namespace

DnsClient.ErrorEventArgs Class

Provides data for the OnError event.

For a list of all members of this type, see DnsClient.ErrorEventArgs Members.

System.Object
  System.EventArgs
    SocketTools.DnsClient.ErrorEventArgs

[Visual Basic]

```
Public Class DnsClient.ErrorEventArgs
    Inherits EventArgs
```

[C#]

```
public class DnsClient.ErrorEventArgs : EventArgs
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

ErrorEventArgs specifies the numeric error code and a description of the error that has occurred.

An OnError event occurs when a method fails.

Requirements

Namespace: SocketTools

Assembly: SocketTools.DnsClient (in SocketTools.DnsClient.dll)

DnsClient.ErrorEventArgs Members | SocketTools Namespace

DnsClient.ErrorEventArgs Members

DnsClient.ErrorEventArgs overview

Public Instance Constructors

DnsClient.ErrorEventArgs Constructor	Initializes a new instance of the DnsClient.ErrorEventArgs class.

Public Instance Properties

Description	Returns a description of the last error that occurred.
Error	Returns the value of the last error that has occurred.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString (inherited from Object)	Returns a String that represents the current Object.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

DnsClient.ErrorEventArgs Class | SocketTools Namespace

DnsClient.ErrorEventArgs Constructor

Initializes a new instance of the DnsClient.ErrorEventArgs class.

[Visual Basic]

```
Public Sub New()
```

[C#]

```
public DnsClient.ErrorEventArgs();
```

See Also

DnsClient.ErrorEventArgs Class | SocketTools Namespace

DnsClient.ErrorEventArgs Properties

The properties of the **DnsClient.ErrorEventArgs** class are listed below. For a complete list of **DnsClient.ErrorEventArgs** class members, see the DnsClient.ErrorEventArgs Members topic.

Public Instance Properties

Description	Returns a description of the last error that occurred.
Error	Returns the value of the last error that has occurred.

See Also

DnsClient.ErrorEventArgs Class | SocketTools Namespace

DnsClient.ErrorEventArgs.Description Property

Returns a description of the last error that occurred.

[Visual Basic]
```
Public ReadOnly Property Description As String
```

[C#]
```
public string Description {get;}
```

Property Value

String which describes the error.

See Also

DnsClient.ErrorEventArgs Class | SocketTools Namespace

DnsClient.ErrorEventArgs.Error Property

Returns the value of the last error that has occurred.

[Visual Basic]

```
Public ReadOnly Property Error As ErrorCode
```

[C#]

```
public DnsClient.ErrorCode Error {get;}
```

Property Value

ErrorCode enumeration which specifies the error.

See Also

DnsClient.ErrorEventArgs Class | SocketTools Namespace

DnsClient.OnTimeout Event

Occurs when a blocking network operation exceeds the timeout period specified by the Timeout property.

[Visual Basic]

```
Public Event OnTimeout As EventHandler
```

[C#]

```
public event EventHandler OnTimeout;
```

Remarks

The event handler receives an argument of type EventArgs.

See Also

DnsClient Class | SocketTools Namespace

DnsClient.ErrorCode Enumeration

Specifies the error codes returned by the DnsClient class.

[Visual Basic]
```
Public Enum DnsClient.ErrorCode
```

[C#]
```
public enum DnsClient.ErrorCode
```

Remarks

The DnsClient class uses the **ErrorCode** enumeration to specify what error has occurred when a method fails. The current error code may be determined by checking the value of the **LastError** property.

Note that the last error code is only meaningful if the previous operation has failed.

Members

Member Name	Description
errorNone	No error.
errorNotHandleOwner	Handle not owned by the current thread.
errorFileNotFound	The specified file or directory does not exist.
errorFileNotCreated	The specified file could not be created.
errorOperationCanceled	The blocking operation has been canceled.
errorInvalidFileType	The specified file is a block or character device, not a regular file.
errorInvalidDevice	The specified file type is invalid or not a regular file.
errorTooManyParameters	The maximum number of function parameters has been exceeded.
errorInvalidFileName	The specified file name contains invalid characters or is too long.
errorInvalidFileHandle	Invalid file handle passed to function.
errorFileReadFailed	Unable to read data from the specified file.
errorFileWriteFailed	Unable to write data to the specified file.
errorOutOfMemory	Out of memory.
errorAccessDenied	Access denied.
errorInvalidParameter	Invalid argument passed to function.
errorClipboardUnavailable	The system clipboard is currently unavailable.
errorClipboardEmpty	The system clipboard is empty or does not contain any text data.
errorFileEmpty	The specified file does not contain any data.
errorFileExists	The specified file already exists.

errorEndOfFile	End of file.
errorDeviceNotFound	The specified device could not be found.
errorDirectoryNotFound	The specified directory could not be found.
errorInvalidbuffer	Invalid memory address passed to function.
errorBufferTooSmall	The specified buffer is not large enough to contain the data.
errorNoHandles	No more handles are available to this process.
errorOperationWouldBlock	The specified operation would block the current thread.
errorOperationInProgress	A blocking operation is currently in progress.
errorAlreadyInProgress	The specified operation is already in progress.
errorInvalidHandle	Invalid handle passed to function.
errorInvalidAddress	Invalid network address specified.
errorInvalidSize	Datagram is too large to fit in specified buffer.
errorInvalidProtocol	Invalid network protocol specified.
errorProtocolNotAvailable	The specified network protocol is not available.
errorProtocolNotSupported	The specified protocol is not supported.
errorSocketNotSupported	The specified socket type is not supported.
errorInvalidOption	The specified option is invalid.
errorProtocolFamily	Specified protocol family is not supported.
errorProtocolAddress	The specified address is invalid for this protocol family.
errorAddressInUse	The specified address is in use by another process.
errorAddressUnavailable	The specified address cannot be assigned.
errorNetworkUnavailable	The networking subsystem is unavailable.
errorNetworkUnreachable	The specified network is unreachable.
errorNetworkReset	Network dropped connection on remote reset.
errorConnectionAborted	Connection was aborted due to timeout or other failure.
errorConnectionReset	Connection was reset by remote network.
errorOutOfBuffers	No buffer space is available.
errorAlreadyConnected	Connection already established with remote host.
errorNotConnected	No connection established with remote host.
errorConnectionShutdown	Unable to send or receive data after connection shutdown.
errorOperationTimeout	The specified operation has timed out.
errorConnectionRefused	The connection has been refused by the remote host.

errorHostUnavailable	The specified host is unavailable.
errorHostUnreachable	Remote host is unreachable.
errorTooManyProcesses	Too many processes are using the networking subsystem.
errorTooManyThreads	Too many threads have been created by the current process.
errorTooManySessions	Too many client sessions have been created by the current process.
errorInternalFailure	An unexpected internal error has occurred.
errorNetworkNotReady	Network subsystem is not ready for communication.
errorInvalidVersion	This version of the operating system is not supported.
errorNetworkNotInitialized	The networking subsystem has not been initialized.
errorRemoteShutdown	The remote host has initiated a graceful shutdown sequence.
errorInvalidHostName	The specified hostname is invalid or could not be resolved.
errorHostNameNotFound	The specified hostname could not be found.
errorHostNameRefused	Unable to resolve hostname, request refused.
errorHostNameNotResolved	Unable to resolve hostname, no address for specified host.
errorInvalidLicense	The license for this product is invalid.
errorProductNotLicensed	This product is not licensed to perform this operation.
errorNotImplemented	This function has not been implemented on this platform.
errorUnknownLocalhost	Unable to determine local host name.
errorInvalidHostAddress	Invalid host address specified.
errorInvalidServicePort	Invalid service port number specified.
errorInvalidServiceName	Invalid or unknown service name specified.
errorInvalidEventId	Invalid event identifier specified.
errorOperationNotBlocking	No blocking operation in progress on this socket.
errorSecurityNotInitialized	Unable to initialize security interface for this process.
errorSecurityContext	Unable to establish security context for this session.
errorSecurityCredentials	Unable to open certificate store or establish security credentials.
errorSecurityCertificate	Unable to validate the certificate chain for this

	session.
errorSecurityDecryption	Unable to decrypt data stream.
errorSecurityEncryption	Unable to encrypt data stream.
errorOperationNotSupported	The specified operation is not supported.
errorInvalidProtocolVersion	Invalid application protocol version specified.
errorNoServerResponse	No data returned from server.
errorInvalidServerResponse	Invalid data returned from server.
errorUnexpectedServerResponse	Unexpected response code returned from server.
errorServerTransactionFailed	Server transaction failed.
errorServiceUnavailable	The service is currently unavailable.
errorServiceNotReady	The service is not ready, try again later.
errorServerResyncFailed	Unable to resynchronize with server.
errorInvalidProxyType	Invalid proxy server type specified.
errorProxyRequired	Resource must be accessed through specified proxy.
errorInvalidProxyLogin	Unable to login to proxy server using specified credentials.
errorProxyResyncFailed	Unable to resynchronize with proxy server.
errorInvalidCommand	Invalid command specified.
errorInvalidCommandParameter	Invalid command parameter specified.
errorInvalidCommandSequence	Invalid command sequence specified.
errorCommandNotImplemented	Specified command not implemented on this server.
errorCommandNotAuthorized	Specified command not authorized for the current user.
errorCommandAborted	Specified command was aborted by the remote host.
errorOptionNotSupported	The specified option is not supported on this server.
errorRequestNotCompleted	The current client request has not been completed.
errorInvalidUserName	The specified username is invalid.
errorInvalidPassword	The specified password is invalid.
errorInvalidAccount	The specified account name is invalid.
errorAccountRequired	Account name has not been specified.
errorInvalidAuthenticationType	Invalid authentication protocol specified.
errorAuthenticationRequired	User authentication is required.
errorProxyAuthenticationRequired	Proxy authentication required.

errorAlreadyAuthenticated	User has already been authenticated.
errorAuthenticationFailed	Unable to authenticate the specified user.
errorNetworkAdapter	Unable to determine network adapter configuration.
errorInvalidRecordType	Invalid record type specified.
errorInvalidRecordName	Invalid record name specified.
errorInvalidRecordData	Invalid record data specified.
errorConnectionOpen	Data connection already established.
errorConnectionClosed	Server closed data connection.
errorConnectionPassive	Data connection is passive.
errorConnectionFailed	Unable to open data connection to server.
errorInvalidSecurityLevel	Data connection cannot be opened with this security setting.
errorCachedTLSRequired	Data connection requires cached TLS session.
errorDataReadOnly	Data connection is read-only.
errorDataWriteOnly	Data connection is write-only.
errorEndOfData	End of data.
errorRemoteFileUnavailable	Remote file is unavailable.
errorInsufficientStorage	Insufficient storage on server.
errorStorageallocation	File exceeded storage allocation on server.
errorDirectoryExists	The specified directory already exists.
errorDirectoryEmpty	No files returned by the server for the specified directory.
errorEndOfDirectory	End of directory listing.
errorUnknownDirectoryFormat	Unknown directory format.
errorInvalidResource	Invalid resource name specified.
errorResourceRedirected	The specified resource has been redirected.
errorResourceRestricted	Access to this resource has been restricted.
errorResourceNotModified	The specified resource has not been modified.
errorResourceNotFound	The specified resource cannot be found.
errorResourceConflict	Request could not be completed due to the current state of the resource.
errorResourceRemoved	The specified resource has been permanently removed from this server.
errorContentLengthRequired	Request must include the content length.
errorRequestPrecondition	Request could not be completed due to server precondition.
errorUnsupportedMediaType	Request specified an unsupported media type.

errorInvalidContentRange	Content range specified for this resource is invalid.
errorInvalidMessagePart	Message is not multipart or an invalid message part was specified.
errorInvalidMessageHeader	The specified message header is invalid or has not been defined.
errorInvalidMessageBoundary	The multipart message boundary has not been defined.
errorNoFileAttachment	The current message part does not contain a file attachment.
errorUnknownFileType	The specified file type could not be determined.
errorDataNotEncoded	The specified data block could not be encoded.
errorDataNotDecoded	The specified data block could not be decoded.
errorFileNotEncoded	The specified file could not be encoded.
errorFileNotDecoded	The specified file could not be decoded.
errorNoMessageText	No message text.
errorInvalidCharacterSet	Invalid character set specified.
errorInvalidEncodingType	Invalid encoding type specified.
errorInvalidMessageNumber	Invalid message number specified.
errorNoReturnAddress	No valid return address specified.
errorNoValidRecipients	No valid recipients specified.
errorInvalidRecipient	The specified recipient address is invalid.
errorRelayNotAuthorized	The specified domain is invalid or server will not relay messages.
errorMailboxUnavailable	Specified mailbox is currently unavailable.
errorMailboxReadOnly	The selected mailbox cannot be modified.
errorMailboxNotSelected	No mailbox has been selected.
errorInvalidMailbox	Specified mailbox is invalid.
errorInvalidDomain	The specified domain name is invalid or not recognized.
errorInvalidSender	The specified sender address is invalid or not recognized.
errorMessageNotDelivered	Message not delivered to any of the specified recipients.
errorEndOfMessageData	No more message data available to be read
errorInvalidmessageSize	The specified message size is invalid.
errorMessageNotCreated	The message could not be created in the specified mailbox.
errorNoMoreMailboxes	No more mailboxes exist on this server.

errorInvalidEmulationType	The specified terminal emulation type is invalid.
errorInvalidFontHandle	The specified font handle is invalid.
errorInvalidFontName	The specified font name is invalid or unavailable.
errorInvalidPacketSize	The specified packet size is invalid.
errorInvalidPacketData	The specified packet data is invalid.
errorInvalidPacketId	The unique packet identifier is invalid.
errorPacketTTLExpired	The specified packet time-to-live period has expired.
errorInvalidNewsGroup	Invalid newsgroup specified.
errorNoNewsgroupSelected	No newsgroup selected.
errorEmptyNewsgroup	No articles in specified newsgroup.
errorInvalidArticle	Invalid article number specified.
errorNoArticleSelected	No article selected in the current newsgroup.
errorFirstArticle	First article in current newsgroup.
errorLastArticle	Last article in current newsgroup.
errorArticleExists	Unable to transfer article, article already exists.
errorArticleRejected	Unable to transfer article, article rejected.
errorArticleTransferFailed	Article transfer failed.
errorArticlePostingDenied	Posting is not permitted on this server.
errorArticlePostingFailed	Unable to post article on this server.
errorInvalidDateFormat	The specified date format is not recognized.
errorFeatureNotSupported	The specified feature is not supported on this server.
errorInvalidFormHandle	The specified form handle is invalid or a form has not been created.
errorInvalidFormAction	The specified form action is invalid or has not been specified.
errorInvalidFormMethod	The specified form method is invalid or not supported.
errorInvalidFormType	The specified form type is invalid or not supported.
errorInvalidFormField	The specified form field name is invalid or does not exist.
errorEmptyForm	The specified form does not contain any field values.
errorMaximumConnections	The maximum number of client connections exceeded.
errorThreadCreationFailed	Unable to create a new thread for the current process.
errorInvalidThreadHandle	The specified thread handle is no longer valid.

errorThreadTerminated	The specified thread has been terminated.
errorThreadDeadlock	The operation would result in the current thread becoming deadlocked.
errorInvalidClientMoniker	The specified moniker is not associated with any client session.
errorClientMonikerExists	The specified moniker has been assigned to another client session.
errorServerInactive	The specified server is not listening for client connections.
errorServerSuspended	The specified server is suspended and not accepting client connections.
errorNoMessageStore	No message store has been specified.
errorMessageStoreChanged	The message store has changed since it was last accessed.
errorMessageNotFound	No message was found that matches the specified criteria.
errorMessageDeleted	The specified message has been deleted.
errorFileChecksumMismatch	The local and remote file checksums do not match.
errorFileSizeMismatch	The local and remote file sizes do not match.
errorInvalidFeedUrl	The news feed URL is invalid or specifies an unsupported protocol.
errorInvalidFeedFormat	The internal format of the news feed is invalid.
errorInvalidFeedVersion	This version of the news feed is not supported.
errorChannelEmpty	There are no valid items found in this news feed.
errorInvalidItemNumber	The specified channel item identifier is invalid.
errorItemNotFound	The specified channel item could not be found.
errorItemEmpty	The specified channel item does not contain any data.
errorInvalidItemProperty	The specified item property name is invalid.
errorItemPropertyNotFound	The specified item property has not been defined.
errorInvalidChannelTitle	The channel title is invalid or has not been defined.
errorInvalidChannelLink	The channel hyperlink is invalid or has not been defined.
errorInvalidChannelDescription	The channel description is invalid or has not been defined.
errorInvalidItemText	The description for an item is invalid or has not been defined.
errorInvalidItemLink	The hyperlink for an item is invalid or has not been defined.

errorInvalidServiceType	The specified service type is invalid.
errorServiceSuspended	Access to the specified service has been suspended.
errorServiceRestricted	Access to the specified service has been restricted.
errorInvalidProviderName	The specified provider name is invalid or unknown.
errorInvalidPhoneNumber	The specified phone number is invalid or not supported in this region.
errorGatewayNotFound	A message gateway cannot be found for the specified provider.
errorMessageTooLong	The message exceeds the maximum number of characters permitted.
errorInvalidProviderData	The request returned invalid or incomplete service provider data.
errorInvalidGatewayData	The request returned invalid or incomplete message gateway data.
errorMultipleProviders	The request has returned multiple service providers.
errorProviderNotFound	The specified service provider could not be found.
errorInvalidMessageService	The specified message is not supported with this service type.
errorInvalidMessageFormat	The specified message format is invalid.
errorInvalidConfiguration	The specified configuration options are invalid.
errorServerActive	The requested action is not permitted while the server is active.
errorServerPortBound	Unable to obtain exclusive use of the specified local port.
errorInvalidClientSession	The specified client identifier is invalid for this session.
errorClientNotIdentified	The specified client has not provided user credentials.
errorInvalidClientState	The requested action cannot be performed at this time.
errorInvalidResultCode	The specified result code is not valid for this protocol
errorCommandRequired	The specified command is required and cannot be disabled.
errorCommandDisabled	The specified command has been disabled.
errorCommandSequence	The command cannot be processed at this time.
errorCommandCompleted	The previous command has completed.
errorInvalidProgramName	The specified program name is invalid or unrecognized.

errorInvalidRequestHeader	The request header contains one or more invalid values.
errorInvalidVirtualHost	The specified virtual host name is invalid.
errorVirtualHostNotFound	The specified virtual host does not exist.
errorTooManyVirtualHosts	Too many virtual hosts created for this server.
errorInvalidVirtualPath	The specified virtual path name is invalid.
errorVirtualPathNotFound	The specified virtual path does not exist.
errorTooManyVirtualPaths	Too many virtual paths created for this server.
errorInvalidTask	The asynchronous task identifier is invalid.
errorTaskActive	The asynchronous task has not finished.
errorTaskQueued	The asynchronous task has been queued.
errorTaskSuspended	The asynchronous task has been suspended.
errorTaskFinished	The asynchronous task has finished.

Requirements

Namespace: SocketTools

Assembly: SocketTools.DnsClient (in SocketTools.DnsClient.dll)

SocketTools Namespace | LastError Property | LastErrorString Property | OnError Event

DnsClient.ProtocolType Enumeration

Provides constant values for the HostProtocol property.

[Visual Basic]

```
Public Enum DnsClient.ProtocolType
```

[C#]

```
public enum DnsClient.ProtocolType
```

Members

Member Name	Description
protocolTCP	Transmission control protocol.
protocolUDP	User datagram protocol.
protocolDefault	The default protocol; the same value as ProtocolType.protocolTCP.

Requirements

Namespace: SocketTools

Assembly: SocketTools.DnsClient (in SocketTools.DnsClient.dll)

See Also

SocketTools Namespace | HostProtocol Property

DnsClient.RecordType Enumeration

Provides constant values for record queries

[Visual Basic]
```
Public Enum DnsClient.RecordType
```

[C#]
```
public enum DnsClient.RecordType
```

Remarks

The **dnsRecordAddress** record type is used to resolve a host name into an Internet address, and is the most common type of nameserver query that is performed. This is the type of query that is used when you set the **HostName** property and then read the **HostAddress** property to obtain its address.

The **dnsRecordPTR** record type is used to resolve an Internet address into a host name, and is also referred to as a reverse DNS lookup. This is the same type of query that is performed when you set the **HostAddress** property and then read the **HostName** property to determine the host name.

Members

Member Name	Description
recordNone	No record type.
recordAddress	Host address record.
recordNS	Authoritative nameserver record.
recordCNAME	Canonical name (alias) record.
recordSOA	Start of Authority record.
recordWKS	Well known services record.
recordPTR	Domain name.
recordHINFO	Host information record.
recordMINFO	Mailbox information record.
recordMX	Mail exchange host record.
recordTXT	Text resource record.
recordRP	Responsible Person (RP) resource record.
recordX25	X.25 resource record.
recordISDN	ISDN resource record.
recordRT	Route Through (RT) resource record.
recordAAAA	IPv6 address record.
recordLOC	Location resource record.
recordUINFO	User information.
recordUID	User ID record.
recordGID	Group ID record.

Requirements

Namespace: SocketTools

Assembly: SocketTools.DnsClient (in SocketTools.DnsClient.dll)

SocketTools Namespace

DnsClient.TraceOptions Enumeration

Specifies the logging options that the DnsClient class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

```
[Visual Basic]
<Flags>
Public Enum DnsClient.TraceOptions
```

```
[C#]
[Flags]
public enum DnsClient.TraceOptions
```

Remarks

The DnsClient class uses the **TraceOptions** enumeration to specify what kind of debugging information is written to the trace logfile. These options are only meaningful when trace logging is enabled by setting the **Trace** property to **true**.

Members

Member Name	Description	Value
traceDefault	The default trace logging option. This is the same as specifying the **traceInfo** option.	0
traceInfo	All network function calls are written to the trace file. This is the default value.	0
traceError	Only those network function calls which fail are recorded in the trace file.	1
traceWarning	Only those network function calls which fail, or return values which indicate a warning, are recorded in the trace file.	2
traceHexDump	All network function calls are written to the trace file, plus all the data that is sent or received is displayed, in both ASCII and hexadecimal format.	4
traceProcess	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for multithreaded applications that are using worker threads.	4096

Requirements

Namespace: SocketTools

Assembly: SocketTools.DnsClient (in SocketTools.DnsClient.dll)

SocketTools Namespace

DnsClient.OnErrorEventHandler Delegate

Represents the method that will handle the OnError event.

[Visual Basic]

```
Public Delegate Sub DnsClient.OnErrorEventHandler( _
   ByVal sender As Object, _
   ByVal e As ErrorEventArgs _
)
```

[C#]

```
public delegate void DnsClient.OnErrorEventHandler(
      object sender,
      ErrorEventArgs e
   );
```

Parameters

sender
The source of the event.

e
An ErrorEventArgs that contains the event data.

Remarks

The event handler receives an argument of type ErrorEventArgs containing data related to this event. The following ErrorEventArgs properties provide information specific to this event.

Property	Description
Error	Returns the value of the last error that has occurred
Description	Returns a description of the last error that occurred

Requirements

Namespace: SocketTools

Assembly: SocketTools.DnsClient (in SocketTools.DnsClient.dll)

SocketTools Namespace

DnsClient.RuntimeLicenseAttribute Class

Attribute that defines the runtime license key for the class.

For a list of all members of this type, see DnsClient.RuntimeLicenseAttribute Members.

System.Object
  System.Attribute
    SocketTools.DnsClient.RuntimeLicenseAttribute

[Visual Basic]

```
<AttributeUsage(ValidOn:=AttributeTargets.Assembly, AllowMultiple:=False,
   Inherited:=True)>
Public Class DnsClient.RuntimeLicenseAttribute
    Inherits Attribute
```

[C#]

```
[AttributeUsage(ValidOn=AttributeTargets.Assembly, AllowMultiple=False,
   Inherited=True)]
public class DnsClient.RuntimeLicenseAttribute : Attribute
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

The RuntimeLicense attribute is used to define the runtime license key that will be used when an instance of the class is created. This attribute is defined in the assembly information module for the language, such as AssemblyInfo.cs when programming C#. The runtime license key must be defined if you wish to redistribute your application.

The runtime license key for your copy of SocketTools can be generated using the License Manager utility that is included with the product. Note that if you have installed an evaluation license, you will not have a runtime license key and cannot redistribute any applications which use SocketTools components.

Example

```
<Assembly: SocketTools.DnsClient.RuntimeLicense("abcdefghijklmnop")>
```

```
[assembly: SocketTools.DnsClient.RuntimeLicense("abcdefghijklmnop")]
```

Requirements

Namespace: SocketTools

Assembly: SocketTools.DnsClient (in SocketTools.DnsClient.dll)

DnsClient.RuntimeLicenseAttribute overview

Public Instance Constructors

DnsClient.RuntimeLicenseAttribute Constructor	Constructor for the RuntimeLicense attribute which defines the runtime license key.

Public Instance Properties

LicenseKey	Returns the value of the runtime license key.
TypeId (inherited from Attribute)	When implemented in a derived class, gets a unique identifier for this Attribute.

Public Instance Methods

Equals (inherited from Attribute)	
GetHashCode (inherited from Attribute)	Returns the hash code for this instance.
GetType (inherited from Object)	Gets the Type of the current instance.
IsDefaultAttribute (inherited from Attribute)	When overridden in a derived class, returns an indication whether the value of this instance is the default value for the derived class.
Match (inherited from Attribute)	When overridden in a derived class, returns a value indicating whether this instance equals a specified object.
ToString (inherited from Object)	Returns a String that represents the current Object.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

DnsClient.RuntimeLicenseAttribute Class | SocketTools Namespace

DnsClient.RuntimeLicenseAttribute Constructor

Constructor for the RuntimeLicense attribute which defines the runtime license key.

[Visual Basic]

```
Public Sub New( _
   ByVal licenseKey As String _
)
```

[C#]

```
public DnsClient.RuntimeLicenseAttribute(
   string licenseKey
);
```

Parameters

licenseKey

A string argument which specifies the runtime license key which will be used to initialize the class library.

Remarks

The runtime license key for your copy of SocketTools can be generated using the License Manager utility that is included with the product. Note that if you have installed an evaluation license, you will not have a runtime license key and cannot redistribute any applications which use SocketTools components.

DnsClient.RuntimeLicenseAttribute Properties

The properties of the **DnsClient.RuntimeLicenseAttribute** class are listed below. For a complete list of **DnsClient.RuntimeLicenseAttribute** class members, see the DnsClient.RuntimeLicenseAttribute Members topic.

Public Instance Properties

LicenseKey	Returns the value of the runtime license key.
TypeId (inherited from Attribute)	When implemented in a derived class, gets a unique identifier for this Attribute.

See Also

DnsClient.RuntimeLicenseAttribute Class | SocketTools Namespace

DnsClient.RuntimeLicenseAttribute.LicenseKey Property

Returns the value of the runtime license key.

[Visual Basic]

```
Public Property LicenseKey As String
```

[C#]

```
public string LicenseKey {get; set;}
```

Property Value

A string which contains the runtime license key.

See Also

DnsClient.RuntimeLicenseAttribute Class | SocketTools Namespace

DnsClientException Class

This exception is thrown when a networking error occurs.

For a list of all members of this type, see DnsClientException Members.

System.Object
  System.Exception
    System.ApplicationException
      SocketTools.DnsClientException

[Visual Basic]
```
Public Class DnsClientException
    Inherits ApplicationException
```

[C#]
```
public class DnsClientException : ApplicationException
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

This exception can be thrown when a property is set that results in a networking error, or as the result of calling a method that fails when the **ThrowError** property has been set to True.

Requirements

Namespace: SocketTools

Assembly: SocketTools.DnsClient (in SocketTools.DnsClient.dll)

DnsClientException Members

DnsClientException overview

Public Instance Constructors

DnsClientException	Overloaded. Initializes a new instance of the DnsClientException class.

Public Instance Properties

HelpLink (inherited from Exception)	Gets or sets a link to the help file associated with this exception.
InnerException (inherited from Exception)	Gets the Exception instance that caused the current exception.
Message	Returns a message that describes the current exception.
Number	Return the last error that occurred.
Source (inherited from Exception)	Gets or sets the name of the application or the object that causes the error.
StackTrace (inherited from Exception)	Gets a string representation of the frames on the call stack at the time the current exception was thrown.
TargetSite (inherited from Exception)	Gets the method that throws the current exception.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetBaseException (inherited from Exception)	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetObjectData (inherited from Exception)	When overridden in a derived class, sets the SerializationInfo with information about the exception.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString	Creates and returns a string representation of the current exception.

Protected Instance Properties

HResult (inherited from Exception)	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

DnsClientException Constructor

Initializes a new instance of the DnsClientException class without a message.

Overload List

Initializes a new instance of the DnsClientException class without a message.

public DnsClientException();

Initializes a new instance of the DnsClientException class with the specific error code value.

public DnsClientException(ErrorCode);

Initializes a new instance of the DnsClientException class with the specific error code value.

public DnsClientException(int);

Initializes a new instance of the DnsClientException class with a message.

public DnsClientException(string);

Initializes a new instance of the DnsClientException class with a message and a reference to the inner exception that is the cause of this exception.

public DnsClientException(string,Exception);

DnsClientException Class | SocketTools Namespace | DnsClientException Constructor Overload List

DnsClientException Constructor (String)

Initializes a new instance of the DnsClientException class with a message.

[Visual Basic]

```
Overloads Public Sub New( _
   ByVal message As String _
)
```

[C#]

```
public DnsClientException(
   string message
);
```

Parameters

message

The message to display with this exception.

See Also

DnsClientException Class | SocketTools Namespace | DnsClientException Constructor Overload List

DnsClientException Constructor (String, Exception)

Initializes a new instance of the DnsClientException class with a message and a reference to the inner exception that is the cause of this exception.

[Visual Basic]

```
Overloads Public Sub New( _
   ByVal message As String, _
   ByVal inner As Exception _
)
```

[C#]

```
public DnsClientException(
   string message,
   Exception inner
);
```

Parameters

message

The message to display with this exception.

inner

The exception that is the cause of the current exception. If the inner parameter is not a null reference (Nothing in Visual Basic), the current exception is raised in a catch block that handles the inner exception.

See Also

DnsClientException Class | SocketTools Namespace | DnsClientException Constructor Overload List

DnsClientException Constructor (Int32)

Initializes a new instance of the DnsClientException class with the specific error code value.

[Visual Basic]

```
Overloads Public Sub New( _
   ByVal code As Integer _
)
```

[C#]

```
public DnsClientException(
   int code
);
```

Parameters

code

An integer value which specifies the error that caused the exception to be raised.

See Also

DnsClientException Class | SocketTools Namespace | DnsClientException Constructor Overload List

DnsClientException Constructor (ErrorCode)

Initializes a new instance of the DnsClientException class with the specific error code value.

[Visual Basic]

```
Overloads Public Sub New( _
   ByVal code As ErrorCode _
)
```

[C#]

```
public DnsClientException(
   ErrorCode code
);
```

Parameters

code

An ErrorCode enumeration which specifies the error that caused the exception to be raised.

See Also

DnsClientException Class | SocketTools Namespace | DnsClientException Constructor Overload List

DnsClientException Properties

The properties of the **DnsClientException** class are listed below. For a complete list of **DnsClientException** class members, see the DnsClientException Members topic.

Public Instance Properties

HelpLink (inherited from Exception)	Gets or sets a link to the help file associated with this exception.
InnerException (inherited from Exception)	Gets the Exception instance that caused the current exception.
Message	Returns a message that describes the current exception.
Number	Return the last error that occurred.
Source (inherited from Exception)	Gets or sets the name of the application or the object that causes the error.
StackTrace (inherited from Exception)	Gets a string representation of the frames on the call stack at the time the current exception was thrown.
TargetSite (inherited from Exception)	Gets the method that throws the current exception.

Protected Instance Properties

HResult (inherited from Exception)	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception.

See Also

DnsClientException Class | SocketTools Namespace

DnsClientException.Message Property

Returns a message that describes the current exception.

[Visual Basic]
```
Overrides Public ReadOnly Property Message As String
```

[C#]
```
public override string Message {get;}
```

Property Value

A string that explains the reason for the exception, or an empty string.

Remarks

The **Message** property returns a description of the last error that caused the exception. This can be used to display a meaningful error message to a user, rather than just the numeric value returned by the **Number** property.

See Also

DnsClientException Class | SocketTools Namespace

DnsClientException.Number Property

Return the last error that occurred.

[Visual Basic]
```
Public ReadOnly Property Number As Integer
```

[C#]
```
public int Number {get;}
```

Property Value

An ErrorCode enumeration type that specifies the error that caused the exception.

See Also

DnsClientException Class | SocketTools Namespace

DnsClientException Methods

The methods of the **DnsClientException** class are listed below. For a complete list of **DnsClientException** class members, see the DnsClientException Members topic.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetBaseException (inherited from Exception)	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetObjectData (inherited from Exception)	When overridden in a derived class, sets the SerializationInfo with information about the exception.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString	Creates and returns a string representation of the current exception.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

DnsClientException Class | SocketTools Namespace

DnsClientException.ToString Method

Creates and returns a string representation of the current exception.

[Visual Basic]
```
Overrides Public Function ToString() As String
```

[C#]
```
public override string ToString();
```

Return Value

A string representation of the current exception.

Remarks

ToString returns a representation of the current exception that is intended to be understood by humans. Where the exception contains culture-sensitive data, the string representation returned by ToString is required to take into account the current system culture. Although there are no exact requirements for the format of the returned string, it should attempt to reflect the value of the object as perceived by the user.

The default implementation of ToString obtains the description of the error that caused the exception. If there is no error message or if it is an empty string (""), then no error message is returned.

This method overrides Object.ToString.

DnsClientException Class | SocketTools Namespace

FileEncoder Class

Encode and decode files using standard algorithms such as base64, uuencode and quoted-printable. The class can also be used to compress and expand files, either separately or as part of the encoding process.

For a list of all members of this type, see FileEncoder Members.

System.Object
  SocketTools.FileEncoder

[Visual Basic]
```
Public Class FileEncoder
    Implements IDisposable
```

[C#]
```
public class FileEncoder : IDisposable
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

The FileEncoding class provides methods for encoding and decoding binary files, typically attachments to email messages. The process of encoding converts the contents of a binary file to printable 7-bit ASCII text. Decoding reverses the process, converting a previously encoded text file back into a binary file.

There are two primary types of encoding used, uucode and base64. The uucode algorithm (so called because the programs to perform the conversion were called uuencode and uudecode) is commonly used on UNIX systems and is still widely used when attaching binary files to USENET newsgroup posts. The base64 algorithm is most commonly used with email attachments, and is often referred to as MIME encoding since this is the encoding method specified in the MIME standards document. The class also supports a newer encoding format called yEnc, which has become popular for posting binary files to Usenet newsgroups.

Requirements

Namespace: SocketTools

Assembly: SocketTools.FileEncoder (in SocketTools.FileEncoder.dll)

FileEncoder Members | SocketTools Namespace

FileEncoder Members

FileEncoder overview

Public Instance Constructors

FileEncoder Constructor	Initializes a new instance of the FileEncoder class.

Public Instance Properties

DecodedText	Set the value of the current decoded text string, or return the decoded value of an encoded string.
DecryptedText	Gets and sets the value of the current decrypted string.
EncodedText	Set the value of the current encoded text string, or return the encoded value of a plain text string.
Encoding	Get or set the current encoding method.
EncryptedText	Gets and sets the value of the current encrypted string.
IsInitialized	Gets a value which indicates if the current instance of the class has been initialized successfully.
LastError	Gets and sets a value which specifies the last error that has occurred.
LastErrorString	Gets a value which describes the last error that has occurred.
Password	Gets and sets the password used to encrypt and decrypt data.
ThrowError	Gets and sets a value which specifies if method calls should throw exceptions when an error occurs.
Version	Gets a value which returns the current version of the FileEncoder class library.

Public Instance Methods

CompressData	Compresses the contents of the specified buffer.
CompressFile	Overloaded. Compress the contents of the specified file.
DecodeFile	Overloaded. Decodes an encoded file, storing the contents in the specified file.
DecryptData	Overloaded. Decrypts the contents of a byte array.
DecryptFile	Overloaded. Decrypts the contents of a file using AES-256 encryption.
Dispose	Overloaded. Releases all resources used by FileEncoder.

EncodeFile	Overloaded. Encodes a file, storing the contents as printable text in the specified file.
EncryptData	Overloaded. Encrypts the contents of a byte array.
EncryptFile	Overloaded. Encrypts the contents of a file using AES-256 encryption.
Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
ExpandData	Expands the contents of the compressed buffer.
ExpandFile	Overloaded. Expands the contents of a previously compressed file.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from Object)	Gets the Type of the current instance.
Initialize	Overloaded. Initializes the component with the specified runtime license key.
Reset	Reset the internal state of the class back to its defaults.
ToString (inherited from Object)	Returns a String that represents the current Object.
Uninitialize	Uninitialize the component.

Public Instance Events

OnError	Occurs when a method fails.

Protected Instance Methods

Dispose	Overloaded. Releases the unmanaged resources allocated by the FileEncoder class and optionally releases the managed resources.
Finalize	Destroys an instance of the class, releasing the resources allocated for the object.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

FileEncoder Constructor

Initializes a new instance of the FileEncoder class.

[Visual Basic]

```
Public Sub New()
```

[C#]

```
public FileEncoder();
```

See Also

FileEncoder Class | SocketTools Namespace

FileEncoder Properties

The properties of the **FileEncoder** class are listed below. For a complete list of **FileEncoder** class members, see the FileEncoder Members topic.

Public Instance Properties

DecodedText	Set the value of the current decoded text string, or return the decoded value of an encoded string.
DecryptedText	Gets and sets the value of the current decrypted string.
EncodedText	Set the value of the current encoded text string, or return the encoded value of a plain text string.
Encoding	Get or set the current encoding method.
EncryptedText	Gets and sets the value of the current encrypted string.
IsInitialized	Gets a value which indicates if the current instance of the class has been initialized successfully.
LastError	Gets and sets a value which specifies the last error that has occurred.
LastErrorString	Gets a value which describes the last error that has occurred.
Password	Gets and sets the password used to encrypt and decrypt data.
ThrowError	Gets and sets a value which specifies if method calls should throw exceptions when an error occurs.
Version	Gets a value which returns the current version of the FileEncoder class library.

See Also

FileEncoder Class | SocketTools Namespace

FileEncoder.DecodedText Property

Set the value of the current decoded text string, or return the decoded value of an encoded string.

[Visual Basic]

```
Public Property DecodedText As String
```

[C#]

```
public string DecodedText {get; set;}
```

Property Value

Returns a string which contains the decoded value of an encoded string.

Remarks

The **DecodedText** property is used to specify the unencoded value of a string, or return the decoded value of a previously encoded string. If the property is set, the current plain (unencoded) text is changed to that value and reading the **EncodedText** property will return the encoded string for this value. If the property is read, it will return the decoded value of the **EncodedText** property.

The class will use the value of the **Encoding** property to determine how the text should be decoded. Note that only base64 and quoted-printable encoding is supported when decoding a string using this property. To decode the contents of a file, it is recommended that you use the **DecodeFile** method.

See Also

FileEncoder Class | SocketTools Namespace

FileEncoder.EncodedText Property

Set the value of the current encoded text string, or return the encoded value of a plain text string.

[Visual Basic]

```
Public Property EncodedText As String
```

[C#]

```
public string EncodedText {get; set;}
```

Property Value

Returns a string which contains the encoded value of a plain text string.

Remarks

The **EncodedText** property is used to specify the encoded value of a string, or return the encoded value of a plain text (decoded) string. If the property is set, the current value will be changed to the encoded value, and the **DecodedText** property will return the plain text value of the encoded string. If the property is read, it will return the encoded value of the **DecodedText** property.

The class will use the value of the **Encoding** property to determine how the text should be encoded. Note that only base64 and quoted-printable encoding is supported when encoding a string using this property. To encode the contents of a file, it is recommended that you use the **EncodeFile** method.

See Also

FileEncoder Class | SocketTools Namespace

FileEncoder.Encoding Property

Get or set the current encoding method.

[Visual Basic]
```
Public Property Encoding As EncodingType
```

[C#]
```
public FileEncoder.EncodingType Encoding {get; set;}
```

Property Value

Returns an EncodingType enumeration value which specifies the current encoding method.

Remarks

The **Encoding** property determines how the specified file will be encoded or decoded by the class. The value of this property specifies the default encoding method for the **DecodeFile** and **EncodeFile** methods. Unless needed for a specific purpose, it is strongly recommended that binary files be encoded with the base64 algorithm for maximum compatibility.

The **Encoding** property also determines the encoding method that is used when the **DecodedText** and **EncodedText** properties are used to decode and encode text strings.

See Also

FileEncoder Class | SocketTools Namespace

FileEncoder.IsInitialized Property

Gets a value which indicates if the current instance of the class has been initialized successfully.

[Visual Basic]

```
Public ReadOnly Property IsInitialized As Boolean
```

[C#]

```
public bool IsInitialized {get;}
```

Property Value

Returns **true** if the class instance has been initialized; otherwise returns **false**.

Remarks

The **IsInitialized** property is used to determine if the current instance of the class has been initialized properly. Normally this is done automatically by the class constructor, however there are circumstances where the class may not be able to initialize itself.

The most common reasons that a class instance may not initialize correctly is that no runtime license key has been defined in the assembly or the license key provided is invalid. It may also indicate a problem with the system configuration or user access rights, such as not being able to load the required networking libraries or not being able to access the system registry.

FileEncoder.LastError Property

Gets and sets a value which specifies the last error that has occurred.

[Visual Basic]

```
Public Property LastError As ErrorCode
```

[C#]

```
public FileEncoder.ErrorCode LastError {get; set;}
```

Property Value

Returns an ErrorCode enumeration value which specifies the last error code.

Remarks

The **LastError** property returns the error code associated with the last error that occurred for the current instance of the class. It is important to note that this value only has meaning if the previous method indicates that an error has actually occurred.

It is possible to explicitly clear the last error code by assigning the property to the value **ErrorCode.errorNone**.

The error code value can be cast to an integer value for display purposes if required. For a description of the error that can be displayed using a message box or some other similar mechanism, get the value of the **LastErrorString** property.

FileEncoder Class | SocketTools Namespace

FileEncoder.LastErrorString Property

Gets a value which describes the last error that has occurred.

[Visual Basic]

```
Public ReadOnly Property LastErrorString As String
```

[C#]

```
public string LastErrorString {get;}
```

Remarks

A string which describes the last error that has occurred. The **LastErrorString** property can be used to obtain a description of the last error that occurred for the current instance of the class. It is important to note that this value only has meaning if the previous method indicates that an error has actually occurred.

See Also

FileEncoder Class | SocketTools Namespace

FileEncoder.ThrowError Property

Gets and sets a value which specifies if method calls should throw exceptions when an error occurs.

[Visual Basic]

```
Public Property ThrowError As Boolean
```

[C#]

```
public bool ThrowError {get; set;}
```

Property Value

Returns **true** if method calls will generate exceptions when an error occurs; otherwise returns **false**. The default value is **false**.

Remarks

Error handling for when calling class methods can be done in either of two different styles, according to the value of this property.

If the **ThrowError** property is set to **false**, the application should check the return value of any method that is used, and report errors based upon the documented value of the return code. It is the responsibility of the application to interpret the error code, if it is desired to explain the error in addition to reporting it. This is the default behavior.

If the **ThrowError** property is set to **true**, then exceptions will be generated whenever a method call fails. The program must be written to catch these exceptions and take the appropriate action when an error occurs. Failure to handle an exception will cause the program to terminate abnormally.

Note that if an error occurs while a property is being read or modified, an exception will be raised regardless of the value of the **ThrowError** property.

FileEncoder Class | SocketTools Namespace

FileEncoder.Version Property

Gets a value which returns the current version of the FileEncoder class library.

[Visual Basic]

```
Public ReadOnly Property Version As String
```

[C#]

```
public string Version {get;}
```

Property Value

A string which specifies the version of the class library.

Remarks

The **Version** property returns a string which identifies the current version and build of the FileEncoder class library. This value can be used by an application for validation and debugging purposes.

FileEncoder Methods

The methods of the **FileEncoder** class are listed below. For a complete list of **FileEncoder** class members, see the FileEncoder Members topic.

Public Instance Methods

CompressData	Compresses the contents of the specified buffer.
CompressFile	Overloaded. Compress the contents of the specified file.
DecodeFile	Overloaded. Decodes an encoded file, storing the contents in the specified file.
DecryptData	Overloaded. Decrypts the contents of a byte array.
DecryptFile	Overloaded. Decrypts the contents of a file using AES-256 encryption.
Dispose	Overloaded. Releases all resources used by FileEncoder.
EncodeFile	Overloaded. Encodes a file, storing the contents as printable text in the specified file.
EncryptData	Overloaded. Encrypts the contents of a byte array.
EncryptFile	Overloaded. Encrypts the contents of a file using AES-256 encryption.
Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
ExpandData	Expands the contents of the compressed buffer.
ExpandFile	Overloaded. Expands the contents of a previously compressed file.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from Object)	Gets the Type of the current instance.
Initialize	Overloaded. Initializes the component with the specified runtime license key.
Reset	Reset the internal state of the class back to its defaults.
ToString (inherited from Object)	Returns a String that represents the current Object.
Uninitialize	Uninitialize the component.

Protected Instance Methods

Dispose	Overloaded. Releases the unmanaged resources allocated by the FileEncoder class and optionally releases the managed resources.
Finalize	Destroys an instance of the class, releasing the

	resources allocated for the object.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

FileEncoder Class | SocketTools Namespace

FileEncoder.CompressData Method

Compresses the contents of the specified buffer.

[Visual Basic]

```
Public Function CompressData( _
   ByVal inputBuffer As Byte(), _
   ByVal inputLength As Integer, _
   ByVal outputBuffer As Byte(), _
   ByRef outputLength As Integer _
) As Boolean
```

[C#]

```
public bool CompressData(
   byte[] inputBuffer,
   int inputLength,
   byte[] outputBuffer,
   ref int outputLength
);
```

Parameters

inputBuffer
A byte array which contains the data to be compressed.

inputLength
An integer value which specifies the number of bytes to be compressed.

outputBuffer
A byte array which will contain the compressed data.

outputLength
An integer value which specifies the maximum number of bytes that can be copied into the output buffer.

Return Value

A boolean value which specifies if the method was successful or not. A return value of True indicates that the method call completed successfully. A return value of False indicates that the method failed and the application should check the value of the **LastError** property.

FileEncoder.CompressFile Method

Compress the contents of the specified file.

Overload List

Compress the contents of the specified file.

public bool CompressFile(string,string);

Compress the contents of the specified file.

public bool CompressFile(string,string,CompressionType);

Compress the contents of the specified file.

public bool CompressFile(string,string,CompressionType,CompressionLevel);

See Also

FileEncoder Class | SocketTools Namespace | CompressData | ExpandData | ExpandFile

FileEncoder.CompressFile Method (String, String)

Compress the contents of the specified file.

[Visual Basic]

```
Overloads Public Function CompressFile( _
   ByVal inputFile As String, _
   ByVal outputFile As String _
) As Boolean
```

[C#]

```
public bool CompressFile(
   string inputFile,
   string outputFile
);
```

Parameters

inputFile

The name of the file that will be compressed. The file must exist, and it must be a regular file that can be opened for reading by the current process. An error will be returned if a character device, such as the console, is specified as the file name.

outputFile

The name of the file that is to contain the compressed file data. If the file exists, it must be a regular file that can be opened for writing by the current process and will be overwritten. If the file does not exist, it will be created. An error will be returned if a character device, such as the console, is specified as the file name.

Return Value

A boolean value which specifies if the method was successful or not. A return value of True indicates that the method call completed successfully. A return value of False indicates that the method failed and the application should check the value of the **LastError** property.

Remarks

It is permitted to specify an empty string as the output file name. In this case, the method will create a temporary file in the directory specified by the TEMP environment variable. After the file has been compressed, the **OutputFile** property will be set the name of the temporary file that has been created. It is the responsibility of the application to delete this temporary file after it is no longer needed.

Note that the compressed file is not stored in an archive format that is recognized by third-party applications such as PKZip or WinZip.

See Also

FileEncoder Class | SocketTools Namespace | FileEncoder.CompressFile Overload List | CompressData | ExpandData | ExpandFile

FileEncoder.CompressFile Method (String, String, CompressionType)

Compress the contents of the specified file.

[Visual Basic]
```
Overloads Public Function CompressFile( _
   ByVal inputFile As String, _
   ByVal outputFile As String, _
   ByVal compressionType As CompressionType _
) As Boolean
```

[C#]
```
public bool CompressFile(
   string inputFile,
   string outputFile,
   CompressionType compressionType
);
```

Parameters

inputFile
The name of the file that will be compressed. The file must exist, and it must be a regular file that can be opened for reading by the current process. An error will be returned if a character device, such as the console, is specified as the file name.

outputFile
The name of the file that is to contain the compressed file data. If the file exists, it must be a regular file that can be opened for writing by the current process and will be overwritten. If the file does not exist, it will be created. An error will be returned if a character device, such as the console, is specified as the file name.

compressionType
One of the CompressionType enumeration values which determines the algorithm that will be used to compress the data.

Return Value

A boolean value which specifies if the method was successful or not. A return value of True indicates that the method call completed successfully. A return value of False indicates that the method failed and the application should check the value of the **LastError** property.

Remarks

It is permitted to specify an empty string as the output file name. In this case, the method will create a temporary file in the directory specified by the TEMP environment variable. After the file has been compressed, the **OutputFile** property will be set the name of the temporary file that has been created. It is the responsibility of the application to delete this temporary file after it is no longer needed.

Note that the compressed file is not stored in an archive format that is recognized by third-party applications such as PKZip or WinZip.

See Also

FileEncoder Class | SocketTools Namespace | FileEncoder.CompressFile Overload List | CompressData | ExpandData | ExpandFile

FileEncoder.CompressFile Method (String, String, CompressionType, CompressionLevel)

Compress the contents of the specified file.

[Visual Basic]
```
Overloads Public Function CompressFile( _
   ByVal inputFile As String, _
   ByVal outputFile As String, _
   ByVal compressionType As CompressionType, _
   ByVal compressionLevel As CompressionLevel _
) As Boolean
```

[C#]
```
public bool CompressFile(
   string inputFile,
   string outputFile,
   CompressionType compressionType,
   CompressionLevel compressionLevel
);
```

Parameters

inputFile

The name of the file that will be compressed. The file must exist, and it must be a regular file that can be opened for reading by the current process. An error will be returned if a character device, such as the console, is specified as the file name.

outputFile

The name of the file that is to contain the compressed file data. If the file exists, it must be a regular file that can be opened for writing by the current process and will be overwritten. If the file does not exist, it will be created. An error will be returned if a character device, such as the console, is specified as the file name.

compressionType

One of the CompressionType enumeration values which determines the algorithm that will be used to compress the data.

compressionLevel

One of the CompressionLevel enumeration values which specifies the compression level to use. A value of zero specifies that the default compression level appropriate for the selected algorithm should be used, balancing resource usage and the compression ratio of the data. A value of 1 specifies that the compression should be performed using minimal memory resources, at the expense of the compression ratio. The maximum value of 9 specifies that the algorithm should use more memory to achieve the maximum compression ratio. It is recommended that most applications use the default compression level.

Return Value

A boolean value which specifies if the method was successful or not. A return value of True indicates that the method call completed successfully. A return value of False indicates that the method failed and the application should check the value of the **LastError** property.

Remarks

It is permitted to specify an empty string as the output file name. In this case, the method will create a temporary file in the directory specified by the TEMP environment variable. After the file has been compressed, the **OutputFile** property will be set the name of the temporary file that has been created. It is the responsibility of the application to delete this temporary file after it is no longer needed.

Note that the compressed file is not stored in an archive format that is recognized by third-party applications such as PKZip or WinZip.

FileEncoder.DecodeFile Method

Decodes an encoded file, storing the contents in the specified file.

Overload List

Decodes an encoded file, storing the contents in the specified file.

public bool DecodeFile(string,string);

Decodes an encoded file, storing the contents in the specified file.

public bool DecodeFile(string,string,EncodingType);

See Also

FileEncoder Class | SocketTools Namespace | DecryptFile | EncodeFile | EncryptFile

FileEncoder.DecodeFile Method (String, String)

Decodes an encoded file, storing the contents in the specified file.

[Visual Basic]

```
Overloads Public Function DecodeFile( _
   ByVal inputFile As String, _
   ByVal outputFile As String _
) As Boolean
```

[C#]

```
public bool DecodeFile(
   string inputFile,
   string outputFile
);
```

Parameters

inputFile

A string which specifies the name of the file to be decoded. The file must exist, and it must be a regular file that can be opened for reading by the current process. An error will be returned if a character device, such as CON: is specified as the file name.

outputFile

The name of the file that is to contain the decoded file data. If the file exists, it must be a regular file that can be opened for writing by the current process and will be overwritten. If the file does not exist, it will be created. An error will be returned if a character device, such as CON: is specified as the file name.

Return Value

A boolean value which specifies if the method was successful or not. A return value of True indicates that the method call completed successfully. A return value of False indicates that the method failed and the application should check the value of the **LastError** property.

FileEncoder.DecodeFile Method (String, String, EncodingType)

Decodes an encoded file, storing the contents in the specified file.

[Visual Basic]

```
Overloads Public Function DecodeFile( _
   ByVal inputFile As String, _
   ByVal outputFile As String, _
   ByVal encodingType As EncodingType _
) As Boolean
```

[C#]

```
public bool DecodeFile(
   string inputFile,
   string outputFile,
   EncodingType encodingType
);
```

Parameters

inputFile
A string which specifies the name of the file to be decoded. The file must exist, and it must be a regular file that can be opened for reading by the current process. An error will be returned if a character device, such as CON: is specified as the file name.

outputFile
The name of the file that is to contain the decoded file data. If the file exists, it must be a regular file that can be opened for writing by the current process and will be overwritten. If the file does not exist, it will be created. An error will be returned if a character device, such as CON: is specified as the file name.

encodingType
An EncodingType enumeration value which specifies the type of encoding that was used to encode the data.

Return Value

A boolean value which specifies if the method was successful or not. A return value of True indicates that the method call completed successfully. A return value of False indicates that the method failed and the application should check the value of the **LastError** property.

FileEncoder.DecryptData Method

Decrypts the contents of a byte array.

Overload List

Decrypts the contents of a byte array.

public bool DecryptData(byte[],int,byte[],ref int);

Decrypts the contents of a **System.IO.MemoryStream** object.

public bool DecryptData(MemoryStream,MemoryStream);

Decrypts the contents of a byte array.

public bool DecryptData(string,byte[],int,byte[],ref int);

Decrypts the contents of a **System.IO.MemoryStream** object.

public bool DecryptData(string,MemoryStream,MemoryStream);

Decrypts the contents of a string.

public bool DecryptData(string,string,ref string);

Decrypts the contents of a string.

public bool DecryptData(string,ref string);

See Also

FileEncoder Class | SocketTools Namespace | DecryptFile | EncryptData | EncryptFile

FileEncoder.DecryptData Method (String, Byte[], Int32, Byte[], Int32)

Decrypts the contents of a byte array.

[Visual Basic]

```
Overloads Public Function DecryptData( _
   ByVal password As String, _
   ByVal inputBuffer As Byte(), _
   ByVal inputSize As Integer, _
   ByVal outputBuffer As Byte(), _
   ByRef outputSize As Integer _
) As Boolean
```

[C#]

```
public bool DecryptData(
   string password,
   byte[] inputBuffer,
   int inputSize,
   byte[] outputBuffer,
   ref int outputSize
);
```

Parameters

password
A string of characters that will be used to generate the decryption key. This parameter may be a zero-length string, in which case a default internal hash value is used to decrypt the data. Password strings that exceed 215 characters will be truncated.

inputBuffer
A byte array which contains the data to be decrypted.

inputSize
An integer value which specifies the number of bytes in the byte array which contains the encrypted data.

outputBuffer
A byte array which will contain the decrypted data when the method returns.

outputSize
An integer value which specifies the maximum number of bytes that can be stored in the output byte array. When the method returns, this parameter will contain the number of decrypted bytes in the buffer.

Return Value

A boolean value which specifies if the method was successful or not. A return value of True indicates that the method call completed successfully. A return value of False indicates that the method failed and the application should check the value of the **LastError** property.

Remarks

This method will decrypt the contents of a byte array using a 256-bit AES (Advanced Encryption Standard) algorithm and returns a copy of the decrypted data to the caller. The password (or passphrase) provided by the caller is used to generate a SHA-256 hash value which is used as part of the decryption process. The password value must be identical to the value used to encrypt the data using the **EncryptData** method.

Due to how the SHA-256 hash is generated, this method cannot be used to decrypt data that was encrypted using another third-party library. It can only be used to decrypt data that was previously encrypted using **EncryptData**.

If you wish to decrypt the contents of a file, use the **DecryptFile** method.

This method uses the Microsoft CryptoAPI and the RSA AES cryptographic provider. This provider may not be available in some languages, countries or regions. The availability of this provider may also be constrained by cryptography export restrictions imposed by the United States or other countries. If the required cryptographic provider is not available, the method will fail.

FileEncoder Class | SocketTools Namespace | FileEncoder.DecryptData Overload List | DecryptFile | EncryptData | EncryptFile

FileEncoder.DecryptData Method (Byte[], Int32, Byte[], Int32)

Decrypts the contents of a byte array.

[Visual Basic]

```
Overloads Public Function DecryptData( _
   ByVal inputBuffer As Byte(), _
   ByVal inputSize As Integer, _
   ByVal outputBuffer As Byte(), _
   ByRef outputSize As Integer _
) As Boolean
```

[C#]

```
public bool DecryptData(
   byte[] inputBuffer,
   int inputSize,
   byte[] outputBuffer,
   ref int outputSize
);
```

Parameters

inputBuffer
A byte array which contains the data to be decrypted.

inputSize
An integer value which specifies the number of bytes in the byte array which contains the encrypted data.

outputBuffer
A byte array which will contain the decrypted data when the method returns.

outputSize
An integer value which specifies the maximum number of bytes that can be stored in the output byte array. When the method returns, this parameter will contain the number of decrypted bytes in the buffer.

Return Value

A boolean value which specifies if the method was successful or not. A return value of True indicates that the method call completed successfully. A return value of False indicates that the method failed and the application should check the value of the **LastError** property.

Remarks

This method will decrypt the contents of a byte array using a 256-bit AES (Advanced Encryption Standard) algorithm and returns a copy of the decrypted data to the caller. The value of the **Password** property is used to generate a SHA-256 hash value which is used as part of the decryption process. The password value must be identical to the value used to encrypt the data using the **EncryptData** method.

Due to how the SHA-256 hash is generated, this method cannot be used to decrypt data that was encrypted using another third-party library. It can only be used to decrypt data that was previously encrypted using **EncryptData**.

If you wish to decrypt the contents of a file, use the **DecryptFile** method.

This method uses the Microsoft CryptoAPI and the RSA AES cryptographic provider. This provider may not be available in some languages, countries or regions. The availability of this provider may also be constrained by cryptography export restrictions imposed by the United States or other countries. If the required cryptographic provider is not available, the method will fail.

FileEncoder Class | SocketTools Namespace | FileEncoder.DecryptData Overload List | DecryptFile | EncryptData | EncryptFile

FileEncoder.DecryptData Method (String, MemoryStream, MemoryStream)

Decrypts the contents of a **System.IO.MemoryStream** object.

```
[Visual Basic]
Overloads Public Function DecryptData( _
   ByVal password As String, _
   ByVal inputStream As MemoryStream, _
   ByVal outputStream As MemoryStream _
) As Boolean
```

```
[C#]
public bool DecryptData(
   string password,
   MemoryStream inputStream,
   MemoryStream outputStream
);
```

Parameters

password
A string of characters that will be used to generate the decryption key. This parameter may be a zero-length string, in which case a default internal hash value is used to decrypt the data. Password strings that exceed 215 characters will be truncated.

inputStream
A **MemoryStream** object which contains the data to be decrypted. The stream must be readable.

outputStream
A **MemoryStream** object which will contain the decrypted data when the method returns. The caller must create a stream that is writable, and the contents of the stream will be replaced with the decrypted data.

Return Value

A boolean value which specifies if the method was successful or not. A return value of True indicates that the method call completed successfully. A return value of False indicates that the method failed and the application should check the value of the **LastError** property.

Remarks

This method will decrypt the contents of a byte array using a 256-bit AES (Advanced Encryption Standard) algorithm and returns a copy of the decrypted data to the caller. The password (or passphrase) provided by the caller is used to generate a SHA-256 hash value which is used as part of the decryption process. The password value must be identical to the value used to encrypt the data using the **EncryptData** method.

Due to how the SHA-256 hash is generated, this method cannot be used to decrypt data that was encrypted using another third-party library. It can only be used to decrypt data that was previously encrypted using **EncryptData**.

If you wish to decrypt the contents of a file, use the **DecryptFile** method.

This method uses the Microsoft CryptoAPI and the RSA AES cryptographic provider. This provider may not be available in some languages, countries or regions. The availability of this provider may also be constrained by cryptography export restrictions imposed by the United States or other countries. If the required cryptographic provider is not available, the method will fail.

FileEncoder.DecryptData Method (MemoryStream, MemoryStream)

Decrypts the contents of a **System.IO.MemoryStream** object.

[Visual Basic]

```
Overloads Public Function DecryptData( _
   ByVal inputStream As MemoryStream, _
   ByVal outputStream As MemoryStream _
) As Boolean
```

[C#]

```
public bool DecryptData(
   MemoryStream inputStream,
   MemoryStream outputStream
);
```

Parameters

inputStream

A **MemoryStream** object which contains the data to be decrypted. The stream must be readable.

outputStream

A **MemoryStream** object which will contain the decrypted data when the method returns. The caller must create a stream that is writable, and the contents of the stream will be replaced with the decrypted data.

Return Value

A boolean value which specifies if the method was successful or not. A return value of True indicates that the method call completed successfully. A return value of False indicates that the method failed and the application should check the value of the **LastError** property.

Remarks

This method will decrypt the contents of a byte array using a 256-bit AES (Advanced Encryption Standard) algorithm and returns a copy of the decrypted data to the caller. The value of the **Password** property is used to generate a SHA-256 hash value which is used as part of the decryption process. The password value must be identical to the value used to encrypt the data using the **EncryptData** method.

Due to how the SHA-256 hash is generated, this method cannot be used to decrypt data that was encrypted using another third-party library. It can only be used to decrypt data that was previously encrypted using **EncryptData**.

FileEncoder.DecryptData Method (String, String, String)

Decrypts the contents of a string.

[Visual Basic]

```
Overloads Public Function DecryptData( _
   ByVal password As String, _
   ByVal inputText As String, _
   ByRef outputText As String _
) As Boolean
```

[C#]

```
public bool DecryptData(
   string password,
   string inputText,
   ref string outputText
);
```

Parameters

password

A string of characters that will be used to generate the decryption key. This parameter may be a zero-length string, in which case a default internal hash value is used to decrypt the data. Password strings that exceed 215 characters will be truncated.

inputText

A string which contains the encoded data to be decrypted.

outputText

A string which will contain the decrypted text when the method returns.

Return Value

A boolean value which specifies if the method was successful or not. A return value of True indicates that the method call completed successfully. A return value of False indicates that the method failed and the application should check the value of the **LastError** property.

Remarks

This method will decrypt the contents of a string using a 256-bit AES (Advanced Encryption Standard) algorithm and returns a copy of the decrypted text to the caller. The password (or passphrase) provided by the caller is used to generate a SHA-256 hash value which is used as part of the decryption process. The password value must be identical to the value used to encrypt the data using the **EncryptData** method.

Due to how the SHA-256 hash is generated, this method cannot be used to decrypt text that was encrypted using another third-party library. It can only be used to decrypt text that was previously encrypted using **EncryptData**.

If you wish to decrypt the contents of a file, use the **DecryptFile** method.

This method uses the Microsoft CryptoAPI and the RSA AES cryptographic provider. This provider may not be available in some languages, countries or regions. The availability of this provider may also be constrained by cryptography export restrictions imposed by the United States or other countries. If the required cryptographic provider is not available, the method will fail.

```
Overloads Public Function DecryptFile( _
   ByVal password As String, _
   ByVal inputFile As String, _
   ByVal outputFile As String _
) As Boolean
```

[C#]

```
public bool DecryptFile(
   string password,
   string inputFile,
   string outputFile
);
```

Parameters

password

A string of characters that will be used to generate the decryption key. Passwords are case sensitive and must match exactly when decrypting data that was previously encrypted using this method. This parameter may be a zero-length string, in which case a default internal hash value is used. Password strings that exceed 215 characters will be truncated.

inputFile

A string which specifies the name of the file to be decrypted. The file must exist, and it must be a regular file that can be opened for reading by the current process. An error will be returned if a character device, such as CON: is specified as the file name.

outputFile

The name of the file that is to contain the decrypted file data. If the file exists, it must be a regular file that can be opened for writing by the current process and will be overwritten. If the file does not exist, it will be created. An error will be returned if a character device, such as CON: is specified as the file name.

Return Value

A boolean value which specifies if the method was successful or not. A return value of True indicates that the method call completed successfully. A return value of False indicates that the method failed and the application should check the value of the **LastError** property.

Remarks

This method will decrypt the contents of a file using a 256-bit AES (Advanced Encryption Standard) algorithm and stores the decrypted data in the specified output file. The password (or passphrase) provided by the caller is used to generate a SHA-256 hash value which is used as part of the decryption process. The password must be identical to the value used to encrypt the data using the **EncryptFile** method.

Due to how the SHA-256 hash is generated, this method cannot be used to decrypt files that were encrypted using another third-party library. It can only be used to decrypt data that was previously encrypted using the **EncryptFile** method.

A temporary file is created during the decryption process and the output file is created or overwritten only if the input file could be successfully encrypted. If the decryption fails, no output file will be created.

If you wish to decrypt the contents of a memory buffer or string, use the **DecryptData** method.

This method uses the Microsoft CryptoAPI and the RSA AES cryptographic provider. This provider may not be available in some languages, countries or regions. The availability of this provider may also be constrained by cryptography export restrictions imposed by the United States or other countries. If the required cryptographic provider is not available, the method will fail.

FileEncoder.DecryptFile Method (String, String)

Decrypts the contents of a file using AES-256 encryption.

[Visual Basic]

```
Overloads Public Function DecryptFile( _
   ByVal inputFile As String, _
   ByVal outputFile As String _
) As Boolean
```

[C#]

```
public bool DecryptFile(
   string inputFile,
   string outputFile
);
```

Parameters

inputFile

A string which specifies the name of the file to be decrypted. The file must exist, and it must be a regular file that can be opened for reading by the current process. An error will be returned if a character device, such as CON: is specified as the file name.

outputFile

The name of the file that is to contain the decrypted file data. If the file exists, it must be a regular file that can be opened for writing by the current process and will be overwritten. If the file does not exist, it will be created. An error will be returned if a character device, such as CON: is specified as the file name.

Return Value

A boolean value which specifies if the method was successful or not. A return value of True indicates that the method call completed successfully. A return value of False indicates that the method failed and the application should check the value of the **LastError** property.

Remarks

This method will decrypt the contents of a file using a 256-bit AES (Advanced Encryption Standard) algorithm and stores the decrypted data in the specified output file. The value of the **Password** property is used to generate a SHA-256 hash value which is used as part of the decryption process. The password must be identical to the value used to encrypt the data using the **EncryptFile** method.

Due to how the SHA-256 hash is generated, this method cannot be used to decrypt files that were encrypted using another third-party library. It can only be used to decrypt data that was previously encrypted using the **EncryptFile** method.

A temporary file is created during the decryption process and the output file is created or overwritten only if the input file could be successfully encrypted. If the decryption fails, no output file will be created.

If you wish to decrypt the contents of a memory buffer or string, use the **DecryptData** method.

This method uses the Microsoft CryptoAPI and the RSA AES cryptographic provider. This provider may not be available in some languages, countries or regions. The availability of this provider may also be constrained by cryptography export restrictions imposed by the United States or other countries. If the required cryptographic provider is not available, the method will fail.

FileEncoder.EncodeFile Method (String, String, EncodingType)

Encodes a file, storing the contents as printable text in the specified file.

[Visual Basic]

```
Overloads Public Function EncodeFile( _
   ByVal inputFile As String, _
   ByVal outputFile As String, _
   ByVal encodingType As EncodingType _
) As Boolean
```

[C#]

```
public bool EncodeFile(
   string inputFile,
   string outputFile,
   EncodingType encodingType
);
```

Parameters

inputFile
: A string which specifies the name of the file to be encoded. The file must exist, and it must be a regular file that can be opened for reading by the current process. An error will be returned if a character device, such as CON: is specified as the file name.

outputFile
: The name of the file that is to contain the encoded file data. If the file exists, it must be a regular file that can be opened for writing by the current process and will be overwritten. If the file does not exist, it will be created. An error will be returned if a character device, such as CON: is specified as the file name.

encodingType
: An EncodingType enumeration value which specifies the type of encoding which should be used.

Return Value

A boolean value which specifies if the method was successful or not. A return value of True indicates that the method call completed successfully. A return value of False indicates that the method failed and the application should check the value of the **LastError** property.

public bool EncryptData(string,ref string);

See Also

FileEncoder Class | SocketTools Namespace | DecryptData | DecryptFile | EncryptFile

FileEncoder.EncryptData Method (String, Byte[], Int32, Byte[], Int32)

Encrypts the contents of a byte array.

[Visual Basic]

```
Overloads Public Function EncryptData( _
   ByVal password As String, _
   ByVal inputBuffer As Byte(), _
   ByVal inputSize As Integer, _
   ByVal outputBuffer As Byte(), _
   ByRef outputSize As Integer _
) As Boolean
```

[C#]

```
public bool EncryptData(
   string password,
   byte[] inputBuffer,
   int inputSize,
   byte[] outputBuffer,
   ref int outputSize
);
```

Parameters

password

A string of characters that will be used to generate the encryption key. This parameter may be a zero-length string, in which case a default internal hash value is used to encrypt the data. Password strings that exceed 215 characters will be truncated.

inputBuffer

A byte array which contains the data to be encrypted.

inputSize

An integer value which specifies the number of bytes in the byte array which contains the unencrypted data.

outputBuffer

A byte array which will contain the encrypted data when the method returns.

outputSize

An integer value which specifies the maximum number of bytes that can be stored in the output byte array. When the method returns, this parameter will contain the number of encrypted bytes of data in the buffer.

Return Value

A boolean value which specifies if the method was successful or not. A return value of True indicates that the method call completed successfully. A return value of False indicates that the method failed and the application should check the value of the **LastError** property.

Remarks

This method will encrypt the contents of a byte array using a 256-bit AES (Advanced Encryption Standard) algorithm and returns a copy of the encrypted data to the caller. The password (or passphrase) provided by the caller is used to generate a SHA-256 hash value which is used as part of the encryption process.

It is recommended that most applications specify a password value. If the password is a zero-length string, a default internal hash value is used. This means that any other application which uses SocketTools will be able to decrypt the data.

The amount of encrypted data returned by this method will always be somewhat larger than original unencrypted data. If your application dynamically allocates a block of memory to store the encrypted data, provide a maximum buffer size that is at least several hundred bytes larger than the unencrypted data. If the output buffer provided is not large enough, the method will fail.

The encrypted data returned by this method can contain embedded null bytes. If you wish to encrypt strings and store the encrypted values as printable text, use the version of this method which accepts string parameters. It will perform the same 256-bit AES encryption, but return the encrypted data as a base64 encoded string rather than binary data.

Due to how the SHA-256 hash is generated, the encrypted data cannot be decrypted using another third-party library with the same password value. It can only be decrypted using the **DecryptData** method.

If you wish to encrypt the contents of a file, use the **EncryptFile** method.

This method uses the Microsoft CryptoAPI and the RSA AES cryptographic provider. This provider may not be available in some languages, countries or regions. The availability of this provider may also be constrained by cryptography export restrictions imposed by the United States or other countries. If the required cryptographic provider is not available, the method will fail.

FileEncoder.EncryptData Method (Byte[], Int32, Byte[], Int32)

Encrypts the contents of a byte array.

[Visual Basic]

```
Overloads Public Function EncryptData( _
   ByVal inputBuffer As Byte(), _
   ByVal inputSize As Integer, _
   ByVal outputBuffer As Byte(), _
   ByRef outputSize As Integer _
) As Boolean
```

[C#]

```
public bool EncryptData(
   byte[] inputBuffer,
   int inputSize,
   byte[] outputBuffer,
   ref int outputSize
);
```

Parameters

inputBuffer
A byte array which contains the data to be encrypted.

inputSize
An integer value which specifies the number of bytes in the byte array which contains the unencrypted data.

outputBuffer
A byte array which will contain the encrypted data when the method returns.

outputSize
An integer value which specifies the maximum number of bytes that can be stored in the output byte array. When the method returns, this parameter will contain the number of encrypted bytes of data in the buffer.

Return Value

A boolean value which specifies if the method was successful or not. A return value of True indicates that the method call completed successfully. A return value of False indicates that the method failed and the application should check the value of the **LastError** property.

Remarks

This method will encrypt the contents of a byte array using a 256-bit AES (Advanced Encryption Standard) algorithm and returns a copy of the encrypted data to the caller. The value of the **Password** property is used to generate a SHA-256 hash value which is used as part of the encryption process.

It is recommended that most applications specify a password value. If the password is a zero-length string, a default internal hash value is used. This means that any other application which uses SocketTools will be able to decrypt the data.

The amount of encrypted data returned by this method will always be somewhat larger than original unencrypted data. If your application dynamically allocates a block of memory to store the encrypted data, provide a maximum buffer size that is at least several hundred bytes larger than the unencrypted data. If the output buffer provided is not large enough, the method will fail.

The encrypted data returned by this method can contain embedded null bytes. If you wish to encrypt strings and store the encrypted values as printable text, use the version of this method which accepts string parameters. It will perform the same 256-bit AES encryption, but return the encrypted data as a base64 encoded string rather than binary data.

Due to how the SHA-256 hash is generated, the encrypted data cannot be decrypted using another third-party library with the same password value. It can only be decrypted using the **DecryptData** method.

If you wish to encrypt the contents of a file, use the **EncryptFile** method.

This method uses the Microsoft CryptoAPI and the RSA AES cryptographic provider. This provider may not be available in some languages, countries or regions. The availability of this provider may also be constrained by cryptography export restrictions imposed by the United States or other countries. If the required cryptographic provider is not available, the method will fail.

FileEncoder.EncryptData Method (String, MemoryStream, MemoryStream)

Encrypts the contents of a **System.IO.MemoryStream** object.

[Visual Basic]

```
Overloads Public Function EncryptData( _
   ByVal password As String, _
   ByVal inputStream As MemoryStream, _
   ByVal outputStream As MemoryStream _
) As Boolean
```

[C#]

```
public bool EncryptData(
   string password,
   MemoryStream inputStream,
   MemoryStream outputStream
);
```

Parameters

password
A string of characters that will be used to generate the encryption key. This parameter may be a zero-length string, in which case a default internal hash value is used to encrypt the data. Password strings that exceed 215 characters will be truncated.

inputStream
A **MemoryStream** object which contains the data to be encrypted. The stream must be readable.

outputStream
A **MemoryStream** object which will contain the encrypted data when the method returns. The caller must create a stream that is writable, and the contents of the stream will be replaced with the encrypted data.

Return Value

A boolean value which specifies if the method was successful or not. A return value of True indicates that the method call completed successfully. A return value of False indicates that the method failed and the application should check the value of the **LastError** property.

Remarks

This method will encrypt the contents of a **MemoryStream** object using a 256-bit AES (Advanced Encryption Standard) algorithm and returns a copy of the encrypted data to the caller. The password (or passphrase) provided by the caller is used to generate a SHA-256 hash value which is used as part of the encryption process.

It is recommended that most applications specify a password value. If the password is a zero-length string, a default internal hash value is used. This means that any other application which uses SocketTools will be able to decrypt the data.

The amount of encrypted data returned by this method will always be somewhat larger than original unencrypted data. If your application dynamically allocates a block of memory to store the encrypted data, provide a maximum buffer size that is at least several hundred bytes larger than the unencrypted data. If the output buffer provided is not large enough, the method will fail.

The encrypted data returned by this method can contain embedded null bytes. If you wish to encrypt strings and store the encrypted values as printable text, use the version of this method which accepts string parameters. It will perform the same 256-bit AES encryption, but return the encrypted data as a base64 encoded string rather than binary data.

Due to how the SHA-256 hash is generated, the encrypted data cannot be decrypted using another third-party library with the same password value. It can only be decrypted using the **DecryptData** method.

If you wish to encrypt the contents of a file, use the **EncryptFile** method.

This method uses the Microsoft CryptoAPI and the RSA AES cryptographic provider. This provider may not be available in some languages, countries or regions. The availability of this provider may also be constrained by cryptography export restrictions imposed by the United States or other countries. If the required cryptographic provider is not available, the method will fail.

FileEncoder.EncryptData Method (String, String, String)

Encrypts the contents of a string.

[Visual Basic]

```
Overloads Public Function EncryptData( _
   ByVal password As String, _
   ByVal inputText As String, _
   ByRef outputText As String _
) As Boolean
```

[C#]

```
public bool EncryptData(
   string password,
   string inputText,
   ref string outputText
);
```

Parameters

password

A string of characters that will be used to generate the encryption key. This parameter may be a zero-length string, in which case a default internal hash value is used to encrypt the data. Password strings that exceed 215 characters will be truncated.

inputText

A string which contains the text to be encrypted.

outputText

A string which contains the base64 encoded encrypted text.

Return Value

A boolean value which specifies if the method was successful or not. A return value of True indicates that the method call completed successfully. A return value of False indicates that the method failed and the application should check the value of the **LastError** property.

Remarks

This method will encrypt a string using a 256-bit AES (Advanced Encryption Standard) algorithm and returns a copy of the encrypted data as a base64 encoded string to the caller. The password (or passphrase) provided by the caller is used to generate a SHA-256 hash value which is used as part of the encryption process.

It is recommended that most applications specify a password value. If the password is a zero-length string, a default internal hash value is used. This means that any other application which uses SocketTools will be able to decrypt the text.

Due to how the SHA-256 hash is generated, the encrypted text cannot be decrypted using another third-party library with the same password value. It can only be decrypted using the **DecryptData** method.

The plaintext string provided to this method cannot contain embedded nulls and and should not be used to encrypt binary data. If you wish to encrypt binary data, use the version of this method which accepts byte arrays. It will perform the same 256-bit AES encryption and return the encrypted data into a byte array provided by the caller.

If you wish to encrypt the contents of a file, use the **EncryptFile** method.

This method uses the Microsoft CryptoAPI and the RSA AES cryptographic provider. This provider may not be available in some languages, countries or regions. The availability of this provider may also be constrained by cryptography export restrictions imposed by the United States or other countries. If the required cryptographic provider is not available, the method will fail.

   ByRef outputText As String _
) As Boolean
```

```
[C#]
public bool EncryptData(
   string inputText,
   ref string outputText
);
```

Parameters

inputText
A string which contains the text to be encrypted.

outputText
A string which contains the base64 encoded encrypted text.

Return Value

A boolean value which specifies if the method was successful or not. A return value of True indicates that the method call completed successfully. A return value of False indicates that the method failed and the application should check the value of the **LastError** property.

Remarks

This method will encrypt a string using a 256-bit AES (Advanced Encryption Standard) algorithm and returns a copy of the encrypted data as a base64 encoded string to the caller. The value of the **Password** property is used to generate a SHA-256 hash value which is used as part of the encryption process.

It is recommended that most applications specify a password value. If the password is a zero-length string, a default internal hash value is used. This means that any other application which uses SocketTools will be able to decrypt the text.

Due to how the SHA-256 hash is generated, the encrypted text cannot be decrypted using another third-party library with the same password value. It can only be decrypted using the **DecryptData** method.

The plaintext string provided to this method cannot contain embedded nulls and and should not be used to encrypt binary data. If you wish to encrypt binary data, use the version of this method which accepts byte arrays. It will perform the same 256-bit AES encryption and return the encrypted data into a byte array provided by the caller.

If you wish to encrypt the contents of a file, use the **EncryptFile** method.

This method uses the Microsoft CryptoAPI and the RSA AES cryptographic provider. This provider may not be available in some languages, countries or regions. The availability of this provider may also be constrained by cryptography export restrictions imposed by the United States or other countries. If the required cryptographic provider is not available, the method will fail.

FileEncoder Class | SocketTools Namespace | DecryptData | DecryptFile | EncryptData

FileEncoder.EncryptFile Method (String, String, String)

Encrypts the contents of a file using AES-256 encryption.

[Visual Basic]

```
Overloads Public Function EncryptFile( _
   ByVal password As String, _
   ByVal inputFile As String, _
   ByVal outputFile As String _
) As Boolean
```

[C#]

```
public bool EncryptFile(
   string password,
   string inputFile,
   string outputFile
);
```

Parameters

password
A string of characters that will be used to generate the encryption key. Passwords are case sensitive and must match exactly when decrypting data that was previously encrypted using this method. This parameter may be a zero-length string, in which case a default internal hash value is used. Password strings that exceed 215 characters will be truncated.

inputFile
A string which specifies the name of the file to be encrypted. The file must exist, and it must be a regular file that can be opened for reading by the current process. An error will be returned if a character device, such as CON: is specified as the file name.

outputFile
The name of the file that is to contain the encrypted file data. If the file exists, it must be a regular file that can be opened for writing by the current process and will be overwritten. If the file does not exist, it will be created. An error will be returned if a character device, such as CON: is specified as the file name.

Return Value

A boolean value which specifies if the method was successful or not. A return value of True indicates that the method call completed successfully. A return value of False indicates that the method failed and the application should check the value of the **LastError** property.

Remarks

This method will encrypt the contents of a file using a 256-bit AES (Advanced Encryption Standard) algorithm and stores the encrypted data in the specified output file.

It is recommended that most applications specify as password value. If the ***password*** parameter is an empty string, a default internal hash value will be used to create the encryption key. This means that any other SocketTools application which uses this method will be able to decrypt the data.

Due to how the SHA-256 hash is generated, the encrypted data cannot be decrypted using another third-party library with the same password value. It can only be decrypted using the **DecryptFile** method.

A temporary file is created during the encryption process and the output file is created or overwritten only if the input file could be successfully encrypted. If the encryption fails, no output file will be created.

The input file contents will always be processed as a binary data stream. If you use this method to encrypt a text file, the output file will contain binary characters, not printable text. If you wish to transfer or store the encrypted data as text, it should be encoded using the **EncodeFile** method after calling this method.

If your application is also using the **CompressFile** method to compress the data, it is recommended that you call **CompressFile** before calling **EncryptFile**. You will typically achieve a better compression rate on unencrypted data than than attempting to compress data which has been encrypted with this method.

If you wish to encrypt the contents of a memory buffer or string, use the **EncryptData** methods.

This method uses the Microsoft CryptoAPI and the RSA AES cryptographic provider. This provider may not be available in some languages, countries or regions. The availability of this provider may also be constrained by cryptography export restrictions imposed by the United States or other countries. If the required cryptographic provider is not available, the method will fail.

FileEncoder.EncryptFile Method (String, String)

Encrypts the contents of a file using AES-256 encryption.

[Visual Basic]

```
Overloads Public Function EncryptFile( _
   ByVal inputFile As String, _
   ByVal outputFile As String _
) As Boolean
```

[C#]

```
public bool EncryptFile(
   string inputFile,
   string outputFile
);
```

Parameters

inputFile

A string which specifies the name of the file to be encrypted. The file must exist, and it must be a regular file that can be opened for reading by the current process. An error will be returned if a character device, such as CON: is specified as the file name.

outputFile

The name of the file that is to contain the encrypted file data. If the file exists, it must be a regular file that can be opened for writing by the current process and will be overwritten. If the file does not exist, it will be created. An error will be returned if a character device, such as CON: is specified as the file name.

Return Value

A boolean value which specifies if the method was successful or not. A return value of True indicates that the method call completed successfully. A return value of False indicates that the method failed and the application should check the value of the **LastError** property.

Remarks

This method will encrypt the contents of a file using a 256-bit AES (Advanced Encryption Standard) algorithm and stores the encrypted data in the specified output file. The value of the **Password** property is used to generate the encryption key.

It is recommended that most applications specify as password value. If the value of the **Password** property is an empty string, a default internal hash value will be used to create the encryption key. This means that any other SocketTools application which uses this method will be able to decrypt the data.

Due to how the SHA-256 hash is generated, the encrypted data cannot be decrypted using another third-party library with the same password value. It can only be decrypted using the **DecryptFile** method.

A temporary file is created during the encryption process and the output file is created or overwritten only if the input file could be successfully encrypted. If the encryption fails, no output file will be created.

The input file contents will always be processed as a binary data stream. If you use this method to encrypt a text file, the output file will contain binary characters, not printable text. If you wish to transfer or store the encrypted data as text, it should be encoded using the **EncodeFile** method after calling this method.

If your application is also using the **CompressFile** method to compress the data, it is recommended that you call **CompressFile** before calling **EncryptFile**. You will typically achieve a better compression rate on unencrypted data than than attempting to compress data which has been encrypted with this method.

If you wish to encrypt the contents of a memory buffer or string, use the **EncryptData** methods.

This method uses the Microsoft CryptoAPI and the RSA AES cryptographic provider. This provider may not be available in some languages, countries or regions. The availability of this provider may also be constrained by cryptography export restrictions imposed by the United States or other countries. If the required cryptographic provider is not available, the method will fail.

FileEncoder Class | SocketTools Namespace | FileEncoder.EncryptFile Overload List | DecryptData | DecryptFile | EncryptData

FileEncoder.ExpandData Method

Expands the contents of the compressed buffer.

[Visual Basic]

```
Public Function ExpandData( _
   ByVal inputBuffer As Byte(), _
   ByVal inputLength As Integer, _
   ByVal outputBuffer As Byte(), _
   ByRef outputLength As Integer _
) As Boolean
```

[C#]

```
public bool ExpandData(
   byte[] inputBuffer,
   int inputLength,
   byte[] outputBuffer,
   ref int outputLength
);
```

Parameters

inputBuffer
A byte array which contains the compressed data to be expanded.

inputLength
An integer value which specifies the number of bytes in the input buffer.

outputBuffer
A byte array which will contain the expanded data.

outputLength
An integer value which specifies the maximum number of bytes that can be copied into the output buffer.

Return Value

A boolean value which specifies if the method was successful or not. A return value of True indicates that the method call completed successfully. A return value of False indicates that the method failed and the application should check the value of the **LastError** property.

See Also

FileEncoder Class | SocketTools Namespace | CompressData | CompressFile | ExpandFile

FileEncoder.ExpandFile Method

Expands the contents of a previously compressed file.

Overload List

Expands the contents of a previously compressed file.

public bool ExpandFile(string,string);

Expands the contents of a previously compressed file.

public bool ExpandFile(string,string,CompressionType);

See Also

FileEncoder Class | SocketTools Namespace | CompressFile | EncodeFile | EncryptFile

FileEncoder.ExpandFile Method (String, String)

Expands the contents of a previously compressed file.

[Visual Basic]

```
Overloads Public Function ExpandFile( _
   ByVal inputFile As String, _
   ByVal outputFile As String _
) As Boolean
```

[C#]

```
public bool ExpandFile(
   string inputFile,
   string outputFile
);
```

Parameters

inputFile

A string which specifies the name of the file to be compressed. The file must exist, and it must be a regular file that can be opened for reading by the current process. An error will be returned if a character device, such as CON: is specified as the file name.

outputFile

The name of the file that is to contain the expanded file data. If the file exists, it must be a regular file that can be opened for writing by the current process and will be overwritten. If the file does not exist, it will be created. An error will be returned if a character device, such as CON: is specified as the file name.

Return Value

A boolean value which specifies if the method was successful or not. A return value of True indicates that the method call completed successfully. A return value of False indicates that the method failed and the application should check the value of the **LastError** property.

See Also

FileEncoder Class | SocketTools Namespace | FileEncoder.ExpandFile Overload List | CompressFile | EncodeFile | EncryptFile

FileEncoder.ExpandFile Method (String, String, CompressionType)

Expands the contents of a previously compressed file.

[Visual Basic]

```
Overloads Public Function ExpandFile( _
   ByVal inputFile As String, _
   ByVal outputFile As String, _
   ByVal compressionType As CompressionType _
) As Boolean
```

[C#]

```
public bool ExpandFile(
   string inputFile,
   string outputFile,
   CompressionType compressionType
);
```

Parameters

inputFile

A string which specifies the name of the file to be compressed. The file must exist, and it must be a regular file that can be opened for reading by the current process. An error will be returned if a character device, such as CON: is specified as the file name.

outputFile

The name of the file that is to contain the expanded file data. If the file exists, it must be a regular file that can be opened for writing by the current process and will be overwritten. If the file does not exist, it will be created. An error will be returned if a character device, such as CON: is specified as the file name.

compressionType

A CompressionType enumeration value which specifies the type of compression that was used to create the compressed data file.

Return Value

A boolean value which specifies if the method was successful or not. A return value of True indicates that the method call completed successfully. A return value of False indicates that the method failed and the application should check the value of the **LastError** property.

FileEncoder Class | SocketTools Namespace | FileEncoder.ExpandFile Overload List | CompressFile | EncodeFile | EncryptFile

FileEncoder.Initialize Method

Initializes the component with the default runtime license key.

Overload List

Initializes the component with the default runtime license key.

public bool Initialize();

Initializes the component with the specified runtime license key.

public bool Initialize(string);

See Also

FileEncoder Class | SocketTools Namespace | RuntimeLicenseAttribute Class | Uninitialize Method

FileEncoder.Initialize Method ()

Initializes the component with the default runtime license key.

[Visual Basic]

```
Overloads Public Function Initialize() As Boolean
```

[C#]

```
public bool Initialize();
```

Return Value

A boolean value which specifies if the component was initialized successfully with the default runtime license key. A return value of False indicates that the license key is not valid.

Remarks

The Initialize method is used to explicitly initialize the component with the runtime license key that has been specified using the RuntimeLicense attribute. Normally it is not necessary to call this method because the component will automatically be initialized when the class constructor is called. This method should only be called if the **Uninitialize** method was previously called.

The runtime license key for your copy of SocketTools can be generated using the License Manager utility that is included with the product. Note that if you have installed an evaluation license, you will not have a runtime license key and cannot redistribute any applications which use SocketTools components.

See Also

FileEncoder Class | SocketTools Namespace | FileEncoder.Initialize Overload List | RuntimeLicenseAttribute Class | Uninitialize Method

FileEncoder.Initialize Method (String)

Initializes the component with the specified runtime license key.

[Visual Basic]

```
Overloads Public Function Initialize( _
   ByVal licenseKey As String _
) As Boolean
```

[C#]

```
public bool Initialize(
   string licenseKey
);
```

Parameters

licenseKey

A string which specifies the runtime license key.

Return Value

A boolean value which specifies if the component was initialized successfully with the runtime license key. A return value of False indicates that the license key is not valid.

Remarks

The Initialize method is used to explicitly initialize the component with a runtime license key, if one has not been specified using the RuntimeLicense attribute.

The runtime license key for your copy of SocketTools can be generated using the License Manager utility that is included with the product. Note that if you have installed an evaluation license, you will not have a runtime license key and cannot redistribute any applications which use SocketTools components.

See Also

FileEncoder Class | SocketTools Namespace | FileEncoder.Initialize Overload List | RuntimeLicenseAttribute Class | Uninitialize Method

FileEncoder.Uninitialize Method

Uninitialize the component.

[Visual Basic]

```
Public Sub Uninitialize()
```

[C#]

```
public void Uninitialize();
```

Remarks

The Uninitialize method explicitly releases resources allocated by the component. Normally it is not required that the application call this method since it is automatically called by the class destructor. This method should only be used if the **Initialize** method was explicitly called.

See Also

FileEncoder Class | SocketTools Namespace | Initialize Method | Reset Method

FileEncoder Events

The events of the **FileEncoder** class are listed below. For a complete list of **FileEncoder** class members, see the FileEncoder Members topic.

Public Instance Events

OnError	Occurs when a method fails.

See Also

FileEncoder Class | SocketTools Namespace

FileEncoder.OnError Event

Occurs when a method fails.

[Visual Basic]
```
Public Event OnError As OnErrorEventHandler
```

[C#]
```
public event OnErrorEventHandler OnError;
```

Event Data

The event handler receives an argument of type FileEncoder.ErrorEventArgs containing data related to this event. The following **FileEncoder.ErrorEventArgs** properties provide information specific to this event.

Property	Description
Description	Returns a description of the last error that occurred.
Error	Returns the value of the last error that has occurred.

Remarks

The event handler receives an argument of type ErrorEventArgs containing data related to this event. The following ErrorEventArgs properties provide information specific to this event.

Property	**Description**
Error	Returns the value of the last error that has occurred
Description	Returns a description of the last error that occurred

See Also

FileEncoder Class | SocketTools Namespace

FileEncoder.ErrorEventArgs Class

Provides data for the OnError event.

For a list of all members of this type, see FileEncoder.ErrorEventArgs Members.

System.Object
  System.EventArgs
    SocketTools.FileEncoder.ErrorEventArgs

[Visual Basic]

```
Public Class FileEncoder.ErrorEventArgs
    Inherits EventArgs
```

[C#]

```
public class FileEncoder.ErrorEventArgs : EventArgs
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

ErrorEventArgs specifies the numeric error code and a description of the error that has occurred.

An OnError event occurs when a method fails.

Requirements

Namespace: SocketTools

Assembly: SocketTools.FileEncoder (in SocketTools.FileEncoder.dll)

FileEncoder.ErrorEventArgs Members | SocketTools Namespace

FileEncoder.ErrorEventArgs Members

FileEncoder.ErrorEventArgs overview

Public Instance Constructors

FileEncoder.ErrorEventArgs Constructor	Initializes a new instance of the FileEncoder.ErrorEventArgs class.

Public Instance Properties

Description	Returns a description of the last error that occurred.
Error	Returns the value of the last error that has occurred.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString (inherited from Object)	Returns a String that represents the current Object.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

FileEncoder.ErrorEventArgs Class | SocketTools Namespace

FileEncoder.ErrorEventArgs Constructor

Initializes a new instance of the FileEncoder.ErrorEventArgs class.

[Visual Basic]

```
Public Sub New()
```

[C#]

```
public FileEncoder.ErrorEventArgs();
```

See Also

FileEncoder.ErrorEventArgs Class | SocketTools Namespace

FileEncoder.ErrorEventArgs Properties

The properties of the **FileEncoder.ErrorEventArgs** class are listed below. For a complete list of **FileEncoder.ErrorEventArgs** class members, see the FileEncoder.ErrorEventArgs Members topic.

Public Instance Properties

Description	Returns a description of the last error that occurred.
Error	Returns the value of the last error that has occurred.

See Also

FileEncoder.ErrorEventArgs Class | SocketTools Namespace

FileEncoder.ErrorEventArgs.Description Property

Returns a description of the last error that occurred.

[Visual Basic]

```
Public ReadOnly Property Description As String
```

[C#]

```
public string Description {get;}
```

Property Value

A string which describes the error.

See Also

FileEncoder.ErrorEventArgs Class | SocketTools Namespace

FileEncoder.ErrorEventArgs.Error Property

Returns the value of the last error that has occurred.

[Visual Basic]

```
Public ReadOnly Property Error As ErrorCode
```

[C#]

```
public FileEncoder.ErrorCode Error {get;}
```

Property Value

An ErrorCode enumeration which specifies the error.

See Also

FileEncoder.ErrorEventArgs Class | SocketTools Namespace

FileEncoder.CompressionLevel Enumeration

Provides constant values for the CompressFile and ExpandFile methods.

[Visual Basic]

```
Public Enum FileEncoder.CompressionLevel
```

[C#]

```
public enum FileEncoder.CompressionLevel
```

Members

Member Name	Description
compressionLevelDefault	The default compression level, which provides the best balance between resource usage and compression rate.
compressionLevelMinimum	The minimum compression level. This level uses the least amount of memory at the expense of a lower compression rate. This compression level requires a minimum of 8 megabytes of memory.
compressionLevel1	Compression level one. This is the minimum compression level and requires a minimum of 8 megabytes memory.
compressionLevel2	Compression level two.
compressionLevel3	Compression level three.
compressionLevel4	Compression level four.
compressionLevel5	Compression level five.
compressionLevel6	Compression level six. This is the default compression level, which provides the best balance between resource usage and compression rate.
compressionLevel7	Compression level seven.
compressionLevel8	Compression level eight.
compresisonLevel9	Compression level 9. This is the maximum compression level and requires a minimum of 32 megabytes of memory.
compressionLevelMaximum	The maximum compression level. This level uses more memory to achieve a higher compression rate. This compression level requires a minimum of 32 megabytes of memory.

Requirements

Namespace: SocketTools

Assembly: SocketTools.FileEncoder (in SocketTools.FileEncoder.dll)

See Also

SocketTools Namespace

FileEncoder.CompressionType Enumeration

Provides constant values for the CompressFile and ExpandFile methods.

[Visual Basic]
```
Public Enum FileEncoder.CompressionType
```

[C#]
```
public enum FileEncoder.CompressionType
```

Members

Member Name	Description
compressionTypeUnknown	The compression type is unknown or the data has not been compressed.
compressionTypeDefault	The default compression type. This is the same as specifying **compressionTypeDeflate**.
compressionTypeDeflate	A compression algorithm that combines LZ77 algorithm for creating common substrings and Huffman coding to process the different frequencies of byte sequences in the data stream. Deflate is widely used by compression software.
compressionTypeBurrowsWheeler	A compression algorithm that rearranges blocks of data in sorted order and then uses Huffman coding to process different frequencies of data within the block. Burrows-Wheeler compression provides a better compression ratio than the Deflate algorithm, however it requires more resources to perform the compression.

Requirements

Namespace: SocketTools

Assembly: SocketTools.FileEncoder (in SocketTools.FileEncoder.dll)

See Also

SocketTools Namespace

FileEncoder.EncodingType Enumeration

Provides constant values for the DecodeFile and EncodeFile methods.

[Visual Basic]

```
Public Enum FileEncoder.EncodingType
```

[C#]

```
public enum FileEncoder.EncodingType
```

Remarks

The EncodingType enumeration is used to specify the default encoding method used by the DecodeFile and EncodeFile methods.

Members

Member Name	Description
encodingDefault	Use the default encoding method. This is the same specifying that the base64 algorithm should be used for encoding and decoding files.
encodingBase64	Use the base64 algorithm for encoding and decoding files. This is the standard method for encoding files as outlined in the Multipurpose Internet Mail Extensions (MIME) protocol. This is the method used by most modern email client software.
encodingQuotedPrintable	This encoding method is typically used for text messages that use characters beyond the standard ASCII character set, in the range of 128-255. This method, called quoted printable encoding, allows text messages to pass through mail systems that do not support characters with the high-bit set. Note that this method should not be used to encode binary files such as executable programs because the resulting output can be very large. For binary files, use the base64 algorithm instead.
encodingUucode	Use the uuencode and uudecode algorithms for encoding and decoding files. This is a common encoding method used with UNIX systems and older email client software.
encodingYencode	Use the yEnc algorithm for encoding the file. This is an encoding method that is commonly used when posting files to Usenet newsgroups.
encodingCompressed	This option specifies the data should be compressed prior to being encoded when the EncodeFile method is called. If the DecodeFile method is called to decode a previously encoded file that was created using this option, it will cause the data to be expanded after it has been

	decoded.

Requirements

Namespace: SocketTools

Assembly: SocketTools.FileEncoder (in SocketTools.FileEncoder.dll)

See Also

SocketTools Namespace

FileEncoder.ErrorCode Enumeration

Provides constant values for error codes.

[Visual Basic]

```
Public Enum FileEncoder.ErrorCode
```

[C#]

```
public enum FileEncoder.ErrorCode
```

Members

Member Name	Description
errorNone	No error.
errorNotHandleOwner	Handle not owned by the current thread.
errorFileNotFound	The specified file or directory does not exist.
errorFileNotCreated	The specified file could not be created.
errorOperationCanceled	The blocking operation has been canceled.
errorInvalidFileType	The specified file is a block or character device, not a regular file.
errorInvalidDevice	The specified file type is invalid or not a regular file.
errorTooManyParameters	The maximum number of function parameters has been exceeded.
errorInvalidFileName	The specified file name contains invalid characters or is too long.
errorInvalidFileHandle	Invalid file handle passed to function.
errorFileReadFailed	Unable to read data from the specified file.
errorFileWriteFailed	Unable to write data to the specified file.
errorOutOfMemory	Out of memory.
errorAccessDenied	Access denied.
errorInvalidParameter	Invalid argument passed to function.
errorClipboardUnavailable	The system clipboard is currently unavailable.
errorClipboardEmpty	The system clipboard is empty or does not contain any text data.
errorFileEmpty	The specified file does not contain any data.
errorFileExists	The specified file already exists.
errorEndOfFile	End of file.
errorDeviceNotFound	The specified device could not be found.
errorDirectoryNotFound	The specified directory could not be found.
errorInvalidbuffer	Invalid memory address passed to function.

errorBufferTooSmall	The specified buffer is not large enough to contain the data.
errorNoHandles	No more handles are available to this process.
errorInvalidLicense	The license for this product is invalid.
errorProductNotLicensed	This product is not licensed to perform this operation.
errorNotImplemented	This function has not been implemented on this platform.
errorUnknownFileType	The specified file type could not be determined.
errorDataNotEncoded	The specified data block could not be encoded.
errorDataNotDecoded	The specified data block could not be decoded.
errorFileNotEncoded	The specified file could not be encoded.
errorFileNotDecoded	The specified file could not be decoded.
errorInvalidEncodingType	Invalid encoding type specified.

Requirements

Namespace: SocketTools

Assembly: SocketTools.FileEncoder (in SocketTools.FileEncoder.dll)

See Also

SocketTools Namespace

FileEncoder.OnErrorEventHandler Delegate

Represents the method that will handle the OnError event.

[Visual Basic]

```
Public Delegate Sub FileEncoder.OnErrorEventHandler( _
   ByVal sender As Object, _
   ByVal e As ErrorEventArgs _
)
```

[C#]

```
public delegate void FileEncoder.OnErrorEventHandler(
      object sender,
      ErrorEventArgs e
   );
```

Parameters

sender

The source of the event.

e

An ErrorEventArgs that contains the event data.

Remarks

The event handler receives an argument of type ErrorEventArgs containing data related to this event. The following KeyPressEventArgs properties provide information specific to this event.

Property	Description
Error	Returns the value of the last error that has occurred
Description	Returns a description of the last error that occurred

Requirements

Namespace: SocketTools

Assembly: SocketTools.FileEncoder (in SocketTools.FileEncoder.dll)

See Also

SocketTools Namespace

FileEncoder.RuntimeLicenseAttribute Class

Attribute that defines the runtime license key for the class.

For a list of all members of this type, see FileEncoder.RuntimeLicenseAttribute Members.

System.Object
  System.Attribute
    SocketTools.FileEncoder.RuntimeLicenseAttribute

[Visual Basic]

```
<AttributeUsage(ValidOn:=AttributeTargets.Assembly, AllowMultiple:=False,
   Inherited:=True)>
Public Class FileEncoder.RuntimeLicenseAttribute
    Inherits Attribute
```

[C#]

```
[AttributeUsage(ValidOn=AttributeTargets.Assembly, AllowMultiple=False,
   Inherited=True)]
public class FileEncoder.RuntimeLicenseAttribute : Attribute
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

The RuntimeLicense attribute is used to define the runtime license key that will be used when an instance of the class is created. This attribute is defined in the assembly information module for the language, such as AssemblyInfo.cs when programming C#. The runtime license key must be defined if you wish to redistribute your application.

The runtime license key for your copy of SocketTools can be generated using the License Manager utility that is included with the product. Note that if you have installed an evaluation license, you will not have a runtime license key and cannot redistribute any applications which use SocketTools components.

Example

```
<Assembly: SocketTools.FileEncoder.RuntimeLicense("abcdefghijklmnop")>
```

```
[assembly: SocketTools.FileEncoder.RuntimeLicense("abcdefghijklmnop")]
```

Requirements

Namespace: SocketTools

Assembly: SocketTools.FileEncoder (in SocketTools.FileEncoder.dll)

See Also

FileEncoder.RuntimeLicenseAttribute Members | SocketTools Namespace

FileEncoder.RuntimeLicenseAttribute Members

FileEncoder.RuntimeLicenseAttribute overview

Public Instance Constructors

FileEncoder.RuntimeLicenseAttribute Constructor	Constructor for the RuntimeLicense attribute which defines the runtime license key.

Public Instance Properties

LicenseKey	Returns the value of the runtime license key.
TypeId (inherited from Attribute)	When implemented in a derived class, gets a unique identifier for this Attribute.

Public Instance Methods

Equals (inherited from Attribute)	
GetHashCode (inherited from Attribute)	Returns the hash code for this instance.
GetType (inherited from Object)	Gets the Type of the current instance.
IsDefaultAttribute (inherited from Attribute)	When overridden in a derived class, returns an indication whether the value of this instance is the default value for the derived class.
Match (inherited from Attribute)	When overridden in a derived class, returns a value indicating whether this instance equals a specified object.
ToString (inherited from Object)	Returns a String that represents the current Object.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

FileEncoder.RuntimeLicenseAttribute Class | SocketTools Namespace

FileEncoder.RuntimeLicenseAttribute Constructor

Constructor for the RuntimeLicense attribute which defines the runtime license key.

[Visual Basic]

```
Public Sub New( _
   ByVal licenseKey As String _
)
```

[C#]

```
public FileEncoder.RuntimeLicenseAttribute(
   string licenseKey
);
```

Parameters

licenseKey

A string argument which specifies the runtime license key which will be used to initialize the class library.

Remarks

The runtime license key for your copy of SocketTools can be generated using the License Manager utility that is included with the product. Note that if you have installed an evaluation license, you will not have a runtime license key and cannot redistribute any applications which use SocketTools components.

See Also

FileEncoder.RuntimeLicenseAttribute Class | SocketTools Namespace

FileEncoder.RuntimeLicenseAttribute Properties

The properties of the **FileEncoder.RuntimeLicenseAttribute** class are listed below. For a complete list of **FileEncoder.RuntimeLicenseAttribute** class members, see the FileEncoder.RuntimeLicenseAttribute Members topic.

Public Instance Properties

LicenseKey	Returns the value of the runtime license key.
TypeId (inherited from Attribute)	When implemented in a derived class, gets a unique identifier for this Attribute.

See Also

FileEncoder.RuntimeLicenseAttribute Class | SocketTools Namespace

FileEncoder.RuntimeLicenseAttribute.LicenseKey Property

Returns the value of the runtime license key.

[Visual Basic]

```
Public Property LicenseKey As String
```

[C#]

```
public string LicenseKey {get; set;}
```

Property Value

A string which contains the runtime license key.

See Also

FileEncoder.RuntimeLicenseAttribute Class | SocketTools Namespace

FileEncoderException Class

This exception is thrown when an error occurs.

For a list of all members of this type, see FileEncoderException Members.

System.Object
  System.Exception
    System.ApplicationException
      SocketTools.FileEncoderException

[Visual Basic]
```
Public Class FileEncoderException
    Inherits ApplicationException
```

[C#]
```
public class FileEncoderException : ApplicationException
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

This exception can be thrown when a property is set that results in an error, or as the result of calling a method that fails when the **ThrowError** property has been set to True.

Requirements

Namespace: SocketTools

Assembly: SocketTools.FileEncoder (in SocketTools.FileEncoder.dll)

FileEncoderException Members

FileEncoderException overview

Public Instance Constructors

FileEncoderException	Overloaded. Initializes a new instance of the FileEncoderException class.

Public Instance Properties

HelpLink (inherited from Exception)	Gets or sets a link to the help file associated with this exception.
InnerException (inherited from Exception)	Gets the Exception instance that caused the current exception.
Message	Returns a message that describes the current exception.
Number	Return the last error that occurred.
Source (inherited from Exception)	Gets or sets the name of the application or the object that causes the error.
StackTrace (inherited from Exception)	Gets a string representation of the frames on the call stack at the time the current exception was thrown.
TargetSite (inherited from Exception)	Gets the method that throws the current exception.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetBaseException (inherited from Exception)	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetObjectData (inherited from Exception)	When overridden in a derived class, sets the SerializationInfo with information about the exception.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString	Creates and returns a string representation of the current exception.

Protected Instance Properties

HResult (inherited from Exception)	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

FileEncoderException Class | SocketTools Namespace

FileEncoderException Constructor

Initializes a new instance of the FileEncoderException class without a message.

Overload List

Initializes a new instance of the FileEncoderException class without a message.

public FileEncoderException();

Initializes a new instance of the FileEncoderException class with the specific error code value.

public FileEncoderException(ErrorCode);

Initializes a new instance of the FileEncoderException class with the specific error code value.

public FileEncoderException(int);

Initializes a new instance of the FileEncoderException class with a message.

public FileEncoderException(string);

Initializes a new instance of the FileEncoderException class with a message and a reference to the inner exception that is the cause of this exception.

public FileEncoderException(string,Exception);

See Also

FileEncoderException Class | SocketTools Namespace

FileEncoderException Constructor ()

Initializes a new instance of the FileEncoderException class without a message.

[Visual Basic]

```
Overloads Public Sub New()
```

[C#]

```
public FileEncoderException();
```

See Also

FileEncoderException Class | SocketTools Namespace | FileEncoderException Constructor Overload List

FileEncoderException Constructor (String)

Initializes a new instance of the FileEncoderException class with a message.

[Visual Basic]

```
Overloads Public Sub New( _
   ByVal message As String _
)
```

[C#]

```
public FileEncoderException(
   string message
);
```

Parameters

message

The message to display with this exception.

See Also

FileEncoderException Class | SocketTools Namespace | FileEncoderException Constructor Overload List

FileEncoderException Constructor (String, Exception)

Initializes a new instance of the FileEncoderException class with a message and a reference to the inner exception that is the cause of this exception.

[Visual Basic]

```
Overloads Public Sub New( _
   ByVal message As String, _
   ByVal inner As Exception _
)
```

[C#]

```
public FileEncoderException(
   string message,
   Exception inner
);
```

Parameters

message

The message to display with this exception.

inner

The exception that is the cause of the current exception. If the inner parameter is not a null reference (Nothing in Visual Basic), the current exception is raised in a catch block that handles the inner exception.

See Also

FileEncoderException Class | SocketTools Namespace | FileEncoderException Constructor Overload List

FileEncoderException Constructor (Int32)

Initializes a new instance of the FileEncoderException class with the specific error code value.

[Visual Basic]

```
Overloads Public Sub New( _
   ByVal code As Integer _
)
```

[C#]

```
public FileEncoderException(
   int code
);
```

Parameters

code
: An integer value which specifies the error that caused the exception to be raised.

See Also

FileEncoderException Class | SocketTools Namespace | FileEncoderException Constructor Overload List

FileEncoderException Constructor (ErrorCode)

Initializes a new instance of the FileEncoderException class with the specific error code value.

[Visual Basic]

```
Overloads Public Sub New( _
   ByVal code As ErrorCode _
)
```

[C#]

```
public FileEncoderException(
   ErrorCode code
);
```

Parameters

code

An ErrorCode enumeration which specifies the error that caused the exception to be raised.

FileEncoderException Properties

The properties of the **FileEncoderException** class are listed below. For a complete list of **FileEncoderException** class members, see the FileEncoderException Members topic.

Public Instance Properties

HelpLink (inherited from Exception)	Gets or sets a link to the help file associated with this exception.
InnerException (inherited from Exception)	Gets the Exception instance that caused the current exception.
Message	Returns a message that describes the current exception.
Number	Return the last error that occurred.
Source (inherited from Exception)	Gets or sets the name of the application or the object that causes the error.
StackTrace (inherited from Exception)	Gets a string representation of the frames on the call stack at the time the current exception was thrown.
TargetSite (inherited from Exception)	Gets the method that throws the current exception.

Protected Instance Properties

HResult (inherited from Exception)	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception.

See Also

FileEncoderException Class | SocketTools Namespace

FileEncoderException.Message Property

Returns a message that describes the current exception.

[Visual Basic]

```
Overrides Public ReadOnly Property Message As String
```

[C#]

```
public override string Message {get;}
```

Property Value

A string that explains the reason for the exception, or an empty string.

Remarks

The **Message** property returns a description of the last error that caused the exception. This can be used to display a meaningful error message to a user, rather than just the numeric value returned by the **Number** property.

See Also

FileEncoderException Class | SocketTools Namespace

FileEncoderException.Number Property

Return the last error that occurred.

[Visual Basic]

```
Public ReadOnly Property Number As Integer
```

[C#]

```
public int Number {get;}
```

Property Value

An ErrorCode enumeration type that specifies the error that caused the exception.

FileEncoderException Class | SocketTools Namespace

FileEncoderException Methods

The methods of the **FileEncoderException** class are listed below. For a complete list of **FileEncoderException** class members, see the FileEncoderException Members topic.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetBaseException (inherited from Exception)	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetObjectData (inherited from Exception)	When overridden in a derived class, sets the SerializationInfo with information about the exception.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString	Creates and returns a string representation of the current exception.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

FileEncoderException Class | SocketTools Namespace

FileEncoderException.ToString Method

Creates and returns a string representation of the current exception.

[Visual Basic]
```
Overrides Public Function ToString() As String
```

[C#]
```
public override string ToString();
```

Return Value

A string representation of the current exception.

Remarks

ToString returns a representation of the current exception that is intended to be understood by humans. Where the exception contains culture-sensitive data, the string representation returned by ToString is required to take into account the current system culture. Although there are no exact requirements for the format of the returned string, it should attempt to reflect the value of the object as perceived by the user.

The default implementation of ToString obtains the description of the error that caused the exception. If there is no error message or if it is an empty string (""), then no error message is returned.

This method overrides Object.ToString.

FileTransfer Class

Implements the File Transfer Protocol and Hypertext Transfer Protocol with a unified client interface.

For a list of all members of this type, see FileTransfer Members.

System.Object
  SocketTools.FileTransfer

[Visual Basic]
```
Public Class FileTransfer
    Implements IDisposable
```

[C#]
```
public class FileTransfer : IDisposable
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

The FileTransfer class provides a comprehensive interface to the File Transfer Protocol which supports both high level operations, such as uploading or downloading files, as well as a collection of lower-level file I/O functions. In addition to file transfers, an application can create, rename and delete files and directories, search for files using wildcards and perform other common file management functions. The class library has three distinct groups of functionality:

File Transfer
Methods which enable an application to upload and download files, as well as send and receive file data using memory buffers. This gives your program the flexibility of handling the data either on disk or in memory, depending on the best needs of your application. If your program needs to transfer more than one file at a time, there are also methods which will automatically download or upload multiple files in a single method call.

File Management
In addition to transferring files, the class can be used to manage files on the server. Methods are provided to delete, rename and move files between directories. For servers that support specific protocol extensions, advanced features such as getting or setting a remote file's modification time or access permissions are also supported. If a server supports site-specific commands, such as the ability to submit a file as job on the server, the control supports this by enabling you to send custom commands to the server and then process the information that it returns.

Directory Management
The class can be used to manage directories as well as files on the server. The application can open a directory and return a list of the files that it contains, as well as create new directories and delete empty ones. The class understands a number of different directory listing formats, including those typically used on UNIX and Linux based systems, Windows server platforms, NetWare servers and VMS systems.

This class supports secure file transfers using TLS 1.2 and the SSH 2.0 protocol using SFTP.

Requirements

Namespace: SocketTools

Assembly: SocketTools.FileTransfer (in SocketTools.FileTransfer.dll)

FileTransfer Members

FileTransfer overview

Public Static (Shared) Fields

filePortFTP	A constant value which specifies the default port number for the File Transfer Protocol.
filePortFTPS	A constant value which specifies the default port number for a secure FTP connection using the SSL or TLS protocols.
filePortHTTP	A constant value which specifies the default port number for the Hypertext Transfer protocol.
filePortHTTPS	A constant value which specifies the default port number for a secure HTTP connection using the SSL or TLS protocols.
filePortSFTP	A constant value which specifies the default port number for a secure SSH connection using the SSH1 or SSH2 protocols.
fileTimeout	A constant value which specifies the default timeout period.

Public Static (Shared) Methods

ErrorText	Returns the description of an error code.

Public Instance Constructors

FileTransfer Constructor	Initializes a new instance of the FileTransfer class.

Public Instance Properties

Account	Get or sets a value that specifies the account name for the current user.
ActivePorts	Gets and sets the port numbers used for active mode file transfers.
CertificateExpires	Get a value that specifies the date that the security certificate expires.
CertificateIssued	Get a value that specifies the date that the security certificate was issued.
CertificateIssuer	Get a value that provides information about the organization that issued the certificate.
CertificateName	Gets and sets a value that specifies the name of the client certificate.
CertificatePassword	Gets and sets the password associated with the client certificate.
CertificateStatus	Gets a value which indicates the status of the security certificate returned by the server.

CertificateStore	Gets and sets a value that specifies the name of the local certificate store.
CertificateSubject	Gets a value that provides information about the organization that the server certificate was issued to.
CertificateUser	Gets and sets the user that owns the client certificate.
ChannelMode	Set or return the security mode for the specified communications channel.
CipherStrength	Gets a value that indicates the length of the key used by the encryption algorithm for a secure connection.
Compression	Gets and sets a value that specifies if data compression should be enabled.
DirectoryFormat	Gets and sets a value which specifies the current directory format type.
Encoding	Gets and sets the character encoding that is used when a file name is sent to the server.
Features	Gets and sets the features that are currently enabled for the current session.
FileType	Gets and sets a value which specifies the type of file that is being transferred.
Handle	Gets a value that specifies the client handle allocated for the current session.
HashStrength	Gets a value which specifies the length of the message digest that was selected for a secure connection.
IsBlocked	Gets a value which indicates if the current thread is performing a blocking client operation.
IsConnected	Gets a value which indicates if a connection to the server has been established.
IsInitialized	Gets a value which indicates if the current instance of the class has been initialized successfully.
KeepAlive	Gets and sets a Boolean value which specifies if the client should attempt to keep the server connection alive.
LastError	Gets and sets a value which specifies the last error that has occurred.
LastErrorString	Gets a value which describes the last error that has occurred.
LocalAddress	Gets the local Internet address that the client is bound to.
LocalFile	Gets and sets the name of the file on the local

	system.
Localize	Gets and sets a value which specifies if time and dates should be adjusted for the current timezone.
LocalName	Gets a value which specifies the host name for the local system.
LocalPort	Gets the local port number the client is bound to.
Options	Gets and sets a value which specifies one or more client options.
Passive	Gets and sets a value which specifies if passive mode file transfers should be enabled.
Password	Gets and sets the password used to authenticate the client session.
Priority	Gets and sets a value which specifies the priority of file transfers.
ProtocolVersion	Gets and sets a value which specifies the default protocol version.
ProxyPassword	Gets and sets the password used to authenticate the connection to a proxy server.
ProxyPort	Gets and sets a value that specifies the proxy server port number.
ProxyServer	Gets and sets the hostname or IP address of a proxy server.
ProxyType	Gets and sets the type of proxy server the client will use to establish a connection.
ProxyUser	Gets and sets the username used to authenticate the connection to a proxy server.
RemoteFile	Gets and sets a value which specifies a file name on the server.
ResultCode	Gets a value which specifies the last result code returned by the server.
ResultString	Gets a string value which describes the result of the previous command.
Secure	Gets and sets a value which specifies if a secure connection is established.
SecureCipher	Gets a value that specifies the encryption algorithm used for a secure connection.
SecureHash	Gets a value that specifies the message digest algorithm used for a secure connection.
SecureKeyExchange	Gets a value that specifies the key exchange algorithm used for a secure connection.
SecureProtocol	Gets and sets a value which specifies the protocol used for a secure connection.

ServerDirectory	Gets and sets a value which specifies the current working directory on the file server.
ServerName	Gets and sets a value which specifies the host name used to establish a connection.
ServerPort	Gets and sets a value which specifies the remote port number.
ServerType	Gets and sets a value which specifies the type of file server the client is connecting to.
System	Gets a string value which identifies the server.
TaskCount	Get the number of active background file transfers.
TaskId	Get the task identifier for the last background file transfer.
TaskList	Get an array of active background task identifiers.
ThreadModel	Gets and sets a value which specifies the threading model for the class instance.
ThrowError	Gets and sets a value which specifies if method calls should throw exceptions when an error occurs.
Timeout	Gets and sets a value which specifies a timeout period in seconds.
TimeZone	Gets and sets the current timezone offset in seconds.
Trace	Gets and sets a value which indicates if network function logging is enabled.
TraceFile	Gets and sets a value which specifies the name of the logfile.
TraceFlags	Gets and sets a value which specifies the client function tracing flags.
TransferBytes	Gets a value which specifies the number of bytes transferred to or from the remote server.
TransferRate	Gets a value which specifies the data transfer rate in bytes per second.
TransferTime	Gets a value which specifies the number of seconds elapsed during a data transfer.
URL	Gets and sets the current URL used to access a file on the server.
UserName	Gets and sets the username used to authenticate the client session.
Version	Gets a value which returns the current version of the FileTransfer class library.

Public Instance Methods

AddFileType	Associate a file name extension with a specific file type.
AsyncGetFile	Overloaded. Download a file from the server to the local system in the background.
AsyncPutFile	Overloaded. Upload a file from the local system to the server in the background.
AttachThread	Attach an instance of the class to the current thread
Cancel	Cancel the current blocking client operation.
ChangeDirectory	Change the current working directory on the remote server.
CloseDirectory	Close the directory that was previously opened with the OpenDirectory method.
Command	Overloaded. Send a custom command to the server.
Connect	Overloaded. Establish a connection with a file server.
DeleteFile	Delete a file on the remote server.
Disconnect	Terminate the connection with the remote server.
Dispose	Overloaded. Releases all resources used by FileTransfer.
Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetData	Overloaded. Transfers the contents of a file on the server and stores it in byte array.
GetDirectory	Return the current working directory.
GetFile	Overloaded. Download a file from the server to the local system.
GetFileList	Overloaded. Returns an unparsed list of files in the specified directory.
GetFilePermissions	Overloaded. Return the access permissions for a file on the remote system.
GetFileSize	Overloaded. Returns the size of the specified file on the remote server.
GetFileStatus	
GetFileTime	Overloaded. Returns the modification date and time for specified file on the remote server.
GetFirstFile	Overloaded. Get information about the first file in a directory listing returned by the server.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.

GetMultipleFiles	Download multiple files from the server to the local system using a wildcard mask.
GetNextFile	Overloaded. Get information about the next file in a directory listing returned by the server.
GetType (inherited from Object)	Gets the Type of the current instance.
Initialize	Overloaded. Initialize an instance of the FileTransfer class.
Login	Overloaded. Login to the remote server.
Logout	Log the current user off the server.
MakeDirectory	Create a new directory on the server.
OpenDirectory	Overloaded. Open the specified directory on the server.
PostFile	Overloaded. Post the contents of the specified file to a script executed on the remote server.
PutData	Overloaded. Transfers data from a byte array and stores it in a file on the remote server.
PutFile	Overloaded. Upload a file from the local system to the server.
PutMultipleFiles	Upload multiple files from the local system to the server using a wildcard mask.
RemoveDirectory	Remove a directory on the server.
RenameFile	Change the name of a file on the server.
Reset	Reset the internal state of the object, resetting all properties to their default values.
SetFilePermissions	Change the access permissions for a file on the server.
SetFileTime	Changes the modification date and time for a file on the server.
TaskAbort	Overloaded. Abort the specified asynchronous task.
TaskDone	Overloaded. Determine if an asynchronous task has completed.
TaskResume	Overloaded. Resume execution of an asynchronous task.
TaskSuspend	Overloaded. Suspend execution of an asynchronous task.
TaskWait	Overloaded. Wait for an asynchronous task to complete.
ToString (inherited from Object)	Returns a String that represents the current Object.
Uninitialize	Uninitialize the class library and release any resources allocated for the current thread.

VerifyFile	Overloaded. Verify that the contents of a file on the local system are the same as the specified file on the server.

Public Instance Events

OnCancel	Occurs when a blocking client operation is canceled.
OnCommand	Occurs when the client sends a command to the server and receives a reply indicating the result of that command.
OnError	Occurs when an network operation fails.
OnGetFile	Occurs when a file download has been initiated.
OnProgress	Occurs as a data stream is being read or written to the server.
OnPutFile	Occurs when a file upload is initiated.
OnTaskBegin	Occurs when an asynchronous task begins execution.
OnTaskEnd	Occurs when an asynchronous task completes.
OnTaskRun	Occurs while a background task is active.
OnTimeout	Occurs when a blocking operation fails to complete before the timeout period elapses.

Protected Instance Methods

Dispose	Overloaded. Releases the unmanaged resources allocated by the FileTransfer class and optionally releases the managed resources.
Finalize	Destroys an instance of the class, releasing the resources allocated for the session and unloading the networking library.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

FileTransfer Fields

The fields of the **FileTransfer** class are listed below. For a complete list of **FileTransfer** class members, see the FileTransfer Members topic.

Public Static (Shared) Fields

filePortFTP	A constant value which specifies the default port number for the File Transfer Protocol.
filePortFTPS	A constant value which specifies the default port number for a secure FTP connection using the SSL or TLS protocols.
filePortHTTP	A constant value which specifies the default port number for the Hypertext Transfer protocol.
filePortHTTPS	A constant value which specifies the default port number for a secure HTTP connection using the SSL or TLS protocols.
filePortSFTP	A constant value which specifies the default port number for a secure SSH connection using the SSH1 or SSH2 protocols.
fileTimeout	A constant value which specifies the default timeout period.

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.filePortFTP Field

A constant value which specifies the default port number for the File Transfer Protocol.

[Visual Basic]

```
Public Const filePortFTP As Integer = 21
```

[C#]

```
public const int filePortFTP = 21;
```

Remarks

The default port number for the File Transfer Protocol is 21.

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.filePortFTPS Field

A constant value which specifies the default port number for a secure FTP connection using the SSL or TLS protocols.

[Visual Basic]

```
Public Const filePortFTPS As Integer = 990
```

[C#]

```
public const int filePortFTPS = 990;
```

Remarks

The default port number for a secure connection using SSL or TLS is 990.

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.filePortHTTP Field

A constant value which specifies the default port number for the Hypertext Transfer protocol.

[Visual Basic]

```
Public Const filePortHTTP As Integer = 80
```

[C#]

```
public const int filePortHTTP = 80;
```

Remarks

The default port number for the Hypertext Transfer Protocol is 80.

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.filePortHTTPS Field

A constant value which specifies the default port number for a secure HTTP connection using the SSL or TLS protocols.

[Visual Basic]

```
Public Const filePortHTTPS As Integer = 443
```

[C#]

```
public const int filePortHTTPS = 443;
```

Remarks

The default port number for a secure connection using SSL or TLS is 443.

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.filePortSFTP Field

A constant value which specifies the default port number for a secure SSH connection using the SSH1 or SSH2 protocols.

[Visual Basic]
```
Public Const filePortSFTP As Integer = 22
```

[C#]
```
public const int filePortSFTP = 22;
```

Remarks

The default port number for a secure connection using SSH is 22.

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.fileTimeout Field

A constant value which specifies the default timeout period.

[Visual Basic]

```
Public Const fileTimeout As Integer = 20
```

[C#]

```
public const int fileTimeout = 20;
```

Remarks

The default timeout period is 20 seconds for each blocking network operation. An error will occur if the operation does not complete within the specified time period.

FileTransfer Properties

The properties of the **FileTransfer** class are listed below. For a complete list of **FileTransfer** class members, see the FileTransfer Members topic.

Public Instance Properties

Account	Get or sets a value that specifies the account name for the current user.
ActivePorts	Gets and sets the port numbers used for active mode file transfers.
CertificateExpires	Get a value that specifies the date that the security certificate expires.
CertificateIssued	Get a value that specifies the date that the security certificate was issued.
CertificateIssuer	Get a value that provides information about the organization that issued the certificate.
CertificateName	Gets and sets a value that specifies the name of the client certificate.
CertificatePassword	Gets and sets the password associated with the client certificate.
CertificateStatus	Gets a value which indicates the status of the security certificate returned by the server.
CertificateStore	Gets and sets a value that specifies the name of the local certificate store.
CertificateSubject	Gets a value that provides information about the organization that the server certificate was issued to.
CertificateUser	Gets and sets the user that owns the client certificate.
ChannelMode	Set or return the security mode for the specified communications channel.
CipherStrength	Gets a value that indicates the length of the key used by the encryption algorithm for a secure connection.
Compression	Gets and sets a value that specifies if data compression should be enabled.
DirectoryFormat	Gets and sets a value which specifies the current directory format type.
Encoding	Gets and sets the character encoding that is used when a file name is sent to the server.
Features	Gets and sets the features that are currently enabled for the current session.
FileType	Gets and sets a value which specifies the type of

	file that is being transferred.
Handle	Gets a value that specifies the client handle allocated for the current session.
HashStrength	Gets a value which specifies the length of the message digest that was selected for a secure connection.
IsBlocked	Gets a value which indicates if the current thread is performing a blocking client operation.
IsConnected	Gets a value which indicates if a connection to the server has been established.
IsInitialized	Gets a value which indicates if the current instance of the class has been initialized successfully.
KeepAlive	Gets and sets a Boolean value which specifies if the client should attempt to keep the server connection alive.
LastError	Gets and sets a value which specifies the last error that has occurred.
LastErrorString	Gets a value which describes the last error that has occurred.
LocalAddress	Gets the local Internet address that the client is bound to.
LocalFile	Gets and sets the name of the file on the local system.
Localize	Gets and sets a value which specifies if time and dates should be adjusted for the current timezone.
LocalName	Gets a value which specifies the host name for the local system.
LocalPort	Gets the local port number the client is bound to.
Options	Gets and sets a value which specifies one or more client options.
Passive	Gets and sets a value which specifies if passive mode file transfers should be enabled.
Password	Gets and sets the password used to authenticate the client session.
Priority	Gets and sets a value which specifies the priority of file transfers.
ProtocolVersion	Gets and sets a value which specifies the default protocol version.
ProxyPassword	Gets and sets the password used to authenticate the connection to a proxy server.
ProxyPort	Gets and sets a value that specifies the proxy server port number.

ProxyServer	Gets and sets the hostname or IP address of a proxy server.
ProxyType	Gets and sets the type of proxy server the client will use to establish a connection.
ProxyUser	Gets and sets the username used to authenticate the connection to a proxy server.
RemoteFile	Gets and sets a value which specifies a file name on the server.
ResultCode	Gets a value which specifies the last result code returned by the server.
ResultString	Gets a string value which describes the result of the previous command.
Secure	Gets and sets a value which specifies if a secure connection is established.
SecureCipher	Gets a value that specifies the encryption algorithm used for a secure connection.
SecureHash	Gets a value that specifies the message digest algorithm used for a secure connection.
SecureKeyExchange	Gets a value that specifies the key exchange algorithm used for a secure connection.
SecureProtocol	Gets and sets a value which specifies the protocol used for a secure connection.
ServerDirectory	Gets and sets a value which specifies the current working directory on the file server.
ServerName	Gets and sets a value which specifies the host name used to establish a connection.
ServerPort	Gets and sets a value which specifies the remote port number.
ServerType	Gets and sets a value which specifies the type of file server the client is connecting to.
System	Gets a string value which identifies the server.
TaskCount	Get the number of active background file transfers.
TaskId	Get the task identifier for the last background file transfer.
TaskList	Get an array of active background task identifiers.
ThreadModel	Gets and sets a value which specifies the threading model for the class instance.
ThrowError	Gets and sets a value which specifies if method calls should throw exceptions when an error occurs.
Timeout	Gets and sets a value which specifies a timeout period in seconds.

TimeZone	Gets and sets the current timezone offset in seconds.
Trace	Gets and sets a value which indicates if network function logging is enabled.
TraceFile	Gets and sets a value which specifies the name of the logfile.
TraceFlags	Gets and sets a value which specifies the client function tracing flags.
TransferBytes	Gets a value which specifies the number of bytes transferred to or from the remote server.
TransferRate	Gets a value which specifies the data transfer rate in bytes per second.
TransferTime	Gets a value which specifies the number of seconds elapsed during a data transfer.
URL	Gets and sets the current URL used to access a file on the server.
UserName	Gets and sets the username used to authenticate the client session.
Version	Gets a value which returns the current version of the FileTransfer class library.

FileTransfer Class | SocketTools Namespace

FileTransfer.Account Property

Get or sets a value that specifies the account name for the current user.

[Visual Basic]

```
Public Property Account As String
```

[C#]

```
public string Account {get; set;}
```

Property Value

A string which specifies the account name for the current user.

Remarks

The **Account** property specifies the account name of the current user, if it is required by the server for authentication. Not all servers require an account name, in which case this property is ignored.

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.ActivePorts Property

Gets and sets the port numbers used for active mode file transfers.

[Visual Basic]

```
Public Property ActivePorts As PortRange
```

[C#]

```
public FileTransfer.PortRange ActivePorts {get; set;}
```

Property Value

A **PortRange** structure which specifies the minimum and maximum port numbers used for active mode file transfers.

Remarks

This property is used to change the default port numbers used for active mode file transfers. Active mode is used when the **Passive** property is set to false. Instead of the client establishing an outbound connection to the server for the file transfer, it listens for an inbound connection from the server back to the client. In most cases, passive mode transfers are preferred because they mitigate potential compatibility issues with firewalls and NAT routers.

If active mode transfers are required, the default port range used when listening for the server connection is between 1024 and 5000. This is the standard range of ephemeral ports used by the Windows operating system. However, under some circumstances that range of ports may be too small, or a firewall may be configured to deny inbound connections on ephemeral ports. In that case, the **ActivePorts** property can be used to specify a different range of port numbers.

While it is technically permissible to assign the low and high port numbers to the same value, effectively specifying a single active port number, this is not recommended as it can cause the transfer to fail unexpectedly if multiple file transfers are performed. A minimum range of at least 1000 ports is recommended. For example, if you specify a low port value of 40000 then it is recommended that the high port value be at least 41000. The maximum port value is 65535.

See Also

FileTransfer Class | SocketTools Namespace | PortRange Structure

FileTransfer.CertificateExpires Property

Get a value that specifies the date that the security certificate expires.

[Visual Basic]

```
Public ReadOnly Property CertificateExpires As String
```

[C#]

```
public string CertificateExpires {get;}
```

Property Value

A string which specifies a date using the local date and time format.

Remarks

The **CertificateExpires** property returns a string that specifies the date and time that the security certificate expires. This property will return an empty string if a secure connection has not been established with the remote host.

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.CertificateIssued Property

Get a value that specifies the date that the security certificate was issued.

[Visual Basic]
```
Public ReadOnly Property CertificateIssued As String
```

[C#]
```
public string CertificateIssued {get;}
```

Property Value

A string which specifies a date using the local date and time format.

Remarks

The **CertificateIssued** property returns a string that specifies the date and time that the security certificate was issued. This property will return an empty string if a secure connection has not been established with the remote host.

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.CertificateIssuer Property

Get a value that provides information about the organization that issued the certificate.

[Visual Basic]

```
Public ReadOnly Property CertificateIssuer As String
```

[C#]

```
public string CertificateIssuer {get;}
```

Property Value

A string that contains a comma separated list of name value pairs.

Remarks

The **CertificateIssuer** property returns a string that contains information about the organization that issued the server certificate. The string value is a comma separated list of tagged name and value pairs. In the nomenclature of the X.500 standard, each of these pairs are called a relative distinguished name (RDN), and when concatenated together, forms the issuer's distinguished name (DN). For example:

```
C=US, O="RSA Data Security, Inc.", OU=Secure Server Certification Authority
```

To obtain a specific value, such as the name of the issuer or the issuer's country, the application must parse the string returned by this property. Some of the common tokens used in the distinguished name are:

Token	Description
C	The ISO standard two character country code.
S	The name of the state or province.
L	The name of the city or locality.
O	The name of the company or organization.
OU	The name of the department or organizational unit
CN	The common name; with X.509 certificates, this is the domain name of the site the certificate was issued for.

This property will return an empty string if a secure connection has not been established with the server.

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.CertificateName Property

Gets and sets a value that specifies the name of the client certificate.

[Visual Basic]
```
Public Property CertificateName As String
```

[C#]
```
public string CertificateName {get; set;}
```

Property Value

A string which specifies the certificate name.

Remarks

The **CertificateName** property is used to specify the name of a client certificate to use when establishing a secure connection. It is only required that you set this property value if the server requires a client certificate for authentication. If this property is not set, a client certificate will not be provided to the server. If a certificate name is specified, the certificate must have a private key associated with it, otherwise the connection attempt will fail because the control will be unable to create a security context for the session.

When the certificate store is searched for a matching certificate, it will first search for any certificate with a friendly name that matches the property value. If no valid certificate is found, it will then search for a certificate with a matching common name.

Certificates may be installed and viewed on the local system using the Certificate Manager that is included with the Windows operating system. For more information, refer to the documentation for the Microsoft Management Console.

See Also

FileTransfer Class | SocketTools Namespace | CertificateStore Property | Secure Property

FileTransfer.CertificateStatus Property

Gets a value which indicates the status of the security certificate returned by the server.

[Visual Basic]

```
Public ReadOnly Property CertificateStatus As SecurityCertificate
```

[C#]

```
public FileTransfer.SecurityCertificate CertificateStatus {get;}
```

Property Value

A SecurityCertificate enumeration value which specifies the status of the certificate.

Remarks

The **CertificateStatus** property is used to determine the status of the security certificate returned by the server when a secure connection has been established. This property value should be checked after the connection to the server has completed, but prior to beginning a transaction.

Note that if the certificate cannot be validated, the secure connection will not be automatically terminated. It is the responsibility of your application to determine the best course of action to take if the certificate is invalid. Even if the security certificate cannot be validated, the data exchanged with the remote host will still be encrypted.

FileTransfer Class | SocketTools Namespace

FileTransfer.CertificateStore Property

Gets and sets a value that specifies the name of the local certificate store.

[Visual Basic]

```
Public Property CertificateStore As String
```

[C#]

```
public string CertificateStore {get; set;}
```

Property Value

A string which specifies the certificate store name. The default value is the current user's personal certificate store.

Remarks

The **CertificateStore** property is used to specify the name of the certificate store which contains the security certificate to use when establishing a secure connection. The certificate may either be stored in the registry or in a file. If the certificate is stored in the registry, then this property should be set to one of the following predefined values:

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as VeriSign and Thawte act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. If a certificate store is not specified, this is the default value that is used.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as VeriSign and Thawte are installed as part of the operating system and periodically updated by Microsoft.

In most cases the client certificate will be installed in the user's personal certificate store, and therefore it is not necessary to set this property value because that is the default location that will be used to search for the certificate. This property is only used if the **CertificateName** property is also set to a valid certificate name.

If you are using a local certificate store, with the certificate and private key stored in the registry, you can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU" for the current user, or "HKLM" for the local machine. For example, a certificate store name of "HKLM:MY" would specify the personal certificate store for the local machine, rather than the current user. If neither prefix is specified, it will default to the certificate store for the current user.

This property may also be used to specify a file that contains the client certificate. In this case, the property should specify the full path to the file and must contain both the certificate and private key in PKCS12

format. If the file is protected by a password, the **CertificatePassword** property must also be set to specify the password.

See Also

FileTransfer Class | SocketTools Namespace | CertificatePassword Property | Secure Property

FileTransfer.CertificateSubject Property

Gets a value that provides information about the organization that the server certificate was issued to.

[Visual Basic]
```
Public ReadOnly Property CertificateSubject As String
```

[C#]
```
public string CertificateSubject {get;}
```

Property Value

A string that contains a comma separated list of name value pairs.

Remarks

The **CertificateSubject** property returns a string that contains information about the organization that the server certificate was issued to. The string value is a comma separated list of tagged name and value pairs. In the nomenclature of the X.500 standard, each of these pairs are called a relative distinguished name (RDN), and when concatenated together, forms the issuer's distinguished name (DN). For example:

```
C=US, O="RSA Data Security, Inc.", OU=Secure Server Certification Authority
```

To obtain a specific value, such as the name of the issuer or the issuer's country, the application must parse the string returned by this property. Some of the common tokens used in the distinguished name are:

Token	Description
C	The ISO standard two character country code.
S	The name of the state or province.
L	The name of the city or locality.
O	The name of the company or organization.
OU	The name of the department or organizational unit
CN	The common name; with X.509 certificates, this is the domain name of the site the certificate was issued for.

This property will return an empty string if a secure connection has not been established with the server.

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.ChannelMode Property

Set or return the security mode for the specified communications channel.

[Visual Basic]

```
Public Property ChannelMode As SecureChannel
```

[C#]

```
public FileTransfer.SecureChannel ChannelMode {get; set;}
```

Property Value

An FtpChannelMode enumeration value which specifies the current channel mode.

Remarks

The **ChannelMode** property is used to change the default mode for the specified channel, and is typically used to control whether or not data is encrypted during a file transfer. If a standard, non-secure connection has been established with the server, an error will be returned if you specify the **channelSecure** mode for either channel.

If you have established a secure connection and then specify the **channelClear** mode for the command channel, the client will send the CCC command to the server to indicate that commands should no longer be encrypted. If the server does not support this command, an error will be returned and the channel mode will remain unchanged. Once the command channel has been changed to clear mode, it cannot be changed back to secure mode. You must disconnect and re-connect to the server if you want to resume sending commands over an encrypted channel.

Changing the mode for the data channel requires that the server support the PROT command. If this command is not supported by the server, an exception will be thrown which must be handled by the application. You can only set a channel to secure mode if the **Secure** property is also set to **true**.

It is important to note that this property should only be used after a connection has been established with the server. If you attempt to read the property or change a value prior to calling the **Connect** method, an exception will be thrown.

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.CipherStrength Property

Gets a value that indicates the length of the key used by the encryption algorithm for a secure connection.

[Visual Basic]

```
Public ReadOnly Property CipherStrength As Integer
```

[C#]

```
public int CipherStrength {get;}
```

Property Value

An integer value which specifies the encryption key length if a secure connection has been established; otherwise a value of 0 is returned.

Remarks

The **CipherStrength** property returns the number of bits in the key used to encrypt the secure data stream. Common values returned by this property are 128 and 256. A key length of 40 or 56 bits is considered insecure and subject to brute force attacks. 128-bit and 256-bit keys are considered secure. If this property returns a value of 0, this means that a secure connection has not been established with the server.

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.Compression Property

Gets and sets a value that specifies if data compression should be enabled.

[Visual Basic]
```
Public Property Compression As Boolean
```

[C#]
```
public bool Compression {get; set;}
```

Property Value

Returns **true** if a data compression is enabled; otherwise returns **false**. The default value is **false.**

Remarks

The **Compression** property is used to indicate to the server whether or not it is acceptable to compress the data that is returned to the client. If compression is enabled, the client will advertise that it will accept compressed data and the server will decide whether a resource being requested can be compressed. If the data is compressed, the control will automatically expand the data before returning it to the caller.

Enabling compression does not guarantee that the data returned by the server will actually be compressed, it only informs the server that the client is willing to accept compressed data. Whether or not a particular resource is compressed depends on the server configuration, and the server may decide to only compress certain types of resources, such as text files. Disabling compression informs the server that the client is not willing to accept compressed data; this is the default.

This property value is only meaningful when downloading files from an HTTP server that supports file compression. It has no effect on file uploads or when transferring files using FTP.

See Also

FileTransfer Class | SocketTools Namespace | GetData Method | GetFile Method

FileTransfer.DirectoryFormat Property

Gets and sets a value which specifies the current directory format type.

[Visual Basic]
```
Public Property DirectoryFormat As FtpDirectoryFormat
```

[C#]
```
public FileTransfer.FtpDirectoryFormat DirectoryFormat {get; set;}
```

Property Value

An FtpDirectoryFormat enumeration value which specifies the current directory format.

Remarks

This property should only be set if the client cannot automatically determine the directory format returned by the server. The default directory format is determined both by the server's operating system and by analyzing the format of the data returned by the server. If the class is unable to automatically determine the format, it will attempt to parse the list of files as though it is a UNIX style listing.

If this property is set to the default value **FtpDirectoryFormat.formatAuto** and the class can determine from the format of the file listing returned by the server, then the property will change value upon the first call to the **GetFirstFile** method or the first time the **OnFileList** event is generated.

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.Features Property

Gets and sets the features that are currently enabled for the current session.

[Visual Basic]

```
Public Property Features As FtpFeatures
```

[C#]

```
public FileTransfer.FtpFeatures Features {get; set;}
```

Property Value

An FtpFeatures enumeration which specifies the features that are available for the current client session.

Remarks

When a client connection is first established, all features are enabled by default. However, as the client issues commands to the server, if the server reports that the command is unrecognized that feature will automatically be disabled in the client.

For example, the first time an application calls the **GetFileSize** method to determine the size of a file, the control will try to use the SIZE command. If the server reports that the SIZE command is not available, that feature will be disabled and the control will not use the command again during the session unless it is explicitly re-enabled. This is designed to prevent the control from repeatedly sending invalid commands to a server, which may result in the server aborting the connection.

Setting the **Features** property enables those features which have been specified. More than one feature may be enabled by combining the above constants using a bitwise Or operator. To test if a particular feature has been enabled, use the bitwise And operator.

Because features are specific to the current session, once you disconnect from the server they are reset. Even if you wish to reconnect to the same server, you must explicitly set the **Features** property again to those features which you wish to enable. Setting the **Features** property when the control is not connected to a server will cause the client session to only use those specified features for the next connection that is established. Setting the **Features** property during an active connection will change the features available for that session.

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.FileType Property

Gets and sets a value which specifies the type of file that is being transferred.

[Visual Basic]

```
Public Property FileType As FileTransferType
```

[C#]

```
public FileTransfer.FileTransferType FileType {get; set;}
```

Property Value

An **FtpFileType** enumeration which specifies the type of file being uploaded or downloaded.

Remarks

The file type should be set before a file is uploaded or downloaded from the remote server. Once the file type is set, it is in effect for all files that are subsequently transferred.

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.Handle Property

Gets a value that specifies the client handle allocated for the current session.

[Visual Basic]

```
Public ReadOnly Property Handle As Integer
```

[C#]

```
public int Handle {get;}
```

Property Value

An integer which represents a client handle. If there is no active connection, a value of -1 is returned.

Remarks

The **Handle** property specifies the numeric descriptor of the current client session and is typically used for debugging or diagnostic purposes.

In SocketTools, handles are used to identify client sessions. A session begins when an instance of the class is used to establish a connection with the server and ends when that connection is terminated. The client handle is defined as an integer type and is used internally to reference the active session. When the connection is terminated, the handle is released, along with any system resources that were allocated for it. An unused handle is identified by the value -1.

It is important to note that the handles returned by this property are not socket handles and cannot be used interchangeably with other objects or Windows API functions. The actual value of the handle is only unique while the client session is active and handle values may be reused. An application should never depend on the **Handle** property returning a specific value.

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.HashStrength Property

Gets a value which specifies the length of the message digest that was selected for a secure connection.

[Visual Basic]

```
Public ReadOnly Property HashStrength As Integer
```

[C#]

```
public int HashStrength {get;}
```

Property Value

An integer value which specifies the length of the message digest if a secure connection has been established; otherwise a value of 0 is returned.

Remarks

The **HashStrength** property returns the number of bits used in the message digest (hash) that was selected. Common values returned by this property are 128 and 160. If this property returns a value of 0, this means that a secure connection has not been established with the server.

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.IsBlocked Property

Gets a value which indicates if the current thread is performing a blocking client operation.

[Visual Basic]

```
Public ReadOnly Property IsBlocked As Boolean
```

[C#]

```
public bool IsBlocked {get;}
```

Property Value

Returns **true** if the current thread is blocking, otherwise returns **false**.

Remarks

The **IsBlocked** property returns **true** if the current thread is blocked performing an operation. Because the Windows Sockets API only permits one blocking operation per thread of execution, this property should be checked before starting any blocking operation in response to an event.

If the **IsBlocked** property returns **false**, this means there are no blocking operations on the current thread at that time. However, this does not guarantee that the next client operation will not fail. An application should always check the return value from a client operation and check the value of the **LastError** property if an error occurs.

Note that this property will return **true** if there is any blocking operation being performed by the current thread, regardless of whether this specific instance of the class is responsible for the blocking operation or not.

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.IsConnected Property

Gets a value which indicates if a connection to the server has been established.

[Visual Basic]

```
Public ReadOnly Property IsConnected As Boolean
```

[C#]

```
public bool IsConnected {get;}
```

Property Value

Returns **true** if the connection has been established; otherwise returns **false**.

Remarks

The **IsConnected** property can only be used to indicate if there is still a logical connection to the server. It cannot be used to detect abnormal conditions such as the server aborting the connection, the physical network connection being lost or other critical errors.

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.IsInitialized Property

Gets a value which indicates if the current instance of the class has been initialized successfully.

[Visual Basic]

```
Public ReadOnly Property IsInitialized As Boolean
```

[C#]

```
public bool IsInitialized {get;}
```

Property Value

Returns **true** if the class instance has been initialized; otherwise returns **false**.

Remarks

The **IsInitialized** property is used to determine if the current instance of the class has been initialized properly. Normally this is done automatically by the class constructor, however there are circumstances where the class may not be able to initialize itself.

The most common reasons that a class instance may not initialize correctly is that no runtime license key has been defined in the assembly or the license key provided is invalid. It may also indicate a problem with the system configuration or user access rights, such as not being able to load the required networking libraries or not being able to access the system registry.

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.KeepAlive Property

Gets and sets a Boolean value which specifies if the client should attempt to keep the server connection alive.

[Visual Basic]
```
Public Property KeepAlive As Boolean
```

[C#]
```
public bool KeepAlive {get; set;}
```

Property Value

A boolean value which specifies if the client should attempt to maintain the connection with the server over a long period of time.

Remarks

If the **KeepAlive** property is set to **true**, the client will attempt to maintain an active connection to the server over a long period of time. If this property is set to **false**, then no attempt will be made to hold the command channel open.

It is important to note that enabling this option does not guarantee that the connection will be maintained. The application must be written to account for situations where the connection to the server is terminated if it is idle for a long period of time, regardless of the value of this property.

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.LastError Property

Gets and sets a value which specifies the last error that has occurred.

[Visual Basic]

```
Public Property LastError As Integer
```

[C#]

```
public int LastError {get; set;}
```

Property Value

Returns an ErrorCode enumeration value which specifies the last error code.

Remarks

The **LastError** property returns the error code associated with the last error that occurred for the current instance of the class. It is important to note that this value only has meaning if the previous method indicates that an error has actually occurred.

It is possible to explicitly clear the last error code by assigning the property to the value **ErrorCode.errorNone**.

The error code value can be cast to an integer value for display purposes if required. For a description of the error that can be displayed using a message box or some other similar mechanism, get the value of the **LastErrorString** property.

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.LastErrorString Property

Gets a value which describes the last error that has occurred.

[Visual Basic]

```
Public ReadOnly Property LastErrorString As String
```

[C#]

```
public string LastErrorString {get;}
```

Property Value

A string which describes the last error that has occurred.

Remarks

The **LastErrorString** property can be used to obtain a description of the last error that occurred for the current instance of the class. It is important to note that this value only has meaning if the previous method indicates that an error has actually occurred.

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.LocalAddress Property

Gets the local Internet address that the client is bound to.

[Visual Basic]

```
Public ReadOnly Property LocalAddress As String
```

[C#]

```
public string LocalAddress {get;}
```

Property Value

A string which specifies an Internet address.

Remarks

The **LocalAddress** property returns the local Internet address that the client is bound to when a connection is established with a server. This property may return either an IPv4 or IPv6 formatted address, depending on the type of connection that was established.

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.LocalFile Property

Gets and sets the name of the file on the local system.

[Visual Basic]

```
Public Property LocalFile As String
```

[C#]

```
public string LocalFile {get; set;}
```

Property Value

A string value which specifies the name of the local file.

Remarks

The **LocalFile** property is used to specify the local file name that will be used when uploading or downloading files. This property is automatically updated whenever the **GetFile** or **PutFile** methods are called, specifying the local file name.

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.Localize Property

Gets and sets a value which specifies if time and dates should be adjusted for the current timezone.

[Visual Basic]

```
Public Property Localize As Boolean
```

[C#]

```
public bool Localize {get; set;}
```

Property Value

A boolean value which specifies if file time and dates should be adjusted for the local timezone. The default value is false.

Remarks

The **Localize** property controls how remote file date and time values are localized when the **GetFileTime** method is called. If the property is set to **true** the file date and time will be adjusted to the current timezone. If the property is set to **false** the file date and time are returned as UTC (Coordinated Universal Time) values.

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.LocalName Property

Gets a value which specifies the host name for the local system.

[Visual Basic]

```
Public ReadOnly Property LocalName As String
```

[C#]

```
public string LocalName {get;}
```

Property Value

A string which specifies the local host name.

Remarks

The **LocalName** property returns the fully-qualified host name assigned to the local system. If the system has not been configured with an Internet domain name, then this property will return the NetBIOS name assigned to the local system.

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.Options Property

Gets and sets a value which specifies one or more client options.

[Visual Basic]

```
Public Property Options As FileTransferOptions
```

[C#]

```
public FileTransfer.FileTransferOptions Options {get; set;}
```

Property Value

Returns one or more FileTransferOptions enumeration flags which specify the options for the client. The default value for this property is **optionNone**.

Remarks

The **Options** property specifies one or more default options options which are used when establishing a connection using the **Connect** method.

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.Passive Property

Gets and sets a value which specifies if passive mode file transfers should be enabled.

[Visual Basic]

```
Public Property Passive As Boolean
```

[C#]

```
public bool Passive {get; set;}
```

Property Value

A boolean value which specifies if passive mode file transfers are enabled. If this value is set to **true**, passive mode is enabled. If the value is set to **false**, then passive mode transfers are disabled. The default value is **true**.

Remarks

When the client uploads or downloads a file and the **Passive** property is set to **false**, the server establishes a second connection back to the client which is used to transfer the file data. However, if the local system is behind a firewall or a NAT router, the server may not be able to create the data connection and the transfer will fail. By setting this property to **true**, it forces the client to establish an outbound data connection with the server. It is recommended that most applications use passive mode whenever possible.

Setting this property to **true** is the same as specifying the optionPassive flag when establishing a connection to the server.

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.Password Property

Gets and sets the password used to authenticate the client session.

[Visual Basic]

```
Public Property Password As String
```

[C#]

```
public string Password {get; set;}
```

Property Value

A string which specifies the password.

Remarks

If a password is not specified when the **Connect** method is called, the value of this property will be used as the default password when establishing a connection with the server.

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.Priority Property

Gets and sets a value which specifies the priority of file transfers.

[Visual Basic]
```
Public Property Priority As FileTransferPriority
```

[C#]
```
public FileTransfer.FileTransferPriority Priority {get; set;}
```

Property Value

Returns a FileTransferPriority enumeration value which specify the current file transfer priority. The default value for this property is **priorityNormal**.

Remarks

The **Priority** property can be used to control the processor usage, memory and network bandwidth allocated for file transfers. The default priority balances resource utilization and transfer speed while ensuring that a single-threaded application remains responsive to the user. Lower priorities reduce the overall resource utilization at the expense of transfer speed. For example, if you create a worker thread to download a file in the background and want to ensure that it has a minimal impact on the process, the **priorityBackground** value can be used.

Higher priority values increase the memory allocated for the transfers and increases processor utilization for the transfer. The **priorityCritical** priority maximizes transfer speed at the expense of system resources. It is not recommended that you increase the file transfer priority unless you understand the implications of doing so and have thoroughly tested your application. If the file transfer is being performed in the main UI thread, increasing the priority may interfere with the normal processing of Windows messages and cause the application to appear to become non-responsive. It is also important to note that when the priority is set to **priorityCritical**, normal progress events will not be generated during the transfer.

See Also

FileTransfer Class | SocketTools Namespace | FileTransferPriority Enumeration

FileTransfer.ProtocolVersion Property

Gets and sets a value which specifies the default protocol version.

[Visual Basic]

```
Public Property ProtocolVersion As HttpVersion
```

[C#]

```
public FileTransfer.HttpVersion ProtocolVersion {get; set;}
```

Property Value

An HttpVersion enumeration which specifies the protocol version.

Remarks

The **ProtocolVersion** property sets or returns the current HTTP version number. It is used to determine how requests are submitted to the server, as well as what header fields are required. The default value for this property is **HttpVersion.version10**, and should be changed before any connection attempt is made by the client.

Note that setting the property value to **HttpVersion.version09** tells the client to use the preliminary protocol specification which only supported a basic version of the GET command, and did not have any provisions for features such as user authentication, virtual hosting, etc. Header fields are not supported in this version of the protocol.

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.ProxyPassword Property

Gets and sets the password used to authenticate the connection to a proxy server.

[Visual Basic]

```
Public Property ProxyPassword As String
```

[C#]

```
public string ProxyPassword {get; set;}
```

Property Value

A string which specifies a password.

Remarks

The **ProxyPassword** property specifies the password used to authenticate the user to the proxy server. If a password is not required by the server, this property is ignored.

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.ProxyPort Property

Gets and sets a value that specifies the proxy server port number.

[Visual Basic]

```
Public Property ProxyPort As Integer
```

[C#]

```
public int ProxyPort {get; set;}
```

Property Value

An integer value which specifies the proxy port number.

Remarks

The **ProxyPort** property is used to set the port number that the control will use to establish a connection with the proxy server. A value of zero specifies that the client will connect to the proxy server using the standard FTP service port.

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.ProxyServer Property

Gets and sets the hostname or IP address of a proxy server.

[Visual Basic]

```
Public Property ProxyServer As String
```

[C#]

```
public string ProxyServer {get; set;}
```

Property Value

A string which specifies the hostname or IP address of the proxy server that will be used when establishing a connection.

Remarks

The **ProxyServer** property should be set to the name of the proxy server that you want to connect to. This property may be set to either a fully qualified domain name, or an IP address. This property is only used if the **ProxyType** property specifies a proxy server type other than **proxyNone**.

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.ProxyType Property

Gets and sets the type of proxy server the client will use to establish a connection.

[Visual Basic]

```
Public Property ProxyType As FileTransferProxy
```

[C#]

```
public FileTransfer.FileTransferProxy ProxyType {get; set;}
```

Property Value

An FileTransferProxy enumeration which specifies the type of proxy that the client will connect through.

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.ProxyUser Property

Gets and sets the username used to authenticate the connection to a proxy server.

[Visual Basic]

```
Public Property ProxyUser As String
```

[C#]

```
public string ProxyUser {get; set;}
```

Property Value

A string which specifies the username.

Remarks

The **ProxyUser** property specifies the user that is logging in to the proxy server. If the proxy server does not require the user to login, then this property is ignored.

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.RemoteFile Property

Gets and sets a value which specifies a file name on the server.

[Visual Basic]

```
Public Property RemoteFile As String
```

[C#]

```
public string RemoteFile {get; set;}
```

Property Value

A string which specifies a file name.

Remarks

The **RemoteFile** property is used to specify the name of a file on the server. Note that this property specifies the name of the file only, not a complete URL. To specify a complete URL, set the **URL** property and the control will automatically set the **RemoteFile** property to the correct value.

In most cases, the remote file name should be specified using an absolute path that begins with a leading slash character.

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.ResultCode Property

Gets a value which specifies the last result code returned by the server.

[Visual Basic]

```
Public ReadOnly Property ResultCode As Integer
```

[C#]

```
public int ResultCode {get;}
```

Property Value

An integer value which specifies the last result code returned by the server.

Remarks

Result codes are three-digit numeric values returned by the remote server and may be broken down into the following ranges:

ResultCode	Description
100-199	Positive preliminary result. This indicates that the requested action is being initiated, and the client should expect another reply from the server before proceeding.
200-299	Positive completion result. This indicates that the server has successfully completed the requested action.
300-399	Positive intermediate result. This indicates that the requested action cannot complete until additional information is provided to the server.
400-499	Transient negative completion result. This indicates that the requested action did not take place, but the error condition is temporary and may be attempted again.
500-599	Permanent negative completion result. This indicates that the requested action did not take place.

It is important to note that while some result codes have become standardized, not all servers respond to commands using the same result codes. For example, one server may respond with a result code of 221 to indicate success, while another may respond with a value of 235. It is recommended that applications check for ranges of values to determine if a command was successful, not a specific value.

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.ResultString Property

Gets a string value which describes the result of the previous command.

[Visual Basic]

```
Public ReadOnly Property ResultString As String
```

[C#]

```
public string ResultString {get;}
```

Property Value

A string which describes the result of the previous command executed on the server.

Remarks

The **ResultString** property returns the result string from the last action taken by the client. This string is generated by the remote server, and typically is used to describe the result code. For example, if an error is indicated by the result code, the result string may describe the condition that caused the error.

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.Secure Property

Gets and sets a value which specifies if a secure connection is established.

[Visual Basic]

```
Public Property Secure As Boolean
```

[C#]

```
public bool Secure {get; set;}
```

Property Value

Returns **true** if a secure connection is established; otherwise returns **false**. The default value is **false**.

Remarks

The **Secure** property determines if a secure connection is established with the server. The default value for this property is **false**, which specifies that a standard connection to the server is used. To establish a secure connection, the application should set this property value to **true** prior to calling the **Connect** method. Once the connection has been established, the client may exchange data with the server as with standard connections.

It is strongly recommended that any application that sets this property **true** use error handling to trap an errors that may occur. If the class is unable to initialize the security libraries, or otherwise cannot create a secure session for the client, an exception may be generated when this property value is set to **true**.

FileTransfer Class | SocketTools Namespace

FileTransfer.SecureCipher Property

Gets a value that specifies the encryption algorithm used for a secure connection.

[Visual Basic]
```
Public ReadOnly Property SecureCipher As SecureCipherAlgorithm
```

[C#]
```
public FileTransfer.SecureCipherAlgorithm SecureCipher {get;}
```

Property Value

A SecureCipherAlgorithm enumeration value which identifies the algorithm.

Remarks

The **SecureCipher** property returns a value which identifies the algorithm used to encrypt the data stream. If a secure connection has not been established, this property will return a value of **cipherNone**.

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.SecureHash Property

Gets a value that specifies the message digest algorithm used for a secure connection.

[Visual Basic]

```
Public ReadOnly Property SecureHash As SecureHashAlgorithm
```

[C#]

```
public FileTransfer.SecureHashAlgorithm SecureHash {get;}
```

Property Value

A SecureHashAlgorithm enumeration value which identifies the algorithm.

Remarks

The **SecureHash** property returns a value which identifies the message digest (hash) algorithm that was selected when a secure connection was established. If a secure connection has not been established, this property will return a value of **hashNone**.

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.SecureKeyExchange Property

Gets a value that specifies the key exchange algorithm used for a secure connection.

[Visual Basic]

```
Public ReadOnly Property SecureKeyExchange As SecureKeyAlgorithm
```

[C#]

```
public FileTransfer.SecureKeyAlgorithm SecureKeyExchange {get;}
```

Property Value

A SecureKeyAlgorithm enumeration value which identifies the algorithm.

Remarks

The **SecureKeyExchange** property returns a value which identifies the key exchange algorithm that was selected when a secure connection was established. If a secure connection has not been established, this property will return a value of **keyExchangeNone**.

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.SecureProtocol Property

Gets and sets a value which specifies the protocol used for a secure connection.

[Visual Basic]

```
Public Property SecureProtocol As SecurityProtocols
```

[C#]

```
public FileTransfer.SecurityProtocols SecureProtocol {get; set;}
```

Property Value

A SecurityProtocols enumeration value which identifies the protocol to be used when establishing a secure connection.

Remarks

The **SecureProtocol** property can be used to specify the security protocol to be used when establishing a secure connection with a server or accepting a secure connection from a client. By default, the class will attempt to use either SSL v3 or TLS v1 to establish the connection, with the appropriate protocol automatically selected based on the capabilities of the remote host. It is recommended that you only change this property value if you fully understand the implications of doing so. Assigning a value to this property will override the default protocol and force the class to attempt to use only the protocol specified.

Multiple security protocols may be specified by combining them using a bitwise **or** operator. After a connection has been established, this property will identify the protocol that was selected. Attempting to set this property after a connection has been established will result in an exception being thrown. This property should only be set after setting the **Secure** property to **true** and before calling the **Accept** or **Connect** methods.

In some cases, a server may only accept a secure connection if the TLS v1 protocol is specified. If the security protocol is not compatible with the server, then the connection will fail with an error indicating that the control is unable to establish a security context for the session. In this case, try assigning the property to **protocolTLS1** and attempt the connection again.

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.ServerDirectory Property

Gets and sets a value which specifies the current working directory on the file server.

[Visual Basic]
```
Public Property ServerDirectory As String
```

[C#]
```
public string ServerDirectory {get; set;}
```

Property Value

A string value which specifies the current working directory on the file server. If there is no active connection to a server, or the File Transfer Protocol has not been used to establish a connection, this property will return an empty string.

Remarks

This property specifies the name of a directory on the file server. When a connection is first established to an FTP server, this property will return the current working directory. Setting this property is equivalent to using the **ChangeDirectory** method.

It is important to note that this property is only valid when connected to an FTP server. If you change the value of this property, and the current working directory cannot be changed on the server, an exception will be thrown which must be handled by the client application.

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.ServerName Property

Gets and sets a value which specifies the host name used to establish a connection.

[Visual Basic]

```
Public Property ServerName As String
```

[C#]

```
public string ServerName {get; set;}
```

Property Value

A string which specifies a server domain name.

Remarks

The **ServerName** property can be used to set the host name for a remote system that you wish to communicate with.

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.ServerPort Property

Gets and sets a value which specifies the remote port number.

[Visual Basic]

```
Public Property ServerPort As Integer
```

[C#]

```
public int ServerPort {get; set;}
```

Property Value

An integer value which specifies a port number.

Remarks

The **ServerPort** property is used to set the port number that will be used to establish a connection with a server.

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.ServerType Property

Gets and sets a value which specifies the type of file server the client is connecting to.

[Visual Basic]
```
Public Property ServerType As FileServerType
```

[C#]
```
public FileTransfer.FileServerType ServerType {get; set;}
```

Property Value

Returns a FileServerType enumeration value which specifies the type of file server, either using the File Transfer Protocol or the Hypertext Transfer Protocol.

Remarks

If this property value is specified as **serverUnknown**, the actual server type will either be determined by the URL or the value of the **ServerPort** property, if the port number is recognized as a standard service port. If the server type cannot be automatically identified, an error will be returned when the **Connect** method is called.

If you are connecting using a non-standard port number, and are not specifying a URL for the remote file name, you should always initialize this property value to the correct server type before attempting to establish a connection.

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.System Property

Gets a string value which identifies the server.

[Visual Basic]
```
Public ReadOnly Property System As String
```

[C#]
```
public string System {get;}
```

Property Value

A string which identifies the type of server the client has connected to.

Remarks

The **System** property returns information about the server operating system. This is a read-only property that can be used by the application to identify the type of server that the client has connected to. Reading this property will cause the SYST command to be sent to the server and will only return a useful value after a connection has been established with the server.

By convention, the first whitespace separated token in the string identifies the general operating system platform. For example, here are some strings commonly returned by various FTP servers:

Examples	Description
UNIX Type: L8	A standard UNIX based server. This is the most common value returned by servers, and this indicates that the server supports UNIX file naming and directory listing conventions. This string may also include additional information such as the specific variant of UNIX and its version. The L8 portion of the string is a convention that lets the client know that a byte consists of 8 bits.
Windows_NT Version 5.0	A standard Windows based server, typically part of Internet Information Services (ISS). The server will use Windows file naming and directory listing conventions. The version identifies the specific release of Windows. For example, version 4.0 specifies Windows NT 4.0 and 5.0 specifies Windows 2000.
VMS V7.1 AlphaServer	A server running the VMS operating system. The server will use the standard file naming and directory listing conventions for that platform. Note that it is possible that a VMS system may also be configured to operate in a UNIX emulation mode, in which case it will return UNIX instead of VMS.
NetWare	A server running the NetWare operating system. The server will use the standard file naming and directory listing conventions for that platform. Note that it is possible that a NetWare system may be configured to operate in a UNIX emulation

	mode, in which case it return UNIX instead of NetWare.
WORLDGROUP Type: L8	A server running the WorldGroup software on the Windows platform. This server supports UNIX file naming and directory listing conventions. WorldGroup is a collaborative workgroup, email and file sharing service which includes an FTP server.

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.TaskCount Property

Get the number of active background file transfers.

[Visual Basic]

```
Public ReadOnly Property TaskCount As Integer
```

[C#]

```
public int TaskCount {get;}
```

Property Value

An integer value that specifies the number of background file transfers that are currently in progress.

Remarks

The **TaskCount** property returns the number of background file transfers that are currently in progress. One common use for this property is to create a timer that periodically checks this value when a series of background transfers are started. When the property returns a value of zero, that indicates all of the background transfers have completed. This property can also be used to enumerate the active background tasks in conjunction with the **TaskList** property.

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.TaskId Property

Get the task identifier for the last background file transfer.

[Visual Basic]

```
Public ReadOnly Property TaskId As Integer
```

[C#]

```
public int TaskId {get;}
```

Property Value

An integer value the uniquely identifies the current background task.

Remarks

The **TaskId** property returns the task ID associated with the current background task. This identifies the last background file transfer that was initiated with a call to the **AsyncGetFile** or **AsyncPutFile** methods. This property value will change with each subsequent background transfer that is performed. If this property returns a value of zero, that indicates that no background tasks have been started for this instance of the class.

To enumerate the active background tasks, use the **TaskCount** property and the **TaskList** array.

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.TaskList Property

Get an array of active background task identifiers.

[Visual Basic]
```
Public ReadOnly Property TaskList As ArrayList
```

[C#]
```
public System.Collections.ArrayList TaskList {get;}
```

Property Value

An **ArrayList** object that contains a list of integer values that uniquely identify the active background tasks that have been started by this instance of the class.

Remarks

The **TaskList** property returns a read-only **ArrayList** object that is popularted with the task identifiers for all active background tasks that have been created by this instance of the class. The current number of active tasks can be determined using the **TaskCount** property.

As background tasks complete and additional tasks are started, the values stored in this array will change. The application should never make any assumptions about the numeric values stored in the array or the order they are returned. Task IDs should be considered opaque values that are unique to the process. When a background task completes, its corresponding ID is removed from the list of active tasks and this can potentially change the task ID values associated with each index into the array.

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.ThreadModel Property

Gets and sets a value which specifies the threading model for the class instance.

[Visual Basic]

```
Public Property ThreadModel As ThreadingModel
```

[C#]

```
public FileTransfer.ThreadingModel ThreadModel {get; set;}
```

Property Value

Returns one or more ThreadingModel enumeration value which specifies the threading model for the client. The default value for this property is **modelSingleThread**.

Remarks

The **ThreadModel** property specifies the threading model that is used by the class instance when a connection is established. The default value for this property is **modelSingleThread**, which specifies that only the thread that established the connection should be permitted to invoke methods. It is important to note that this threading model does not limit the application to a single thread of execution. When a session is established using the **Connect** method, that session is attached to the thread that created it. From that point on, until the session is terminated, only the owner may invoke methods in that instance of the class. The ownership of the class instance may be transferred from one thread to another using the **AttachThread** method.

Setting this property to **modelFreeThread** disables certain internal safety checks that are performed by the class and may result in unexpected behavior unless you ensure that access to the class instance is synchronized across multiple threads. The application must ensure that no two threads will attempt to invoke a blocking method at the same time. In other words, if one thread invokes a method, the application must ensure that another thread will not attempt to invoke any other method at the same time using the same instance of the class.

Changing the value of this property will not affect an active client session. The threading model must be specified prior to invoking the **Connect** method.

See Also

FileTransfer Class | SocketTools Namespace | AttachThread Method | ThreadingModel Enumeration | ThreadModel Attribute

FileTransfer.ThrowError Property

Gets and sets a value which specifies if method calls should throw exceptions when an error occurs.

[Visual Basic]

```
Public Property ThrowError As Boolean
```

[C#]

```
public bool ThrowError {get; set;}
```

Property Value

Returns **true** if method calls will generate exceptions when an error occurs; otherwise returns **false**. The default value is **false**.

Remarks

Error handling for when calling class methods can be done in either of two different styles, according to the value of this property.

If the **ThrowError** property is set to **false**, the application should check the return value of any method that is used, and report errors based upon the documented value of the return code. It is the responsibility of the application to interpret the error code, if it is desired to explain the error in addition to reporting it. This is the default behavior.

If the **ThrowError** property is set to **true**, then exceptions will be generated whenever a method call fails. The program must be written to catch these exceptions and take the appropriate action when an error occurs. Failure to handle an exception will cause the program to terminate abnormally.

Note that if an error occurs while a property is being read or modified, an exception will be raised regardless of the value of the **ThrowError** property.

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.Timeout Property

Gets and sets a value which specifies a timeout period in seconds.

[Visual Basic]

```
Public Property Timeout As Integer
```

[C#]

```
public int Timeout {get; set;}
```

Property Value

An integer value which specifies a timeout period in seconds.

Remarks

Setting the **Timeout** property specifies the number of seconds until a blocking operation fails and returns an error.

The timeout period is only used when the client is in blocking mode. Although this property can be changed when the client is in non-blocking mode, the value will be ignored until the client is returned to blocking mode.

For most applications it is recommended the timeout period be set between 10 and 20 seconds.

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.TimeZone Property

Gets and sets the current timezone offset in seconds.

[Visual Basic]

```
Public Property TimeZone As Integer
```

[C#]

```
public int TimeZone {get; set;}
```

Property Value

An integer value which specifies the current timezone offset in seconds.

Remarks

The **TimeZone** property returns the current offset from UTC in seconds. Setting the property changes the current timezone offset to the specified value. The value of this property is initially determined by the date and time settings on the local system.

This property value is used in conjunction with the **Localize** property to control how date and time localization is handled.

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.Trace Property

Gets and sets a value which indicates if network function logging is enabled.

[Visual Basic]

```
Public Property Trace As Boolean
```

[C#]

```
public bool Trace {get; set;}
```

Property Value

Returns **true** if network function tracing is enabled; otherwise returns **false**. The default value is **false**.

Remarks

The **Trace** property is used to enable (or disable) the tracing of network function calls. When enabled, each function call is logged to a file, including the function parameters, return value and error code if applicable. This facility can be enabled and disabled at run time, and the trace log file can be specified by setting the **TraceFile** property. All function calls that are being logged are appended to the trace file, if it exists. If no trace file exists when tracing is enabled, the trace file is created.

The tracing facility is available in all of the SocketTools networking classes and is enabled or disabled for an entire process. This means that once trace logging is enabled for a given component, all of the function calls made by the process using any of the SocketTools classes will be logged. For example, if you have an application using both the File Transfer Protocol and Post Office Protocol classes, and you set the **Trace** property to **true**, function calls made by both classes will be logged. Additionally, enabling a trace is cumulative, and tracing is not stopped until it is disabled for all classes used by the process.

If trace logging is not enabled, there is no negative impact on performance or throughput. Once enabled, application performance can degrade, especially in those situations in which multiple processes are being traced or the logfile is fairly large. Since logfiles can grow very quickly, even with modest applications, it is recommended that you delete the file when it is no longer needed.

When redistributing your application, make sure that you include the **SocketTools10.TraceLog.dll** module with your installation. If this library is not present, then no trace output will be generated and the value of the **Trace** property will be ignored. Only those function calls made by the SocketTools networking classes will be logged. Calls made directly to the Windows Sockets API, or calls made by other classes, will not be logged.

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.TraceFile Property

Gets and sets a value which specifies the name of the logfile.

[Visual Basic]

```
Public Property TraceFile As String
```

[C#]

```
public string TraceFile {get; set;}
```

Property Value

A string which specifies the name of the file.

Remarks

The **TraceFile** property is used to specify the name of the trace file that is created when network function tracing is enabled. If this property is set to an empty string (the default value), then a file named **SocketTools.log** is created in the system's temporary directory. If no temporary directory exists, then the file is created in the current working directory.

If the file exists, the trace output is appended to the file, otherwise the file is created. Since network function tracing is enabled per-process, the trace file is shared by all instances of the class being used. If multiple class instances have tracing enabled, the **TraceFile** property should be set to the same value for each instance. Since trace files can grow very quickly, even with modest applications, it is recommended that you delete the file when it is no longer needed.

The trace file has the following format:

```
 MyApp INF: WSAAsyncSelect(46, 0xcc4, 0x7e9, 0x27) returned 0 MyApp WRN:
connect(46, 192.0.0.1:1234, 16) returned -1 [10035] MyApp ERR: accept(46,
NULL, 0x0) returned -1 [10038]
```

The first column contains the name of the process that is being traced. The second column identifies if the trace record is reporting information, a warning, or an error. What follows is the name of the function being called, the arguments passed to the function and the function's return value. If a warning or error is reported, the error code is appended to the record (the value is placed inside brackets).

If parameters are passed as integer values, they are recorded in decimal. If the parameter or return value is a pointer (a memory address), it is recorded as a hexadecimal value preceded with "0x". A special type of pointer, called a null pointer, is recorded as NULL. Those functions which expect socket addresses are displayed in the following format:

```
aa.bb.cc.dd:nnnn
```

The first four numbers separated by periods represent the IP address, and the number following the colon represents the port number in host byte order. Note that in the second line of the above example, the control is attempting to connect to a system with the IP address 192.0.0.1 on port 1234.

Note that if the specified file cannot be created, or the user does not have permission to modify an existing file, the error is silently ignored and no trace output will be generated.

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.TraceFlags Property

Gets and sets a value which specifies the client function tracing flags.

[Visual Basic]

```
Public Property TraceFlags As TraceOptions
```

[C#]

```
public FileTransfer.TraceOptions TraceFlags {get; set;}
```

Property Value

A TraceOptions enumeration which specifies the amount of detail written to the trace logfile.

Remarks

The **TraceFlags** property is used to specify the type of information written to the trace file when network function tracing is enabled.

Because network function tracing is enabled per-process, the trace flags are shared by all instances of the class being used. If multiple class instances have tracing enabled, the **TraceFlags** property should be set to the same value for each instance. Changing the trace flags for any one instance of the class will affect the logging performed for all SocketTools classes used by the application.

Warnings are generated when a non-fatal error is returned by a network function. For example, if data is being written and the error **errorOperationWouldBlock** occurs, a warning is generated because the application simply needs to attempt to write the data at a later time.

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.TransferBytes Property

Gets a value which specifies the number of bytes transferred to or from the remote server.

[Visual Basic]

```
Public ReadOnly Property TransferBytes As Long
```

[C#]

```
public long TransferBytes {get;}
```

Property Value

An integer value which specifies the number of bytes of data transferred to or from the server.

Remarks

The **TransferBytes** property returns the number of bytes that have been copied to or from the remote FTP server. If this property is read while a transfer is ongoing, the property returns the number of bytes that have been copied up to that point. If read after a transfer has completed, the total number of bytes copied is returned. This property value is reset with every data transfer.

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.TransferTime Property

Gets a value which specifies the number of seconds elapsed during a data transfer.

[Visual Basic]

```
Public ReadOnly Property TransferTime As Integer
```

[C#]

```
public int TransferTime {get;}
```

Property Value

An integer value which specifies the transfer time in seconds.

Remarks

The **TransferTime** returns the number of seconds that have elapsed since the data connection was opened on the remote server. If the property is read while a transfer is ongoing, it returns the elapsed time. If the property is read after the transfer is complete, it returns the total number of seconds it took to transfer the data. This property value is reset with every data transfer.

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.URL Property

Gets and sets the current URL used to access a file on the server.

[Visual Basic]

```
Public Property URL As String
```

[C#]

```
public string URL {get; set;}
```

Property Value

A string which specifies the current URL.

Remarks

The **URL** property returns the current Uniform Resource Locator string which is used by the control to access a file on the server. URLs have a specific format which provides information about the server, port, path and file name, as well as optional information such as a username and password for authentication:

```
ftp://[username : [password] @] remotehost [:remoteport] / [path/...]
filename [;type=id]
```

The first part of the URL is the protocol and in this case will always be "ftp", or "ftps" if a secure connection is being used. If a username and password is required for authentication, then this will be included in the URL before the name of the server; otherwise an anonymous FTP session is assumed. Next, there is the name of the server to connect to, optionally followed by a port number. If no port number is given, then the default port for the protocol will be used. This is followed by the path, and then the name of the file on the server. An optional file type may be specified as well, with the type identifier being either "a" for text files or "i" for binary files.

One important consideration when using FTP URLs is that the path is relative to the user's home directory and should not be considered an absolute path from the root directory on the server. If no username and password is provided, then an anonymous session is used and the path is relative to the public directory used by the FTP server.

Here are some typical examples of URLs used to access files on an FTP server:

```
ftp://www.example.com/pub/financial/jan2020.xls
```

In this example, the server is www.example.com, the path is "pub/financial" and the file name is "jan2020.xls". The default port will be used to access the file, and no username and password is provided for authentication so this file must be publicly available to anonymous users.

```
ftp://www.example.com:2121/employees/picnic.doc
```

In this example, the server is www.example.com, the path is "employees" and the file name is "picnic.doc". However, the client should connect to an alternative port number, in this case 2121. This file must also be available to anonymous users because no username or password has been specified.

```
ftps://executive:secret@www.example.com/corporate/projections/sales2020.xls
```

In this example, the server is www.example.com and, the path is "corporate/projections" and the file name is "sales2020.xls". Because the protocol is ftps, a secure connection on port 990 will be established. The user name "executive" and password "secret" will be used to authenticate the session.

When setting the **URL** property, the class will parse the string and automatically update the **HostName**, **RemotePort**, **UserName**, **Password**, **RemotePath** and **RemoteFile** properties according to the values specified in the URL. This enables an application to simply provide the URL and then call the **Connect** method to establish the connection.

Note that if this property is assigned a value which cannot be parsed, an exception will be thrown that indicates that the property value is invalid. If the user enters an invalid URL and there is no exception handler, the unhandled exception will terminate the application.

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.UserName Property

Gets and sets the username used to authenticate the client session.

[Visual Basic]

```
Public Property UserName As String
```

[C#]

```
public string UserName {get; set;}
```

Property Value

A string which specifies the username.

Remarks

If a username is not specified when the **Connect** method is called, the value of this property will be used as the default username when establishing a connection with the server.

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.Version Property

Gets a value which returns the current version of the FileTransfer class library.

[Visual Basic]

```
Public ReadOnly Property Version As String
```

[C#]

```
public string Version {get;}
```

Property Value

A string which specifies the version of the class library.

Remarks

The **Version** property returns a string which identifies the current version and build of the FileTransfer class library. This value can be used by an application for validation and debugging purposes.

FileTransfer Class | SocketTools Namespace

FileTransfer Methods

The methods of the **FileTransfer** class are listed below. For a complete list of **FileTransfer** class members, see the FileTransfer Members topic.

Public Static (Shared) Methods

ErrorText	Returns the description of an error code.

Public Instance Methods

AddFileType	Associate a file name extension with a specific file type.
AsyncGetFile	Overloaded. Download a file from the server to the local system in the background.
AsyncPutFile	Overloaded. Upload a file from the local system to the server in the background.
AttachThread	Attach an instance of the class to the current thread
Cancel	Cancel the current blocking client operation.
ChangeDirectory	Change the current working directory on the remote server.
CloseDirectory	Close the directory that was previously opened with the OpenDirectory method.
Command	Overloaded. Send a custom command to the server.
Connect	Overloaded. Establish a connection with a file server.
DeleteFile	Delete a file on the remote server.
Disconnect	Terminate the connection with the remote server.
Dispose	Overloaded. Releases all resources used by FileTransfer.
Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetData	Overloaded. Transfers the contents of a file on the server and stores it in byte array.
GetDirectory	Return the current working directory.
GetFile	Overloaded. Download a file from the server to the local system.
GetFileList	Overloaded. Returns an unparsed list of files in the specified directory.
GetFilePermissions	Overloaded. Return the access permissions for a file on the remote system.
GetFileSize	Overloaded. Returns the size of the specified file

	on the remote server.
GetFileStatus	
GetFileTime	Overloaded. Returns the modification date and time for specified file on the remote server.
GetFirstFile	Overloaded. Get information about the first file in a directory listing returned by the server.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetMultipleFiles	Download multiple files from the server to the local system using a wildcard mask.
GetNextFile	Overloaded. Get information about the next file in a directory listing returned by the server.
GetType (inherited from Object)	Gets the Type of the current instance.
Initialize	Overloaded. Initialize an instance of the FileTransfer class.
Login	Overloaded. Login to the remote server.
Logout	Log the current user off the server.
MakeDirectory	Create a new directory on the server.
OpenDirectory	Overloaded. Open the specified directory on the server.
PostFile	Overloaded. Post the contents of the specified file to a script executed on the remote server.
PutData	Overloaded. Transfers data from a byte array and stores it in a file on the remote server.
PutFile	Overloaded. Upload a file from the local system to the server.
PutMultipleFiles	Upload multiple files from the local system to the server using a wildcard mask.
RemoveDirectory	Remove a directory on the server.
RenameFile	Change the name of a file on the server.
Reset	Reset the internal state of the object, resetting all properties to their default values.
SetFilePermissions	Change the access permissions for a file on the server.
SetFileTime	Changes the modification date and time for a file on the server.
TaskAbort	Overloaded. Abort the specified asynchronous task.
TaskDone	Overloaded. Determine if an asynchronous task has completed.

TaskResume	Overloaded. Resume execution of an asynchronous task.
TaskSuspend	Overloaded. Suspend execution of an asynchronous task.
TaskWait	Overloaded. Wait for an asynchronous task to complete.
ToString (inherited from Object)	Returns a String that represents the current Object.
Uninitialize	Uninitialize the class library and release any resources allocated for the current thread.
VerifyFile	Overloaded. Verify that the contents of a file on the local system are the same as the specified file on the server.

Protected Instance Methods

Dispose	Overloaded. Releases the unmanaged resources allocated by the FileTransfer class and optionally releases the managed resources.
Finalize	Destroys an instance of the class, releasing the resources allocated for the session and unloading the networking library.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.AddFileType Method

Associate a file name extension with a specific file type.

[Visual Basic]

```
Public Function AddFileType( _
   ByVal fileExtension As String, _
   ByVal fileType As FileTransferType _
) As Boolean
```

[C#]

```
public bool AddFileType(
   string fileExtension,
   FileTransferType fileType
);
```

Parameters

fileExtension

A string value which specifies the file name extension.

fileType

A FileTransferType enumeration which specifies the type of file associated with the file extension.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

This method is used to associate specific file types with file name extensions. The class has an internal list of standard text file extensions which it automatically recognizes. This method can be used to extend or modify that list for the client session.

FileTransfer Class | SocketTools Namespace | AsyncPutFile Method

FileTransfer.AsyncGetFile Method (String)

Download a file from the server to the local system in the background.

```
[Visual Basic]
Overloads Public Function AsyncGetFile( _
   ByVal localFile As String _
) As Boolean
```

```
[C#]
public bool AsyncGetFile(
   string localFile
);
```

Parameters

localFile

A string that specifies the file on the local system that will be created, overwritten or appended to. The file pathing and name conventions must be that of the local host.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **AsyncGetFile** method will download the contents of a remote file to a file on the local system. It is similar to the **GetFile** method, however it retrieves the file using a background worker thread and does not block the current working thread. This enables the application to continue to perform other operations while the file is being downloaded from the server. This method requires that you explicitly establish a connection using the **Connect** method. All background tasks will duplicate the active connection and use it establish a secondary connection with the server to perform the file transfer. If you wish to perform multiple asynchronous file transfers from different servers, you must create a new instance of this class for each server.

After this method is called, the **OnTaskBegin** event will be fired, indicating that the background task has begun the process of connecting to the server and performing the file transfer. As the file is downloaded, the class will periodically invoke the **OnTaskRun** event handler. When the transfer has completed, the **OnTaskEnd** event will be fired. It is not required that you implement handlers for these events.

To determine when a transfer has completed without implementing any event handlers, periodically call the **TaskDone** method. If you wish to block the current thread and wait for the transfer to complete, call the **TaskWait** method. To stop a background file transfer that is in progress, call the **TaskAbort** method. This will signal the background worker thread to cancel the transfer and terminate the session.

This method can be called multiple times to download more than one file in the background; however, most servers limit the number of simultaneous connections that can originate from a single IP address. The application should not make any assumptions about the sequence in which background transfers are performed or the order in which they may complete.

---

FileTransfer.AsyncGetFile Method (String, String, Int64)

Download a file from the server to the local system in the background.

[Visual Basic]

```
Overloads Public Function AsyncGetFile( _
   ByVal localFile As String, _
   ByVal remoteFile As String, _
   ByVal offset As Long _
) As Boolean
```

[C#]

```
public bool AsyncGetFile(
   string localFile,
   string remoteFile,
   long offset
);
```

Parameters

localFile
A string that specifies the file on the local system that will be created, overwritten or appended to. The file pathing and name conventions must be that of the local host.

remoteFile
A string that specifies the file on the server that will be transferred to the local system. The file pathing and name conventions must be that of the server.

offset
A integer value which specifies the offset where the file transfer should begin. A value of zero specifies that the file transfer should start at the beginning of the file. A value greater than zero is typically used to restart a transfer that has not completed successfully. Note that specifying a non-zero offset requires that the server support the command to restart file transfers.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **AsyncGetFile** method will download the contents of a remote file to a file on the local system. It is similar to the **GetFile** method, however it retrieves the file using a background worker thread and does not block the current working thread. This enables the application to continue to perform other operations while the file is being downloaded from the server. This method requires that you explicitly establish a connection using the **Connect** method. All background tasks will duplicate the active connection and use it establish a secondary connection with the server to perform the file transfer. If you wish to perform multiple asynchronous file transfers from different servers, you must create a new instance of this class for each server.

After this method is called, the **OnTaskBegin** event will be fired, indicating that the background task has begun the process of connecting to the server and performing the file transfer. As the file is downloaded, the class will periodically invoke the **OnTaskRun** event handler. When the transfer has completed, the **OnTaskEnd** event will be fired. It is not required that you implement handlers for these events.

To determine when a transfer has completed without implementing any event handlers, periodically call the **TaskDone** method. If you wish to block the current thread and wait for the transfer to complete, call the **TaskWait** method. To stop a background file transfer that is in progress, call the **TaskAbort** method. This will signal the background worker thread to cancel the transfer and terminate the session.

This method can be called multiple times to download more than one file in the background; however, most servers limit the number of simultaneous connections that can originate from a single IP address. The application should not make any assumptions about the sequence in which background transfers are performed or the order in which they may complete.

FileTransfer Class | SocketTools Namespace | FileTransfer.AsyncGetFile Overload List | AsyncPutFile Method

FileTransfer.AsyncGetFile Method (String, String, Int64, Boolean)

Download a file from the server to the local system in the background.

[Visual Basic]

```
Overloads Public Function AsyncGetFile( _
   ByVal localFile As String, _
   ByVal remoteFile As String, _
   ByVal offset As Long, _
   ByVal appendFile As Boolean _
) As Boolean
```

[C#]

```
public bool AsyncGetFile(
   string localFile,
   string remoteFile,
   long offset,
   bool appendFile
);
```

Parameters

localFile
: A string that specifies the file on the local system that will be created, overwritten or appended to. The file pathing and name conventions must be that of the local host.

remoteFile
: A string that specifies the file on the server that will be transferred to the local system. The file pathing and name conventions must be that of the server.

offset
: A integer value which specifies the offset where the file transfer should begin. A value of zero specifies that the file transfer should start at the beginning of the file. A value greater than zero is typically used to restart a transfer that has not completed successfully. Note that specifying a non-zero offset requires that the server support the command to restart file transfers.

appendFile
: A boolean value which specifies if the contents of the remote file should be appended to the local file, rather than overwriting it. A value of **true** specifies that the local file should be appended to. A value of **false** specifies that the local file should be overwritten. This parameter is only used with the File Transfer Protocol.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **AsyncGetFile** method will download the contents of a remote file to a file on the local system. It is similar to the **GetFile** method, however it retrieves the file using a background worker thread and does not block the current working thread. This enables the application to continue to perform other operations while the file is being downloaded from the server. This method requires that you explicitly establish a connection using the **Connect** method. All background tasks will duplicate the active connection and use it establish a secondary connection with the server to perform the file transfer. If you wish to perform multiple asynchronous file transfers from different servers, you must create a new instance of this class for each server.

After this method is called, the **OnTaskBegin** event will be fired, indicating that the background task has begun the process of connecting to the server and performing the file transfer. As the file is downloaded, the class will periodically invoke the **OnTaskRun** event handler. When the transfer has completed, the **OnTaskEnd** event will be fired. It is not required that you implement handlers for these events.

To determine when a transfer has completed without implementing any event handlers, periodically call the **TaskDone** method. If you wish to block the current thread and wait for the transfer to complete, call the **TaskWait** method. To stop a background file transfer that is in progress, call the **TaskAbort** method. This will signal the background worker thread to cancel the transfer and terminate the session.

This method can be called multiple times to download more than one file in the background; however, most servers limit the number of simultaneous connections that can originate from a single IP address. The application should not make any assumptions about the sequence in which background transfers are performed or the order in which they may complete.

FileTransfer Class | SocketTools Namespace | FileTransfer.AsyncPutFile Overload List | AsyncGetFile Method

FileTransfer.AsyncPutFile Method (String, String, Int64, Boolean)

Upload a file from the local system to the server in the background.

[Visual Basic]

```
Overloads Public Function AsyncPutFile( _
   ByVal localFile As String, _
   ByVal remoteFile As String, _
   ByVal offset As Long, _
   ByVal appendFile As Boolean _
) As Boolean
```

[C#]

```
public bool AsyncPutFile(
   string localFile,
   string remoteFile,
   long offset,
   bool appendFile
);
```

Parameters

localFile
A string that specifies the file on the local system that will be transferred to the server. The file pathing and name conventions must be that of the local host.

remoteFile
A string that specifies the file on the server that will be created, overwritten or appended to. The file pathing and name conventions must be that of the server.

offset
A integer value which specifies the offset where the file transfer should begin. A value of zero specifies that the file transfer should start at the beginning of the file. A value greater than zero is typically used to restart a transfer that has not completed successfully. Note that specifying a non-zero offset requires that the server support the command to restart file transfers.

appendFile
A boolean value which specifies if the contents of the remote file should be appended to the local file, rather than overwriting it. A value of **true** specifies that the local file should be appended to. A value of **false** specifies that the local file should be overwritten. This parameter is only used with the File Transfer Protocol.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **AsyncPutFile** method will upload the contents of a file on the local system to the server. It is similar to the **PutFile** method, however it retrieves the file using a background worker thread and does not block the current working thread. This enables the application to continue to perform other operations while the file is being uploaded to the server. This method requires that you explicitly establish a connection using the **Connect** method. All background tasks will duplicate the active connection and use it establish a secondary connection with the server to perform the file transfer. If you wish to perform multiple asynchronous file transfers from different servers, you must create an instance of the control for each server.

After this method is called, the **OnTaskBegin** event will be fired, indicating that the background task has begun the process of connecting to the server and performing the file transfer. As the file is uploaded, the control will periodically invoke the **OnTaskRun** event handler. When the transfer has completed, the **OnTaskEnd** event will be fired. It is not required that you implement handlers for these events.

To determine when a transfer has completed without implementing any event handlers, periodically call the **TaskDone** method. If you wish to block the current thread and wait for the transfer to complete, call the **TaskWait** method. To stop a background file transfer that is in progress, call the **TaskAbort** method. This will signal the background worker thread to cancel the transfer and terminate the session.

This method can be called multiple times to upload more than one file in the background; however, most servers limit the number of simultaneous connections that can originate from a single IP address. The application should not make any assumptions about the sequence in which background transfers are performed or the order in which they may complete.

FileTransfer Class | SocketTools Namespace | FileTransfer.AsyncPutFile Overload List | AsyncGetFile Method

FileTransfer.AttachThread Method

Attach an instance of the class to the current thread

[Visual Basic]
```
Public Function AttachThread() As Boolean
```

[C#]
```
public bool AttachThread();
```

Return Value

A boolean value which specifies if the client could be attached to the current thread. If this method returns **false**, the client could not be attached to the thread and the application should check the value of the LastError property to determine the cause of the failure.

Remarks

When an instance of the class is created it is associated with the current thread that created it. Normally, if another thread attempts to perform an operation using that instance, an error is returned. This is used to ensure that other threads cannot interfere with an operation being performed by the owner thread. In some cases, it may be desirable for one thread in an application to create an instance of the class, establish a connection and then pass that instance to another worker thread. The **AttachThread** method can be used to change the ownership of the class instance to the new worker thread.

This method should be called by the new thread immediately after it has been created, and if the new thread does not release the handle itself, the ownership of the handle should be restored by the original thread. Under no circumstances should **AttachThread** be used to forcibly destroy an instance of a class allocated by another thread while a blocking operation is in progress. To cancel a blocking operation, use the **Cancel** method and then delete the class instance after the blocking function exits and control is returned to the current thread.

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.Cancel Method

Cancel the current blocking client operation.

[Visual Basic]

```
Public Sub Cancel()
```

[C#]

```
public void Cancel();
```

Remarks

When the **Cancel** method is called, the blocking client operation will not immediately fail. An internal flag is set which causes the blocking operation to exit with an error. This means that the application cannot cancel an operation and immediately perform some other blocking function. Instead it must allow the calling stack to unwind, returning back to the blocking operation before making any further function calls.

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.ChangeDirectory Method

Change the current working directory on the remote server.

[Visual Basic]
```
Public Function ChangeDirectory( _
   ByVal pathName As String _
) As Boolean
```

[C#]
```
public bool ChangeDirectory(
   string pathName
);
```

Parameters

pathName
A string which specifies the directory on the remote server. The file pathing and name conventions must be that of the server.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.CloseDirectory Method

Close the directory that was previously opened with the OpenDirectory method.

[Visual Basic]

```
Public Function CloseDirectory() As Boolean
```

[C#]

```
public bool CloseDirectory();
```

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

FileTransfer Class | SocketTools Namespace

FileTransfer.Command Method (String)

Send a custom command to the server.

[Visual Basic]

```
Overloads Public Function Command( _
   ByVal command As String _
) As Boolean
```

[C#]

```
public bool Command(
   string command
);
```

Parameters

command

A string which specifies the command to send. Valid commands vary based on the Internet protocol and the type of server that the client is connected to. Consult the protocol standard and/or the technical reference documentation for the server to determine what commands may be issued by a client application.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **Command** method sends a command to the server and processes the result code sent back in response to that command. This method can be used to send custom commands to a server to take advantage of features or capabilities that may not be supported internally by the class library.

To determine the specific status code returned by the server, check the value of the **ResultCode** property after the method returns.

   ByVal command As String, _
   ByVal parameters As String _
) As Boolean
```

[C#]

```
public bool Command(
   string command,
   string parameters
);
```

Parameters

command

A string which specifies the command to send. Valid commands vary based on the Internet protocol and the type of server that the client is connected to. Consult the protocol standard and/or the technical reference documentation for the server to determine what commands may be issued by a client application.

parameters

An string which specifies one or more parameters to be sent along with the command. If more than one parameter is required, they must be separated by a single space character. Consult the protocol standard and/or technical reference documentation for the server to determine what parameters should be provided when issuing a specific command.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **Command** method sends a command to the server and processes the result code sent back in response to that command. This method can be used to send custom commands to a server to take advantage of features or capabilities that may not be supported internally by the class library.

To determine the specific status code returned by the server, check the value of the **ResultCode** property after the method returns.

FileTransfer Class | SocketTools Namespace | ServerName Property | ServerPort Property | ServerType Property | URL Property

FileTransfer.Connect Method ()

Establish a connection with a file server.

[Visual Basic]

```
Overloads Public Function Connect() As Boolean
```

[C#]

```
public bool Connect();
```

Return Value

A boolean value which specifies if the connection has been established. A return value of **true** indicates that the connection has completed and the application may transfer files between the local system and the server. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

Remarks

The **Connect** method is used to establish a connection with the server. It is the first method that must be called prior to the application transferring files or issuing commands to the server. If a connection already exists, the current connection will be closed and a new connection will be established.

It is permissible to specify a complete URL as the first argument to the method and the connection will be established with the server using specified protocol. Passing a complete URL to the **Connect** method has the same effect as setting the **URL** property and then calling the method with no arguments.

FileTransfer.Connect Method (String)

Establish a connection with a file server.

[Visual Basic]

```
Overloads Public Function Connect( _
   ByVal hostName As String _
) As Boolean
```

[C#]

```
public bool Connect(
   string hostName
);
```

Parameters

hostName

A string which specifies the server to establish a connection with. This may specify a host name or an Internet address in dot-notation.

Return Value

A boolean value which specifies if the connection has been established. A return value of **true** indicates that the connection has completed and the application may transfer files between the local system and the server. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

Remarks

The **Connect** method is used to establish a connection with the server. It is the first method that must be called prior to the application transferring files or issuing commands to the server. If a connection already exists, the current connection will be closed and a new connection will be established.

It is permissible to specify a complete URL as the first argument to the method and the connection will be established with the server using specified protocol. Passing a complete URL to the **Connect** method has the same effect as setting the **URL** property and then calling the method with no arguments.

FileTransfer.Connect Method (String, Int32)

Establish a connection with a file server.

```
[Visual Basic]
Overloads Public Function Connect( _
   ByVal hostName As String, _
   ByVal hostPort As Integer _
) As Boolean
```

```
[C#]
public bool Connect(
   string hostName,
   int hostPort
);
```

Parameters

hostName

A string which specifies the server to establish a connection with. This may specify a host name or an Internet address in dot-notation.

hostPort

An integer which specifies the port number for the connection. This value must be greater than zero and the maximum valid port number is 65535.

Return Value

A boolean value which specifies if the connection has been established. A return value of **true** indicates that the connection has completed and the application may transfer files between the local system and the server. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

Remarks

FileTransfer.Connect Method (String, Int32, String, String)

Establish a connection with a file server.

[Visual Basic]

```
Overloads Public Function Connect( _
   ByVal hostName As String, _
   ByVal hostPort As Integer, _
   ByVal userName As String, _
   ByVal userPassword As String _
) As Boolean
```

[C#]

```
public bool Connect(
   string hostName,
   int hostPort,
   string userName,
   string userPassword
);
```

Parameters

hostName
A string which specifies the server to establish a connection with. This may specify a host name or an Internet address in dot-notation.

hostPort
An integer which specifies the port number for the connection. This value must be greater than zero and the maximum valid port number is 65535.

userName
A string which specifies the user name which will be used to authenticate the client session. If the user name is specified as an empty string, then the login is considered to be anonymous.

userPassword
A string which specifies the password which will be used to authenticate the client session. This argument may be an empty string if no password is required for the specified user, or if no username has been specified.

Return Value

A boolean value which specifies if the connection has been established. A return value of **true** indicates that the connection has completed and the application may transfer files between the local system and the server. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

Remarks

The **Connect** method is used to establish a connection with the server. It is the first method that must be called prior to the application transferring files or issuing commands to the server. ```

[C#]

```
public bool Connect(
   string hostName,
   int hostPort,
   string userName,
   string userPassword,
   int timeout
);
```

Parameters

hostName

A string which specifies the server to establish a connection with. This may specify a host name or an Internet address in dot-notation.

hostPort

An integer which specifies the port number for the connection. This value must be greater than zero and the maximum valid port number is 65535.

userName

A string which specifies the user name which will be used to authenticate the client session. If the user name is specified as an empty string, then the login is considered to be anonymous.

userPassword

A string which specifies the password which will be used to authenticate the client session. This argument may be an empty string if no password is required for the specified user, or if no username has been specified.

timeout

An integer value that specifies the number of seconds that the method will wait for the connection to complete before failing the operation and returning to the caller.

Return Value

A boolean value which specifies if the connection has been established. A return value of **true** indicates that the connection has completed and the application may transfer files between the local system and the server. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

Remarks

The **Connect** method is used to establish a connection with the server. It is the first method that must be called prior to the application transferring files or issuing commands to the server.    string userPassword,
   int timeout,
   FileTransferOptions options
);
```

Parameters

hostName

A string which specifies the server to establish a connection with. This may specify a host name or an Internet address in dot-notation.

hostPort

An integer which specifies the port number for the connection. This value must be greater than zero and the maximum valid port number is 65535.

userName

A string which specifies the user name which will be used to authenticate the client session. If the user name is specified as an empty string, then the login is considered to be anonymous.

userPassword

A string which specifies the password which will be used to authenticate the client session. This argument may be an empty string if no password is required for the specified user, or if no username has been specified.

timeout

An integer value that specifies the number of seconds that the method will wait for the connection to complete before failing the operation and returning to the caller.

options

One or more of the FileTransferOptions enumeration flags.

Return Value

A boolean value which specifies if the connection has been established. A return value of **true** indicates that the connection has completed and the application may transfer files between the local system and the server. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

Remarks

The **Connect** method is used to establish a connection with the server. It is the first method that must be called prior to the application transferring files or issuing commands to the server. ```

[C#]

```
public bool Connect(
   string hostName,
   int hostPort,
   string userName,
   string userPassword,
   string userAccount
);
```

Parameters

hostName

A string which specifies the server to establish a connection with. This may specify a host name or an Internet address in dot-notation.

hostPort

An integer which specifies the port number for the connection. This value must be greater than zero and the maximum valid port number is 65535.

userName

A string which specifies the user name which will be used to authenticate the client session. If the user name is specified as an empty string, then the login is considered to be anonymous.

userPassword

A string which specifies the password which will be used to authenticate the client session. This argument may be an empty string if no password is required for the specified user, or if no username has been specified.

userAccount

A string that specifies the account name to be used to authenticate the current client session. This parameter may be an empty string if no account name is required for the specified user.

Return Value

A boolean value which specifies if the connection has been established. A return value of **true** indicates that the connection has completed and the application may transfer files between the local system and the server. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

Remarks

The **Connect** method is used to establish a connection with the server. It is the first method that must be called prior to the application transferring files or issuing commands to the server. If a connection already exists, the current connection will be closed and a new connection will be established.

It is permissible to specify a complete URL as the first argument to the method and the connection will be established with the server using specified protocol. ```
public bool Connect(
   string hostName,
   int hostPort,
   string userName,
   string userPassword,
   string userAccount,
   int timeout
);
```

Parameters

hostName
A string which specifies the server to establish a connection with. This may specify a host name or an Internet address in dot-notation.

hostPort
An integer which specifies the port number for the connection. This value must be greater than zero and the maximum valid port number is 65535.

userName
A string which specifies the user name which will be used to authenticate the client session. If the user name is specified as an empty string, then the login is considered to be anonymous.

userPassword
A string which specifies the password which will be used to authenticate the client session. This argument may be an empty string if no password is required for the specified user, or if no username has been specified.

userAccount
A string that specifies the account name to be used to authenticate the current client session. This parameter may be an empty string if no account name is required for the specified user. Note that this parameter is only used with the File Transfer Protocol.

timeout
An integer value that specifies the number of seconds that the method will wait for the connection to complete before failing the operation and returning to the caller.

Return Value

A boolean value which specifies if the connection has been established. A return value of **true** indicates that the connection has completed and the application may transfer files between the local system and the server. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

Remarks

The **Connect** method is used to establish a connection with the server. It is the first method that must be called prior to the application transferring files or issuing commands to the server. If a connection already exists, the current connection will be closed and a new connection will be established.

It is permissible to specify a complete URL as the first argument to the method and the connection will be established with the server using specified protocol. FileTransfer.Connect Method (String, String, String)

Establish a connection with a file server.

[Visual Basic]

```
Overloads Public Function Connect( _
   ByVal hostName As String, _
   ByVal userName As String, _
   ByVal userPassword As String _
) As Boolean
```

[C#]

```
public bool Connect(
   string hostName,
   string userName,
   string userPassword
);
```

Parameters

hostName

A string which specifies the server to establish a connection with. This may specify a host name or an Internet address in dot-notation.

userName

A string which specifies the user name which will be used to authenticate the client session. If the user name is specified as an empty string, then the login is considered to be anonymous.

userPassword

A string which specifies the password which will be used to authenticate the client session. This argument may be an empty string if no password is required for the specified user, or if no username has been specified.

Return Value

A boolean value which specifies if the connection has been established. A return value of **true** indicates that the connection has completed and the application may transfer files between the local system and the server. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

Remarks

The **Connect** method is used to establish a connection with the server. It is the first method that must be called prior to the application transferring files or issuing commands to the server. If a connection already exists, the current connection will be closed and a new connection will be established.

It is permissible to specify a complete URL as the first argument to the method and the connection will be established with the server using specified protocol. Passing a complete URL to the **Connect** method has the same effect as setting the **URL** property and then calling the method with no arguments.

FileTransfer.DeleteFile Method

Delete a file on the remote server.

[Visual Basic]

```
Public Function DeleteFile( _
   ByVal remoteFile As String _
) As Boolean
```

[C#]

```
public bool DeleteFile(
   string remoteFile
);
```

Parameters

remoteFile

A string which specifies the name of the file on the remote server that is to be deleted. The file pathing and name conventions must be that of the server.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **DeleteFile** method deletes an existing file from the remote server. The user must have the appropriate permission to delete the specified file.

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.Disconnect Method

Terminate the connection with the remote server.

[Visual Basic]
```
Public Sub Disconnect()
```

[C#]
```
public void Disconnect();
```

Remarks

The **Disconnect** method terminates the connection with the remote host and closes the handle allocated by the class. Note that the handle is not immediately released when the connection is terminated and will enter a wait state for two minutes. After the time wait period has elapsed, the handle will be released by the operating system. This is a normal safety mechanism to handle any packets that may arrive after the connection has been closed.

FileTransfer Class | SocketTools Namespace

FileTransfer.Dispose Method

Releases all resources used by FileTransfer.

Overload List

Releases all resources used by FileTransfer.

public void Dispose();

Releases the unmanaged resources allocated by the FileTransfer class and optionally releases the managed resources.

protected virtual void Dispose(bool);

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.Dispose Method ()

Releases all resources used by FileTransfer.

[Visual Basic]

```
NotOverridable Overloads Public Sub Dispose() _
    Implements IDisposable.Dispose
```

[C#]

```
public void Dispose();
```

Implements

IDisposable.Dispose

Remarks

The **Dispose** method terminates any active connection and explicitly releases the resources allocated for this instance of the class. In some cases, better performance can be achieved if the programmer explicitly releases resources when they are no longer being used. The **Dispose** method provides explicit control over these resources.

Unlike the **Uninitialize** method, once the **Dispose** method has been called, that instance of the class cannot be re-initialized and you should not attempt to access class properties or invoke any methods. Note that this method can be called even if other references to the object are active.

See Also

FileTransfer Class | SocketTools Namespace | FileTransfer.Dispose Overload List

FileTransfer.Dispose Method (Boolean)

Releases the unmanaged resources allocated by the FileTransfer class and optionally releases the managed resources.

[Visual Basic]

```
Overridable Overloads Protected Sub Dispose( _
   ByVal disposing As Boolean _
)
```

[C#]

```
protected virtual void Dispose(
   bool disposing
);
```

Parameters

disposing

A boolean value which should be specified as **true** to release both managed and unmanaged resources; **false** to release only unmanaged resources.

Remarks

The **Dispose** method terminates any active connection and explicitly releases the resources allocated for this instance of the class. In some cases, better performance can be achieved if the programmer explicitly releases resources when they are no longer being used. The **Dispose** method provides explicit control over these resources.

Unlike the **Uninitialize** method, once the **Dispose** method has been called, that instance of the class cannot be re-initialized and you should not attempt to access class properties or invoke any methods. Note that this method can be called even if other references to the object are active.

You should call **Dispose** in your derived class when you are finished using the derived class. The **Dispose** method leaves the derived class in an unusable state. After calling **Dispose**, you must release all references to the derived class and the **FileTransfer** class so the memory they were occupying can be reclaimed by garbage collection.

See Also

FileTransfer Class | SocketTools Namespace | FileTransfer.Dispose Overload List

FileTransfer.Finalize Method

Destroys an instance of the class, releasing the resources allocated for the session and unloading the networking library.

[Visual Basic]

```
Overrides Protected Sub Finalize()
```

[C#]

```
protected override void Finalize();
```

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.GetDirectory Method

Return the current working directory.

[Visual Basic]

```
Public Function GetDirectory( _
   ByRef pathName As String _
) As Boolean
```

[C#]

```
public bool GetDirectory(
   ref string pathName
);
```

Parameters

pathName

A string passed by reference which will contain the current working directory on the server when the method returns.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.GetFile Method

Download a file from the server to the local system.

Overload List

Download a file from the server to the local system.

public bool GetFile();

Download a file from the server to the local system.

public bool GetFile(string);

Download a file from the server to the local system.

public bool GetFile(string,string);

Download a file from the server to the local system.

public bool GetFile(string,string,bool);

Download a file from the server to the local system.

public bool GetFile(string,string,long);

Download a file from the server to the local system.

public bool GetFile(string,string,long,bool);

FileTransfer Class | SocketTools Namespace

FileTransfer.GetFile Method ()

Download a file from the server to the local system.

[Visual Basic]

```
Overloads Public Function GetFile() As Boolean
```

[C#]

```
public bool GetFile();
```

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetFile** method copies an existing file from the server to the local system. This method will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

```
Overloads Public Function GetFile( _
   ByVal localFile As String _
) As Boolean
```

[C#]

```
public bool GetFile(
   string localFile
);
```

Parameters

localFile

A string that specifies the file on the local system that will be created, overwritten or appended to. The file pathing and name conventions must be that of the local host.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetFile** method copies an existing file from the server to the local system. This method will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

FileTransfer.GetFile Method (String, String)

Download a file from the server to the local system.

[Visual Basic]

```
Overloads Public Function GetFile( _
   ByVal localFile As String, _
   ByVal remoteFile As String _
) As Boolean
```

[C#]

```
public bool GetFile(
   string localFile,
   string remoteFile
);
```

Parameters

localFile
A string that specifies the file on the local system that will be created, overwritten or appended to. The file pathing and name conventions must be that of the local host.

remoteFile
A string that specifies the file on the remote system that will be transferred to the local system. The file pathing and name conventions must be that of the remote host.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetFile** method copies an existing file from the server to the local system. This method will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

) As Boolean
```

[C#]

```
public bool GetFile(
   string localFile,
   string remoteFile,
   bool appendFile
);
```

Parameters

localFile

A string that specifies the file on the local system that will be created, overwritten or appended to. The file pathing and name conventions must be that of the local host.

remoteFile

A string that specifies the file on the remote system that will be transferred to the local system. The file pathing and name conventions must be that of the remote host.

appendFile

A boolean value which specifies if the contents of the remote file should be appended to the local file, rather than overwriting it. A value of **true** specifies that the local file should be appended to. A value of **false** specifies that the local file should be overwritten. This parameter is only used with the File Transfer Protocol.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetFile** method copies an existing file from the server to the local system. This method will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

See Also

FileTransfer Class | SocketTools Namespace | FileTransfer.GetFile Overload List

FileTransfer.GetFile Method (String, String, Int64)

Download a file from the server to the local system.

[Visual Basic]

```
Overloads Public Function GetFile( _
   ByVal localFile As String, _
   ByVal remoteFile As String, _
   ByVal offset As Long _
) As Boolean
```

[C#]

```
public bool GetFile(
   string localFile,
   string remoteFile,
   long offset
);
```

Parameters

localFile

A string that specifies the file on the local system that will be created, overwritten or appended to. The file pathing and name conventions must be that of the local host.

remoteFile

A string that specifies the file on the remote system that will be transferred to the local system. The file pathing and name conventions must be that of the remote host.

offset

A integer value which specifies the offset where the file transfer should begin. A value of zero specifies that the file transfer should start at the beginning of the file. A value greater than zero is typically used to restart a transfer that has not completed successfully. Note that specifying a non-zero offset requires that the server support the command to restart file transfers.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetFile** method copies an existing file from the server to the local system. This method will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

FileTransfer Class | SocketTools Namespace | FileTransfer.GetFile Overload List

FileTransfer.GetFile Method (String, String, Int64, Boolean)

Download a file from the server to the local system.

[Visual Basic]

```
Overloads Public Function GetFile( _
   ByVal localFile As String, _
   ByVal remoteFile As String, _
   ByVal offset As Long, _
   ByVal appendFile As Boolean _
) As Boolean
```

[C#]

```
public bool GetFile(
   string localFile,
   string remoteFile,
   long offset,
   bool appendFile
);
```

Parameters

localFile
A string that specifies the file on the local system that will be created, overwritten or appended to. The file pathing and name conventions must be that of the local host.

remoteFile
A string that specifies the file on the remote system that will be transferred to the local system. The file pathing and name conventions must be that of the remote host.

offset
A integer value which specifies the offset where the file transfer should begin. A value of zero specifies that the file transfer should start at the beginning of the file. A value greater than zero is typically used to restart a transfer that has not completed successfully. Note that specifying a non-zero offset requires that the server support the command to restart file transfers.

appendFile
A boolean value which specifies if the contents of the remote file should be appended to the local file, rather than overwriting it. A value of **true** specifies that the local file should be appended to. A value of **false** specifies that the local file should be overwritten. This parameter is only used with the File Transfer Protocol.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetFile** method copies an existing file from the server to the local system. This method will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

FileTransfer Class | SocketTools Namespace

FileTransfer.GetFilePermissions Method (FilePermissions)

Return the access permissions for a file on the remote system.

[Visual Basic]

```
Overloads Public Function GetFilePermissions( _
   ByRef filePerms As FilePermissions _
) As Boolean
```

[C#]

```
public bool GetFilePermissions(
   ref FilePermissions filePerms
);
```

Parameters

filePerms

An FilePermissions enumeration value which is passed by reference and set to the file permissions when the method returns.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetFilePermissions** method returns information about the access permissions for a specific file on the server. This method uses the STAT command to retrieve information about the specified file. If the server does not support the use of this command, an error will be returned. You can use the **Features** property to determine what features are available and/or enabled on the server.

Note that on some systems, the STAT command will not return information on files that contain spaces or tabs in the filename. In this case, the method will fail.

FileTransfer Class | SocketTools Namespace | FileTransfer.GetFilePermissions Overload List

FileTransfer.GetFilePermissions Method (String, FilePermissions)

Return the access permissions for a file on the remote system.

[Visual Basic]

```
Overloads Public Function GetFilePermissions( _
   ByVal remoteFile As String, _
   ByRef filePerms As FilePermissions _
) As Boolean
```

[C#]

```
public bool GetFilePermissions(
   string remoteFile,
   ref FilePermissions filePerms
);
```

Parameters

remoteFile

A string that specifies the name of the file that the access permissions are to be returned for. The filename cannot contain any wildcard characters.

filePerms

An FilePermissions enumeration value which is passed by reference and set to the file permissions when the method returns.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetFilePermissions** method returns information about the access permissions for a specific file on the server. This method uses the STAT command to retrieve information about the specified file. If the server does not support the use of this command, an error will be returned. You can use the **Features** property to determine what features are available and/or enabled on the server.

Note that on some systems, the STAT command will not return information on files that contain spaces or tabs in the filename. In this case, the method will fail.

FileTransfer.GetFileSize Method

Returns the size of the specified file on the remote server.

Overload List

Returns the size of the specified file on the remote server.

public bool GetFileSize(ref int);

Returns the size of the specified file on the remote server.

public bool GetFileSize(ref long);

Returns the size of the specified file on the remote server.

public bool GetFileSize(string,ref int);

Returns the size of the specified file on the remote server.

public bool GetFileSize(string,ref long);

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.GetFileSize Method (String, Int32)

Returns the size of the specified file on the remote server.

[Visual Basic]

```
Overloads Public Function GetFileSize( _
   ByVal remoteFile As String, _
   ByRef fileSize As Integer _
) As Boolean
```

[C#]

```
public bool GetFileSize(
   string remoteFile,
   ref int fileSize
);
```

Parameters

remoteFile

A string that specifies the name of the file on the server. The filename cannot contain any wildcard characters and must follow the naming conventions of the operating system the server is hosted on.

fileSize

An integer value which is passed by reference and will specify the size of the file on the server when the method returns.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

This method returns the size of the specified file in bytes. If an FTP connection has been established, the server must support the SIZE command. If this command is not supported, the method will fail. You can use the **Features** property to determine what features are available and/or enabled on the server.

Note that if the file on the server is a text file, it is possible that the value returned by this method will not match the size of the file when it is downloaded to the local system. This is because different operating systems use different sequences of characters to mark the end of a line of text, and when a file is transferred in text mode, the end of line character sequence is automatically converted to a carriage return-linefeed, which is the convention used by the Windows platform.

See Also

FileTransfer Class | SocketTools Namespace | FileTransfer.GetFileSize Overload List

FileTransfer.GetFileSize Method (String, Int64)

Returns the size of the specified file on the remote server.

[Visual Basic]

```
Overloads Public Function GetFileSize( _
   ByVal remoteFile As String, _
   ByRef fileSize As Long _
) As Boolean
```

[C#]

```
public bool GetFileSize(
   string remoteFile,
   ref long fileSize
);
```

Parameters

remoteFile
: A string that specifies the name of the file on the server. The filename cannot contain any wildcard characters and must follow the naming conventions of the operating system the server is hosted on.

fileSize
: An integer value which is passed by reference and will specify the size of the file on the server when the method returns.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

This method returns the size of the specified file in bytes. If an FTP connection has been established, the server must support the SIZE command. If this command is not supported, the method will fail. You can use the **Features** property to determine what features are available and/or enabled on the server.

Note that if the file on the server is a text file, it is possible that the value returned by this method will not match the size of the file when it is downloaded to the local system. This is because different operating systems use different sequences of characters to mark the end of a line of text, and when a file is transferred in text mode, the end of line character sequence is automatically converted to a carriage return-linefeed, which is the convention used by the Windows platform.

FileTransfer Class | SocketTools Namespace | FileTransfer.GetFileSize Overload List

FileTransfer.GetFileStatus Method

[Visual Basic]

```
Public Function GetFileStatus( _
   ByVal remoteFile As String, _
   ByRef fileInfo As FileInformation _
) As Boolean
```

[C#]

```
public bool GetFileStatus(
   string remoteFile,
   ref FileInformation fileInfo
);
```

Parameters

remoteFile

A string which specifies the name of the file that status information is to be returned for.

fileInfo

A FileInformation structure that is passed by reference. When the method returns, the members of this structure will be populated with information about the file on the server.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetFileStatus** method returns information about the specified file. The filename must be specified using the server file naming conventions, and cannot include wildcard characters. The primary difference between using this method and using the **OpenDirectory, GetFirstFile** and **GetNextFile** methods to obtain file information is that the file status information is returned on the command channel. This method cannot be used while a file transfer is in progress or while a file listing is being returned by the server.

This method requires that the server return file status information in response to the STAT command. Some servers, for example on VMS platforms, do not provide this information. On some systems, the STAT command will not return information on files that contain spaces or tabs in the filename. In this case, the method will return an empty structure.

FileTransfer Class | SocketTools Namespace

FileTransfer.GetFileTime Method

Returns the modification date and time for specified file on the remote server.

Overload List

Returns the modification date and time for specified file on the remote server.

public bool GetFileTime(string,ref DateTime);

Returns the modification date and time for specified file on the remote server.

public bool GetFileTime(string,ref DateTime,bool);

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.GetFileTime Method (String, DateTime)

Returns the modification date and time for specified file on the remote server.

[Visual Basic]

```
Overloads Public Function GetFileTime( _
   ByVal remoteFile As String, _
   ByRef fileDate As Date _
) As Boolean
```

[C#]

```
public bool GetFileTime(
   string remoteFile,
   ref DateTime fileDate
);
```

Parameters

remoteFile

A string that specifies the name of the file on the server. The filename cannot contain any wildcard characters and must follow the naming conventions of the operating system the server is hosted on.

fileDate

A **System.DateTime** structure which is passed by reference. When the method returns, this object will be set to the date and time that the file was created or last modified.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

This method uses the MTDM command to determine the modification time for the file. If the server does not support this command, the method will attempt to use the STAT command to determine the file modification time. You can use the **Features** property to determine what features are available and/or enabled on the server.

The value of the Localize property determines if the date and time are adjusted for the local timezone.

FileTransfer Class | SocketTools Namespace | FileTransfer.GetFileTime Overload List

FileTransfer.GetFileTime Method (String, DateTime, Boolean)

Returns the modification date and time for specified file on the remote server.

[Visual Basic]

```
Overloads Public Function GetFileTime( _
   ByVal remoteFile As String, _
   ByRef fileDate As Date, _
   ByVal localDate As Boolean _
) As Boolean
```

[C#]

```
public bool GetFileTime(
   string remoteFile,
   ref DateTime fileDate,
   bool localDate
);
```

Parameters

remoteFile

A string that specifies the name of the file on the server. The filename cannot contain any wildcard characters and must follow the naming conventions of the operating system the server is hosted on.

fileDate

A **System.DateTime** structure which is passed by reference. When the method returns, this object will be set to the date and time that the file was created or last modified.

localDate

A boolean flag which specifies if the date and time for the file should adjusted for the local timezone. A value of **true** specifies that the date and time should be adjusted for the local timezone. A value of **false** specifies that the date and time should be returned as a UTC (Coordinated Universal Time) value.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

This method uses the MTDM command to determine the modification time for the file. If the server does not support this command, the method will attempt to use the STAT command to determine the file modification time. You can use the **Features** property to determine what features are available and/or enabled on the server.

FileTransfer Class | SocketTools Namespace

FileTransfer.GetFirstFile Method (FileInformation)

Get information about the first file in a directory listing returned by the server.

[Visual Basic]

```
Overloads Public Function GetFirstFile( _
   ByRef fileInfo As FileInformation _
) As Boolean
```

[C#]

```
public bool GetFirstFile(
   ref FileInformation fileInfo
);
```

Parameters

fileInfo

A FileInformation structure that is passed by reference. When the method returns, the members of this structure will be populated with information about the file on the server.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

A file listing is initiated by calling the **OpenDirectory** method. Then, the application must call **GetFirstFile**, followed by calling **GetNextFile** in a loop until the method returns **false**. Once the complete directory listing has been returned, the **CloseDirectory** method must be called.

See Also

FileTransfer Class | SocketTools Namespace | FileTransfer.GetFirstFile Overload List

FileTransfer.GetFirstFile Method (String)

Get the first file name in a directory listing returned by the server.

[Visual Basic]

```
Overloads Public Function GetFirstFile( _
   ByRef fileName As String _
) As Boolean
```

[C#]

```
public bool GetFirstFile(
   ref string fileName
);
```

Parameters

fileName
A string passed by reference which will contain a file name when the method returns.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

A file listing is initiated by calling the **OpenDirectory** method. Then, the application must call **GetFirstFile**, followed by calling **GetNextFile** in a loop until the method returns **false**. Once the complete directory listing has been returned, the **CloseDirectory** method must be called.

FileTransfer.GetFirstFile Method (String, Boolean)

Get information about the first file in a directory listing returned by the server.

[Visual Basic]

```
Overloads Public Function GetFirstFile( _
   ByRef fileName As String, _
   ByRef isDirectory As Boolean _
) As Boolean
```

[C#]

```
public bool GetFirstFile(
   ref string fileName,
   ref bool isDirectory
);
```

Parameters

fileName

A string passed by reference which will contain a file name when the method returns.

isDirectory

A boolean passed by reference which will specify if the file is a regular file or a directory. A value of **true** indicates that the file is a directory. A value of **false** indicates that it is a regular file.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

A file listing is initiated by calling the **OpenDirectory** method. Then, the application must call **GetFirstFile**, followed by calling **GetNextFile** in a loop until the method returns **false**. Once the complete directory listing has been returned, the **CloseDirectory** method must be called.

See Also

FileTransfer Class | SocketTools Namespace | FileTransfer.GetFirstFile Overload List

FileTransfer.GetFirstFile Method (String, Int64, Boolean)

Get information about the first file in a directory listing returned by the server.

[Visual Basic]

```
Overloads Public Function GetFirstFile( _
   ByRef fileName As String, _
   ByRef fileSize As Long, _
   ByRef isDirectory As Boolean _
) As Boolean
```

[C#]

```
public bool GetFirstFile(
   ref string fileName,
   ref long fileSize,
   ref bool isDirectory
);
```

Parameters

fileName

A string passed by reference which will contain a file name when the method returns.

fileSize

An integer passed by reference which will contain the size of the file when the method returns.

isDirectory

A boolean passed by reference which will specify if the file is a regular file or a directory. A value of **true** indicates that the file is a directory. A value of **false** indicates that it is a regular file.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

A file listing is initiated by calling the **OpenDirectory** method. Then, the application must call **GetFirstFile**, followed by calling **GetNextFile** in a loop until the method returns **false**. Once the complete directory listing has been returned, the **CloseDirectory** method must be called.

FileTransfer Class | SocketTools Namespace | FileTransfer.GetFirstFile Overload List

FileTransfer.GetMultipleFiles Method

Download multiple files from the server to the local system using a wildcard mask.

[Visual Basic]

```
Public Function GetMultipleFiles( _
   ByVal localPath As String, _
   ByVal remotePath As String, _
   ByVal fileMask As String _
) As Boolean
```

[C#]

```
public bool GetMultipleFiles(
   string localPath,
   string remotePath,
   string fileMask
);
```

Parameters

localPath
A string argument which specifies the name of the directory on the local system where the files will be stored. If a file by the same name already exists, it will be overwritten

remotePath
A string argument which specifies the name of the directory on the remote system where the files will be copied from. You must have permission to read the contents of the directory.

fileMask
An string argument which specifies the wildcard mask to be used when selecting what files should be transferred. Typically, this argument is a wildcard mask that limits the files downloaded from the server to those which match a specific extension.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetMultipleFiles** method copies multiple files from the remote system to the local system. If the local file already exists, it is overwritten. This method will cause the current thread to block until all of the files have been transferred, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

FileTransfer.GetNextFile Method (FileInformation)

Get information about the next file in a directory listing returned by the server.

[Visual Basic]

```
Overloads Public Function GetNextFile( _
   ByRef fileInfo As FileInformation _
) As Boolean
```

[C#]

```
public bool GetNextFile(
   ref FileInformation fileInfo
);
```

Parameters

fileInfo

A FileInformation structure that is passed by reference. When the method returns, the members of this structure will be populated with information about the file on the server.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

A file listing is initiated by calling the **OpenDirectory** method. Then, the application must call **GetFirstFile**, followed by calling **GetNextFile** in a loop until the method returns **false**. Once the complete directory listing has been returned, the **CloseDirectory** method must be called.

FileTransfer.GetNextFile Method (String, Boolean)

Get information about the next file in a directory listing returned by the server.

[Visual Basic]

```
Overloads Public Function GetNextFile( _
   ByRef fileName As String, _
   ByRef isDirectory As Boolean _
) As Boolean
```

[C#]

```
public bool GetNextFile(
   ref string fileName,
   ref bool isDirectory
);
```

Parameters

fileName

A string passed by reference which will contain a file name when the method returns.

isDirectory

A boolean passed by reference which will specify if the file is a regular file or a directory. A value of **true** indicates that the file is a directory. A value of **false** indicates that it is a regular file.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

A file listing is initiated by calling the **OpenDirectory** method. Then, the application must call **GetFirstFile**, followed by calling **GetNextFile** in a loop until the method returns **false**. Once the complete directory listing has been returned, the **CloseDirectory** method must be called.

See Also

FileTransfer Class | SocketTools Namespace | FileTransfer.GetNextFile Overload List

FileTransfer.GetNextFile Method (String, Int64, Boolean)

Get information about the next file in a directory listing returned by the server.

[Visual Basic]

```
Overloads Public Function GetNextFile( _
   ByRef fileName As String, _
   ByRef fileSize As Long, _
   ByRef isDirectory As Boolean _
) As Boolean
```

[C#]

```
public bool GetNextFile(
   ref string fileName,
   ref long fileSize,
   ref bool isDirectory
);
```

Parameters

fileName

A string passed by reference which will contain a file name when the method returns.

fileSize

An integer passed by reference which will contain the size of the file when the method returns.

isDirectory

A boolean passed by reference which will specify if the file is a regular file or a directory. A value of **true** indicates that the file is a directory. A value of **false** indicates that it is a regular file.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

A file listing is initiated by calling the **OpenDirectory** method. Then, the application must call **GetFirstFile**, followed by calling **GetNextFile** in a loop until the method returns **false**. Once the complete directory listing has been returned, the **CloseDirectory** method must be called.

See Also

FileTransfer Class | SocketTools Namespace | FileTransfer.GetNextFile Overload List

FileTransfer.Initialize Method

Initialize an instance of the FileTransfer class.

Overload List

Initialize an instance of the FileTransfer class.

public bool Initialize();

Initialize an instance of the FileTransfer class.

public bool Initialize(string);

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.Initialize Method ()

Initialize an instance of the FileTransfer class.

[Visual Basic]
```
Overloads Public Function Initialize() As Boolean
```

[C#]
```
public bool Initialize();
```

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **Initialize** method can be used to explicitly initialize an instance of the **FileTransfer** class, loading the networking library and allocating resources for the current thread. Typically an application would define the license key as a custom attribute, however this method can be used to initialize the class directly.

The runtime license key for your copy of SocketTools can be generated using the License Manager utility that is included with the product. Note that if you have installed an evaluation license, you will not have a runtime license key and cannot redistribute any applications which use the **FileTransfer** class

See Also

FileTransfer Class | SocketTools Namespace | FileTransfer.Initialize Overload List

FileTransfer.Initialize Method (String)

Initialize an instance of the FileTransfer class.

[Visual Basic]

```
Overloads Public Function Initialize( _
   ByVal licenseKey As String _
) As Boolean
```

[C#]

```
public bool Initialize(
   string licenseKey
);
```

Parameters

licenseKey

A string argument which specifies the runtime license key which will be used to initialize the class library.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **Initialize** method can be used to explicitly initialize an instance of the **FileTransfer** class, loading the networking library and allocating resources for the current thread. Typically an application would define the license key as a custom attribute, however this method can be used to initialize the class directly.

The runtime license key for your copy of SocketTools can be generated using the License Manager utility that is included with the product. Note that if you have installed an evaluation license, you will not have a runtime license key and cannot redistribute any applications which use the **FileTransfer** class

FileTransfer Class | SocketTools Namespace

FileTransfer.Login Method ()

Login to the remote server.

[Visual Basic]
```
Overloads Public Function Login() As Boolean
```

[C#]
```
public bool Login();
```

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **Login** method identifies the user to the remote server. The value of the **UserName** and **Password** properties will be used to authenticate the client session. If the user name or password is invalid, an error will occur. By default, when a connection is established, the user is automatically authenticated. This method is typically used if you wish to log in as another user during the same session.

FileTransfer Class | SocketTools Namespace | FileTransfer.Login Overload List

FileTransfer.Login Method (String, String)

Login to the remote server.

```
[Visual Basic]
Overloads Public Function Login( _
   ByVal userName As String, _
   ByVal userPassword As String _
) As Boolean
```

```
[C#]
public bool Login(
   string userName,
   string userPassword
);
```

Parameters

userName
A string that specifies the name of the user logging into the server.

userPassword
A string that specifies the password used to authenticate the user.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **Login** method identifies the user to the remote server. If the user name or password is invalid, an error will occur. By default, when a connection is established, the **UserName** and **Password** properties are used to automatically log the user in to the server. This method is typically used if you wish to log in as another user during the same session.

FileTransfer.Login Method (String, String, String)

Login to the remote server.

[Visual Basic]

```
Overloads Public Function Login( _
   ByVal userName As String, _
   ByVal userPassword As String, _
   ByVal userAccount As String _
) As Boolean
```

[C#]

```
public bool Login(
   string userName,
   string userPassword,
   string userAccount
);
```

Parameters

userName

A string that specifies the name of the user logging into the server.

userPassword

A string that specifies the password used to authenticate the user.

userAccount

A string that specifies the account name to be used when authenticating the user.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **Login** method identifies the user to the remote server. If the user name or password is invalid, an error will occur. By default, when a connection is established, the **UserName**, **Password** and **Account** properties are used to automatically log the user in to the server. This method is typically used if you wish to log in as another user during the same session.

FileTransfer.Logout Method

Log the current user off the server.

[Visual Basic]
```
Public Function Logout() As Boolean
```

[C#]
```
public bool Logout();
```

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **Logout** method logs the current user off the server. The **Login** method may then be used to login as another user during the same session. Note that this method will not terminate the connection with the server.

FileTransfer Class | SocketTools Namespace

FileTransfer.MakeDirectory Method

Create a new directory on the server.

[Visual Basic]

```
Public Function MakeDirectory( _
   ByVal pathName As String _
) As Boolean
```

[C#]

```
public bool MakeDirectory(
   string pathName
);
```

Parameters

pathName

A string that specifies the name of the directory to create on the server. The naming and pathing conventions used for the directory must be compatible with what is used on the operating system that hosts the server.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

Servers may not support creating multiple subdirectories in a single call, so applications should not assume that this can be done. For example, an error may be returned by the server if the new directory name "/Projects/Today" is specified, but the "/Projects" directory does not already exist.

It is also important to note that files and directories on UNIX based systems are case sensitive, so the directory names "Projects" and "projects" refer to two different directories. This is not the case on Windows systems, where either name would refer to the same directory.

FileTransfer Class | SocketTools Namespace

FileTransfer.OpenDirectory Method

Open the current working directory on the server.

Overload List

Open the current working directory on the server.

public bool OpenDirectory();

Open the specified directory on the server.

public bool OpenDirectory(string);

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.OpenDirectory Method ()

Open the current working directory on the server.

[Visual Basic]

```
Overloads Public Function OpenDirectory() As Boolean
```

[C#]

```
public bool OpenDirectory();
```

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **OpenDirectory** method opens the current working directory on the server so that the list of files in that directory may be obtained using the **GetFirstFile** and **GetNextFile** methods. Once all of the files in the directory have been read, the application must call the **CloseDirectory** method in order to close the data channel to the server. Failure to do this will result in an error the next time the application attempts to transfer a file or open another directory.

FileTransfer Class | SocketTools Namespace | FileTransfer.OpenDirectory Overload List

FileTransfer.OpenDirectory Method (String)

Open the specified directory on the server.

[Visual Basic]

```
Overloads Public Function OpenDirectory( _
   ByVal pathName As String _
) As Boolean
```

[C#]

```
public bool OpenDirectory(
   string pathName
);
```

Parameters

pathName

A string that specifies the name of the directory to open on the server. The naming and pathing conventions used for the directory must be compatible with what is used on the operating system that hosts the server.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **OpenDirectory** method opens the specified directory on the server so that the list of files in that directory may be obtained using the **GetFirstFile** and **GetNextFile** methods. Once all of the files in the directory have been read, the application must call the **CloseDirectory** method in order to close the data channel to the server. Failure to do this will result in an error the next time the application attempts to transfer a file or open another directory.

Note that files and directories on UNIX based systems are case sensitive, so the directory names "Projects" and "projects" refer to two different directories. This is not the case on Windows systems, where either name would refer to the same directory.

Overload List

Post the contents of the specified file to a script executed on the remote server.

public bool PostFile();

Post the contents of the specified file to a script executed on the remote server.

public bool PostFile(string);

Post the contents of the specified file to a script executed on the remote server.

public bool PostFile(string,string);

Post the contents of the specified file to a script executed on the remote server.

public bool PostFile(string,string,string);

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.PostFile Method ()

Post the contents of the specified file to a script executed on the remote server.

[Visual Basic]

```
Overloads Public Function PostFile() As Boolean
```

[C#]

```
public bool PostFile();
```

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **PostFile** method posts the contents of a file to a script that is executed on the server, and can only be used when connected to a web server. This method will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

The **PostFile** method is similar to the **PutFile** method in that it can be used to upload the contents of a local file to a server. However, instead of using the HTTP PUT command, the POST command is used to send the file data to a script that is executed on the server. This method has the advantage of not requiring any special configuration settings on the server, however it does require that the script be able to process multipart/form-data as defined in RFC 2388.

To support uploading files from a form on a webpage, the FILE input type is used along with the action that specifies the script that will accept the file data and process it. For example, the HTML code could look like this:

```
 <form action="/cgi-bin/upload.cgi" method="post" enctype="multipart/form-
data"> <input type="file" name="datafile" size="20"> <input type="submit">
</form>
```

In this example, the script /cgi-bin/upload.cgi is responsible for processing the file data that is posted by the client, and the form field name "datafile" is used. The user can select a file, and when the Submit button is clicked, the file data is posted to the script. To simulate this using the **PostFile** method, the ***fileName*** argument should be set to the name of the local file that is to be posted to the server. The ***resourceName*** argument should be the name of the script, in this case "/cgi-bin/upload.cgi". The ***fieldName*** argument should be specified as the string "datafile" to match the name of the field used by the form.

Note that the **PostFile** function always submits the file contents as multipart/form-data with the content type set to application/octet-stream. The script that accepts the posted data must be able to parse the multipart header block and correctly process 8-bit data. If the script assumes that the data will be posted using a specific encoding type such as base64, then the file data may not be accepted or may be corrupted by the script.

FileTransfer.PostFile Method (String)

Post the contents of the specified file to a script executed on the remote server.

[Visual Basic]

```
Overloads Public Function PostFile( _
   ByVal localFile As String _
) As Boolean
```

[C#]

```
public bool PostFile(
   string localFile
);
```

Parameters

localFile

A string that specifies the file on the local system that will be transferred to the server. The file pathing and name conventions must be that of the local host.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **PostFile** method posts the contents of a file to a script that is executed on the server, and can only be used when connected to a web server. This method will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

The **PostFile** method is similar to the **PutFile** method in that it can be used to upload the contents of a local file to a server. FileTransfer.PostFile Method (String, String)

Post the contents of the specified file to a script executed on the remote server.

[Visual Basic]

```
Overloads Public Function PostFile( _
   ByVal localFile As String, _
   ByVal resourceName As String _
) As Boolean
```

[C#]

```
public bool PostFile(
   string localFile,
   string resourceName
);
```

Parameters

localFile
: A string that specifies the file on the local system that will be transferred to the server. The file pathing and name conventions must be that of the local host.

resourceName
: A string that specifies the resource on the server that the data will be posted to. Typically this is the name of an executable script on the server. The resource name should be specified using an absolute path that begins with a leading slash character.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **PostFile** method posts the contents of a file to a script that is executed on the server, and can only be used when connected to a web server. This method will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

FileTransfer.PostFile Method (String, String, String)

Post the contents of the specified file to a script executed on the remote server.

[Visual Basic]

```
Overloads Public Function PostFile( _
   ByVal localFile As String, _
   ByVal resourceName As String, _
   ByVal fieldName As String _
) As Boolean
```

[C#]

```
public bool PostFile(
   string localFile,
   string resourceName,
   string fieldName
);
```

Parameters

localFile

A string that specifies the file on the local system that will be transferred to the server. The file pathing and name conventions must be that of the local host.

resourceName

A string that specifies the resource on the server that the data will be posted to. Typically this is the name of an executable script on the server. The resource name should be specified using an absolute path that begins with a leading slash character.

fieldName

A string argument that specifies the form field name that the script expects. If this argument is omitted or is an empty string, a default field name of "File1" is used.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **PostFile** method posts the contents of a file to a script that is executed on the server, and can only be used when connected to a web server. This method will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

FileTransfer.PutFile Method (String, String, Boolean)

Upload a file from the local system to the server.

[Visual Basic]
```
Overloads Public Function PutFile( _
   ByVal localFile As String, _
   ByVal remoteFile As String, _
   ByVal appendFile As Boolean _
) As Boolean
```

[C#]
```
public bool PutFile(
   string localFile,
   string remoteFile,
   bool appendFile
);
```

Parameters

localFile
A string that specifies the file on the local system that will be transferred to the server. The file pathing and name conventions must be that of the local host.

remoteFile
A string that specifies the file on the server that will be created, overwritten or appended to. The file pathing and name conventions must be that of the remote host.

appendFile
A boolean value which specifies if the contents of the local file should be appended to the remote file, rather than overwriting it. A value of **true** specifies that the remote file should be appended to. A value of **false** specifies that the remote file should be overwritten. This parameter is only used with the File Transfer Protocol.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **PutFile** method copies an existing file from the local system to the server. This method will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

FileTransfer.PutFile Method (String, String, Int64)

Upload a file from the local system to the server.

[Visual Basic]

```
Overloads Public Function PutFile( _
   ByVal localFile As String, _
   ByVal remoteFile As String, _
   ByVal offset As Long _
) As Boolean
```

[C#]

```
public bool PutFile(
   string localFile,
   string remoteFile,
   long offset
);
```

Parameters

localFile
: A string that specifies the file on the local system that will be transferred to the server. The file pathing and name conventions must be that of the local host.

remoteFile
: A string that specifies the file on the server that will be created, overwritten or appended to. The file pathing and name conventions must be that of the remote host.

offset
: A numeric value which specifies the byte offset where the file transfer should begin. The default value of zero specifies that the file transfer should start at the beginning of the file. A value greater than zero is typically used to restart a transfer that has not completed successfully. Note that specifying a non-zero offset requires that the server support the REST command to restart transfers.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **PutFile** method copies an existing file from the local system to the server. This method will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

) As Boolean
```

[C#]

```
public bool PutFile(
   string localFile,
   string remoteFile,
   long offset,
   bool appendFile
);
```

Parameters

localFile

A string that specifies the file on the local system that will be transferred to the server. The file pathing and name conventions must be that of the local host.

remoteFile

A string that specifies the file on the server that will be created, overwritten or appended to. The file pathing and name conventions must be that of the remote host.

offset

A numeric value which specifies the byte offset where the file transfer should begin. The default value of zero specifies that the file transfer should start at the beginning of the file. A value greater than zero is typically used to restart a transfer that has not completed successfully. Note that specifying a non-zero offset requires that the server support the REST command to restart transfers.

appendFile

A boolean value which specifies if the contents of the local file should be appended to the remote file, rather than overwriting it. A value of **true** specifies that the remote file should be appended to. A value of **false** specifies that the remote file should be overwritten. This parameter is only used with the File Transfer Protocol.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **PutFile** method copies an existing file from the local system to the server. This method will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

See Also

FileTransfer Class | SocketTools Namespace | FileTransfer.PutFile Overload List

FileTransfer.PutMultipleFiles Method

Upload multiple files from the local system to the server using a wildcard mask.

[Visual Basic]

```
Public Function PutMultipleFiles( _
   ByVal localPath As String, _
   ByVal remotePath As String, _
   ByVal fileMask As String _
) As Boolean
```

[C#]

```
public bool PutMultipleFiles(
   string localPath,
   string remotePath,
   string fileMask
);
```

Parameters

localPath
A string argument which specifies the name of the directory on the local system where the files will be copied from. You must have permission to read the contents of the directory.

remotePath
A string argument which specifies the name of the directory on the remote system where the files will be stored. You must have permission to modify the contents of the directory and create files.

fileMask
A string argument which specifies the wildcard mask to be used when selecting what files should be transferred. An empty string indicates that all files in the specified directory should be uploaded. Typically, this argument is a wildcard mask that limits the files uploaded to the server to those which match a specific extension.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **PutMultipleFiles** method copies multiple files from the local system to the remote server. If the remote file already exists, it is overwritten. This method will cause the current thread to block until all of the files have been transferred, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

FileTransfer Class | SocketTools Namespace

FileTransfer.RemoveDirectory Method

Remove a directory on the server.

```
[Visual Basic]
Public Function RemoveDirectory( _
   ByVal pathName As String _
) As Boolean
```

```
[C#]
public bool RemoveDirectory(
   string pathName
);
```

Parameters

pathName

A string that specifies the name of the directory to remove from the server. The naming and pathing conventions used for the directory must be compatible with what is used on the operating system that hosts the server.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **RemoveDirectory** method removes an existing directory on the remote host. You must have the appropriate permission to remove the directory, or an error will occur. Note that most operating systems will not permit you to remove a directory that contains files or other subdirectories.

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.RenameFile Method

Change the name of a file on the server.

[Visual Basic]

```
Public Function RenameFile( _
   ByVal oldName As String, _
   ByVal newName As String _
) As Boolean
```

[C#]

```
public bool RenameFile(
   string oldName,
   string newName
);
```

Parameters

oldName

A string that specifies the name of the file to be renamed on the server. The file must exist on the server, otherwise an error will be returned.

newName

A string that specifies the new name for the file on the server. The naming conventions used for the file must be compatible with what is used on the operating system that hosts the server. Note that some servers may not permit you to rename the file if a file with the new name already exists.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **RenameFile** method changes the name of an existing file on the server to a new name. Note that you must have permission to rename the file or an error will occur. On UNIX based systems this means that you must have write permission to the directory where the file is being renamed.

FileTransfer.Reset Method

Reset the internal state of the object, resetting all properties to their default values.

[Visual Basic]

```
Public Sub Reset()
```

[C#]

```
public void Reset();
```

Remarks

The **Reset** method returns the object to its default state. If a connection to a server has been established, it will be terminated the resources allocated for the client session will be released. All properties will be reset to their default values.

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.SetFilePermissions Method

Change the access permissions for a file on the server.

[Visual Basic]

```
Public Function SetFilePermissions( _
   ByVal remoteFile As String, _
   ByVal filePerms As FilePermissions _
) As Boolean
```

[C#]

```
public bool SetFilePermissions(
   string remoteFile,
   FilePermissions filePerms
);
```

Parameters

remoteFile
A string that specifies the name of the file that the access permissions are to be returned for. The filename cannot contain any wildcard characters.

filePerms
An FilePermissions enumeration which specifies the new permissions for the file.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

This method uses the SITE CHMOD command to set the permissions for the file. This command is typically only supported on servers that are hosted on UNIX based systems. If the command is not supported, an error will be returned. You can use the **Features** property to determine what features are available and/or enabled on the server.

Users who are familiar with the UNIX operating system will recognize the **chmod** command used to change the file permissions. However, it should be noted that the numeric value used as an argument to the command is in octal, not decimal. For example, issuing the command **chmod 644 filename.txt** on a UNIX based system will make the file readable and writable by the owner, and readable by other users in the owner's group as well as all other users. The value 644 is an octal value, which is equivalent to the decimal value 420. If you were to mistakenly specify 644 as the value for the *Permissions* argument, rather than the decimal value of 420, the permissions on the file would be incorrect. It is strongly recommended that you use the enumeration values and do not cast a numeric value as the argument.

Note that Visual Basic allows you to specify an integer value in octal by prefixing it with &O. For example, &O644 could be used as the file permissions value. C# and C++ consider any integer with a preceding 0 to be an octal number, so 0644 would be a valid permissions value.

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.SetFileTime Method

Changes the modification date and time for a file on the server.

[Visual Basic]

```
Public Function SetFileTime( _
   ByVal remoteFile As String, _
   ByVal fileDate As Date _
) As Boolean
```

[C#]

```
public bool SetFileTime(
   string remoteFile,
   DateTime fileDate
);
```

Parameters

remoteFile

A string that specifies the name of the file on the server. The filename cannot contain any wildcard characters and must follow the naming conventions of the operating system the server is hosted on.

fileDate

A **System.DateTime** value that specifies the new date and time for the file.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **SetFileTime** method changes the modification date and time for the specified file on the remote server. This method uses the MTDM command to change the modification time for the file. If the server does not support this command, the method will return an error. Note that some servers only support the MDTM command to return, but not change, the file modification time.

FileTransfer.TaskAbort Method

Abort all asynchronous tasks that are currently active.

Overload List

Abort all asynchronous tasks that are currently active.

public bool TaskAbort();

Abort the specified asynchronous task.

public bool TaskAbort(int);

Abort the specified asynchronous task.

public bool TaskAbort(int,int);

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.TaskAbort Method ()

Abort all asynchronous tasks that are currently active.

[Visual Basic]

```
Overloads Public Function TaskAbort() As Boolean
```

[C#]

```
public bool TaskAbort();
```

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **TaskAbort** method signals all background worker threads created by this instance of the class to abort their current operation and terminate as soon as possible. This version of the method will signal each active task and return immediately to the caller.

The **Reset** and **Uninitialize** methods will abort all active background transfers and wait for those tasks to complete before returning to the caller. It is recommended that your application explicitly wait for background transfers to complete or abort them using this method before allowing the program to terminate. This will ensure that your program can perform any necessary cleanup operations. If there are active background tasks running at the time that the class instance is disposed, it can force the instance to stop those worker threads immediately without waiting for them to terminate gracefully.

See Also

FileTransfer Class | SocketTools Namespace | FileTransfer.TaskAbort Overload List

FileTransfer.TaskAbort Method (Int32)

Abort the specified asynchronous task.

[Visual Basic]

```
Overloads Public Function TaskAbort( _
   ByVal taskId As Integer _
) As Boolean
```

[C#]

```
public bool TaskAbort(
   int taskId
);
```

Parameters

taskId

An integer value that specifies the unique identifier associated with a background task.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **TaskAbort** method signals the background worker thread associated with the task ID to abort the current operation and terminate as soon as possible. This version of the method returns immediately after the background thread has been signaled.

See Also

FileTransfer Class | SocketTools Namespace | FileTransfer.TaskAbort Overload List

FileTransfer.TaskAbort Method (Int32, Int32)

Abort the specified asynchronous task.

[Visual Basic]

```
Overloads Public Function TaskAbort( _
   ByVal taskId As Integer, _
   ByVal timeWait As Integer _
) As Boolean
```

[C#]

```
public bool TaskAbort(
   int taskId,
   int timeWait
);
```

Parameters

taskId

An integer value that specifies the unique identifier associated with a background task.

timeWait

An integer value that specifies the number of milliseconds to wait for the background task to abort.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **TaskAbort** method signals the background worker thread associated with the task ID to abort the current operation and terminate as soon as possible. If the ***timeWait*** parameter has a value of zero, the method returns immediately after the background thread has been signaled. If the ***timeWait*** parameter is non-zero, the method will wait that amount of time for the background thread to terminate.

The **Reset** and **Uninitialize** methods will abort all active background transfers and wait for those tasks to complete before returning to the caller. It is recommended that your application explicitly wait for background transfers to complete or abort them using this method before allowing the program to terminate. This will ensure that your program can perform any necessary cleanup operations. If there are active background tasks running at the time that the class instance is disposed, it can force the instance to stop those worker threads immediately without waiting for them to terminate gracefully.

FileTransfer.TaskDone Method

Determine if the current asynchronous task has completed.

Overload List

Determine if the current asynchronous task has completed.

public bool TaskDone();

Determine if an asynchronous task has completed.

public bool TaskDone(int);

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.TaskDone Method ()

Determine if the current asynchronous task has completed.

[Visual Basic]

```
Overloads Public Function TaskDone() As Boolean
```

[C#]

```
public bool TaskDone();
```

Return Value

This method returns a Boolean value. If the task has finished, the return value is **true**. If the background task is still active, the return value is **false**.

Remarks

The **TaskDone** method is used to determine if the current asynchronous task has completed. This overloaded version of the method is functionally equivalent to providing the value of the **TaskId** property as the unique task identifier.

If you use this method to poll the status of a background task from within the main UI thread, you must ensure that Windows messages are processed so that the application remains responsive to the end-user. To check if a background transfer has completed, it is recommended that you use a timer to periodically call this method rather than calling it repeatedly within a loop.

To determine if the task completed successfully, the **TaskWait** method will provide the last error code associated with the task. Note that if this method returns **true**, it is guaranteed that calling **TaskWait** using the same task ID will return the error code to the caller immediately without causing the current thread to block.

See Also

FileTransfer Class | SocketTools Namespace | FileTransfer.TaskDone Overload List

FileTransfer.TaskDone Method (Int32)

Determine if an asynchronous task has completed.

[Visual Basic]

```
Overloads Public Function TaskDone( _
   ByVal taskId As Integer _
) As Boolean
```

[C#]

```
public bool TaskDone(
   int taskId
);
```

Parameters

taskId

An optional integer value that specifies the unique identifier associated with a background task.

Return Value

This method returns a Boolean value. If the task has finished, the return value is **true**. If the background task is still active, the return value is **false**.

Remarks

The **TaskDone** method is used to determine if the specified asynchronous task has completed.

If you use this method to poll the status of a background task from within the main UI thread, you must ensure that Windows messages are processed so that the application remains responsive to the end-user. To check if a background transfer has completed, it is recommended that you use a timer to periodically call this method rather than calling it repeatedly within a loop.

To determine if the task completed successfully, the **TaskWait** method will provide the last error code associated with the task. Note that if this method returns **true**, it is guaranteed that calling **TaskWait** using the same task ID will return the error code to the caller immediately without causing the current thread to block.

Resume execution of the current asynchronous task.

Overload List

Resume execution of the current asynchronous task.

public bool TaskResume();

Resume execution of an asynchronous task.

public bool TaskResume(int);

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.TaskResume Method ()

Resume execution of the current asynchronous task.

[Visual Basic]

```
Overloads Public Function TaskResume() As Boolean
```

[C#]

```
public bool TaskResume();
```

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **TaskResume** method resumes execution of the current background task that was previously suspended using the **TaskSuspend** method. This overloaded version of the method is functionally equivalent to providing the value of the **TaskId** property as the unique task identifier.

See Also

FileTransfer Class | SocketTools Namespace | FileTransfer.TaskResume Overload List

FileTransfer.TaskResume Method (Int32)

Resume execution of an asynchronous task.

[Visual Basic]

```
Overloads Public Function TaskResume( _
   ByVal taskId As Integer _
) As Boolean
```

[C#]

```
public bool TaskResume(
   int taskId
);
```

Parameters

taskId

An integer value that specifies the unique identifier associated with a background task.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **TaskResume** method resumes execution of the background worker thread that was previously suspended using the **TaskSuspend** method.

See Also

FileTransfer Class | SocketTools Namespace | FileTransfer.TaskResume Overload List

FileTransfer.TaskSuspend Method

Suspend execution of the current asynchronous task.

Overload List

Suspend execution of the current asynchronous task.

public bool TaskSuspend();

Suspend execution of an asynchronous task.

public bool TaskSuspend(int);

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.TaskSuspend Method ()

Suspend execution of the current asynchronous task.

[Visual Basic]

```
Overloads Public Function TaskSuspend() As Boolean
```

[C#]

```
public bool TaskSuspend();
```

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **TaskSuspend** method will suspend execution of the background worker thread associated with the current task. This overloaded version of the method is functionally equivalent to providing the value of the **TaskId** property as the unique task identifier.

Once the task has been suspended, it will no longer be scheduled for execution, however the client session will remain active and the task may be resumed using the **TaskResume** method. Note that if a task is suspended for a long period of time, the background operation may fail because it has exceeded the timeout period imposed by the server.

See Also

FileTransfer Class | SocketTools Namespace | FileTransfer.TaskSuspend Overload List

FileTransfer.TaskSuspend Method (Int32)

Suspend execution of an asynchronous task.

[Visual Basic]

```
Overloads Public Function TaskSuspend( _
   ByVal taskId As Integer _
) As Boolean
```

[C#]

```
public bool TaskSuspend(
   int taskId
);
```

Parameters

taskId

An integer value that specifies the unique identifier associated with a background task.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **TaskSuspend** method will suspend execution of the background worker thread associated with the task.

Once the task has been suspended, it will no longer be scheduled for execution, however the client session will remain active and the task may be resumed using the **TaskResume** method. Note that if a task is suspended for a long period of time, the background operation may fail because it has exceeded the timeout period imposed by the server.

public bool TaskWait();

Wait for an asynchronous task to complete.

public bool TaskWait(int);

Wait for an asynchronous task to complete.

public bool TaskWait(int,int);

Wait for an asynchronous task to complete.

public bool TaskWait(int,int,ref ErrorCode);

Wait for an asynchronous task to complete.

public bool TaskWait(int,int,ref int,ref ErrorCode);

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.TaskWait Method ()

Wait for all asynchronous tasks to complete.

[Visual Basic]
```
Overloads Public Function TaskWait() As Boolean
```

[C#]
```
public bool TaskWait();
```

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

This overloaded version of the **TaskWait** method will cause the current working thread to block until all background tasks created by this instance of the class have completed. If there are no active background tasks, this method will return to the caller immediately.

You should not call this version of the method from the main UI thread. Windows messages will not be processed while this method is blocked waiting for the background tasks to complete, and this can cause your application to appear non-responsive to the end-user. If you have a GUI application and you need to determine if all tasks have completed, create a timer to periodically check the value of the **TaskCount** property. When it returns zero, there are no active background tasks executing.

See Also

FileTransfer Class | SocketTools Namespace | FileTransfer.TaskWait Overload List

FileTransfer.TaskWait Method (Int32)

Wait for an asynchronous task to complete.

[Visual Basic]

```
Overloads Public Function TaskWait( _
   ByVal taskId As Integer _
) As Boolean
```

[C#]

```
public bool TaskWait(
   int taskId
);
```

Parameters

taskId

An integer value that specifies the unique identifier associated with a background task.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **TaskWait** method waits for the specified task to complete. This method will cause the current working thread to block for an indefinite period of time until the task completes. If the specified task has already completed at the time this method is called, the method will return immediately without causing the current thread to block.

You should not call this overloaded version of the method from the main UI thread. Windows messages will not be processed while this method is blocked waiting for the background task to complete, and this can cause your application to appear non-responsive to the end-user. If you have a GUI application and you need to determine if a background task has finished, create a timer to periodically call the **TaskDone** method. When it returns **true** (indicating that the task has completed), you can safely call **TaskWait** to obtain the elapsed time and last error code without blocking the current thread.

See Also

FileTransfer.TaskWait Method (Int32, Int32)

Wait for an asynchronous task to complete.

[Visual Basic]

```
Overloads Public Function TaskWait( _
   ByVal taskId As Integer, _
   ByVal timeWait As Integer _
) As Boolean
```

[C#]

```
public bool TaskWait(
   int taskId,
   int timeWait
);
```

Parameters

taskId

An integer value that specifies the unique identifier associated with a background task.

timeWait

An integer value that specifies the number of milliseconds to wait for the background task to complete.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **TaskWait** method waits for the specified task to complete. This method will cause the current working thread to block until the task completes or the amount of time exceeds the number of milliseconds specified by the caller. If the *timeWait* parameter is zero, then this method will poll the status of the task and return immediately to the caller. If the specified task has already completed at the time this method is called, the method will return immediately without causing the current thread to block.

You should not call this method from the main UI thread with a long timeout period to wait for a background task to complete. Windows messages will not be processed while this method is blocked waiting for the background task to complete, and this can cause your application to appear non-responsive to the end-user. If you have a GUI application and you need to determine if a background task has finished, create a timer to periodically call the **TaskDone** method. When it returns **true** (indicating that the task has completed), you can safely call **TaskWait** to obtain the elapsed time and last error code without blocking the current thread.

FileTransfer Class | SocketTools Namespace | FileTransfer.TaskWait Overload List

FileTransfer.TaskWait Method (Int32, Int32, ErrorCode)

Wait for an asynchronous task to complete.

[Visual Basic]

```
Overloads Public Function TaskWait( _
   ByVal taskId As Integer, _
   ByVal timeWait As Integer, _
   ByRef taskError As ErrorCode _
) As Boolean
```

[C#]

```
public bool TaskWait(
   int taskId,
   int timeWait,
   ref ErrorCode taskError
);
```

Parameters

taskId

An integer value that specifies the unique identifier associated with a background task.

timeWait

An integer value that specifies the number of milliseconds to wait for the background task to complete.

taskError

An ErrorCode value passed by reference that will contain the last error code set by the asynchronous task.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **TaskWait** method waits for the specified task to complete. This method will cause the current working thread to block until the task completes or the amount of time exceeds the number of milliseconds specified by the caller. If the *timeWait* parameter is zero, then this method will poll the status of the task and return immediately to the caller.

If the specified task has already completed at the time this method is called, the method will return immediately without causing the current thread to block. The ***taskError*** parameter will contain the last error code value that was set by the worker thread before it terminated. If the ***taskError*** value is zero, that means that the background task was successful and no error occurred. A non-zero value will indicate that the background task has failed.

You should not call this method from the main UI thread with a long timeout period to wait for a background task to complete. Windows messages will not be processed while this method is blocked waiting for the background task to complete, and this can cause your application to appear non-responsive to the end-user. If you have a GUI application and you need to determine if a background task has finished, create a timer to periodically call the **TaskDone** method. When it returns **true** (indicating that the task has completed), you can safely call **TaskWait** to obtain the elapsed time and last error code without blocking the current thread.

FileTransfer.TaskWait Method (Int32, Int32, Int32, ErrorCode)

Wait for an asynchronous task to complete.

[Visual Basic]

```
Overloads Public Function TaskWait( _
   ByVal taskId As Integer, _
   ByVal timeWait As Integer, _
   ByRef timeElapsed As Integer, _
   ByRef taskError As ErrorCode _
) As Boolean
```

[C#]

```
public bool TaskWait(
   int taskId,
   int timeWait,
   ref int timeElapsed,
   ref ErrorCode taskError
);
```

Parameters

taskId
: An integer value that specifies the unique identifier associated with a background task.

timeWait
: An integer value that specifies the number of milliseconds to wait for the background task to complete.

timeElapsed
: An integer value passed by reference that will contain the elapsed time for the task in milliseconds when the method returns.

taskError
: An ErrorCode value passed by reference that will contain the last error code set by the asynchronous task.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **TaskWait** method waits for the specified task to complete. This method will cause the current working thread to block until the task completes or the amount of time exceeds the number of milliseconds specified by the caller. If the *timeWait* parameter is zero, then this method will poll the status of the task and return immediately to the caller.

If the specified task has already completed at the time this method is called, the method will return immediately without causing the current thread to block. The *timeElapsed* parameter contain the number of milliseconds that it took for the task to complete. The *taskError* parameter will contain the last error code value that was set by the worker thread before it terminated. If the *taskError* value is zero, that means that the background task was successful and no error occurred. A non-zero value will indicate that the background task has failed.

You should not call this method from the main UI thread with a long timeout period to wait for a background task to complete. Windows messages will not be processed while this method is blocked

waiting for the background task to complete, and this can cause your application to appear non-responsive to the end-user. If you have a GUI application and you need to determine if a background task has finished, create a timer to periodically call the **TaskDone** method. When it returns **true** (indicating that the task has completed), you can safely call **TaskWait** to obtain the elapsed time and last error code without blocking the current thread.

FileTransfer.Uninitialize Method

Uninitialize the class library and release any resources allocated for the current thread.

[Visual Basic]

```
Public Sub Uninitialize()
```

[C#]

```
public void Uninitialize();
```

Remarks

The **Uninitialize** method terminates any active connection, releases resources allocated for the current thread and unloads the networking library. After this method has been called, no further network operations may be performed until the class instance has been re-initialized.

If the **Initialize** method is explicitly called by the application, it should be matched by a call to the **Uninitialize** method when that instance of the class is no longer needed.

FileTransfer Class | SocketTools Namespace

FileTransfer.VerifyFile Method (String, String)

Verify that the contents of a file on the local system are the same as the specified file on the server.

[Visual Basic]

```
Overloads Public Function VerifyFile( _
   ByVal localFile As String, _
   ByVal remoteFile As String _
) As Boolean
```

[C#]

```
public bool VerifyFile(
   string localFile,
   string remoteFile
);
```

Parameters

localFile

A string value which specifies the name of the local file.

remoteFile

A string value which specifies the name of the file on the server.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **VerifyFile** method will attempt to verify that the contents of the local and remote files are identical using one of several methods, based on the features that the server supports. Preference will be given to the most reliable method available, using either an MD5 hash, a CRC32 checksum or comparing the size of the file, in that order.

See Also

FileTransfer Class | SocketTools Namespace | FileTransfer.VerifyFile Overload List

FileTransfer.VerifyFile Method (String, String, FileVerifyOptions)

Verify that the contents of a file on the local system are the same as the specified file on the server.

[Visual Basic]

```
Overloads Public Function VerifyFile( _
   ByVal localFile As String, _
   ByVal remoteFile As String, _
   ByVal options As FileVerifyOptions _
) As Boolean
```

[C#]

```
public bool VerifyFile(
   string localFile,
   string remoteFile,
   FileVerifyOptions options
);
```

Parameters

localFile

A string value which specifies the name of the local file.

remoteFile

A string value which specifies the name of the file on the server.

options

An FileVerifyOptions enumeration which specifies one or more options that should be used when comparing the files.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **VerifyFile** method will attempt to verify that the contents of the local and remote files are identical using one of several methods, based on the features that the server supports. Preference will be given to the most reliable method available, using either an MD5 hash, a CRC32 checksum or comparing the size of the file, in that order.

FileTransfer Events

The events of the **FileTransfer** class are listed below. For a complete list of **FileTransfer** class members, see the FileTransfer Members topic.

Public Instance Events

⚡ OnCancel	Occurs when a blocking client operation is canceled.
⚡ OnCommand	Occurs when the client sends a command to the server and receives a reply indicating the result of that command.
⚡ OnError	Occurs when an network operation fails.
⚡ OnGetFile	Occurs when a file download has been initiated.
⚡ OnProgress	Occurs as a data stream is being read or written to the server.
⚡ OnPutFile	Occurs when a file upload is initiated.
⚡ OnTaskBegin	Occurs when an asynchronous task begins execution.
⚡ OnTaskEnd	Occurs when an asynchronous task completes.
⚡ OnTaskRun	Occurs while a background task is active.
⚡ OnTimeout	Occurs when a blocking operation fails to complete before the timeout period elapses.

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.OnCancel Event

Occurs when a blocking client operation is canceled.

[Visual Basic]

```
Public Event OnCancel As EventHandler
```

[C#]

```
public event EventHandler OnCancel;
```

Remarks

The **OnCancel** event is generated when a blocking client operation, such as sending or receiving data, is canceled with the **Cancel** method. To assist in determining which operation was canceled, check the value of the **Status** property.

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.OnCommand Event

Occurs when the client sends a command to the server and receives a reply indicating the result of that command.

[Visual Basic]
```
Public Event OnCommand As OnCommandEventHandler
```

[C#]
```
public event OnCommandEventHandler OnCommand;
```

Event Data

The event handler receives an argument of type FileTransfer.CommandEventArgs containing data related to this event. The following **FileTransfer.CommandEventArgs** properties provide information specific to this event.

Property	Description
ResultCode	Gets a value which specifies the last result code returned by the server.
ResultString	Gets a string value which describes the result of the previous command.

Remarks

The **OnCommand** event is generated when the client receives a reply from the server after some action has been taken.

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.CommandEventArgs Class

Provides data for the OnCommand event.

For a list of all members of this type, see FileTransfer.CommandEventArgs Members.

System.Object
  System.EventArgs
    SocketTools.FileTransfer.CommandEventArgs

[Visual Basic]

```
Public Class FileTransfer.CommandEventArgs
    Inherits EventArgs
```

[C#]

```
public class FileTransfer.CommandEventArgs : EventArgs
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

CommandEventArgs specifies the result code and result string for the last command executed by the server.

The OnCommand event occurs whenever a command is executed on the server.

Requirements

Namespace: SocketTools

Assembly: SocketTools.FileTransfer (in SocketTools.FileTransfer.dll)

FileTransfer.CommandEventArgs overview

Public Instance Constructors

FileTransfer.CommandEventArgs Constructor	Initializes a new instance of the FileTransfer.CommandEventArgs class.

Public Instance Properties

ResultCode	Gets a value which specifies the last result code returned by the server.
ResultString	Gets a string value which describes the result of the previous command.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString (inherited from Object)	Returns a String that represents the current Object.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

FileTransfer.CommandEventArgs Properties

The properties of the **FileTransfer.CommandEventArgs** class are listed below. For a complete list of **FileTransfer.CommandEventArgs** class members, see the FileTransfer.CommandEventArgs Members topic.

Public Instance Properties

ResultCode	Gets a value which specifies the last result code returned by the server.
ResultString	Gets a string value which describes the result of the previous command.

See Also

FileTransfer.CommandEventArgs Class | SocketTools Namespace

FileTransfer.CommandEventArgs.ResultCode Property

Gets a value which specifies the last result code returned by the server.

[Visual Basic]
```
Public ReadOnly Property ResultCode As Integer
```

[C#]
```
public int ResultCode {get;}
```

Property Value

An integer value which specifies the last result code returned by the server.

Remarks

This property should be checked after the **Command** method is used to execute a command on the server to determine if the operation was successful. Result codes are three-digit numeric values returned by the remote server and may be broken down into the following ranges:

ResultCode	Description
100-199	Positive preliminary result. This indicates that the requested action is being initiated, and the client should expect another reply from the server before proceeding.
200-299	Positive completion result. This indicates that the server has successfully completed the requested action.
300-399	Positive intermediate result. This indicates that the requested action cannot complete until additional information is provided to the server.
400-499	Transient negative completion result. This indicates that the requested action did not take place, but the error condition is temporary and may be attempted again.
500-599	Permanent negative completion result. This indicates that the requested action did not take place.

It is important to note that while some result codes have become standardized, not all servers respond to commands using the same result codes. For example, one server may respond with a result code of 221 to indicate success, while another may respond with a value of 235. It is recommended that applications check for ranges of values to determine if a command was successful, not a specific value.

See Also

FileTransfer.CommandEventArgs Class | SocketTools Namespace

FileTransfer.CommandEventArgs.ResultString Property

Gets a string value which describes the result of the previous command.

[Visual Basic]

```
Public ReadOnly Property ResultString As String
```

[C#]

```
public string ResultString {get;}
```

Property Value

A string which describes the result of the previous command executed on the server.

Remarks

This string is generated by the remote server, and typically is used to describe the result code. For example, if an error is indicated by the result code, the result string may describe the condition that caused the error.

FileTransfer.CommandEventArgs Class | SocketTools Namespace

FileTransfer.OnError Event

Occurs when an network operation fails.

[Visual Basic]
```
Public Event OnError As OnErrorEventHandler
```

[C#]
```
public event OnErrorEventHandler OnError;
```

Event Data

The event handler receives an argument of type FileTransfer.ErrorEventArgs containing data related to this event. The following **FileTransfer.ErrorEventArgs** properties provide information specific to this event.

Property	Description
Description	Gets a value which describes the last error that has occurred.
Error	Gets a value which specifies the last error that has occurred.

Remarks

The **OnError** event occurs when a client operation fails.

See Also

FileTransfer Class | SocketTools Namespace

FileTransfer.ErrorEventArgs Class

Provides data for the OnError event.

For a list of all members of this type, see FileTransfer.ErrorEventArgs Members.

System.Object
  System.EventArgs
    SocketTools.FileTransfer.ErrorEventArgs

[Visual Basic]
```
Public Class FileTransfer.ErrorEventArgs
    Inherits EventArgs
```

[C#]
```
public class FileTransfer.ErrorEventArgs : EventArgs
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

ErrorEventArgs specifies the numeric error code and a description of the error that has occurred.

An OnError event occurs when a method fails.

Requirements

Namespace: SocketTools

Assembly: SocketTools.FileTransfer (in SocketTools.FileTransfer.dll)

FileTransfer.OnGetFile Event

Occurs when a file download has been initiated.

[Visual Basic]
```
Public Event OnGetFile As OnGetFileEventHandler
```

[C#]
```
public event OnGetFileEventHandler OnGetFile;
```

Event Data

The event handler receives an argument of type FileTransfer.GetFileEventArgs containing data related to this event. The following **FileTransfer.GetFileEventArgs** properties provide information specific to this event.

Property	Description
LocalFile	Gets a value which specifies the name of the local file.
RemoteFile	Gets a value which specifies the name of the remote file.

Remarks

The **OnGetFile** event is generated when a file transfer is initiated by calling the **GetFile** or **GetMultipleFiles** methods. This will be followed by one or more **OnProgress** events which will indicate the progress of the transfer. If multiple files are being downloaded, this event will fire for each file as it is transferred.

[C#]

```
public class FileTransfer.GetFileEventArgs : EventArgs
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

GetFileEventArgs specifies information about the start of a file transfer from the server to the local system.

The OnGetFile event occurs when either the **GetFile** or **GetMultipleFiles** methods are called.

Requirements

Namespace: SocketTools

Assembly: SocketTools.FileTransfer (in SocketTools.FileTransfer.dll)

[C#]

```
public string RemoteFile {get;}
```

Property Value

A string value which specifies the name of the remote file.

See Also

FileTransfer.GetFileEventArgs Class | SocketTools Namespace

FileTransfer.OnProgress Event

Occurs as a data stream is being read or written to the server.

[Visual Basic]
```
Public Event OnProgress As OnProgressEventHandler
```

[C#]
```
public event OnProgressEventHandler OnProgress;
```

Event Data

The event handler receives an argument of type FileTransfer.ProgressEventArgs containing data related to this event. The following **FileTransfer.ProgressEventArgs** properties provide information specific to this event.

Property	Description
BytesCopied	Gets a value which specifies the number of bytes of data that has been read or written.
FileName	Gets a value which specifies a file name.
FileSize	Gets a value which specifies the size of the file being transferred.
Percent	Gets a value which specifies the percentage of data that has been read or written.

Remarks

The **OnProgress** event occurs as a data stream is being read or written to the server. If large amounts of data are being read or written, this event can be used to update a progress bar or other user-interface component to provide the user with some visual feedback on the progress of the operation.

See Also

[Visual Basic]

```
Public Class FileTransfer.ProgressEventArgs
    Inherits EventArgs
```

[C#]

```
public class FileTransfer.ProgressEventArgs : EventArgs
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

ProgressEventArgs specifies the number of bytes copied from the data stream, the total number of bytes in the data stream and a completion percentage.

The OnProgress event occurs as a data stream is being read or written to the server.

Requirements

Namespace: SocketTools

Assembly: SocketTools.FileTransfer (in SocketTools.FileTransfer.dll)

FileTransfer.ProgressEventArgs Properties

The properties of the **FileTransfer.ProgressEventArgs** class are listed below. For a complete list of **FileTransfer.ProgressEventArgs** class members, see the FileTransfer.ProgressEventArgs Members topic.

Public Instance Properties

BytesCopied	Gets a value which specifies the number of bytes of data that has been read or written.
FileName	Gets a value which specifies a file name.
FileSize	Gets a value which specifies the size of the file being transferred.
Percent	Gets a value which specifies the percentage of data that has been read or written.

See Also

FileTransfer.ProgressEventArgs Class | SocketTools Namespace

FileTransfer.ProgressEventArgs.BytesCopied Property

Gets a value which specifies the number of bytes of data that has been read or written.

[Visual Basic]

```
Public ReadOnly Property BytesCopied As Long
```

[C#]

```
public long BytesCopied {get;}
```

Property Value

An integer value which specifies the number of bytes of data.

Remarks

The **BytesCopied** property specifies the number of bytes that have been read from the server and stored in the local stream buffer, or written from the stream buffer to the server.

See Also

FileTransfer.ProgressEventArgs Class | SocketTools Namespace | FileSize Property | Percent Property

FileTransfer.ProgressEventArgs.FileName Property

Gets a value which specifies a file name.

[Visual Basic]

```
Public ReadOnly Property FileName As String
```

[C#]

```
public string FileName {get;}
```

Property Value

A string value which specifies the name of the file being transferred.

See Also

FileTransfer.ProgressEventArgs Class | SocketTools Namespace

FileTransfer.ProgressEventArgs.FileSize Property

Gets a value which specifies the size of the file being transferred.

[Visual Basic]

```
Public ReadOnly Property FileSize As Long
```

[C#]

```
public long FileSize {get;}
```

Property Value

An integer value which specifies the number of bytes of data.

Remarks

The **FileSize** property specifies the total amount of data being read from the server and written to the local file, or sent from the local system to the server. If the amount of data was unknown or unspecified at the time the method call was made, then this value will always be the same as the **BytesCopied** property.

See Also

FileTransfer.ProgressEventArgs Class | SocketTools Namespace | BytesCopied Property | Percent Property

FileTransfer.ProgressEventArgs.Percent Property

Gets a value which specifies the percentage of data that has been read or written.

[Visual Basic]

```
Public ReadOnly Property Percent As Integer
```

[C#]

```
public int Percent {get;}
```

Property Value

An integer value which specifies a percentage.

Remarks

The **Percent** property specifies the percentage of data that has been transmitted, expressed as an integer value between 0 and 100, inclusive. If the maximum size of the data stream was not specified by the caller, this value will always be 100.

See Also

FileTransfer.ProgressEventArgs Class | SocketTools Namespace | BytesCopied Property | FileSize Property

FileTransfer.OnPutFile Event

Occurs when a file upload is initiated.

[Visual Basic]
```
Public Event OnPutFile As OnPutFileEventHandler
```

[C#]
```
public event OnPutFileEventHandler OnPutFile;
```

Event Data

The event handler receives an argument of type FileTransfer.PutFileEventArgs containing data related to this event. The following **FileTransfer.PutFileEventArgs** properties provide information specific to this event.

Property	Description
LocalFile	Gets a value which specifies the name of the local file.
RemoteFile	Gets a value which specifies the name of the remote file.

Remarks

The **OnPutFile** event is generated when a file transfer is initiated by calling the **PutFile** or **PutMultipleFiles** methods. This will be followed by one or more **OnProgress** events which will indicate the progress of the transfer. If multiple files are being uploaded, this event will fire for each file as it is transferred.

FileTransfer.OnTaskBegin Event

Occurs when an asynchronous task begins execution.

[Visual Basic]

```
Public Event OnTaskBegin As OnTaskBeginEventHandler
```

[C#]

```
public event OnTaskBeginEventHandler OnTaskBegin;
```

Event Data

The event handler receives an argument of type FileTransfer.TaskBeginEventArgs containing data related to this event. The following **FileTransfer.TaskBeginEventArgs** property provides information specific to this event.

Property	Description
TaskId	Get the unique task identifier associated with the event.

Remarks

The **OnTaskBegin** event occurs when a background task associated with an asynchronous file transfer begins executing. This event can be used in conjunction with the **OnTaskEnd** event to monitor one or more background tasks that are created to perform asynchronous file transfers.

This event and the related asynchronous task events are invoked from the context of the thread that is managing the background task, and not the thread that created the class instance. If a handler is implemented for this event, its code will be executing in a different thread than the main UI thread. You should never attempt to update your application's user interface directly from within this event handler. Instead, you must create a delegate and use the **Invoke** method to ensure that any changes to the user interface are done within the context of the main UI thread.

Because background tasks are managed in separate threads, this has the effect of making your application multi-threaded, even if you do not explicitly create any worker threads in your own code. If the code in your event handler modifies a public member variable or shared object, you must ensure that access to that object is synchronized. For example, if your event handler updates a shared instance of a **Hashtable** object, you should ensure that all operations are performed through the thread-safe wrapper returned by the **Synchronized** method for that class. Refer to the MSDN documentation for more information about creating thread-safe applications.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString (inherited from Object)	Returns a String that represents the current Object.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

FileTransfer.TaskBeginEventArgs Properties

The properties of the **FileTransfer.TaskBeginEventArgs** class are listed below. For a complete list of **FileTransfer.TaskBeginEventArgs** class members, see the FileTransfer.TaskBeginEventArgs Members topic.

Public Instance Properties

TaskId	Get the unique task identifier associated with the event.

See Also

FileTransfer.TaskBeginEventArgs Class | SocketTools Namespace

FileTransfer.TaskBeginEventArgs.TaskId Property

Get the unique task identifier associated with the event.

[Visual Basic]

```
Public ReadOnly Property TaskId As Integer
```

[C#]

```
public int TaskId {get;}
```

Property Value

An integer value that uniquely identifies the task that invoked the event handler.

See Also

FileTransfer.TaskBeginEventArgs Class | SocketTools Namespace

FileTransfer.OnTaskEnd Event

Occurs when an asynchronous task completes.

[Visual Basic]
```
Public Event OnTaskEnd As OnTaskEndEventHandler
```

[C#]
```
public event OnTaskEndEventHandler OnTaskEnd;
```

Event Data

The event handler receives an argument of type FileTransfer.TaskEndEventArgs containing data related to this event. The following **FileTransfer.TaskEndEventArgs** properties provide information specific to this event.

Property	Description
Error	Get the last error code for the background task.
TaskId	Get the unique task identifier associated with the event.
TimeElapsed	Gets the amount of time that has elapsed in milliseconds.

Remarks

The **OnTaskEnd** event occurs when a file transfer completes and the background task has terminated. Refer to the **OnTaskBegin** event for additional information about implementing a handler for this event.

See Also

FileTransfer Class | SocketTools Namespace | OnTaskBegin Event | OnTaskRun Event

FileTransfer.TaskEndEventArgs Class

Provides data for the OnTaskEnd event.

For a list of all members of this type, see FileTransfer.TaskEndEventArgs Members.

System.Object
  System.EventArgs
    SocketTools.FileTransfer.TaskEndEventArgs

[Visual Basic]

```
Public Class FileTransfer.TaskEndEventArgs
    Inherits EventArgs
```

[C#]

```
public class FileTransfer.TaskEndEventArgs : EventArgs
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Requirements

Namespace: SocketTools

Assembly: SocketTools.FileTransfer (in SocketTools.FileTransfer.dll)

FileTransfer.TaskEndEventArgs Properties

The properties of the **FileTransfer.TaskEndEventArgs** class are listed below. For a complete list of **FileTransfer.TaskEndEventArgs** class members, see the FileTransfer.TaskEndEventArgs Members topic.

Public Instance Properties

Error	Get the last error code for the background task.
TaskId	Get the unique task identifier associated with the event.
TimeElapsed	Gets the amount of time that has elapsed in milliseconds.

See Also

FileTransfer.TaskEndEventArgs Class | SocketTools Namespace

FileTransfer.TaskEndEventArgs.Error Property

Get the last error code for the background task.

[Visual Basic]

```
Public ReadOnly Property Error As ErrorCode
```

[C#]

```
public FileTransfer.ErrorCode Error {get;}
```

Property Value

An **ErrorCode** enumeration that specifies the last error code set by the background task.

See Also

FileTransfer.TaskEndEventArgs Class | SocketTools Namespace

FileTransfer.TaskEndEventArgs.TaskId Property

Get the unique task identifier associated with the event.

[Visual Basic]

```
Public ReadOnly Property TaskId As Integer
```

[C#]

```
public int TaskId {get;}
```

Property Value

An integer value that uniquely identifies the task that invoked the event handler.

See Also

FileTransfer.TaskEndEventArgs Class | SocketTools Namespace

FileTransfer.TaskEndEventArgs.TimeElapsed Property

Gets the amount of time that has elapsed in milliseconds.

[Visual Basic]

```
Public ReadOnly Property TimeElapsed As Integer
```

[C#]

```
public int TimeElapsed {get;}
```

Property Value

An integer value that specifies the number of milliseconds that the background task has executed.

See Also

FileTransfer.TaskEndEventArgs Class | SocketTools Namespace

FileTransfer.OnTaskRun Event

Occurs while a background task is active.

```
[Visual Basic]
Public Event OnTaskRun As OnTaskRunEventHandler
```

```
[C#]
public event OnTaskRunEventHandler OnTaskRun;
```

Event Data

The event handler receives an argument of type FileTransfer.TaskRunEventArgs containing data related to this event. The following **FileTransfer.TaskRunEventArgs** properties provide information specific to this event.

Property	Description
Completed	Gets an estimate of the progress of the background task.
TaskId	Get the unique task identifier associated with the event.
TimeElapsed	Gets the amount of time that has elapsed in milliseconds.

Remarks

The **OnTaskRun** event is generated periodically during a file transfer while the background task is active. The rate and number of times that this event will be generated depends on the task being performed. This event is generally analogous to the **OnProgress** event for file transfers that are performed in the current working thread, however the **OnTaskRun** event will occur for each individual background task that is active.

Refer to the **OnTaskBegin** event for additional information about implementing a handler for this event.

FileTransfer.TaskRunEventArgs Properties

The properties of the **FileTransfer.TaskRunEventArgs** class are listed below. For a complete list of **FileTransfer.TaskRunEventArgs** class members, see the FileTransfer.TaskRunEventArgs Members topic.

Public Instance Properties

Completed	Gets an estimate of the progress of the background task.
TaskId	Get the unique task identifier associated with the event.
TimeElapsed	Gets the amount of time that has elapsed in milliseconds.

See Also

FileTransfer.TaskRunEventArgs Class | SocketTools Namespace

FileTransfer.TaskRunEventArgs.Completed Property

Gets an estimate of the progress of the background task.

[Visual Basic]

```
Public ReadOnly Property Completed As Integer
```

[C#]

```
public int Completed {get;}
```

Property Value

An integer value that returns a number between 0 and 100 inclusive that specifies the estimated percentage of completion for the task. A value of zero indicates that the task has just begun executing, while a value of 100 indicates that the task is at or near completion.

See Also

FileTransfer.TaskRunEventArgs Class | SocketTools Namespace

FileTransfer.TaskRunEventArgs.TaskId Property

Get the unique task identifier associated with the event.

[Visual Basic]

```
Public ReadOnly Property TaskId As Integer
```

[C#]

```
public int TaskId {get;}
```

Property Value

An integer value that uniquely identifies the task that invoked the event handler.

See Also

FileTransfer.TaskRunEventArgs Class | SocketTools Namespace

FileTransfer.TaskRunEventArgs.TimeElapsed Property

Gets the amount of time that has elapsed in milliseconds.

[Visual Basic]

```
Public ReadOnly Property TimeElapsed As Integer
```

[C#]

```
public int TimeElapsed {get;}
```

Property Value

An integer value that specifies the number of milliseconds that the background task has been executing.

See Also

FileTransfer.TaskRunEventArgs Class | SocketTools Namespace

FileTransfer.OnTimeout Event

Occurs when a blocking operation fails to complete before the timeout period elapses.

[Visual Basic]

```
Public Event OnTimeout As EventHandler
```

[C#]

```
public event EventHandler OnTimeout;
```

Remarks

The **OnTimeout** event occurs when a blocking operation, such as sending or receiving data on the client, fails to complete before the specified timeout period elapses. The timeout period for a blocking operation can be adjusted by setting the **Timeout** property.

FileTransfer.FileInformation Structure

This structure is used by the GetFirstFile and GetNextFile methods to return information about a file on the server.

For a list of all members of this type, see FileTransfer.FileInformation Members.

System.Object
  System.ValueType
    SocketTools.FileTransfer.FileInformation

[Visual Basic]
```
Public Structure FileTransfer.FileInformation
```

[C#]
```
public struct FileTransfer.FileInformation
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Requirements

Namespace: SocketTools

Assembly: SocketTools.FileTransfer (in SocketTools.FileTransfer.dll)

See Also

FileTransfer.FileInformation Members | SocketTools Namespace

FileTransfer.FileInformation Members

FileTransfer.FileInformation overview

Public Instance Fields

FileDate	Specifies the date and time the file was created or last modified.
FileGroup	Specifies the name of the group that owns the file.
FileLinks	Specifies the number of links to the file.
FileName	Specifies the name of the file.
FileOwner	Specifies the name of the file owner.
FilePerms	Specifies the permissions for the file.
FileSize	Specifies the size of the file in bytes.
FileVersion	Specifies the number of revisions made to the file.
IsDirectory	Specifies if the file is a directory or regular file.

Public Instance Methods

Equals (inherited from ValueType)	Indicates whether this instance and a specified object are equal.
GetHashCode (inherited from ValueType)	Returns the hash code for this instance.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString (inherited from ValueType)	Returns the fully qualified type name of this instance.

See Also

FileTransfer.FileInformation Class | SocketTools Namespace

FileTransfer.FileInformation Fields

The fields of the **FileTransfer.FileInformation** structure are listed below. For a complete list of **FileTransfer.FileInformation** structure members, see the FileTransfer.FileInformation Members topic.

Public Instance Fields

FileDate	Specifies the date and time the file was created or last modified.
FileGroup	Specifies the name of the group that owns the file.
FileLinks	Specifies the number of links to the file.
FileName	Specifies the name of the file.
FileOwner	Specifies the name of the file owner.
FilePerms	Specifies the permissions for the file.
FileSize	Specifies the size of the file in bytes.
FileVersion	Specifies the number of revisions made to the file.
IsDirectory	Specifies if the file is a directory or regular file.

See Also

FileTransfer.FileInformation Class | SocketTools Namespace

FileTransfer.FileInformation.FileDate Field

Specifies the date and time the file was created or last modified.

[Visual Basic]
```
Public FileDate As Date
```

[C#]
```
public DateTime FileDate;
```

Remarks

Some file servers may not return a specific time value if the file was last created or modified more than six months ago. In that case, only the date will be returned.

See Also

FileTransfer.FileInformation Class | SocketTools Namespace

FileTransfer.FileInformation.FileGroup Field

Specifies the name of the group that owns the file.

[Visual Basic]

```
Public FileGroup As String
```

[C#]

```
public string FileGroup;
```

See Also

FileTransfer.FileInformation Class | SocketTools Namespace

FileTransfer.FileInformation.FileLinks Field

Specifies the number of links to the file.

[Visual Basic]
```
Public FileLinks As Integer
```

[C#]
```
public int FileLinks;
```

See Also

FileTransfer.FileInformation Class | SocketTools Namespace

FileTransfer.FileInformation.FileName Field

Specifies the name of the file.

[Visual Basic]

```
Public FileName As String
```

[C#]

```
public string FileName;
```

See Also

FileTransfer.FileInformation Class | SocketTools Namespace

FileTransfer.FileInformation.FileOwner Field

Specifies the name of the file owner.

[Visual Basic]

```
Public FileOwner As String
```

[C#]

```
public string FileOwner;
```

See Also

FileTransfer.FileInformation Class | SocketTools Namespace

FileTransfer.FileInformation.FilePerms Field

Specifies the permissions for the file.

[Visual Basic]
```
Public FilePerms As FilePermissions
```

[C#]
```
public FilePermissions FilePerms;
```

Remarks

For those familiar with UNIX, the file permissions are the same as those used by the **chmod** command. For the proprietary Sterling directory formats, a bit map representing the status codes and transfer protocol of the file are stored in this member.

See Also

FileTransfer.FileInformation Class | SocketTools Namespace

FileTransfer.FileInformation.FileSize Field

Specifies the size of the file in bytes.

[Visual Basic]

```
Public FileSize As Long
```

[C#]

```
public long FileSize;
```

See Also

FileTransfer.FileInformation Class | SocketTools Namespace

FileTransfer.FileInformation.FileVersion Field

Specifies the number of revisions made to the file.

[Visual Basic]

```
Public FileVersion As Integer
```

[C#]

```
public int FileVersion;
```

See Also

FileTransfer.FileInformation Class | SocketTools Namespace

FileTransfer.FileInformation.IsDirectory Field

Specifies if the file is a directory or regular file.

[Visual Basic]

```
Public IsDirectory As Boolean
```

[C#]

```
public bool IsDirectory;
```

See Also

FileTransfer.FileInformation Class | SocketTools Namespace

FileTransfer.PortRange Structure

This structure is used by the ActivePorts property which allows the client to specify the port range used for active mode file transfers.

For a list of all members of this type, see FileTransfer.PortRange Members.

System.Object
  System.ValueType
    SocketTools.FileTransfer.PortRange

[Visual Basic]
```
Public Structure FileTransfer.PortRange
```

[C#]
```
public struct FileTransfer.PortRange
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Requirements

Namespace: SocketTools

Assembly: SocketTools.FileTransfer (in SocketTools.FileTransfer.dll)

See Also

FileTransfer.PortRange Members | SocketTools Namespace

FileTransfer.PortRange Members

FileTransfer.PortRange overview

Public Instance Constructors

FileTransfer.PortRange Constructor	Initializes a new instance of the **PortRange** structure with a specified range of port numbers.

Public Instance Fields

HighPort	Specifies the high port number used for active file transfers.
LowPort	Specifies the low port number used for active file transfers.

Public Instance Methods

Equals (inherited from ValueType)	Indicates whether this instance and a specified object are equal.
GetHashCode (inherited from ValueType)	Returns the hash code for this instance.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString (inherited from ValueType)	Returns the fully qualified type name of this instance.

See Also

FileTransfer.PortRange Class | SocketTools Namespace

FileTransfer.PortRange Constructor

Initializes a new instance of the **PortRange** structure with a specified range of port numbers.

[Visual Basic]

```
Public Sub New( _
   ByVal lowPort As Integer, _
   ByVal highPort As Integer _
)
```

[C#]

```
public FileTransfer.PortRange(
   int lowPort,
   int highPort
);
```

Parameters

lowPort

An integer value which specifies the low port number.

highPort

An integer value which specifies the high port number.

Return Value

The minimum port number is 1025 and the maximum port number is 65535. Port numbers outside of this range of values will be silently adjusted.

See Also

FileTransfer.PortRange Class | SocketTools Namespace

FileTransfer.PortRange Fields

The fields of the **FileTransfer.PortRange** structure are listed below. For a complete list of **FileTransfer.PortRange** structure members, see the FileTransfer.PortRange Members topic.

Public Instance Fields

HighPort	Specifies the high port number used for active file transfers.
LowPort	Specifies the low port number used for active file transfers.

See Also

FileTransfer.PortRange Class | SocketTools Namespace

FileTransfer.PortRange.HighPort Field

Specifies the high port number used for active file transfers.

[Visual Basic]

```
Public HighPort As Integer
```

[C#]

```
public int HighPort;
```

Remarks

While this member may be assigned to any integer value, the port range is normalized and the maximum port number that may be used is 65535.

See Also

FileTransfer.PortRange Class | SocketTools Namespace

FileTransfer.PortRange.LowPort Field

Specifies the low port number used for active file transfers.

[Visual Basic]

```
Public LowPort As Integer
```

[C#]

```
public int LowPort;
```

Remarks

While this member may be assigned to any integer value, the port range is normalized and the minimum port number that may be used is 1025.

See Also

FileTransfer.PortRange Class | SocketTools Namespace

FileTransfer.SecureChannel Structure

The structure used to modify or return the current mode for the secure command or data channel.

For a list of all members of this type, see FileTransfer.SecureChannel Members.

System.Object
  System.ValueType
    SocketTools.FileTransfer.SecureChannel

[Visual Basic]
```
Public Structure FileTransfer.SecureChannel
```

[C#]
```
public struct FileTransfer.SecureChannel
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

The **SecureChannel** structure specifies the current channel modes for the client session. This structure is used with the **ChannelMode** property when a secure connection is established with the server.

Requirements

Namespace: SocketTools

Assembly: SocketTools.FileTransfer (in SocketTools.FileTransfer.dll)

See Also

FileTransfer.SecureChannel Members | SocketTools Namespace

FileTransfer.SecureChannel Members

FileTransfer.SecureChannel overview

Public Instance Constructors

FileTransfer.SecureChannel Constructor	Initializes a new instance of the **SecureChannel** structure with the specified values.

Public Instance Fields

Command	Specifies the secure channel mode used when sending commands to the server.
Data	Specifies the secure channel mode used when uploading or downloading files.

Public Instance Methods

Equals (inherited from ValueType)	Indicates whether this instance and a specified object are equal.
GetHashCode (inherited from ValueType)	Returns the hash code for this instance.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString (inherited from ValueType)	Returns the fully qualified type name of this instance.

See Also

FileTransfer.SecureChannel Class | SocketTools Namespace

FileTransfer.SecureChannel Constructor

Initializes a new instance of the **SecureChannel** structure with the specified values.

[Visual Basic]

```
Public Sub New( _
   ByVal commandMode As FtpChannelMode, _
   ByVal dataMode As FtpChannelMode _
)
```

[C#]

```
public FileTransfer.SecureChannel(
   FtpChannelMode commandMode,
   FtpChannelMode dataMode
);
```

Parameters

commandMode

A FtpChannelMode enumeration which specifies the channel mode used for commands sent to the server.

dataMode

A FtpChannelMode enumeration which specifies the channel mode used for file transfers.

See Also

FileTransfer.SecureChannel Class | SocketTools Namespace

FileTransfer.SecureChannel Fields

The fields of the **FileTransfer.SecureChannel** structure are listed below. For a complete list of **FileTransfer.SecureChannel** structure members, see the FileTransfer.SecureChannel Members topic.

Public Instance Fields

◆ Command	Specifies the secure channel mode used when sending commands to the server.
◆ Data	Specifies the secure channel mode used when uploading or downloading files.

See Also

FileTransfer.SecureChannel Class | SocketTools Namespace

FileTransfer.SecureChannel.Command Field

Specifies the secure channel mode used when sending commands to the server.

[Visual Basic]

```
Public Command As FtpChannelMode
```

[C#]

```
public FtpChannelMode Command;
```

See Also

FileTransfer.SecureChannel Class | SocketTools Namespace

FileTransfer.SecureChannel.Data Field

Specifies the secure channel mode used when uploading or downloading files.

[Visual Basic]
```
Public Data As FtpChannelMode
```

[C#]
```
public FtpChannelMode Data;
```

See Also

FileTransfer.SecureChannel Class | SocketTools Namespace

FileTransfer.OnCommandEventHandler Delegate

Represents the method that will handle the OnCommand event.

[Visual Basic]

```
Public Delegate Sub FileTransfer.OnCommandEventHandler( _
   ByVal sender As Object, _
   ByVal e As CommandEventArgs _
)
```

[C#]

```
public delegate void FileTransfer.OnCommandEventHandler(
      object sender,
      CommandEventArgs e
   );
```

Parameters

sender

The source of the event.

e

A CommandEventArgs object that contains the event data.

Remarks

When you create an **OnCommandEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnCommandEventHandler** delegate declaration.

Requirements

Namespace: SocketTools

Assembly: SocketTools.FileTransfer (in SocketTools.FileTransfer.dll)

See Also

SocketTools Namespace

FileTransfer.OnErrorEventHandler Delegate

Represents the method that will handle the OnError event.

[Visual Basic]

```
Public Delegate Sub FileTransfer.OnErrorEventHandler( _
   ByVal sender As Object, _
   ByVal e As ErrorEventArgs _
)
```

[C#]

```
public delegate void FileTransfer.OnErrorEventHandler(
      object sender,
      ErrorEventArgs e
   );
```

Parameters

sender
The source of the event.

e
An ErrorEventArgs object that contains the event data.

Remarks

When you create an **OnErrorEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnErrorEventHandler** delegate declaration.

Requirements

Namespace: SocketTools

Assembly: SocketTools.FileTransfer (in SocketTools.FileTransfer.dll)

See Also

SocketTools Namespace

FileTransfer.OnGetFileEventHandler Delegate

Represents the method that will handle the OnGetFile event.

[Visual Basic]

```
Public Delegate Sub FileTransfer.OnGetFileEventHandler( _
   ByVal sender As Object, _
   ByVal e As GetFileEventArgs _
)
```

[C#]

```
public delegate void FileTransfer.OnGetFileEventHandler(
      object sender,
      GetFileEventArgs e
   );
```

Parameters

sender

The source of the event.

e

A GetFileEventArgs object which contains the event data.

Remarks

When you create an **OnGetFileEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnGetFileEventHandler** delegate declaration.

Requirements

Namespace: SocketTools

Assembly: SocketTools.FileTransfer (in SocketTools.FileTransfer.dll)

See Also

SocketTools Namespace

FileTransfer.OnProgressEventHandler Delegate

Represents the method that will handle the OnProgress event.

[Visual Basic]

```
Public Delegate Sub FileTransfer.OnProgressEventHandler( _
   ByVal sender As Object, _
   ByVal e As ProgressEventArgs _
)
```

[C#]

```
public delegate void FileTransfer.OnProgressEventHandler(
      object sender,
      ProgressEventArgs e
   );
```

Parameters

sender

The source of the event.

e

A ProgressEventArgs object that contains the event data.

Remarks

When you create an **OnProgressEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnProgressEventHandler** delegate declaration.

Requirements

Namespace: SocketTools

Assembly: SocketTools.FileTransfer (in SocketTools.FileTransfer.dll)

See Also

SocketTools Namespace

FileTransfer.OnPutFileEventHandler Delegate

Represents the method that will handle the OnPutFile event.

[Visual Basic]

```
Public Delegate Sub FileTransfer.OnPutFileEventHandler( _
   ByVal sender As Object, _
   ByVal e As PutFileEventArgs _
)
```

[C#]

```
public delegate void FileTransfer.OnPutFileEventHandler(
      object sender,
      PutFileEventArgs e
   );
```

Parameters

sender

The source of the event.

e

A PutFileEventArgs object that contains the event data.

Remarks

When you create an **OnPutFileEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnPutFileEventHandler** delegate declaration.

Requirements

Namespace: SocketTools

Assembly: SocketTools.FileTransfer (in SocketTools.FileTransfer.dll)

See Also

SocketTools Namespace

FileTransfer.FilePermissions Enumeration

Specifies the access permissions for a file on the server.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

```
[Visual Basic]
<Flags>
Public Enum FileTransfer.FilePermissions
```

```
[C#]
[Flags]
public enum FileTransfer.FilePermissions
```

Members

Member Name	Description	Value
symbolicLink	The file is a symbolic link to another file. Symbolic links are special types of files found on UNIX based systems which are similar to Windows shortcuts.	4096
ownerRead	The owner has permission to open the file for reading. If the current user is the owner of the file, this grants the user the right to download the file to the local system.	1024
ownerWrite	The owner has permission to open the file for writing. If the current user is the owner of the file, this grants the user the right to replace the file. If this permission is set for a directory, this grants the user the right to create and delete files.	512
ownerExecute	The owner has permission to execute the contents of the file. The file is typically either a binary executable, script or batch file. If this permission is set for a directory, this may also grant the user the right to open that directory and search for files in that directory.	256
groupRead	Users in the specified group have permission to open the file for reading. If the current user is in the same group as the file owner, this grants the user the right to download the file.	64
groupWrite	Users in the specified group have permission to open the file for writing. On some platforms, this may also imply permission to delete the file. If the current user is in the same group as the	32

	file owner, this grants the user the right to replace the file. If this permission is set for a directory, this grants the user the right to create and delete files.	
groupExecute	Users in the specified group have permission to execute the contents of the file. If this permission is set for a directory, this may also grant the user the right to open that directory and search for files in that directory.	16
worldRead	All users have permission to open the file for reading. This permission grants any user the right to download the file to the local system.	4
worldWrite	All users have permission to open the file for writing. This permission grants any user the right to replace the file. If this permission is set for a directory, this grants any user the right to create and delete files.	2
worldExecute	All users have permission to execute the contents of the file. If this permission is set for a directory, this may also grant all users the right to open that directory and search for files in that directory.	1

FileTransfer.ErrorCode Enumeration

Specifies the error codes returned by the FileTransfer class.

[Visual Basic]
```
Public Enum FileTransfer.ErrorCode
```

[C#]
```
public enum FileTransfer.ErrorCode
```

Remarks

The FileTransfer class uses the **ErrorCode** enumeration to specify what error has occurred when a method fails. The current error code may be determined by checking the value of the **LastError** property.

Note that the last error code is only meaningful if the previous operation has failed.

Members

Member Name	Description
errorNone	No error.
errorNotHandleOwner	Handle not owned by the current thread.
errorFileNotFound	The specified file or directory does not exist.
errorFileNotCreated	The specified file could not be created.
errorOperationCanceled	The blocking operation has been canceled.
errorInvalidFileType	The specified file is a block or character device, not a regular file.
errorInvalidDevice	The specified file type is invalid or not a regular file.
errorTooManyParameters	The maximum number of function parameters has been exceeded.
errorInvalidFileName	The specified file name contains invalid characters or is too long.
errorInvalidFileHandle	Invalid file handle passed to function.
errorFileReadFailed	Unable to read data from the specified file.
errorFileWriteFailed	Unable to write data to the specified file.
errorOutOfMemory	Out of memory.
errorAccessDenied	Access denied.
errorInvalidParameter	Invalid argument passed to function.
errorClipboardUnavailable	The system clipboard is currently unavailable.
errorClipboardEmpty	The system clipboard is empty or does not contain any text data.
errorFileEmpty	The specified file does not contain any data.
errorFileExists	The specified file already exists.

errorEndOfFile	End of file.
errorDeviceNotFound	The specified device could not be found.
errorDirectoryNotFound	The specified directory could not be found.
errorInvalidbuffer	Invalid memory address passed to function.
errorBufferTooSmall	The specified buffer is not large enough to contain the data.
errorNoHandles	No more handles are available to this process.
errorOperationWouldBlock	The specified operation would block the current thread.
errorOperationInProgress	A blocking operation is currently in progress.
errorAlreadyInProgress	The specified operation is already in progress.
errorInvalidHandle	Invalid handle passed to function.
errorInvalidAddress	Invalid network address specified.
errorInvalidSize	Datagram is too large to fit in specified buffer.
errorInvalidProtocol	Invalid network protocol specified.
errorProtocolNotAvailable	The specified network protocol is not available.
errorProtocolNotSupported	The specified protocol is not supported.
errorSocketNotSupported	The specified socket type is not supported.
errorInvalidOption	The specified option is invalid.
errorProtocolFamily	Specified protocol family is not supported.
errorProtocolAddress	The specified address is invalid for this protocol family.
errorAddressInUse	The specified address is in use by another process.
errorAddressUnavailable	The specified address cannot be assigned.
errorNetworkUnavailable	The networking subsystem is unavailable.
errorNetworkUnreachable	The specified network is unreachable.
errorNetworkReset	Network dropped connection on remote reset.
errorConnectionAborted	Connection was aborted due to timeout or other failure.
errorConnectionReset	Connection was reset by remote network.
errorOutOfBuffers	No buffer space is available.
errorAlreadyConnected	Connection already established with remote host.
errorNotConnected	No connection established with remote host.
errorConnectionShutdown	Unable to send or receive data after connection shutdown.
errorOperationTimeout	The specified operation has timed out.
errorConnectionRefused	The connection has been refused by the remote host.

errorHostUnavailable	The specified host is unavailable.
errorHostUnreachable	Remote host is unreachable.
errorTooManyProcesses	Too many processes are using the networking subsystem.
errorTooManyThreads	Too many threads have been created by the current process.
errorTooManySessions	Too many client sessions have been created by the current process.
errorInternalFailure	An unexpected internal error has occurred.
errorNetworkNotReady	Network subsystem is not ready for communication.
errorInvalidVersion	This version of the operating system is not supported.
errorNetworkNotInitialized	The networking subsystem has not been initialized.
errorRemoteShutdown	The remote host has initiated a graceful shutdown sequence.
errorInvalidHostName	The specified hostname is invalid or could not be resolved.
errorHostNameNotFound	The specified hostname could not be found.
errorHostNameRefused	Unable to resolve hostname, request refused.
errorHostNameNotResolved	Unable to resolve hostname, no address for specified host.
errorInvalidLicense	The license for this product is invalid.
errorProductNotLicensed	This product is not licensed to perform this operation.
errorNotImplemented	This function has not been implemented on this platform.
errorUnknownLocalhost	Unable to determine local host name.
errorInvalidHostAddress	Invalid host address specified.
errorInvalidServicePort	Invalid service port number specified.
errorInvalidServiceName	Invalid or unknown service name specified.
errorInvalidEventId	Invalid event identifier specified.
errorOperationNotBlocking	No blocking operation in progress on this socket.
errorSecurityNotInitialized	Unable to initialize security interface for this process.
errorSecurityContext	Unable to establish security context for this session.
errorSecurityCredentials	Unable to open certificate store or establish security credentials.
errorSecurityCertificate	Unable to validate the certificate chain for this

	session.
errorSecurityDecryption	Unable to decrypt data stream.
errorSecurityEncryption	Unable to encrypt data stream.
errorOperationNotSupported	The specified operation is not supported.
errorInvalidProtocolVersion	Invalid application protocol version specified.
errorNoServerResponse	No data returned from server.
errorInvalidServerResponse	Invalid data returned from server.
errorUnexpectedServerResponse	Unexpected response code returned from server.
errorServerTransactionFailed	Server transaction failed.
errorServiceUnavailable	The service is currently unavailable.
errorServiceNotReady	The service is not ready, try again later.
errorServerResyncFailed	Unable to resynchronize with server.
errorInvalidProxyType	Invalid proxy server type specified.
errorProxyRequired	Resource must be accessed through specified proxy.
errorInvalidProxyLogin	Unable to login to proxy server using specified credentials.
errorProxyResyncFailed	Unable to resynchronize with proxy server.
errorInvalidCommand	Invalid command specified.
errorInvalidCommandParameter	Invalid command parameter specified.
errorInvalidCommandSequence	Invalid command sequence specified.
errorCommandNotImplemented	Specified command not implemented on this server.
errorCommandNotAuthorized	Specified command not authorized for the current user.
errorCommandAborted	Specified command was aborted by the remote host.
errorOptionNotSupported	The specified option is not supported on this server.
errorRequestNotCompleted	The current client request has not been completed.
errorInvalidUserName	The specified username is invalid.
errorInvalidPassword	The specified password is invalid.
errorInvalidAccount	The specified account name is invalid.
errorAccountRequired	Account name has not been specified.
errorInvalidAuthenticationType	Invalid authentication protocol specified.
errorAuthenticationRequired	User authentication is required.
errorProxyAuthenticationRequired	Proxy authentication required.

errorAlreadyAuthenticated	User has already been authenticated.
errorAuthenticationFailed	Unable to authenticate the specified user.
errorNetworkAdapter	Unable to determine network adapter configuration.
errorInvalidRecordType	Invalid record type specified.
errorInvalidRecordName	Invalid record name specified.
errorInvalidRecordData	Invalid record data specified.
errorConnectionOpen	Data connection already established.
errorConnectionClosed	Server closed data connection.
errorConnectionPassive	Data connection is passive.
errorConnectionFailed	Unable to open data connection to server.
errorInvalidSecurityLevel	Data connection cannot be opened with this security setting.
errorCachedTLSRequired	Data connection requires cached TLS session.
errorDataReadOnly	Data connection is read-only.
errorDataWriteOnly	Data connection is write-only.
errorEndOfData	End of data.
errorRemoteFileUnavailable	Remote file is unavailable.
errorInsufficientStorage	Insufficient storage on server.
errorStorageallocation	File exceeded storage allocation on server.
errorDirectoryExists	The specified directory already exists.
errorDirectoryEmpty	No files returned by the server for the specified directory.
errorEndOfDirectory	End of directory listing.
errorUnknownDirectoryFormat	Unknown directory format.
errorInvalidResource	Invalid resource name specified.
errorResourceRedirected	The specified resource has been redirected.
errorResourceRestricted	Access to this resource has been restricted.
errorResourceNotModified	The specified resource has not been modified.
errorResourceNotFound	The specified resource cannot be found.
errorResourceConflict	Request could not be completed due to the current state of the resource.
errorResourceRemoved	The specified resource has been permanently removed from this server.
errorContentLengthRequired	Request must include the content length.
errorRequestPrecondition	Request could not be completed due to server precondition.
errorUnsupportedMediaType	Request specified an unsupported media type.

errorInvalidContentRange	Content range specified for this resource is invalid.
errorInvalidMessagePart	Message is not multipart or an invalid message part was specified.
errorInvalidMessageHeader	The specified message header is invalid or has not been defined.
errorInvalidMessageBoundary	The multipart message boundary has not been defined.
errorNoFileAttachment	The current message part does not contain a file attachment.
errorUnknownFileType	The specified file type could not be determined.
errorDataNotEncoded	The specified data block could not be encoded.
errorDataNotDecoded	The specified data block could not be decoded.
errorFileNotEncoded	The specified file could not be encoded.
errorFileNotDecoded	The specified file could not be decoded.
errorNoMessageText	No message text.
errorInvalidCharacterSet	Invalid character set specified.
errorInvalidEncodingType	Invalid encoding type specified.
errorInvalidMessageNumber	Invalid message number specified.
errorNoReturnAddress	No valid return address specified.
errorNoValidRecipients	No valid recipients specified.
errorInvalidRecipient	The specified recipient address is invalid.
errorRelayNotAuthorized	The specified domain is invalid or server will not relay messages.
errorMailboxUnavailable	Specified mailbox is currently unavailable.
errorMailboxReadOnly	The selected mailbox cannot be modified.
errorMailboxNotSelected	No mailbox has been selected.
errorInvalidMailbox	Specified mailbox is invalid.
errorInvalidDomain	The specified domain name is invalid or not recognized.
errorInvalidSender	The specified sender address is invalid or not recognized.
errorMessageNotDelivered	Message not delivered to any of the specified recipients.
errorEndOfMessageData	No more message data available to be read
errorInvalidmessageSize	The specified message size is invalid.
errorMessageNotCreated	The message could not be created in the specified mailbox.
errorNoMoreMailboxes	No more mailboxes exist on this server.

errorInvalidEmulationType	The specified terminal emulation type is invalid.
errorInvalidFontHandle	The specified font handle is invalid.
errorInvalidFontName	The specified font name is invalid or unavailable.
errorInvalidPacketSize	The specified packet size is invalid.
errorInvalidPacketData	The specified packet data is invalid.
errorInvalidPacketId	The unique packet identifier is invalid.
errorPacketTTLExpired	The specified packet time-to-live period has expired.
errorInvalidNewsGroup	Invalid newsgroup specified.
errorNoNewsgroupSelected	No newsgroup selected.
errorEmptyNewsgroup	No articles in specified newsgroup.
errorInvalidArticle	Invalid article number specified.
errorNoArticleSelected	No article selected in the current newsgroup.
errorFirstArticle	First article in current newsgroup.
errorLastArticle	Last article in current newsgroup.
errorArticleExists	Unable to transfer article, article already exists.
errorArticleRejected	Unable to transfer article, article rejected.
errorArticleTransferFailed	Article transfer failed.
errorArticlePostingDenied	Posting is not permitted on this server.
errorArticlePostingFailed	Unable to post article on this server.
errorInvalidDateFormat	The specified date format is not recognized.
errorFeatureNotSupported	The specified feature is not supported on this server.
errorInvalidFormHandle	The specified form handle is invalid or a form has not been created.
errorInvalidFormAction	The specified form action is invalid or has not been specified.
errorInvalidFormMethod	The specified form method is invalid or not supported.
errorInvalidFormType	The specified form type is invalid or not supported.
errorInvalidFormField	The specified form field name is invalid or does not exist.
errorEmptyForm	The specified form does not contain any field values.
errorMaximumConnections	The maximum number of client connections exceeded.
errorThreadCreationFailed	Unable to create a new thread for the current process.
errorInvalidThreadHandle	The specified thread handle is no longer valid.

errorThreadTerminated	The specified thread has been terminated.
errorThreadDeadlock	The operation would result in the current thread becoming deadlocked.
errorInvalidClientMoniker	The specified moniker is not associated with any client session.
errorClientMonikerExists	The specified moniker has been assigned to another client session.
errorServerInactive	The specified server is not listening for client connections.
errorServerSuspended	The specified server is suspended and not accepting client connections.
errorNoMessageStore	No message store has been specified.
errorMessageStoreChanged	The message store has changed since it was last accessed.
errorMessageNotFound	No message was found that matches the specified criteria.
errorMessageDeleted	The specified message has been deleted.
errorFileChecksumMismatch	The local and remote file checksums do not match.
errorFileSizeMismatch	The local and remote file sizes do not match.
errorInvalidFeedUrl	The news feed URL is invalid or specifies an unsupported protocol.
errorInvalidFeedFormat	The internal format of the news feed is invalid.
errorInvalidFeedVersion	This version of the news feed is not supported.
errorChannelEmpty	There are no valid items found in this news feed.
errorInvalidItemNumber	The specified channel item identifier is invalid.
errorItemNotFound	The specified channel item could not be found.
errorItemEmpty	The specified channel item does not contain any data.
errorInvalidItemProperty	The specified item property name is invalid.
errorItemPropertyNotFound	The specified item property has not been defined.
errorInvalidChannelTitle	The channel title is invalid or has not been defined.
errorInvalidChannelLink	The channel hyperlink is invalid or has not been defined.
errorInvalidChannelDescription	The channel description is invalid or has not been defined.
errorInvalidItemText	The description for an item is invalid or has not been defined.
errorInvalidItemLink	The hyperlink for an item is invalid or has not been defined.

errorInvalidServiceType	The specified service type is invalid.
errorServiceSuspended	Access to the specified service has been suspended.
errorServiceRestricted	Access to the specified service has been restricted.
errorInvalidProviderName	The specified provider name is invalid or unknown.
errorInvalidPhoneNumber	The specified phone number is invalid or not supported in this region.
errorGatewayNotFound	A message gateway cannot be found for the specified provider.
errorMessageTooLong	The message exceeds the maximum number of characters permitted.
errorInvalidProviderData	The request returned invalid or incomplete service provider data.
errorInvalidGatewayData	The request returned invalid or incomplete message gateway data.
errorMultipleProviders	The request has returned multiple service providers.
errorProviderNotFound	The specified service provider could not be found.
errorInvalidMessageService	The specified message is not supported with this service type.
errorInvalidMessageFormat	The specified message format is invalid.
errorInvalidConfiguration	The specified configuration options are invalid.
errorServerActive	The requested action is not permitted while the server is active.
errorServerPortBound	Unable to obtain exclusive use of the specified local port.
errorInvalidClientSession	The specified client identifier is invalid for this session.
errorClientNotIdentified	The specified client has not provided user credentials.
errorInvalidClientState	The requested action cannot be performed at this time.
errorInvalidResultCode	The specified result code is not valid for this protocol
errorCommandRequired	The specified command is required and cannot be disabled.
errorCommandDisabled	The specified command has been disabled.
errorCommandSequence	The command cannot be processed at this time.
errorCommandCompleted	The previous command has completed.
errorInvalidProgramName	The specified program name is invalid or unrecognized.

errorInvalidRequestHeader	The request header contains one or more invalid values.
errorInvalidVirtualHost	The specified virtual host name is invalid.
errorVirtualHostNotFound	The specified virtual host does not exist.
errorTooManyVirtualHosts	Too many virtual hosts created for this server.
errorInvalidVirtualPath	The specified virtual path name is invalid.
errorVirtualPathNotFound	The specified virtual path does not exist.
errorTooManyVirtualPaths	Too many virtual paths created for this server.
errorInvalidTask	The asynchronous task identifier is invalid.
errorTaskActive	The asynchronous task has not finished.
errorTaskQueued	The asynchronous task has been queued.
errorTaskSuspended	The asynchronous task has been suspended.
errorTaskFinished	The asynchronous task has finished.

SocketTools Namespace | LastError Property | LastErrorString Property | OnError Event

FileTransfer.FileServerType Enumeration

Specifies the type of server that the client is connected to.

[Visual Basic]

```
Public Enum FileTransfer.FileServerType
```

[C#]

```
public enum FileTransfer.FileServerType
```

Members

Member Name	Description
serverUnknown	The server type has not been explicitly set. The server type will be automatically determined by the value of the remote file URL or the service port number specified by the value of the **ServerPort** property.
serverFtp	The File Transfer Protocol is used when establishing a connection to the server.
serverHttp	The Hypertext Transfer Protocol is used when establishing a connection to the server.

Requirements

Namespace: SocketTools

Assembly: SocketTools.FileTransfer (in SocketTools.FileTransfer.dll)

See Also

SocketTools Namespace | ServerType Property (SocketTools.FileTransfer)

FileTransfer.FileTransferOptions Enumeration

Specifies the options that the FileTransfer class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]

```
<Flags>
Public Enum FileTransfer.FileTransferOptions
```

[C#]

```
[Flags]
public enum FileTransfer.FileTransferOptions
```

Remarks

The FileTransfer class uses the **FileTransferOptions** enumeration to specify one or more options to be used when establishing a connection with a remote host. Multiple options may be specified if necessary.

Members

Member Name	Description	Value
optionNone	No option specified.	0
optionDefault	The default connection option. This is the same as specifying **optionPassive**.	1
optionPassive	This option specifies the client should attempt to establish a passive connection to the server. This means that instead of the client opening a port on the local system and waiting for the server to establish a connection back to the client, the client will establish a second data connection to the server. This mode is recommended for most systems that are behind a NAT router or firewall.	1
optionSecure	This option specifies the client should attempt to establish a secure connection with the server. Note that the server must support secure connections using either the SSL or TLS protocol. This option specifies the client should attempt to establish a secure connection with the server. Note that the server must support secure connections using either the SSL or TLS protocol.	4096
optionImplicitSSL	This option specifies the client should attempt to establish a secure implicit SSL session. The SSL handshake is initiated immediately after the	4096

	connection to the server has been established.	
optionExplicitSSL	This option specifies the client should attempt to establish a secure explicit SSL session. The initial connection to the server is not encrypted, and the client will attempt to negotiate a secure connection by sending a command to the server. Some servers may require this option when connecting to the server on ports other than the default secure port of 990.	8192
optionSecureShell	This option specifies the client should attempt to establish a secure connection using the Secure Shell (SSH) protocol. This option is automatically selected if the connection is established on port 22, the standard port for SSH connections. It is only necessary to specify this option if the SSH connection must be established on a non-standard port.	16384
optionSecureFallback	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will permit connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.	32768
optionFreeThread	This option specifies that class methods may be called from any thread, and not only the thread that established the connection. Using this option disables certain internal safety checks that are made by the class and may result in unexpected behavior unless you ensure that access to the class instance is synchronized across multiple threads.	524288
optionHiResTimer	This option specifies that elapsed time values should be returned in milliseconds rather than seconds. This option is intended to provide greater accuracy with smaller file transfers over a high speed network connection.	1048576
optionTLSReuse	This option specifies that TLS session reuse should be enabled when establishing a secure FTP connection. This option is only supported on Windows 8.1 or Windows Server 2012	2097152

	R2 and later platforms, and it should only be used when explicitly required by the server. This option is not compatible with servers built using OpenSSL 1.0.2 and earlier versions which do not provide Extended Master Secret (EMS) support as outlined in RFC7627.

FileTransfer.FileTransferPriority Enumeration

Specifies the transfer priorities that the FileTransfer class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]

```
<Flags>
Public Enum FileTransfer.FileTransferPriority
```

[C#]

```
[Flags]
public enum FileTransfer.FileTransferPriority
```

Members

Member Name	Description	Value
priorityBackground	This priority significantly reduces the memory, processor and network resource utilization for the transfer. It is typically used with worker threads running in the background when the amount of time required perform the transfer is not critical.	0
priorityLow	This priority lowers the overall resource utilization for the transfer and meters the bandwidth allocated for the transfer. This priority will increase the average amount of time required to complete a file transfer.	1
priorityNormal	The default priority which balances resource utilization and transfer speed. It is recommended that most applications use this priority.	2
priorityHigh	This priority increases the overall resource utilization for the transfer, allocating more memory for internal buffering. It can be used when it is important to transfer the file quickly, and there are no other threads currently performing file transfers at the time.	3
priorityCritical	This priority can significantly increase processor, memory and network utilization while attempting to transfer the file as quickly as possible. If the file transfer is being performed in the main UI thread, this priority can cause the application to appear to become non-responsive. No events will be generated during the transfer.	4

priorityInvalid	An invalid transfer priority which indicates an error condition.	-1
priorityDefault	The default transfer priority. This is the same as specifying **priorityNormal**.	2
priorityLowest	The lowest valid transfer priority. This is the same as specifying **priorityBackground**.	0
priorityHighest	The highest valid transfer priority. This is the same as specifying **priorityCritical**.	4

Requirements

Namespace: SocketTools

Assembly: SocketTools.FileTransfer (in SocketTools.FileTransfer.dll)

SocketTools Namespace

FileTransfer.FileTransferProxy Enumeration

Specifies the type of proxy server that is being used by the FileTransfer class.

[Visual Basic]
```
Public Enum FileTransfer.FileTransferProxy
```

[C#]
```
public enum FileTransfer.FileTransferProxy
```

Members

Member Name	Description
proxyNone	No proxy server is being used. This is the default value.
proxyFtpUser	The client is not logged into the proxy server. The USER command is sent in the format username@ftpsite followed by the password. This is the format used with the Gauntlet proxy server.
proxyFtpLogin	The client is logged into the FTP proxy server. The USER command is then sent in the format username@ftpsite followed by the password. This is the format used by the InterLock proxy server.
proxyFtpOpen	The client is not logged into the FTP proxy server. The OPEN command is sent specifying the host name, followed by the username and password.
proxyFtpSite	The client is logged into the FTP server. The SITE command is sent, specifying the host name, followed by the username and the password.
proxyFtpOther	This special proxy type specifies that another, undefined FTP proxy server is being used. The client connects to the proxy host, but does not attempt to authenticate the client. The application is responsible for negotiating with the proxy server, typically using the Command property to send specific command sequences.
proxyHttpStandard	A standard HTTP connection is established through the specified proxy server, and all resource requests will be specified using a complete URL. This proxy type should be used with standard HTTP connections.
proxyHttpSecure	A secure HTTP connection is established through the specified proxy server. This proxy type should only be used with secure connections and the Secure property should also be set to a value of true.
proxyHttpWindows	The configuration options for the current system should be used. These options are found in the

	Network and Internet settings for Windows.

Requirements

SocketTools Namespace

FileTransfer.FileTransferType Enumeration

Specifies the type of file being transferred.

[Visual Basic]
```
Public Enum FileTransfer.FileTransferType
```

[C#]
```
public enum FileTransfer.FileTransferType
```

Members

Member Name	Description
fileAuto	The file type should be automatically determined based on the file name extension. If the file extension is unknown, the file type should be determined based on the contents of the file. The class has an internal list of common text file extensions, and additional file extensions can be registered using the **AddFileType** method.
fileAscii	The file being transferred is an ASCII text file. The characters the mark the end of a line (for example, a carriage return/linefeed pair under MS-DOS) are automatically converted to the format used by the target operating system.
fileEbcdic	The file being transferred is a text file created using the EBCDIC character set. If a file is being copied to a remote system, the ASCII characters are automatically converted to EBCDIC. If the file is being retrieved from a remote system, the EBCDIC characters are automatically converted to ASCII.
fileImage	The file is transferred without any modification. This is the default file transfer type, and should be used when transferring binary (non-text) data.
fileText	The same value as **fileAscii**.
fileBinary	The same value as **fileImage**.

FileTransfer.FtpChannelMode Enumeration

Specifies the channel mode specified by setting the ChannelMode property.

[Visual Basic]

```
Public Enum FileTransfer.FtpChannelMode
```

[C#]

```
public enum FileTransfer.FtpChannelMode
```

Members

Member Name	Description
channelClear	Data sent and received on this channel should not be encrypted.
channelSecure	Data sent and received on this channel should be encrypted. Specifying this option requires that a secure connection has already been established with the server.

Requirements

Namespace: SocketTools

Assembly: SocketTools.FileTransfer (in SocketTools.FileTransfer.dll)

SocketTools Namespace

FileTransfer.FtpChannelType Enumeration

Specifies the channel used by the ChannelMode property.

[Visual Basic]
```
Public Enum FileTransfer.FtpChannelType
```

[C#]
```
public enum FileTransfer.FtpChannelType
```

Members

Member Name	Description
channelCommand	The communication channel used to send commands to the server and receive command result and status information from the server.
channelData	The communication channel used to send or receive data during a file transfer.

Requirements

Namespace: SocketTools

Assembly: SocketTools.FileTransfer (in SocketTools.FileTransfer.dll)

See Also

SocketTools Namespace

FileTransfer.FtpDirectoryFormat Enumeration

A value which specifies the format of a directory listing returned by the server.

[Visual Basic]
```
Public Enum FileTransfer.FtpDirectoryFormat
```

[C#]
```
public enum FileTransfer.FtpDirectoryFormat
```

Remarks

Values other than **formatAuto** should only be set if the class library cannot automatically determine the directory format returned by the server. The default directory format is determined both by the server's operating system and by analyzing the format of the data returned by the server. If the class is unable to automatically determine the format, it will attempt to parse the list of files as though it is a UNIX style listing.

Members

Member Name	Description
formatAuto	This value specifies that the control should automatically determine the format of the file lists returned by the server. It is recommended that most applications use this value and allow the control to automatically determine the appropriate file listing format used by the server.
formatUnix	This value specifies that the server returns file lists in the format commonly used by UNIX servers. Note that many servers can be configured to return file listings in this format, even if they are not actually a UNIX based platform. Consult the technical reference documentation for your server for more information.
formatMsdos	This value specifies that the server returns file lists in the format commonly used by MS-DOS based systems. This includes Windows NT servers. Long file names will be returned if supported by the underlying filesystem, such as NTFS or FAT32.
formatVms	This value specifies that the server returns file lists in the format commonly used by VMS servers. Note that VMS servers can be configured to return a standard UNIX style listing in additional to the default VMS format.
formatSterling1	This value specifies that the server returns file listings in a proprietary format used by the Sterling server, which is used for EDI (Electronic Data Interchange) applications. This format uses a 13 byte status code.
formatSterling2	This value specifies that the server returns file

	listings in a proprietary format used by the Sterling server, which is used for EDI (Electronic Data Interchange) applications. This format uses a 10 byte status code.
formatNetware	This value specifies that the server returns file listings in a proprietary format used by NetWare servers. The format is similar to UNIX style listings except that file access and permissions are indicated by letter codes enclosed in brackets. This is the default format selected if the server identifies itself as a NetWare system.
formatMlsd	This value specifies that the server should return file listings in a machine-independent format as defined by RFC 3659. This format specifies file information as a sequence of name and value pairs, with the same format being used regardless of the operating system that the server is hosted on. Note that not all servers support this format, and some proxy servers may reject the command even if the remote server supports its use.

SocketTools Namespace

FileTransfer.FtpFeatures Enumeration

Specifies the server features that are available for the current client session.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]
```
<Flags>
Public Enum FileTransfer.FtpFeatures
```

[C#]
```
[Flags]
public enum FileTransfer.FtpFeatures
```

Remarks

When a client connection is first established, all features are enabled by default. However, as the client issues commands to the server, if the server reports that the command is unrecognized that feature will automatically be disabled in the client.

For example, the first time an application calls the **GetFileSize** method to determine the size of a file, the class library will try to use the SIZE command. If the server reports that the SIZE command is not available, that feature will be disabled and the class will not use the command again during the session unless it is explicitly re-enabled. This is designed to prevent the class from repeatedly sending invalid commands to a server, which may result in the server aborting the connection.

Members

Member Name	Description	Value
featureSIZE	The server supports the SIZE command to determine the size of a file. If this feature is not enabled, the library will attempt to use the STAT command to determine the file size.	1
featureSTAT	The server supports using the STAT command to return information about a specific file. If this feature is not enabled, the client may not be able to obtain information about a specific file such as its size, permissions or modification time.	2
featureMDTM	The server supports the MDTM command to obtain information about the modification time for a specific file. This command may also be used to set the file time on the server.	4
featureREST	The server supports restarting file transfers using the REST command. If this feature is not enabled, the client will not be able to restart file transfers and must upload or download the complete file.	8

featureSITE	The server supports site specific commands using the SITE command. If this feature is not enabled, no site specific commands will be sent to the server.	16
featureIDLE	The server supports setting the idle timeout period using the SITE IDLE command to specify the number of seconds that the client may idle before the server terminates the connection.	32
featureCHMOD	The server supports modifying the permissions of a specific file using the SITE CHMOD command. If this feature is not enabled, the client will not be able to set the permissions for a file.	64
featureAUTH	The server supports explicit SSL sessions using the AUTH command. If this feature is not enabled, the client will only be able to connect to a secure server that uses implicit SSL connections. Changing this feature has no effect on standard, non-secure connections.	128
featurePBSZ	The server supports the PBSZ command which specifies the buffer size used with secure data connections. If this feature is disabled, it may prevent the client from changing the protection level on the data channel. Changing this feature has no effect on standard, non-secure connections.	256
featurePROT	The server supports the PROT command which specifies the protection level for the data channel. If this feature is disabled, the client will be unable to change the protection level on the data channel. Changing this feature has no effect on standard, non-secure connections.	512
featureCCC	The server supports the CCC command which returns the command channel to a non-secure mode. Changing this feature has no effect on standard, non-secure connections.	1024
featureHOST	The server supports the HOST command which enables a client to specify the hostname after establishing a connection with a server that supports virtual hosting.	2048

featureMLST	The server supports the MLST command which returns status information for files. If this feature is enabled, the MLST command will be used instead of the STAT command.	4096
featureMFMT	The server supports the MFMT command which is used to change the last modification time for a file. If this command is supported, it is used instead of the MDTM command to change the modification time for a file.	8192
featureXCRC	The server supports the XCRC command which returns the CRC32 checksum for the contents of a specified file. This command is used for file verification.	16384
featureXMD5	The server supports the XMD5 command which returns an MD5 hash for the contents of a specified file. This command is used for file verification.	32768
featureLANG	The server supports the LANG command which sets the language used for the current client session. Command responses and file naming conventions will use the specified language.	65536
featureUTF8	The server supports the OPTS UTF-8 command which specifies UTF-8 encoding when specifying filenames. This feature is typically used in conjunction with setting the default language for the client session.	131072
featureXQUOTA	The server supports the XQUOTA command which returns quota information for the current client session.	262144
featureUTIME	The server supports the UTIME command which is used to change the last modification time for a specified file.	524288

FileTransfer.HttpVersion Enumeration

Specifies the protocol versions supported by the FileTransfer class.

[Visual Basic]

```
Public Enum FileTransfer.HttpVersion
```

[C#]

```
public enum FileTransfer.HttpVersion
```

Remarks

The FileTransfer class uses the **HttpVersion** enumeration to specify the protocol version to be used when establishing a connection to the server.

Members

Member Name	Description
version09	Version 0.9 of the protocol. This value specifies that the client should use the preliminary protocol version which only supports the use of the GET command. Header fields are not supported with this version of the protocol.
version10	Version 1.0 of the protocol.
version11	Version 1.1 of the protocol.

Requirements

Namespace: SocketTools

Assembly: SocketTools.FileTransfer (in SocketTools.FileTransfer.dll)

FileTransfer.SecureCipherAlgorithm Enumeration

Specifies the encryption algorithms that the FileTransfer class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]

```
<Flags>
Public Enum FileTransfer.SecureCipherAlgorithm
```

[C#]

```
[Flags]
public enum FileTransfer.SecureCipherAlgorithm
```

Remarks

The FileTransfer class uses the **SecureCipherAlgorithm** enumeration to identify which encryption algorithm was selected when a secure connection was established with the server.

Members

Member Name	Description	Value
cipherNone	No cipher has been selected. A secure connection has not been established with the server.	0
cipherRC2	The RC2 block cipher was selected. This is a variable key length cipher which supports keys between 40- and 128-bits in length, in 8-bit increments.	1
cipherRC4	The RC4 stream cipher was selected. This is a variable key length cipher which supports keys between 40- and 128-bits in length, in 8-bit increments.	2
cipherRC5	The RC5 block cipher was selected. This is a variable key length cipher which supports keys up to 2040 bits, in 8-bit increments.	4
cipherDES	The DES (Data Encryption Standard) block cipher was selected. This is a fixed key length cipher using 56-bit keys.	8
cipherDES3	The Triple DES block cipher was selected. This cipher encrypts the data three times using different keys, effectively using a 168-bit key length.	16
cipherDESX	A variant of the DES block cipher which XORs an extra 64-bits of the key before and after the plaintext has been encrypted, increasing the key size to 184 bits.	32
cipherAES	The Advanced Encryption Standard	64

	cipher (also known as the Rijndael cipher) is a fixed block size cipher which use a key size of 128, 192 or 256 bits. This cipher is supported on Windows XP SP3 SP3 and later versions of the operating system.	
cipherSkipjack	The Skipjack block cipher was selected. This is a fixed key length cipher, using 80-bit keys.	128
cipherBlowfish	The Blowfish block cipher was selected. This is a variable key length cipher up to 448 bits, using a 64-bit block size.	256

FileTransfer.SecureHashAlgorithm Enumeration

Specifies the hash algorithms that the FileTransfer class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]

```
<Flags>
Public Enum FileTransfer.SecureHashAlgorithm
```

[C#]

```
[Flags]
public enum FileTransfer.SecureHashAlgorithm
```

Remarks

The FileTransfer class uses the **SecureHashAlgorithm** enumeration to identify the message digest (hash) algorithm that was selected when a secure connection was established with the server.

Members

Member Name	Description	Value
hashNone	No hash algorithm has been selected. This is not a secure connection with the server.	0
hashMD5	The MD5 algorithm was selected. This algorithm produces a 128-bit message digest. This algorithm is no longer considered to be cryptographically secure.	1
hashSHA	The SHA-1 algorithm was selected. This algorithm produces a 160-bit message digest. This algorithm is no longer considered to be cryptographically secure.	2
hashSHA256	The SHA-256 algorithm was selected. This algorithm produces a 256-bit message digest.	4
hashSHA384	The SHA-384 algorithm was selected. This algorithm produces a 384-bit message digest.	8
hashSHA512	The SHA-512 algorithm was selected. This algorithm produces a 512-bit message digest.	16

FileTransfer.SecureKeyAlgorithm Enumeration

Specifies the key exchange algorithms that the FileTransfer class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

```
[Visual Basic]
<Flags>
Public Enum FileTransfer.SecureKeyAlgorithm
```

```
[C#]
[Flags]
public enum FileTransfer.SecureKeyAlgorithm
```

Remarks

The FileTransfer class uses the **SecureKeyAlgorithm** enumeration to identify the key exchange algorithm that was selected when a secure connection was established with the server.

Members

Member Name	Description	Value
keyExchangeNone	No key exchange algorithm has been selected. This is not a secure connection with the server.	0
keyExchangeRSA	The RSA public key exchange algorithm has been selected.	1
keyExchangeKEA	The KEA public key exchange algorithm has been selected. This is an improved version of the Diffie-Hellman public key algorithm.	2
keyExchangeDH	The Diffie-Hellman public key exchange algorithm has been selected.	4
keyExchangeECDH	The Elliptic Curve Diffie-Hellman key exchange algorithm was selected. This is a variant of the Diffie-Hellman algorithm which uses elliptic curve cryptography. This key exchange algorithm is only supported on Windows XP SP3 SP3 and later versions of the operating system.	8

Requirements

Namespace: SocketTools

Assembly: SocketTools.FileTransfer (in SocketTools.FileTransfer.dll)

FileTransfer.SecurityCertificate Enumeration

Specifies the security certificate status values that may be returned by the FileTransfer class.

[Visual Basic]

```
Public Enum FileTransfer.SecurityCertificate
```

[C#]

```
public enum FileTransfer.SecurityCertificate
```

Remarks

The FileTransfer class uses the **SecurityCertificate** enumeration to identify the current status of the certificate that was provided by the server when a secure connection was established.

Members

Member Name	Description
certificateNone	No certificate information is available. A secure connection was not established with the server.
certificateValid	The certificate is valid.
certificateNoMatch	The certificate is valid, however the domain name specified in the certificate does not match the domain name of the server. The application can examine the **CertificateSubject** property to determine the site the certificate was issued to.
certificateExpired	The certificate has expired and is no longer valid. The application can examine the **CertificateExpires** property to determine when the certificate expired.
certificateRevoked	The certificate has been revoked and is no longer valid. It is recommended that the application immediately terminate the connection if this status is returned.
certificateUntrusted	The certificate has not been issued by a trusted authority, or the certificate is not trusted on the local host. It is recommended that the application immediately terminate the connection if this status is returned.
certificateInvalid	The certificate is invalid. This typically indicates that the internal structure of the certificate is damaged. It is recommended that the application immediately terminate the connection if this status is returned.

Requirements

Namespace: SocketTools

Assembly: SocketTools.FileTransfer (in SocketTools.FileTransfer.dll)

SocketTools Namespace

FileTransfer.SecurityProtocols Enumeration

Specifies the security protocols that the FileTransfer class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

```
[Visual Basic]
<Flags>
Public Enum FileTransfer.SecurityProtocols
```

```
[C#]
[Flags]
public enum FileTransfer.SecurityProtocols
```

Remarks

The FileTransfer class uses the **SecurityProtocols** enumeration to specify one or more security protocols to be used when establishing a connection with a server. Multiple protocols may be specified if necessary and the actual protocol used will be negotiated with the server. It is recommended that most applications use **protocolDefault** when creating a secure connection.

Members

Member Name	Description	Value
protocolNone	No security protocol will be used, a secure connection will not be established.	0
protocolSSL2	The SSL 2.0 protocol has been selected. This protocol has been deprecated and is no longer widely used. It is not recommended that this protocol be used when establishing secure connections.	1
protocolSSL3	The SSL 3.0 protocol has been selected. This protocol has been deprecated and is no longer widely used. It is not recommended that this protocol be used when establishing secure connections. In most cases, this protocol is only selected if TLS is not supported by the server.	2
protocolTLS10	The TLS 1.0 protocol has been selected. This version of the protocol is commonly used by older servers and is the only version of TLS supported on Windows platforms prior to Windows 7 SP1 and Windows Server 2008 R2.	4
protocolTLS11	The TLS 1.1 protocol has been selected. This version of TLS is supported on Windows 7 SP1 and Windows Server 2008 R2 and later versions of the	8

	operating system.	
protocolTLS12	The TLS 1.2 protocol has been selected. This is the default version of the protocol and is supported on Windows 7 SP1 and Windows Server 2008 R2 and later versions of Windows. It is recommended that you use this version of TLS.	16
protocolSSH1	The Secure Shell 1.0 protocol has been selected. This version of the protocol has been deprecated and is no longer widely used. It is not recommended that this version of the protocol be used to establish a connection.	256
protocolSSH2	The Secure Shell 2.0 protocol has been selected. This is the most commonly used version of the protocol. It is recommended that this version of the protocol be used unless the server explicitly requires the client to use an earlier version.	512
protocolSSL	Any version of the Secure Sockets Layer (SSL) protocol should be used. The actual protocol version used will be negotiated with the remote host.	3
protocolTLS	Any version of the the Transport Layer Security (TLS) protocol should be used. The actual protocol version used will be negotiated with the remote host, with with preference for TLS 1.2.	28
protocolTLS1	Version 1.0, 1.1 or 1.2 of the the Transport Layer Security (TLS) protocol should be used. The actual protocol version used will be negotiated with the remote host, with preference for TLS 1.2.	28
protocolSSH	Any version of the the Secure Shell (SSH) protocol should be used. The actual protocol version used will be negotiated with the remote host.	768
protocolDefault	The default selection of security protocols will be used when establishing a connection. The TLS 1.2, 1.1 and 1.0 protocols will be negotiated with the host, in that order of preference. This option will always request the latest version of the preferred security protocols and is the recommended	16

	value.	
protocolUnknown	An unknown or unsupported security protocol has been specified. This value indicates an error condition.	4096

Requirements

Namespace: SocketTools

Assembly: SocketTools.FileTransfer (in SocketTools.FileTransfer.dll)

SocketTools Namespace

FileTransfer.TraceOptions Enumeration

Specifies the logging options that the FileTransfer class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

```
[Visual Basic]
<Flags>
Public Enum FileTransfer.TraceOptions
```

```
[C#]
[Flags]
public enum FileTransfer.TraceOptions
```

Remarks

The FileTransfer class uses the **TraceOptions** enumeration to specify what kind of debugging information is written to the trace logfile. These options are only meaningful when trace logging is enabled by setting the **Trace** property to **true**.

Members

Member Name	Description	Value
traceDefault	The default trace logging option. This is the same as specifying the **traceInfo** option.	0
traceInfo	All network function calls are written to the trace file. This is the default value.	0
traceError	Only those network function calls which fail are recorded in the trace file.	1
traceWarning	Only those network function calls which fail, or return values which indicate a warning, are recorded in the trace file.	2
traceHexDump	All network function calls are written to the trace file, plus all the data that is sent or received is displayed, in both ASCII and hexadecimal format.	4
traceProcess	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for multithreaded applications that are using worker threads.	4096

Requirements

Namespace: SocketTools

Assembly: SocketTools.FileTransfer (in SocketTools.FileTransfer.dll)

SocketTools Namespace

FileTransfer.RuntimeLicenseAttribute Class

Attribute that defines the runtime license key for the class.

For a list of all members of this type, see FileTransfer.RuntimeLicenseAttribute Members.

System.Object
  System.Attribute
    SocketTools.FileTransfer.RuntimeLicenseAttribute

[Visual Basic]

```
<AttributeUsage(ValidOn:=AttributeTargets.Assembly, AllowMultiple:=False,
   Inherited:=True)>
Public Class FileTransfer.RuntimeLicenseAttribute
    Inherits Attribute
```

[C#]

```
[AttributeUsage(ValidOn=AttributeTargets.Assembly, AllowMultiple=False,
   Inherited=True)]
public class FileTransfer.RuntimeLicenseAttribute : Attribute
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

The RuntimeLicense attribute is used to define the runtime license key that will be used when an instance of the class is created. This attribute is defined in the assembly information module for the language, such as AssemblyInfo.cs when programming C#. The runtime license key must be defined if you wish to redistribute your application.

The runtime license key for your copy of SocketTools can be generated using the License Manager utility that is included with the product. Note that if you have installed an evaluation license, you will not have a runtime license key and cannot redistribute any applications which use the FileTransfer class.

Example

```
<Assembly: SocketTools.FileTransfer.RuntimeLicense("abcdefghijklmnop")>
```

```
[assembly: SocketTools.FileTransfer.RuntimeLicense("abcdefghijklmnop")]
```

Requirements

Namespace: SocketTools

Assembly: SocketTools.FileTransfer (in SocketTools.FileTransfer.dll)

FileTransfer.RuntimeLicenseAttribute Members

FileTransfer.RuntimeLicenseAttribute overview

Public Instance Constructors

FileTransfer.RuntimeLicenseAttribute Constructor	Constructor for the RuntimeLicense attribute which defines the runtime license key.

Public Instance Properties

LicenseKey	Returns the value of the runtime license key.
TypeId (inherited from Attribute)	When implemented in a derived class, gets a unique identifier for this Attribute.

Public Instance Methods

Equals (inherited from Attribute)	
GetHashCode (inherited from Attribute)	Returns the hash code for this instance.
GetType (inherited from Object)	Gets the Type of the current instance.
IsDefaultAttribute (inherited from Attribute)	When overridden in a derived class, returns an indication whether the value of this instance is the default value for the derived class.
Match (inherited from Attribute)	When overridden in a derived class, returns a value indicating whether this instance equals a specified object.
ToString (inherited from Object)	Returns a String that represents the current Object.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

FileTransfer.RuntimeLicenseAttribute Class | SocketTools Namespace

FileTransfer.RuntimeLicenseAttribute Constructor

Constructor for the RuntimeLicense attribute which defines the runtime license key.

[Visual Basic]

```
Public Sub New( _
   ByVal licenseKey As String _
)
```

[C#]

```
public FileTransfer.RuntimeLicenseAttribute(
   string licenseKey
);
```

Parameters

licenseKey

A string argument which specifies the runtime license key which will be used to initialize the class library.

Remarks

The runtime license key for your copy of SocketTools can be generated using the License Manager utility that is included with the product. Note that if you have installed an evaluation license, you will not have a runtime license key and cannot redistribute any applications which use the FileTransfer class.

FileTransfer.RuntimeLicenseAttribute Class | SocketTools Namespace

FileTransfer.ThreadModelAttribute Class

Attribute that defines the threading model for the class.

For a list of all members of this type, see FileTransfer.ThreadModelAttribute Members.

System.Object
  System.Attribute
    SocketTools.FileTransfer.ThreadModelAttribute

[Visual Basic]

```
<AttributeUsage(ValidOn:=AttributeTargets.Assembly, AllowMultiple:=False, Inherited:=True)>
Public Class FileTransfer.ThreadModelAttribute
    Inherits Attribute
```

[C#]

```
[AttributeUsage(ValidOn=AttributeTargets.Assembly, AllowMultiple=False, Inherited=True)]
public class FileTransfer.ThreadModelAttribute : Attribute
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

The ThreadModel attribute is used to define the threading model that is to be used when an instance of the class is created. This attribute is defined in the assembly information module for the language, such as AssemblyInfo.cs when programming C#.

Example

```
<Assembly:
SocketTools.FileTransfer.ThreadModel(SocketTools.FileTransfer.ThreadModelAttribute.Model.SingleThread)>
```

```
[assembly:
SocketTools.FileTransfer.ThreadModel(SocketTools.FileTransfer.ThreadModelAttribute.Model.SingleThread)]
```

Requirements

Namespace: SocketTools

Assembly: SocketTools.FileTransfer (in SocketTools.FileTransfer.dll)

FileTransfer.ThreadModelAttribute overview

Public Instance Constructors

FileTransfer.ThreadModelAttribute Constructor	Constructor for the ThreadModel attribute which defines the threading model.

Public Instance Properties

ThreadModel	Returns the threading model used by the class.
TypeId (inherited from Attribute)	When implemented in a derived class, gets a unique identifier for this Attribute.

Public Instance Methods

Equals (inherited from Attribute)	
GetHashCode (inherited from Attribute)	Returns the hash code for this instance.
GetType (inherited from Object)	Gets the Type of the current instance.
IsDefaultAttribute (inherited from Attribute)	When overridden in a derived class, returns an indication whether the value of this instance is the default value for the derived class.
Match (inherited from Attribute)	When overridden in a derived class, returns a value indicating whether this instance equals a specified object.
ToString (inherited from Object)	Returns a String that represents the current Object.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

FileTransfer.ThreadModelAttribute Class | SocketTools Namespace | ThreadModel Property (SocketTools.FileTransfer)

FileTransfer.ThreadModelAttribute Constructor

Constructor for the ThreadModel attribute which defines the threading model.

[Visual Basic]

```
Public Sub New( _
   ByVal threadModel As Model _
)
```

[C#]

```
public FileTransfer.ThreadModelAttribute(
   Model threadModel
);
```

Parameters

threadModel

A Model enumeration value which specifies the threading model which will be used when creating an instance of the class. A value of zero specifies a single threaded model, while a non-zero value specifies a free threaded model.

Remarks

The **ThreadModel** attribute specifies the threading model that is used by the class instance when a connection is established. The default threading model is single threaded, which specifies that only the thread that established the connection should be permitted to invoke methods.

It is important to note that the single threading model does not limit the application to a single thread of execution. When a session is established using the **Connect** method, that session is attached to the thread that created it. From that point on, until the session is terminated, only the owner may invoke methods in that instance of the class. The ownership of the class instance may be transferred from one thread to another using the **AttachThread** method.

Setting this attribute to a non-zero value disables certain internal safety checks that are performed by the class and may result in unexpected behavior unless you ensure that access to the class instance is synchronized across multiple threads. The application must ensure that no two threads will attempt to invoke a blocking method at the same time. In other words, if one thread invokes a method, the application must ensure that another thread will not attempt to invoke any other method at the same time using the same instance of the class.

Changing the value of this attribute will also change the default value for the **ThreadModel** property for all instances of the class.

FileTransfer.ThreadModelAttribute Class | SocketTools Namespace

FileTransfer.ThreadModelAttribute Properties

The properties of the **FileTransfer.ThreadModelAttribute** class are listed below. For a complete list of **FileTransfer.ThreadModelAttribute** class members, see the FileTransfer.ThreadModelAttribute Members topic.

Public Instance Properties

ThreadModel	Returns the threading model used by the class.
TypeId (inherited from Attribute)	When implemented in a derived class, gets a unique identifier for this Attribute.

See Also

FileTransfer.ThreadModelAttribute Class | SocketTools Namespace | ThreadModel Property (SocketTools.FileTransfer)

FileTransfer.ThreadModelAttribute.ThreadModel Property

Returns the threading model used by the class.

[Visual Basic]

```
Public Property ThreadModel As Model
```

[C#]

```
public FileTransfer.ThreadModelAttribute.Model ThreadModel {get; set;}
```

Property Value

A Model enumeration value which specifies the threading model which will be used when an instance of the class is created.

See Also

FileTransfer.ThreadModelAttribute Class | SocketTools Namespace

FileTransfer.ThreadModelAttribute.Model Enumeration

Specifies the threading model used by the class instance.

[Visual Basic]
```
Public Enum FileTransfer.ThreadModelAttribute.Model
```

[C#]
```
public enum FileTransfer.ThreadModelAttribute.Model
```

Remarks

The threading model **SingleThread** does not limit the application to a single thread of execution. It specifies that only a single thread may invoke methods in a class instance. When a session is established using the **Connect** method, that session is attached to the thread that created it. From that point on, until the session is terminated, only the owner may invoke methods in that instance of the class. The ownership of the class instance may be transferred from one thread to another using the **AttachThread** method.

The threading model **FreeThread** disables certain internal safety checks that are performed by the class and may result in unexpected behavior unless you ensure that access to the class instance is synchronized across multiple threads. The application must ensure that no two threads will attempt to invoke a blocking method at the same time. In other words, if one thread invokes a method, the application must ensure that another thread will not attempt to invoke any other method at the same time using the same instance of the class.

Members

Member Name	Description
SingleThread	Methods in the class instance may only be invoked by a single thread. This threading model specifies that only the thread which established the connection should be permitted to invoke methods. This is the default threading model.
FreeThread	Methods in the class instance may be invoked by any thread. This threading model permits methods to be invoked across multiple threads without being explicitly attached to the object.

Requirements

Namespace: SocketTools

Assembly: SocketTools.FileTransfer (in SocketTools.FileTransfer.dll)

SocketTools Namespace

FileTransferException Class

The exception that is thrown when a client error occurs.

For a list of all members of this type, see FileTransferException Members.

System.Object
  System.Exception
    System.ApplicationException
      SocketTools.FileTransferException

[Visual Basic]

```
Public Class FileTransferException
    Inherits ApplicationException
```

[C#]

```
public class FileTransferException : ApplicationException
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

A FileTransferException is thrown by the FileTransfer class when an error occurs.

The default constructor for the FileTransferException class sets the **ErrorCode** property to the last error that occurred.

Requirements

Namespace: SocketTools

Assembly: SocketTools.FileTransfer (in SocketTools.FileTransfer.dll)

FileTransferException Members | SocketTools Namespace

FileTransferException Members

FileTransferException overview

Public Instance Constructors

FileTransferException	Overloaded. Initializes a new instance of the FileTransferException class.

Public Instance Properties

HelpLink (inherited from Exception)	Gets or sets a link to the help file associated with this exception.
InnerException (inherited from Exception)	Gets the Exception instance that caused the current exception.
Message	Gets a value which describes the error that caused the exception.
Number	Gets a value which specifies the numeric value of the error that caused the exception.
Source (inherited from Exception)	Gets or sets the name of the application or the object that causes the error.
StackTrace (inherited from Exception)	Gets a string representation of the frames on the call stack at the time the current exception was thrown.
TargetSite (inherited from Exception)	Gets the method that throws the current exception.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetBaseException (inherited from Exception)	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetObjectData (inherited from Exception)	When overridden in a derived class, sets the SerializationInfo with information about the exception.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString	Creates and returns a string representation of the current exception.

Protected Instance Properties

HResult (inherited from Exception)	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

FileTransferException Class | SocketTools Namespace

FileTransferException Constructor

Initializes a new instance of the FileTransferException class with the last client error code.

Overload List

Initializes a new instance of the FileTransferException class with the last client error code.

public FileTransferException();

Initializes a new instance of the FileTransferException class with a specified error number.

public FileTransferException(int);

Initializes a new instance of the FileTransferException class with a specified error message.

public FileTransferException(string);

Initializes a new instance of the FileTransferException class with a specified error message and a reference to the inner exception that is the cause of this exception.

public FileTransferException(string,Exception);

See Also

FileTransferException Class | SocketTools Namespace

FileTransferException Constructor ()

Initializes a new instance of the FileTransferException class with the last client error code.

[Visual Basic]
```
Overloads Public Sub New()
```

[C#]
```
public FileTransferException();
```

Remarks

The ctor constructor sets the **ErrorCode** property to the last client error that occurred. For more information about the errors that may occur, refer to the FileTransfer.ErrorCode enumeration.

See Also

FileTransferException Class | SocketTools Namespace | FileTransferException Constructor Overload List

FileTransferException Constructor (String)

Initializes a new instance of the FileTransferException class with a specified error message.

[Visual Basic]

```
Overloads Public Sub New( _
   ByVal message As String _
)
```

[C#]

```
public FileTransferException(
   string message
);
```

Parameters

message
The error message that explains the reason for the exception.

Remarks

The content of the ***message*** parameter is intended to be understood by humans. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

See Also

FileTransferException Class | SocketTools Namespace | FileTransferException Constructor Overload List

FileTransferException Constructor (String, Exception)

Initializes a new instance of the FileTransferException class with a specified error message and a reference to the inner exception that is the cause of this exception.

[Visual Basic]

```
Overloads Public Sub New( _
   ByVal message As String, _
   ByVal inner As Exception _
)
```

[C#]

```
public FileTransferException(
   string message,
   Exception inner
);
```

Parameters

message

The error message that explains the reason for the exception.

inner

The exception that is the cause of the current exception. If the ***innerException*** parameter is not a null reference, the current exception is raised in a **catch** block that handles the inner exception.

Remarks

The content of the message parameter is intended to be understood by humans. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

An exception that is thrown as a direct result of a previous exception should include a reference to the previous exception in the **InnerException** property. The **InnerException** property returns the same value that is passed into the constructor, or a null reference if the **InnerException** property does not supply the inner exception value to the constructor.

See Also

FileTransferException Class | SocketTools Namespace | FileTransferException Constructor Overload List

FileTransferException Constructor (Int32)

Initializes a new instance of the FileTransferException class with a specified error number.

[Visual Basic]

```
Overloads Public Sub New( _
   ByVal code As Integer _
)
```

[C#]

```
public FileTransferException(
   int code
);
```

Parameters

code

An integer value which specifies an error code.

Remarks

This constructor sets the **ErrorCode** property to the specified error code. For more information about the errors that may occur, refer to the FileTransfer.ErrorCode enumeration.

See Also

FileTransferException Class | SocketTools Namespace | FileTransferException Constructor Overload List

FileTransferException Properties

The properties of the **FileTransferException** class are listed below. For a complete list of **FileTransferException** class members, see the FileTransferException Members topic.

Public Instance Properties

HelpLink (inherited from Exception)	Gets or sets a link to the help file associated with this exception.
InnerException (inherited from Exception)	Gets the Exception instance that caused the current exception.
Message	Gets a value which describes the error that caused the exception.
Number	Gets a value which specifies the numeric value of the error that caused the exception.
Source (inherited from Exception)	Gets or sets the name of the application or the object that causes the error.
StackTrace (inherited from Exception)	Gets a string representation of the frames on the call stack at the time the current exception was thrown.
TargetSite (inherited from Exception)	Gets the method that throws the current exception.

Protected Instance Properties

HResult (inherited from Exception)	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception.

See Also

FileTransferException Class | SocketTools Namespace

FileTransferException.Message Property

Gets a value which describes the error that caused the exception.

[Visual Basic]

```
Overrides Public ReadOnly Property Message As String
```

[C#]

```
public override string Message {get;}
```

Property Value

A string which describes the error that caused the exception.

Remarks

The **Message** property returns a string which describes the error that caused the exception.

See Also

FileTransferException Class | SocketTools Namespace

FileTransferException.Number Property

Gets a value which specifies the numeric value of the error that caused the exception.

[Visual Basic]
```
Public ReadOnly Property Number As Integer
```

[C#]
```
public int Number {get;}
```

Property Value

An integer value that specifies the error that caused the exception.

Remarks

The **Number** property returns an integer value which specifies the numeric value of the error that caused the exception. If a network error occurs, this value is the same as the values returned by the Windows Sockets API. For more information about network error codes, see the Windows Socket Version 2 API error code documentation in MSDN.

FileTransferException Class | SocketTools Namespace

FileTransferException Methods

The methods of the **FileTransferException** class are listed below. For a complete list of **FileTransferException** class members, see the FileTransferException Members topic.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetBaseException (inherited from Exception)	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetObjectData (inherited from Exception)	When overridden in a derived class, sets the SerializationInfo with information about the exception.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString	Creates and returns a string representation of the current exception.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

FileTransferException Class | SocketTools Namespace

FileTransferException.ToString Method

Creates and returns a string representation of the current exception.

[Visual Basic]
```
Overrides Public Function ToString() As String
```

[C#]
```
public override string ToString();
```

Return Value

A string representation of the current exception.

Remarks

The **ToString** method returns a representation of the current exception that is intended to be understood by humans. Where the exception contains culture-sensitive data, the string representation returned by **ToString** is required to take into account the current system culture. Although there are no exact requirements for the format of the returned string, it should attempt to reflect the value of the object as perceived by the user.

This implementation of **ToString** obtains the numeric error code value and a description of the error that caused the current exception. If there is no error message or it is an empty string, then no error message is returned.

This method overrides **ApplicationException.ToString**.

FileTransferException Class | SocketTools Namespace

FtpClient Class

Implements the File Transfer Protocol.

For a list of all members of this type, see FtpClient Members.

System.Object
  SocketTools.FtpClient

```
[Visual Basic]
Public Class FtpClient
    Implements IDisposable
```

```
[C#]
public class FtpClient : IDisposable
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

The FtpClient class provides a comprehensive interface to the File Transfer Protocol which supports both high level operations, such as uploading or downloading files, as well as a collection of lower-level file I/O functions. In addition to file transfers, an application can create, rename and delete files and directories, search for files using wildcards and perform other common file management functions. The class library has three distinct groups of functionality:

File Transfer
Methods which enable an application to upload and download files, as well as send and receive file data using memory buffers. This gives your program the flexibility of handling the data either on disk or in memory, depending on the best needs of your application. If your program needs to transfer more than one file at a time, there are also methods which will automatically download or upload multiple files in a single method call.

File Management
In addition to transferring files, the class can be used to manage files on the server. Methods are provided to delete, rename and move files between directories. For servers that support specific protocol extensions, advanced features such as getting or setting a remote file's modification time or access permissions are also supported. If a server supports site-specific commands, such as the ability to submit a file as job on the server, the control supports this by enabling you to send custom commands to the server and then process the information that it returns.

Directory Management
The class can be used to manage directories as well as files on the server. The application can open a directory and return a list of the files that it contains, as well as create new directories and delete empty ones. The class understands a number of different directory listing formats, including those typically used on UNIX and Linux based systems, Windows server platforms, NetWare servers and VMS systems.

This class supports secure file transfers using TLS 1.2 and the SSH 2.0 protocol using SFTP.

Requirements

Namespace: SocketTools

Assembly: SocketTools.FtpClient (in SocketTools.FtpClient.dll)

See Also

FtpClient Members | SocketTools Namespace

FtpClient Members

FtpClient overview

Public Static (Shared) Fields

ftpPortDefault	A constant value which specifies the default port number.
ftpPortSecure	A constant value which specifies the default port number for a secure connection using the SSL or TLS protocols.
ftpPortSSH	A constant value which specifies the default port number for a secure connection using the SSH1 or SSH2 protocols.
ftpTimeout	A constant value which specifies the default timeout period.

Public Static (Shared) Methods

ErrorText	Returns the description of an error code.

Public Instance Constructors

FtpClient Constructor	Initializes a new instance of the FtpClient class.

Public Instance Properties

Account	Get or sets a value that specifies the account name for the current user.
ActivePorts	Gets and sets the port numbers used for active mode file transfers.
AutoResolve	Gets and sets a value that determines if host names and addresses are automatically resolved.
Blocking	Gets and sets a value which indicates if the client is in blocking mode.
BufferSize	Gets and sets the size of the internal send and receive buffer that will be used during data transfers.
CertificateExpires	Get a value that specifies the date that the security certificate expires.
CertificateIssued	Get a value that specifies the date that the security certificate was issued.
CertificateIssuer	Get a value that provides information about the organization that issued the certificate.
CertificateName	Gets and sets a value that specifies the name of the client certificate.
CertificatePassword	Gets and sets the password associated with the client certificate.

CertificateStatus	Gets a value which indicates the status of the security certificate returned by the remote host.
CertificateStore	Gets and sets a value that specifies the name of the local certificate store.
CertificateSubject	Gets a value that provides information about the organization that the server certificate was issued to.
CertificateUser	Gets and sets the user that owns the client certificate.
ChannelMode	Set or return the security mode for the specified communications channel.
CipherStrength	Gets a value that indicates the length of the key used by the encryption algorithm for a secure connection.
DirectoryFormat	Gets and sets a value which specifies the current directory format type.
Encoding	Gets and sets the character encoding that is used when a file name is sent to the server.
Features	Gets and sets the features that are currently enabled for the current session.
FileMask	Gets and sets the value which specifies the default wildcard file mask.
FileType	Gets and sets a value which specifies the type of file that is being transferred.
Fingerprint	Gets a value that can be used to uniquely identify the server.
Handle	Gets a value that specifies the client handle allocated for the current session.
HashStrength	Gets a value which specifies the length of the message digest that was selected for a secure connection.
HostAddress	Gets and sets a value which specifies the Internet address used to establish a connection.
HostName	Gets and sets a value which specifies the host name used to establish a connection.
IsBlocked	Gets a value which indicates if the current thread is performing a blocking client operation.
IsConnected	Gets a value which indicates if a connection to the remote host has been established.
IsInitialized	Gets a value which indicates if the current instance of the class has been initialized successfully.
IsReadable	Gets a value which indicates if there is data available to be read from the socket connection to

	the server.
IsWritable	Gets a value which indicates if data can be written to the client without blocking.
KeepAlive	Gets and sets a Boolean value which specifies if the client should attempt to keep the server connection alive.
LastError	Gets and sets a value which specifies the last error that has occurred.
LastErrorString	Gets a value which describes the last error that has occurred.
LocalAddress	Gets the local Internet address that the client is bound to.
Localize	Gets and sets a value which specifies if time and dates should be adjusted for the current timezone.
LocalName	Gets a value which specifies the host name for the local system.
LocalPort	Gets the local port number the client is bound to.
Options	Gets and sets a value which specifies one or more client options.
ParseList	Gets and sets a value that specifies if directory listings should be automatically parsed
Passive	Gets and sets a value which specifies if passive mode file transfers should be enabled.
Password	Gets and sets the password used to authenticate the client session.
Priority	Gets and sets a value which specifies the priority of file transfers.
ProxyHost	Gets and sets the hostname or IP address of a proxy server.
ProxyPassword	Gets and sets the password used to authenticate the connection to a proxy server.
ProxyPort	Gets and sets a value that specifies the proxy server port number.
ProxyType	Gets and sets the type of proxy server the client will use to establish a connection.
ProxyUser	Gets and sets the username used to authenticate the connection to a proxy server.
RemoteFile	Gets and sets the file name specified in the current URL.
RemotePath	Gets and sets the path specified in the current URL.
RemotePort	Gets and sets a value which specifies the remote

	port number.
RemoteService	Gets and sets a value which specifies the remote service.
ResultCode	Gets a value which specifies the last result code returned by the server.
ResultString	Gets a string value which describes the result of the previous command.
Secure	Gets and sets a value which specifies if a secure connection is established.
SecureCipher	Gets a value that specifies the encryption algorithm used for a secure connection.
SecureHash	Gets a value that specifies the message digest algorithm used for a secure connection.
SecureKeyExchange	Gets a value that specifies the key exchange algorithm used for a secure connection.
SecureProtocol	Gets and sets a value which specifies the protocol used for a secure connection.
Status	Gets a value which specifies the current status of the client.
System	Gets a string value which identifies the server.
TaskCount	Get the number of active background file transfers.
TaskId	Get the task identifier for the last background file transfer.
TaskList	Get an array of active background task identifiers.
ThreadModel	Gets and sets a value which specifies the threading model for the class instance.
ThrowError	Gets and sets a value which specifies if method calls should throw exceptions when an error occurs.
Timeout	Gets and sets a value which specifies a timeout period in seconds.
TimeZone	Gets and sets the current timezone offset in seconds.
Trace	Gets and sets a value which indicates if network function logging is enabled.
TraceFile	Gets and sets a value which specifies the name of the logfile.
TraceFlags	Gets and sets a value which specifies the client function tracing flags.
TransferBytes	Gets a value which specifies the number of bytes transferred to or from the remote server.
TransferRate	Gets a value which specifies the data transfer rate

	in bytes per second.
TransferTime	Gets a value which specifies the number of seconds elapsed during a data transfer.
URL	Gets and sets the current URL used to access a file on the server.
UserName	Gets and sets the username used to authenticate the client session.
Version	Gets a value which returns the current version of the FtpClient class library.

Public Instance Methods

AddFileType	Associate a file name extension with a specific file type.
AsyncGetFile	Overloaded. Download a file from the server to the local system in the background.
AsyncPutFile	Overloaded. Upload a file from the local system to the server in the background.
AttachThread	Attach an instance of the class to the current thread
Cancel	Cancel the current blocking client operation.
ChangeDirectory	Change the current working directory on the remote server.
CloseDirectory	Close the directory that was previously opened with the OpenDirectory method.
CloseFile	Close the file that was previously opened with the OpenFile method.
Command	Overloaded. Send a custom command to the server.
Connect	Overloaded. Establish a connection with a remote host.
CreateFile	Create a new file or overwrite an existing file.
DeleteFile	Delete a file on the remote server.
Disconnect	Terminate the connection with the remote server.
Dispose	Overloaded. Releases all resources used by FtpClient.
Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
FileList	Overloaded. Return a list of files on the remote host.
GetData	Overloaded. Transfers the contents of a file on the server and stores it in a byte array.
GetDirectory	Return the current working directory.

GetFile	Overloaded. Download a file from the server to the local system.
GetFileList	Overloaded. Returns an unparsed list of files in the specified directory.
GetFilePermissions	Return the access permissions for a file on the remote system.
GetFileSize	Overloaded. Returns the size of the specified file on the remote server.
GetFileStatus	Returns status information about the specified file.
GetFileTime	Overloaded. Returns the modification date and time for specified file on the remote server.
GetFirstFile	Overloaded. Get information about the first file in a directory listing returned by the server.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetMultipleFiles	Overloaded. Download multiple files from the server to the local system using a wildcard mask.
GetNextFile	Overloaded. Get information about the next file in a directory listing returned by the server.
GetType (inherited from Object)	Gets the Type of the current instance.
Initialize	Overloaded. Initialize an instance of the FtpClient class.
Login	Overloaded. Login to the remote server.
Logout	Log the current user off the server.
MakeDirectory	Create a new directory on the server.
OpenDirectory	Overloaded. Open the specified directory on the server.
OpenFile	Overloaded. Open an existing file or create a new file on the server.
PutData	Overloaded. Transfers data from a byte array and stores it in a file on the remote server.
PutFile	Overloaded. Upload a file from the local system to the server.
PutMultipleFiles	Overloaded. Upload multiple files from the local system to the server using a wildcard mask.
Read	Overloaded. Read file data from the server and store it in a byte array.
RemoveDirectory	Remove a directory on the server.
RenameFile	Change the name of a file on the server.
Reset	Reset the internal state of the object, resetting all

	properties to their default values.
SetFilePermissions	Change the access permissions for a file on the server.
SetFileTime	Changes the modification date and time for a file on the server.
TaskAbort	Overloaded. Abort the specified asynchronous task.
TaskDone	Overloaded. Determine if an asynchronous task has completed.
TaskResume	Overloaded. Resume execution of an asynchronous task.
TaskSuspend	Overloaded. Suspend execution of an asynchronous task.
TaskWait	Overloaded. Wait for an asynchronous task to complete.
ToString (inherited from Object)	Returns a String that represents the current Object.
Uninitialize	Uninitialize the class library and release any resources allocated for the current thread.
VerifyFile	Overloaded. Verify that the contents of a file on the local system are the same as the specified file on the server.
Write	Overloaded. Write one or more bytes of data to the server.

Public Instance Events

OnCancel	Occurs when a blocking client operation is canceled.
OnCommand	Occurs when the client sends a command to the remote host and receives a reply indicating the result of that command.
OnConnect	Occurs when a connection is established with the remote host.
OnDisconnect	Occurs when the remote host disconnects from the local system.
OnError	Occurs when an socket operation fails.
OnFileList	Occurs when a directory listing is parsed by the class.
OnGetFile	Occurs when a file download has been initiated.
OnLastFile	Occurs when the last file in a directory listing has been processed.
OnProgress	Occurs as a data stream is being read or written to the socket.

OnPutFile	Occurs when a file upload is initiated.
OnRead	Occurs when data is available to be read from the socket.
OnTaskBegin	Occurs when an asynchronous task begins execution.
OnTaskEnd	Occurs when an asynchronous task completes.
OnTaskRun	Occurs while a background task is active.
OnTimeout	Occurs when a blocking operation fails to complete before the timeout period elapses.
OnWrite	Occurs when data can be written to the socket.

Protected Instance Methods

Dispose	Overloaded. Releases the unmanaged resources allocated by the FtpClient class and optionally releases the managed resources.
Finalize	Destroys an instance of the class, releasing the resources allocated for the session and unloading the networking library.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

FtpClient.FileInformation overview

Public Instance Fields

FileDate	Specifies the date and time the file was created or last modified.
FileGroup	Specifies the name of the group that owns the file.
FileLinks	Specifies the number of links to the file.
FileName	Specifies the name of the file.
FileOwner	Specifies the name of the file owner.
FilePerms	Specifies the permissions for the file.
FileSize	Specifies the size of the file in bytes.
FileVersion	Specifies the number of revisions made to the file.
IsDirectory	Specifies if the file is a directory or regular file.

Public Instance Methods

Equals (inherited from ValueType)	Indicates whether this instance and a specified object are equal.
GetHashCode (inherited from ValueType)	Returns the hash code for this instance.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString (inherited from ValueType)	Returns the fully qualified type name of this instance.

FtpClient.FileInformation Fields

The fields of the **FtpClient.FileInformation** structure are listed below. For a complete list of **FtpClient.FileInformation** structure members, see the FtpClient.FileInformation Members topic.

Public Instance Fields

FileDate	Specifies the date and time the file was created or last modified.
FileGroup	Specifies the name of the group that owns the file.
FileLinks	Specifies the number of links to the file.
FileName	Specifies the name of the file.
FileOwner	Specifies the name of the file owner.
FilePerms	Specifies the permissions for the file.
FileSize	Specifies the size of the file in bytes.
FileVersion	Specifies the number of revisions made to the file.
IsDirectory	Specifies if the file is a directory or regular file.

See Also

FtpClient.FileInformation Class | SocketTools Namespace

FtpClient.FileInformation.FileDate Field

Specifies the date and time the file was created or last modified.

[Visual Basic]

```
Public FileDate As Date
```

[C#]

```
public DateTime FileDate;
```

Remarks

Some file servers may not return a specific time value if the file was last created or modified more than six months ago. In that case, only the date will be returned.

FtpClient.PortRange overview

Public Instance Constructors

FtpClient.PortRange Constructor	Initializes a new instance of the **PortRange** structure with a specified range of port numbers.

Public Instance Fields

HighPort	Specifies the high port number used for active file transfers.
LowPort	Specifies the low port number used for active file transfers.

Public Instance Methods

Equals (inherited from ValueType)	Indicates whether this instance and a specified object are equal.
GetHashCode (inherited from ValueType)	Returns the hash code for this instance.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString (inherited from ValueType)	Returns the fully qualified type name of this instance.

See Also

FtpClient.PortRange Class | SocketTools Namespace

FtpClient.PortRange Constructor

Initializes a new instance of the **PortRange** structure with a specified range of port numbers.

[Visual Basic]
```
Public Sub New( _
   ByVal lowPort As Integer, _
   ByVal highPort As Integer _
)
```

[C#]
```
public FtpClient.PortRange(
   int lowPort,
   int highPort
);
```

Parameters

lowPort
An integer value which specifies the low port number.

highPort
An integer value which specifies the high port number.

Return Value

The minimum port number is 1025 and the maximum port number is 65535. Port numbers outside of this range of values will be silently adjusted.

See Also

FtpClient.PortRange Class | SocketTools Namespace

FtpClient.PortRange Fields

The fields of the **FtpClient.PortRange** structure are listed below. For a complete list of **FtpClient.PortRange** structure members, see the FtpClient.PortRange Members topic.

Public Instance Fields

◆ HighPort	Specifies the high port number used for active file transfers.
◆ LowPort	Specifies the low port number used for active file transfers.

See Also

FtpClient.PortRange Class | SocketTools Namespace

FtpClient.PortRange.HighPort Field

Specifies the high port number used for active file transfers.

[Visual Basic]

```
Public HighPort As Integer
```

[C#]

```
public int HighPort;
```

Remarks

While this member may be assigned to any integer value, the port range is normalized and the maximum port number that may be used is 65535.

See Also

FtpClient.PortRange Class | SocketTools Namespace

FtpClient.PortRange.LowPort Field

Specifies the low port number used for active file transfers.

[Visual Basic]
```
Public LowPort As Integer
```

[C#]
```
public int LowPort;
```

Remarks

While this member may be assigned to any integer value, the port range is normalized and the minimum port number that may be used is 1025.

See Also

FtpClient.PortRange Class | SocketTools Namespace

FtpClient.SecureChannel Structure

The structure used to modify or return the current mode for the secure command or data channel.

For a list of all members of this type, see FtpClient.SecureChannel Members.

System.Object
  System.ValueType
    SocketTools.FtpClient.SecureChannel

[Visual Basic]
```
Public Structure FtpClient.SecureChannel
```

[C#]
```
public struct FtpClient.SecureChannel
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

The **SecureChannel** structure specifies the current channel modes for the client session. This structure is used with the **ChannelMode** property when a secure connection is established with the server.

Requirements

Namespace: SocketTools

Assembly: SocketTools.FtpClient (in SocketTools.FtpClient.dll)

See Also

FtpClient.SecureChannel Members | SocketTools Namespace

FtpClient.SecureChannel Members

FtpClient.SecureChannel overview

Public Instance Constructors

FtpClient.SecureChannel Constructor	Initializes a new instance of the **SecureChannel** structure with the specified values.

Public Instance Fields

Command	Specifies the secure channel mode used when sending commands to the server.
Data	Specifies the secure channel mode used when uploading or downloading files.

Public Instance Methods

Equals (inherited from ValueType)	Indicates whether this instance and a specified object are equal.
GetHashCode (inherited from ValueType)	Returns the hash code for this instance.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString (inherited from ValueType)	Returns the fully qualified type name of this instance.

See Also

FtpClient.SecureChannel Class | SocketTools Namespace

FtpClient.SecureChannel Constructor

Initializes a new instance of the **SecureChannel** structure with the specified values.

[Visual Basic]

```
Public Sub New( _
   ByVal commandMode As FtpChannelMode, _
   ByVal dataMode As FtpChannelMode _
)
```

[C#]

```
public FtpClient.SecureChannel(
   FtpChannelMode commandMode,
   FtpChannelMode dataMode
);
```

Parameters

commandMode
A FtpChannelMode enumeration which specifies the channel mode used for commands sent to the server.

dataMode
A FtpChannelMode enumeration which specifies the channel mode used for file transfers.

FtpClient Properties

The properties of the **FtpClient** class are listed below. For a complete list of **FtpClient** class members, see the FtpClient Members topic.

Public Instance Properties

Account	Get or sets a value that specifies the account name for the current user.
ActivePorts	Gets and sets the port numbers used for active mode file transfers.
AutoResolve	Gets and sets a value that determines if host names and addresses are automatically resolved.
Blocking	Gets and sets a value which indicates if the client is in blocking mode.
BufferSize	Gets and sets the size of the internal send and receive buffer that will be used during data transfers.
CertificateExpires	Get a value that specifies the date that the security certificate expires.
CertificateIssued	Get a value that specifies the date that the security certificate was issued.
CertificateIssuer	Get a value that provides information about the organization that issued the certificate.
CertificateName	Gets and sets a value that specifies the name of the client certificate.
CertificatePassword	Gets and sets the password associated with the client certificate.
CertificateStatus	Gets a value which indicates the status of the security certificate returned by the remote host.
CertificateStore	Gets and sets a value that specifies the name of the local certificate store.
CertificateSubject	Gets a value that provides information about the organization that the server certificate was issued to.
CertificateUser	Gets and sets the user that owns the client certificate.
ChannelMode	Set or return the security mode for the specified communications channel.
CipherStrength	Gets a value that indicates the length of the key used by the encryption algorithm for a secure connection.
DirectoryFormat	Gets and sets a value which specifies the current directory format type.

Encoding	Gets and sets the character encoding that is used when a file name is sent to the server.
Features	Gets and sets the features that are currently enabled for the current session.
FileMask	Gets and sets the value which specifies the default wildcard file mask.
FileType	Gets and sets a value which specifies the type of file that is being transferred.
Fingerprint	Gets a value that can be used to uniquely identify the server.
Handle	Gets a value that specifies the client handle allocated for the current session.
HashStrength	Gets a value which specifies the length of the message digest that was selected for a secure connection.
HostAddress	Gets and sets a value which specifies the Internet address used to establish a connection.
HostName	Gets and sets a value which specifies the host name used to establish a connection.
IsBlocked	Gets a value which indicates if the current thread is performing a blocking client operation.
IsConnected	Gets a value which indicates if a connection to the remote host has been established.
IsInitialized	Gets a value which indicates if the current instance of the class has been initialized successfully.
IsReadable	Gets a value which indicates if there is data available to be read from the socket connection to the server.
IsWritable	Gets a value which indicates if data can be written to the client without blocking.
KeepAlive	Gets and sets a Boolean value which specifies if the client should attempt to keep the server connection alive.
LastError	Gets and sets a value which specifies the last error that has occurred.
LastErrorString	Gets a value which describes the last error that has occurred.
LocalAddress	Gets the local Internet address that the client is bound to.
Localize	Gets and sets a value which specifies if time and dates should be adjusted for the current timezone.
LocalName	Gets a value which specifies the host name for the local system.

LocalPort	Gets the local port number the client is bound to.
Options	Gets and sets a value which specifies one or more client options.
ParseList	Gets and sets a value that specifies if directory listings should be automatically parsed
Passive	Gets and sets a value which specifies if passive mode file transfers should be enabled.
Password	Gets and sets the password used to authenticate the client session.
Priority	Gets and sets a value which specifies the priority of file transfers.
ProxyHost	Gets and sets the hostname or IP address of a proxy server.
ProxyPassword	Gets and sets the password used to authenticate the connection to a proxy server.
ProxyPort	Gets and sets a value that specifies the proxy server port number.
ProxyType	Gets and sets the type of proxy server the client will use to establish a connection.
ProxyUser	Gets and sets the username used to authenticate the connection to a proxy server.
RemoteFile	Gets and sets the file name specified in the current URL.
RemotePath	Gets and sets the path specified in the current URL.
RemotePort	Gets and sets a value which specifies the remote port number.
RemoteService	Gets and sets a value which specifies the remote service.
ResultCode	Gets a value which specifies the last result code returned by the server.
ResultString	Gets a string value which describes the result of the previous command.
Secure	Gets and sets a value which specifies if a secure connection is established.
SecureCipher	Gets a value that specifies the encryption algorithm used for a secure connection.
SecureHash	Gets a value that specifies the message digest algorithm used for a secure connection.
SecureKeyExchange	Gets a value that specifies the key exchange algorithm used for a secure connection.
SecureProtocol	Gets and sets a value which specifies the protocol

	used for a secure connection.
Status	Gets a value which specifies the current status of the client.
System	Gets a string value which identifies the server.
TaskCount	Get the number of active background file transfers.
TaskId	Get the task identifier for the last background file transfer.
TaskList	Get an array of active background task identifiers.
ThreadModel	Gets and sets a value which specifies the threading model for the class instance.
ThrowError	Gets and sets a value which specifies if method calls should throw exceptions when an error occurs.
Timeout	Gets and sets a value which specifies a timeout period in seconds.
TimeZone	Gets and sets the current timezone offset in seconds.
Trace	Gets and sets a value which indicates if network function logging is enabled.
TraceFile	Gets and sets a value which specifies the name of the logfile.
TraceFlags	Gets and sets a value which specifies the client function tracing flags.
TransferBytes	Gets a value which specifies the number of bytes transferred to or from the remote server.
TransferRate	Gets a value which specifies the data transfer rate in bytes per second.
TransferTime	Gets a value which specifies the number of seconds elapsed during a data transfer.
URL	Gets and sets the current URL used to access a file on the server.
UserName	Gets and sets the username used to authenticate the client session.
Version	Gets a value which returns the current version of the FtpClient class library.

FtpClient Class | SocketTools Namespace

FtpClient.Account Property

Get or sets a value that specifies the account name for the current user.

[Visual Basic]

```
Public Property Account As String
```

[C#]

```
public string Account {get; set;}
```

Property Value

A string which specifies the account name for the current user.

Remarks

The **Account** property specifies the account name of the current user, if it is required by the server for authentication. Not all servers require an account name, in which case this property is ignored.

See Also

FtpClient Class | SocketTools Namespace

FtpClient.ActivePorts Property

Gets and sets the port numbers used for active mode file transfers.

[Visual Basic]

```
Public Property ActivePorts As PortRange
```

[C#]

```
public FtpClient.PortRange ActivePorts {get; set;}
```

Property Value

A **PortRange** structure which specifies the minimum and maximum port numbers used for active mode file transfers.

Remarks

This property is used to change the default port numbers used for active mode file transfers. Active mode is used when the **Passive** property is set to false. Instead of the client establishing an outbound connection to the server for the file transfer, it listens for an inbound connection from the server back to the client. In most cases, passive mode transfers are preferred because they mitigate potential compatibility issues with firewalls and NAT routers.

If active mode transfers are required, the default port range used when listening for the server connection is between 1024 and 5000. This is the standard range of ephemeral ports used by the Windows operating system. However, under some circumstances that range of ports may be too small, or a firewall may be configured to deny inbound connections on ephemeral ports. In that case, the **ActivePorts** property can be used to specify a different range of port numbers.

While it is technically permissible to assign the low and high port numbers to the same value, effectively specifying a single active port number, this is not recommended as it can cause the transfer to fail unexpectedly if multiple file transfers are performed. A minimum range of at least 1000 ports is recommended. For example, if you specify a low port value of 40000 then it is recommended that the high port value be at least 41000. The maximum port value is 65535.

See Also

FtpClient Class | SocketTools Namespace | PortRange Structure

FtpClient.AutoResolve Property

Gets and sets a value that determines if host names and addresses are automatically resolved.

[Visual Basic]

```
Public Property AutoResolve As Boolean
```

[C#]

```
public bool AutoResolve {get; set;}
```

Property Value

Returns **true** if host names are automatically resolved to Internet addresses. The default value is **false**.

Remarks

Setting the **AutoResolve** property determines if the class automatically resolves host names and addresses specified by the **HostName** and **HostAddress** properties. If set to **true**, setting the **HostName** property will cause the class to automatically determine the corresponding IP address and update the **HostAddress** property accordingly. Likewise, setting the **HostAddress** property will cause the class to determine the host name and update the **HostName** property. Setting this property to **false** prevents the class from resolving host names until a connection attempt is made.

It is important to note that setting the **HostName** or **HostAddress** property may cause the current thread to block, sometimes for several seconds, until the name or address is resolved. To prevent this behavior, set this property value to **false**.

See Also

FtpClient Class | SocketTools Namespace

FtpClient.Blocking Property

Gets and sets a value which indicates if the client is in blocking mode.

[Visual Basic]

```
Public Property Blocking As Boolean
```

[C#]

```
public bool Blocking {get; set;}
```

Property Value

Returns **true** if the client is in blocking mode; otherwise it returns **false**. The default value is **true**.

Remarks

Setting the **Blocking** property determines if client operations complete synchronously or asynchronously. If set to **true**, then each client operation (such as sending or receiving data) will return when the operation has completed or timed-out. If set to **false**, client operations will return immediately. If the operation would result in the client blocking (such as attempting to read data when no data has been sent by the remote host), an error is generated.

It is important to note that certain events, such as **OnDisconnect, OnRead** and **OnWrite** are only fired if the client is in non-blocking mode.

See Also

FtpClient Class | SocketTools Namespace

FtpClient.BufferSize Property

Gets and sets the size of the internal send and receive buffer that will be used during data transfers.

[Visual Basic]

```
Public Property BufferSize As Integer
```

[C#]

```
public int BufferSize {get; set;}
```

Property Value

An integer value which specifies the size of the internal transfer buffer, expressed in bytes.

Remarks

Setting the **BufferSize** property specifies the size in bytes of an internal buffer that will be used during data transfers. Any set value greater than or equal to zero is acceptable. If the value is set to zero, then the default value of 4096 will be used. If the set value is between 1 and 255, inclusive, the buffer size will be set to 256. The maximum value is 1048576.

The speed of data transfers, particularly on uploads, may be sensitive to network type and configuration, and the size of the internal buffer used for data transfers. The default size of this buffer will result in good performance for a wide range of network characteristics. A larger buffer will not necessarily result in better performance. For example, a multiple of 1460, which is the typical Maximum Transmission Unit (MTU), may be optimal in many situations.

See Also

FtpClient Class | SocketTools Namespace

FtpClient.CertificateExpires Property

Get a value that specifies the date that the security certificate expires.

[Visual Basic]

```
Public ReadOnly Property CertificateExpires As String
```

[C#]

```
public string CertificateExpires {get;}
```

Property Value

A string which specifies a date using the local date and time format.

Remarks

The **CertificateExpires** property returns a string that specifies the date and time that the security certificate expires. This property will return an empty string if a secure connection has not been established with the remote host.

See Also

FtpClient Class | SocketTools Namespace

FtpClient.CertificateIssued Property

Get a value that specifies the date that the security certificate was issued.

[Visual Basic]
```
Public ReadOnly Property CertificateIssued As String
```

[C#]
```
public string CertificateIssued {get;}
```

Property Value

A string which specifies a date using the local date and time format.

Remarks

The **CertificateIssued** property returns a string that specifies the date and time that the security certificate was issued. This property will return an empty string if a secure connection has not been established with the remote host.

See Also

FtpClient Class | SocketTools Namespace

FtpClient.CertificateIssuer Property

Get a value that provides information about the organization that issued the certificate.

[Visual Basic]
```
Public ReadOnly Property CertificateIssuer As String
```

[C#]
```
public string CertificateIssuer {get;}
```

Property Value

A string that contains a comma separated list of name value pairs.

Remarks

The **CertificateIssuer** property returns a string that contains information about the organization that issued the server certificate. The string value is a comma separated list of tagged name and value pairs. In the nomenclature of the X.500 standard, each of these pairs are called a relative distinguished name (RDN), and when concatenated together, forms the issuer's distinguished name (DN). For example:

```
C=US, O="RSA Data Security, Inc.", OU=Secure Server Certification Authority
```

To obtain a specific value, such as the name of the issuer or the issuer's country, the application must parse the string returned by this property. Some of the common tokens used in the distinguished name are:

Token	Description
C	The ISO standard two character country code.
S	The name of the state or province.
L	The name of the city or locality.
O	The name of the company or organization.
OU	The name of the department or organizational unit
CN	The common name; with X.509 certificates, this is the domain name of the site the certificate was issued for.

This property will return an empty string if a secure connection has not been established with the remote host.

See Also

FtpClient Class | SocketTools Namespace

FtpClient.CertificateName Property

Gets and sets a value that specifies the name of the client certificate.

[Visual Basic]

```
Public Property CertificateName As String
```

[C#]

```
public string CertificateName {get; set;}
```

Property Value

A string which specifies the certificate name.

Remarks

The **CertificateName** property is used to specify the name of a client certificate to use when establishing a secure connection. It is only required that you set this property value if the server requires a client certificate for authentication. If this property is not set, a client certificate will not be provided to the server. If a certificate name is specified, the certificate must have a private key associated with it, otherwise the connection attempt will fail because the control will be unable to create a security context for the session.

When the certificate store is searched for a matching certificate, it will first search for any certificate with a friendly name that matches the property value. If no valid certificate is found, it will then search for a certificate with a matching common name.

Certificates may be installed and viewed on the local system using the Certificate Manager that is included with the Windows operating system. For more information, refer to the documentation for the Microsoft Management Console.

See Also

FtpClient Class | SocketTools Namespace | CertificateStore Property | Secure Property

FtpClient.CertificateStatus Property

Gets a value which indicates the status of the security certificate returned by the remote host.

[Visual Basic]

```
Public ReadOnly Property CertificateStatus As SecurityCertificate
```

[C#]

```
public FtpClient.SecurityCertificate CertificateStatus {get;}
```

Property Value

A SecurityCertificate enumeration value which specifies the status of the certificate.

Remarks

The **CertificateStatus** property is used to determine the status of the security certificate returned by the remote host when a secure connection has been established. This property value should be checked after the connection to the server has completed, but prior to beginning a transaction.

Note that if the certificate cannot be validated, the secure connection will not be automatically terminated. It is the responsibility of your application to determine the best course of action to take if the certificate is invalid. Even if the security certificate cannot be validated, the data exchanged with the remote host will still be encrypted.

See Also

FtpClient Class | SocketTools Namespace

FtpClient.CertificateStore Property

Gets and sets a value that specifies the name of the local certificate store.

[Visual Basic]

```
Public Property CertificateStore As String
```

[C#]

```
public string CertificateStore {get; set;}
```

Property Value

A string which specifies the certificate store name. The default value is the current user's personal certificate store.

Remarks

The **CertificateStore** property is used to specify the name of the certificate store which contains the security certificate to use when establishing a secure connection. The certificate may either be stored in the registry or in a file. If the certificate is stored in the registry, then this property should be set to one of the following predefined values:

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as VeriSign and Thawte act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. If a certificate store is not specified, this is the default value that is used.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as VeriSign and Thawte are installed as part of the operating system and periodically updated by Microsoft.

In most cases the client certificate will be installed in the user's personal certificate store, and therefore it is not necessary to set this property value because that is the default location that will be used to search for the certificate. This property is only used if the **CertificateName** property is also set to a valid certificate name.

If you are using a local certificate store, with the certificate and private key stored in the registry, you can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU" for the current user, or "HKLM" for the local machine. For example, a certificate store name of "HKLM:MY" would specify the personal certificate store for the local machine, rather than the current user. If neither prefix is specified, it will default to the certificate store for the current user.

This property may also be used to specify a file that contains the client certificate. In this case, the property should specify the full path to the file and must contain both the certificate and private key in PKCS12

format. If the file is protected by a password, the **CertificatePassword** property must also be set to specify the password.

See Also

FtpClient Class | SocketTools Namespace | CertificatePassword Property | Secure Property

FtpClient.CertificateSubject Property

Gets a value that provides information about the organization that the server certificate was issued to.

[Visual Basic]

```
Public ReadOnly Property CertificateSubject As String
```

[C#]

```
public string CertificateSubject {get;}
```

Property Value

A string that contains a comma separated list of name value pairs.

Remarks

The **CertificateSubject** property returns a string that contains information about the organization that the server certificate was issued to. The string value is a comma separated list of tagged name and value pairs. In the nomenclature of the X.500 standard, each of these pairs are called a relative distinguished name (RDN), and when concatenated together, forms the issuer's distinguished name (DN). For example:

```
C=US, O="RSA Data Security, Inc.", OU=Secure Server Certification Authority
```

To obtain a specific value, such as the name of the issuer or the issuer's country, the application must parse the string returned by this property. Some of the common tokens used in the distinguished name are:

Token	Description
C	The ISO standard two character country code.
S	The name of the state or province.
L	The name of the city or locality.
O	The name of the company or organization.
OU	The name of the department or organizational unit
CN	The common name; with X.509 certificates, this is the domain name of the site the certificate was issued for.

This property will return an empty string if a secure connection has not been established with the remote host.

See Also

FtpClient Class | SocketTools Namespace

FtpClient.ChannelMode Property

Set or return the security mode for the specified communications channel.

[Visual Basic]

```
Public Property ChannelMode As SecureChannel
```

[C#]

```
public FtpClient.SecureChannel ChannelMode {get; set;}
```

Property Value

An FtpChannelMode enumeration value which specifies the current channel mode.

Remarks

The **ChannelMode** property is used to change the default mode for the specified channel, and is typically used to control whether or not data is encrypted during a file transfer. If a standard, non-secure connection has been established with the server, an error will be returned if you specify the **channelSecure** mode for either channel.

If you have established a secure connection and then specify the **channelClear** mode for the command channel, the client will send the CCC command to the server to indicate that commands should no longer be encrypted. If the server does not support this command, an error will be returned and the channel mode will remain unchanged. Once the command channel has been changed to clear mode, it cannot be changed back to secure mode. You must disconnect and re-connect to the server if you want to resume sending commands over an encrypted channel.

Changing the mode for the data channel requires that the server support the PROT command. If this command is not supported by the server, an exception will be thrown which must be handled by the application. You can only set a channel to secure mode if the **Secure** property is also set to **true**.

It is important to note that this property should only be used after a connection has been established with the server. If you attempt to read the property or change a value prior to calling the **Connect** method, an exception will be thrown.

See Also

FtpClient Class | SocketTools Namespace

FtpClient.CipherStrength Property

Gets a value that indicates the length of the key used by the encryption algorithm for a secure connection.

[Visual Basic]
```
Public ReadOnly Property CipherStrength As Integer
```

[C#]
```
public int CipherStrength {get;}
```

Property Value

An integer value which specifies the encryption key length if a secure connection has been established; otherwise a value of 0 is returned.

Remarks

The **CipherStrength** property returns the number of bits in the key used to encrypt the secure data stream. Common values returned by this property are 128 and 256. A key length of 40 or 56 bits is considered insecure and subject to brute force attacks. 128-bit and 256-bit keys are considered secure. If this property returns a value of 0, this means that a secure connection has not been established with the remote host.

See Also

FtpClient Class | SocketTools Namespace

FtpClient.DirectoryFormat Property

Gets and sets a value which specifies the current directory format type.

[Visual Basic]

```
Public Property DirectoryFormat As FtpDirectoryFormat
```

[C#]

```
public FtpClient.FtpDirectoryFormat DirectoryFormat {get; set;}
```

Property Value

An FtpDirectoryFormat enumeration value which specifies the current directory format.

Remarks

This property should only be set if the client cannot automatically determine the directory format returned by the server. The default directory format is determined both by the server's operating system and by analyzing the format of the data returned by the server. If the class is unable to automatically determine the format, it will attempt to parse the list of files as though it is a UNIX style listing.

If this property is set to the default value **FtpDirectoryFormat.formatAuto** and the class can determine from the format of the file listing returned by the server, then the property will change value upon the first call to the **GetFirstFile** method.

See Also

FtpClient Class | SocketTools Namespace

FtpClient.Features Property

Gets and sets the features that are currently enabled for the current session.

[Visual Basic]

```
Public Property Features As FtpFeatures
```

[C#]

```
public FtpClient.FtpFeatures Features {get; set;}
```

Property Value

An FtpFeatures enumeration which specifies the features that are available for the current client session.

Remarks

When a client connection is first established, all features are enabled by default. However, as the client issues commands to the server, if the server reports that the command is unrecognized that feature will automatically be disabled in the client.

For example, the first time an application calls the **GetFileSize** method to determine the size of a file, the control will try to use the SIZE command. If the server reports that the SIZE command is not available, that feature will be disabled and the control will not use the command again during the session unless it is explicitly re-enabled. This is designed to prevent the control from repeatedly sending invalid commands to a server, which may result in the server aborting the connection.

Setting the **Features** property enables those features which have been specified. More than one feature may be enabled by combining the above constants using a bitwise Or operator. To test if a particular feature has been enabled, use the bitwise And operator.

Because features are specific to the current session, once you disconnect from the server they are reset. Even if you wish to reconnect to the same server, you must explicitly set the **Features** property again to those features which you wish to enable. Setting the **Features** property when the control is not connected to a server will cause the client session to only use those specified features for the next connection that is established. Setting the **Features** property during an active connection will change the features available for that session.

See Also

FtpClient Class | SocketTools Namespace

FtpClient.FileMask Property

Gets and sets the value which specifies the default wildcard file mask.

[Visual Basic]

```
Public Property FileMask As String
```

[C#]

```
public string FileMask {get; set;}
```

Property Value

A string which specifies the current wildcard file mask.

Remarks

The **FileMask** property specifies the default wildcard mask to be used when uploading or downloading multiple files. The default value of an empty string indicates that all files in the specified directory should be uploaded or downloaded. Typically, this property is set to a wildcard mask that limits the files downloaded from the server to those which match a specific extension. For example, to download only those files that end in a ".dat" extension, the property could be set to the value "*.dat"

Note that the type of wildcards which may be used depend on the server and the type of file system that it is using. Take particular care when dealing with file systems that distinguish between upper- and lower-case letters in a filename.

See Also

FtpClient Class | SocketTools Namespace

FtpClient.FileType Property

Gets and sets a value which specifies the type of file that is being transferred.

[Visual Basic]
```
Public Property FileType As FtpFileType
```

[C#]
```
public FtpClient.FtpFileType FileType {get; set;}
```

Property Value

An **FtpFileType** enumeration which specifies the type of file being uploaded or downloaded.

Remarks

The file type should be set before a file is uploaded or downloaded from the remote server. Once the file type is set, it is in effect for all files that are subsequently transferred.

See Also

FtpClient Class | SocketTools Namespace

FtpClient.Fingerprint Property

Gets a value that can be used to uniquely identify the server.

[Visual Basic]

```
Public ReadOnly Property Fingerprint As String
```

[C#]

```
public string Fingerprint {get;}
```

Property Value

A string value that can be used to uniquely identify a server when the SSH protocol is used.

Remarks

The **Fingerprint** property returns a string that consists of a series of hexadecimal values separated by colons. The value is unique to the server, and is an MD5 hash of the RSA host key. An application can use this value to determine if a connection has been established with the server previously by storing the server's host name, IP address and fingerprint in a file, registry key or a database.

Note that this property only returns a meaningful value after a secure connection has been established using the SSH protocol. For all other connections, it will return an empty string.

See Also

FtpClient Class | SocketTools Namespace

FtpClient.Handle Property

Gets a value that specifies the client handle allocated for the current session.

[Visual Basic]

```
Public ReadOnly Property Handle As Integer
```

[C#]

```
public int Handle {get;}
```

Property Value

An integer which represents a client handle. If there is no active connection, a value of -1 is returned.

Remarks

The **Handle** property specifies the numeric descriptor of the current client session and is typically used for debugging or diagnostic purposes.

In SocketTools, handles are used to identify client sessions. A session begins when an instance of the class is used to establish a connection with the server and ends when that connection is terminated. The client handle is defined as an integer type and is used internally to reference the active session. When the connection is terminated, the handle is released, along with any system resources that were allocated for it. An unused handle is identified by the value -1.

It is important to note that the handles returned by this property are not socket handles and cannot be used interchangeably with other objects or Windows API functions. The actual value of the handle is only unique while the client session is active and handle values may be reused. An application should never depend on the **Handle** property returning a specific value.

See Also

FtpClient Class | SocketTools Namespace

FtpClient.HashStrength Property

Gets a value which specifies the length of the message digest that was selected for a secure connection.

[Visual Basic]

```
Public ReadOnly Property HashStrength As Integer
```

[C#]

```
public int HashStrength {get;}
```

Property Value

An integer value which specifies the length of the message digest if a secure connection has been established; otherwise a value of 0 is returned.

Remarks

The **HashStrength** property returns the number of bits used in the message digest (hash) that was selected. Common values returned by this property are 128 and 160. If this property returns a value of 0, this means that a secure connection has not been established with the remote host.

See Also

FtpClient Class | SocketTools Namespace

FtpClient.HostAddress Property

Gets and sets a value which specifies the Internet address used to establish a connection.

[Visual Basic]

```
Public Property HostAddress As String
```

[C#]

```
public string HostAddress {get; set;}
```

Property Value

A string which specifies an Internet address.

Remarks

The **HostAddress** property can be used to set the Internet address for a remote system that you wish to communicate with. If the **AutoResolve** property is set to **true** and the address is assigned to a valid host name, the **HostName** property will be updated with that value.

See Also

FtpClient Class | SocketTools Namespace

FtpClient.HostName Property

Gets and sets a value which specifies the host name used to establish a connection.

[Visual Basic]

```
Public Property HostName As String
```

[C#]

```
public string HostName {get; set;}
```

Property Value

A string which specifies a host name.

Remarks

The **HostName** property can be used to set the host name for a remote system that you wish to communicate with. If the **AutoResolve** property is set to **true** and the name can be resolved to a valid Internet address, the **HostAddress** property will be updated with that value.

See Also

FtpClient Class | SocketTools Namespace

FtpClient.IsBlocked Property

Gets a value which indicates if the current thread is performing a blocking client operation.

[Visual Basic]

```
Public ReadOnly Property IsBlocked As Boolean
```

[C#]

```
public bool IsBlocked {get;}
```

Property Value

Returns **true** if the current thread is blocking, otherwise returns **false**.

Remarks

The **IsBlocked** property returns **true** if the current thread is blocked performing an operation. Because the Windows Sockets API only permits one blocking operation per thread of execution, this property should be checked before starting any blocking operation in response to an event.

If the **IsBlocked** property returns **false**, this means there are no blocking operations on the current thread at that time. However, this does not guarantee that the next client operation will not fail. An application should always check the return value from a client operation and check the value of the **LastError** property if an error occurs.

Note that this property will return **true** if there is any blocking operation being performed by the current thread, regardless of whether this specific instance of the class is responsible for the blocking operation or not.

See Also

FtpClient Class | SocketTools Namespace

FtpClient.IsConnected Property

Gets a value which indicates if a connection to the remote host has been established.

[Visual Basic]

```
Public ReadOnly Property IsConnected As Boolean
```

[C#]

```
public bool IsConnected {get;}
```

Property Value

Returns **true** if the connection has been established; otherwise returns **false**.

Remarks

The **IsConnected** property can only be used to indicate if there is still a logical connection to the remote host. It cannot be used to detect abnormal conditions such as the remote host aborting the connection, the physical network connection being lost or other critical errors.

See Also

FtpClient Class | SocketTools Namespace

FtpClient.IsInitialized Property

Gets a value which indicates if the current instance of the class has been initialized successfully.

[Visual Basic]
```
Public ReadOnly Property IsInitialized As Boolean
```

[C#]
```
public bool IsInitialized {get;}
```

Property Value

Returns **true** if the class instance has been initialized; otherwise returns **false**.

Remarks

The **IsInitialized** property is used to determine if the current instance of the class has been initialized properly. Normally this is done automatically by the class constructor, however there are circumstances where the class may not be able to initialize itself.

The most common reasons that a class instance may not initialize correctly is that no runtime license key has been defined in the assembly or the license key provided is invalid. It may also indicate a problem with the system configuration or user access rights, such as not being able to load the required networking libraries or not being able to access the system registry.

See Also

FtpClient Class | SocketTools Namespace

FtpClient.IsReadable Property

Gets a value which indicates if there is data available to be read from the socket connection to the server.

[Visual Basic]
```
Public ReadOnly Property IsReadable As Boolean
```

[C#]
```
public bool IsReadable {get;}
```

Property Value

Returns **true** if there is data available to be read; otherwise returns **false**.

Remarks

The **IsReadable** property returns **true** if data can be read from the client without blocking. For non-blocking sessions, this property can be checked before the application attempts to read the client. Note that even if this property does return **true** indicating that there is data available to be read, applications should always check the return value from the **Read** method.

See Also

FtpClient Class | SocketTools Namespace

FtpClient.IsWritable Property

Gets a value which indicates if data can be written to the client without blocking.

[Visual Basic]
```
Public ReadOnly Property IsWritable As Boolean
```

[C#]
```
public bool IsWritable {get;}
```

Property Value

Returns **true** if data can be written to the client; otherwise returns **false**.

Remarks

The **IsWritable** property returns **true** if data can be written to the client without blocking. For non-blocking sessions, this property can be checked before the application attempts to write data to the client. Note that even if this property does return **true** indicating that data can be written to the client, applications should always check the return value from the **Write** method.

See Also

FtpClient Class | SocketTools Namespace

FtpClient.KeepAlive Property

Gets and sets a Boolean value which specifies if the client should attempt to keep the server connection alive.

[Visual Basic]

```
Public Property KeepAlive As Boolean
```

[C#]

```
public bool KeepAlive {get; set;}
```

Property Value

A boolean value which specifies if the client should attempt to maintain the connection with the server over a long period of time.

Remarks

If the **KeepAlive** property is set to **true**, the client will attempt to maintain an active connection to the server over a long period of time. If this property is set to **false**, then no attempt will be made to hold the command channel open.

It is important to note that enabling this option does not guarantee that the connection will be maintained. The application must be written to account for situations where the connection to the server is terminated if it is idle for a long period of time, regardless of the value of this property.

See Also

FtpClient Class | SocketTools Namespace

FtpClient.LastError Property

Gets and sets a value which specifies the last error that has occurred.

[Visual Basic]

```
Public Property LastError As Integer
```

[C#]

```
public int LastError {get; set;}
```

Property Value

Returns an ErrorCode enumeration value which specifies the last error code.

Remarks

The **LastError** property returns the error code associated with the last error that occurred for the current instance of the class. It is important to note that this value only has meaning if the previous method indicates that an error has actually occurred.

It is possible to explicitly clear the last error code by assigning the property to the value **ErrorCode.errorNone**.

The error code value can be cast to an integer value for display purposes if required. For a description of the error that can be displayed using a message box or some other similar mechanism, get the value of the **LastErrorString** property.

See Also

FtpClient Class | SocketTools Namespace

FtpClient.LastErrorString Property

Gets a value which describes the last error that has occurred.

[Visual Basic]

```
Public ReadOnly Property LastErrorString As String
```

[C#]

```
public string LastErrorString {get;}
```

Property Value

A string which describes the last error that has occurred.

Remarks

The **LastErrorString** property can be used to obtain a description of the last error that occurred for the current instance of the class. It is important to note that this value only has meaning if the previous method indicates that an error has actually occurred.

See Also

FtpClient Class | SocketTools Namespace

FtpClient.LocalAddress Property

Gets the local Internet address that the client is bound to.

[Visual Basic]

```
Public ReadOnly Property LocalAddress As String
```

[C#]

```
public string LocalAddress {get;}
```

Property Value

A string which specifies an Internet address.

Remarks

The **LocalAddress** property returns the local Internet address that the client is bound to when a connection is established with a remote host. This property may return either an IPv4 or IPv6 formatted address, depending on the type of connection that was established.

See Also

FtpClient Class | SocketTools Namespace

FtpClient.Localize Property

Gets and sets a value which specifies if time and dates should be adjusted for the current timezone.

[Visual Basic]

```
Public Property Localize As Boolean
```

[C#]

```
public bool Localize {get; set;}
```

Property Value

A boolean value which specifies if file time and dates should be adjusted for the local timezone. The default value is false.

Remarks

The **Localize** property controls how remote file date and time values are localized when the **GetFileTime** method is called. If the property is set to **true** the file date and time will be adjusted to the current timezone. If the property is set to **false** the file date and time are returned as UTC (Coordinated Universal Time) values.

See Also

FtpClient Class | SocketTools Namespace

FtpClient.LocalName Property

Gets a value which specifies the host name for the local system.

[Visual Basic]

```
Public ReadOnly Property LocalName As String
```

[C#]

```
public string LocalName {get;}
```

Property Value

A string which specifies the local host name.

Remarks

The **LocalName** property returns the fully-qualified host name assigned to the local system. If the system has not been configured with an Internet domain name, then this property will return the NetBIOS name assigned to the local system.

See Also

FtpClient Class | SocketTools Namespace

FtpClient.LocalPort Property

Gets the local port number the client is bound to.

[Visual Basic]
```
Public ReadOnly Property LocalPort As Integer
```

[C#]
```
public int LocalPort {get;}
```

Property Value

An integer value which specifies a port number. The default value is 0.

Remarks

The **LocalPort** property is used to identify the local port number that the client is bound to to when a connection is established with a remote host.

See Also

FtpClient Class | SocketTools Namespace

FtpClient.Options Property

Gets and sets a value which specifies one or more client options.

[Visual Basic]

```
Public Property Options As FtpOptions
```

[C#]

```
public FtpClient.FtpOptions Options {get; set;}
```

Property Value

Returns one or more FtpOptions enumeration flags which specify the options for the client. The default value for this property is **optionNone**.

Remarks

The **Options** property specifies one or more default options options which are used when establishing a connection using the **Connect** method.

See Also

FtpClient Class | SocketTools Namespace

FtpClient.ParseList Property

Gets and sets a value that specifies if directory listings should be automatically parsed

[Visual Basic]

```
Public Property ParseList As Boolean
```

[C#]

```
public bool ParseList {get; set;}
```

Property Value

A boolean value which specifies if directory listings should be automatically parsed. If the value is **true**, then the class will attempt to parse directory listings returned by the server. If the value is **false**, raw directory listings will be returned to the client.

Remarks

The **ParseList** property is used to control how remote file lists are processed. If the property is set to **false**, file lists are not parsed and the application is responsible for parsing the list of files returned by the server.

The class recognizes file listings in UNIX, MS-DOS, VMS, Windows and NetWare formats, and will attempt to automatically determine the format that is being returned by the server. If the server does not return file lists in one of these formats, the **ParseList** property should be set to **false**, and the application must parse the file listing itself.

See Also

FtpClient Class | SocketTools Namespace

FtpClient.Passive Property

Gets and sets a value which specifies if passive mode file transfers should be enabled.

[Visual Basic]

```
Public Property Passive As Boolean
```

[C#]

```
public bool Passive {get; set;}
```

Property Value

A boolean value which specifies if passive mode file transfers are enabled. If this value is set to **true**, passive mode is enabled. If the value is set to **false**, then passive mode transfers are disabled. The default value is **true**.

Remarks

When the client uploads or downloads a file and the **Passive** property is set to **false**, the server establishes a second connection back to the client which is used to transfer the file data. However, if the local system is behind a firewall or a NAT router, the server may not be able to create the data connection and the transfer will fail. By setting this property to **true**, it forces the client to establish an outbound data connection with the server. It is recommended that most applications use passive mode whenever possible.

Setting this property to **true** is the same as specifying the optionPassive flag when establishing a connection to the server.

See Also

FtpClient Class | SocketTools Namespace

FtpClient.Password Property

Gets and sets the password used to authenticate the client session.

[Visual Basic]

```
Public Property Password As String
```

[C#]

```
public string Password {get; set;}
```

Property Value

A string which specifies the password.

Remarks

If a password is not specified when the **Connect** method is called, the value of this property will be used as the default password when establishing a connection with the server.

See Also

FtpClient Class | SocketTools Namespace

FtpClient.Priority Property

Gets and sets a value which specifies the priority of file transfers.

[Visual Basic]
```
Public Property Priority As FtpPriority
```

[C#]
```
public FtpClient.FtpPriority Priority {get; set;}
```

Property Value

Returns a FtpPriority enumeration value which specify the current file transfer priority. The default value for this property is **priorityNormal**.

Remarks

The **Priority** property can be used to control the processor usage, memory and network bandwidth allocated for file transfers. The default priority balances resource utilization and transfer speed while ensuring that a single-threaded application remains responsive to the user. Lower priorities reduce the overall resource utilization at the expense of transfer speed. For example, if you create a worker thread to download a file in the background and want to ensure that it has a minimal impact on the process, the **priorityBackground** value can be used.

Higher priority values increase the memory allocated for the transfers and increases processor utilization for the transfer. The **priorityCritical** priority maximizes transfer speed at the expense of system resources. It is not recommended that you increase the file transfer priority unless you understand the implications of doing so and have thoroughly tested your application. If the file transfer is being performed in the main UI thread, increasing the priority may interfere with the normal processing of Windows messages and cause the application to appear to become non-responsive. It is also important to note that when the priority is set to **priorityCritical**, normal progress events will not be generated during the transfer.

See Also

FtpClient Class | SocketTools Namespace | FtpPriority Enumeration

FtpClient.ProxyHost Property

Gets and sets the hostname or IP address of a proxy server.

[Visual Basic]

```
Public Property ProxyHost As String
```

[C#]

```
public string ProxyHost {get; set;}
```

Property Value

A string which specifies the hostname or IP address of the proxy server that will be used when establishing a connection.

Remarks

The **ProxyHost** property should be set to the name of the proxy server that you want to connect to. This property may be set to either a fully qualified domain name, or an IP address. This property is only used if the **ProxyType** property specifies a proxy server type other than **proxyNone**.

See Also

FtpClient Class | SocketTools Namespace

FtpClient.ProxyPassword Property

Gets and sets the password used to authenticate the connection to a proxy server.

[Visual Basic]

```
Public Property ProxyPassword As String
```

[C#]

```
public string ProxyPassword {get; set;}
```

Property Value

A string which specifies a password.

Remarks

The **ProxyPassword** property specifies the password used to authenticate the user to the proxy server. If a password is not required by the server, this property is ignored.

See Also

FtpClient Class | SocketTools Namespace

FtpClient.ProxyPort Property

Gets and sets a value that specifies the proxy server port number.

[Visual Basic]

```
Public Property ProxyPort As Integer
```

[C#]

```
public int ProxyPort {get; set;}
```

Property Value

An integer value which specifies the proxy port number.

Remarks

The **ProxyPort** property is used to set the port number that the control will use to establish a connection with the proxy server. A value of zero specifies that the client will connect to the proxy server using the standard FTP service port.

See Also

FtpClient Class | SocketTools Namespace

FtpClient.ProxyType Property

Gets and sets the type of proxy server the client will use to establish a connection.

[Visual Basic]

```
Public Property ProxyType As FtpProxyType
```

[C#]

```
public FtpClient.FtpProxyType ProxyType {get; set;}
```

Property Value

An FtpProxyType enumeration which specifies the type of proxy that the client will connect through.

See Also

FtpClient Class | SocketTools Namespace

FtpClient.ProxyUser Property

Gets and sets the username used to authenticate the connection to a proxy server.

[Visual Basic]

```
Public Property ProxyUser As String
```

[C#]

```
public string ProxyUser {get; set;}
```

Property Value

A string which specifies the username.

Remarks

The **ProxyUser** property specifies the user that is logging in to the proxy server. If the proxy server does not require the user to login, then this property is ignored.

See Also

FtpClient Class | SocketTools Namespace

FtpClient.RemoteFile Property

Gets and sets the file name specified in the current URL.

[Visual Basic]
```
Public Property RemoteFile As String
```

[C#]
```
public string RemoteFile {get; set;}
```

Property Value

A string which specifies a file name on the server.

Remarks

The **RemoteFile** property returns the name of the file that was specified when the **URL** property was set. Changing the value of this property causes the current URL to change. The class does not check to make sure that the remote file name is valid or that it actually exists on the server.

See Also

FtpClient Class | SocketTools Namespace

FtpClient.RemotePath Property

Gets and sets the path specified in the current URL.

[Visual Basic]

```
Public Property RemotePath As String
```

[C#]

```
public string RemotePath {get; set;}
```

Property Value

A string which specifies a directory path on the server.

Remarks

The **RemotePath** property returns the path that was specified when the **URL** property was set. Changing the value of this property causes the current URL to change. The class does not check to make sure that the remote path is valid or that it actually exists on the server.

Note that the path is relative to the user's home directory and should not be considered an absolute path from the root directory on the server. If no username and password are provided when the connection is established, then an anonymous session is used and the path is relative to the public directory defined by the FTP server.

See Also

FtpClient Class | SocketTools Namespace

FtpClient.RemotePort Property

Gets and sets a value which specifies the remote port number.

[Visual Basic]

```
Public Property RemotePort As Integer
```

[C#]

```
public int RemotePort {get; set;}
```

Property Value

An integer value which specifies a port number.

Remarks

The **RemotePort** property is used to set the port number that will be used to establish a connection with a remote host. If the port number specifies a well-known port, the **RemoteService** property will be updated with that name.

See Also

FtpClient Class | SocketTools Namespace

FtpClient.ResultCode Property

Gets a value which specifies the last result code returned by the server.

[Visual Basic]

```
Public ReadOnly Property ResultCode As Integer
```

[C#]

```
public int ResultCode {get;}
```

Property Value

An integer value which specifies the last result code returned by the server.

Remarks

Result codes are three-digit numeric values returned by the remote server and may be broken down into the following ranges:

ResultCode	Description
100-199	Positive preliminary result. This indicates that the requested action is being initiated, and the client should expect another reply from the server before proceeding.
200-299	Positive completion result. This indicates that the server has successfully completed the requested action.
300-399	Positive intermediate result. This indicates that the requested action cannot complete until additional information is provided to the server.
400-499	Transient negative completion result. This indicates that the requested action did not take place, but the error condition is temporary and may be attempted again.
500-599	Permanent negative completion result. This indicates that the requested action did not take place.

It is important to note that while some result codes have become standardized, not all servers respond to commands using the same result codes. For example, one server may respond with a result code of 221 to indicate success, while another may respond with a value of 235. It is recommended that applications check for ranges of values to determine if a command was successful, not a specific value.

See Also

FtpClient Class | SocketTools Namespace

FtpClient.ResultString Property

Gets a string value which describes the result of the previous command.

[Visual Basic]

```
Public ReadOnly Property ResultString As String
```

[C#]

```
public string ResultString {get;}
```

Property Value

A string which describes the result of the previous command executed on the server.

Remarks

The **ResultString** property returns the result string from the last action taken by the client. This string is generated by the remote server, and typically is used to describe the result code. For example, if an error is indicated by the result code, the result string may describe the condition that caused the error.

See Also

FtpClient Class | SocketTools Namespace

FtpClient.Secure Property

Gets and sets a value which specifies if a secure connection is established.

[Visual Basic]

```
Public Property Secure As Boolean
```

[C#]

```
public bool Secure {get; set;}
```

Property Value

Returns **true** if a secure connection is established; otherwise returns **false**. The default value is **false**.

Remarks

The **Secure** property determines if a secure connection is established with the remote host. The default value for this property is **false**, which specifies that a standard connection to the server is used. To establish a secure connection, the application should set this property value to **true** prior to calling the **Connect** method. Once the connection has been established, the client may exchange data with the server as with standard connections.

It is strongly recommended that any application that sets this property **true** use error handling to trap an errors that may occur. If the class is unable to initialize the security libraries, or otherwise cannot create a secure session for the client, an exception may be generated when this property value is set to **true**.

See Also

FtpClient Class | SocketTools Namespace

FtpClient.SecureCipher Property

Gets a value that specifies the encryption algorithm used for a secure connection.

[Visual Basic]

```
Public ReadOnly Property SecureCipher As SecureCipherAlgorithm
```

[C#]

```
public FtpClient.SecureCipherAlgorithm SecureCipher {get;}
```

Property Value

A SecureCipherAlgorithm enumeration value which identifies the algorithm.

Remarks

The **SecureCipher** property returns a value which identifies the algorithm used to encrypt the data stream. If a secure connection has not been established, this property will return a value of **cipherNone**.

See Also

FtpClient Class | SocketTools Namespace

FtpClient.SecureHash Property

Gets a value that specifies the message digest algorithm used for a secure connection.

[Visual Basic]

```
Public ReadOnly Property SecureHash As SecureHashAlgorithm
```

[C#]

```
public FtpClient.SecureHashAlgorithm SecureHash {get;}
```

Property Value

A SecureHashAlgorithm enumeration value which identifies the algorithm.

Remarks

The **SecureHash** property returns a value which identifies the message digest (hash) algorithm that was selected when a secure connection was established. If a secure connection has not been established, this property will return a value of **hashNone**.

See Also

FtpClient Class | SocketTools Namespace

FtpClient.SecureKeyExchange Property

Gets a value that specifies the key exchange algorithm used for a secure connection.

[Visual Basic]

```
Public ReadOnly Property SecureKeyExchange As SecureKeyAlgorithm
```

[C#]

```
public FtpClient.SecureKeyAlgorithm SecureKeyExchange {get;}
```

Property Value

A SecureKeyAlgorithm enumeration value which identifies the algorithm.

Remarks

The **SecureKeyExchange** property returns a value which identifies the key exchange algorithm that was selected when a secure connection was established. If a secure connection has not been established, this property will return a value of **keyExchangeNone**.

See Also

FtpClient Class | SocketTools Namespace

FtpClient.SecureProtocol Property

Gets and sets a value which specifies the protocol used for a secure connection.

[Visual Basic]
```
Public Property SecureProtocol As SecurityProtocols
```

[C#]
```
public FtpClient.SecurityProtocols SecureProtocol {get; set;}
```

Property Value

A SecurityProtocols enumeration value which identifies the protocol to be used when establishing a secure connection.

Remarks

The **SecureProtocol** property can be used to specify the security protocol to be used when establishing a secure connection with a server or accepting a secure connection from a client. By default, the class will attempt to use either SSL v3 or TLS v1 to establish the connection, with the appropriate protocol automatically selected based on the capabilities of the remote host. It is recommended that you only change this property value if you fully understand the implications of doing so. Assigning a value to this property will override the default protocol and force the class to attempt to use only the protocol specified.

Multiple security protocols may be specified by combining them using a bitwise **or** operator. After a connection has been established, this property will identify the protocol that was selected. Attempting to set this property after a connection has been established will result in an exception being thrown. This property should only be set after setting the **Secure** property to **true** and before calling the **Accept** or **Connect** methods.

In some cases, a server may only accept a secure connection if the TLS v1 protocol is specified. If the security protocol is not compatible with the server, then the connection will fail with an error indicating that the control is unable to establish a security context for the session. In this case, try assigning the property to **protocolTLS1** and attempt the connection again.

See Also

FtpClient Class | SocketTools Namespace

FtpClient.Status Property

Gets a value which specifies the current status of the client.

[Visual Basic]

```
Public ReadOnly Property Status As FtpStatus
```

[C#]

```
public FtpClient.FtpStatus Status {get;}
```

Property Value

A FtpStatus enumeration value which specifies the current client status.

Remarks

The **Status** property returns the current status of the client. This property can be used to check on blocking connections to determine if the client is interacting with the remote host before taking some action.

See Also

FtpClient Class | SocketTools Namespace

FtpClient.System Property

Gets a string value which identifies the server.

[Visual Basic]

```
Public ReadOnly Property System As String
```

[C#]

```
public string System {get;}
```

Property Value

A string which identifies the type of server the client has connected to.

Remarks

The **System** property returns information about the remote host operating system. This is a read-only property that can be used by the application to identify the type of server that the client has connected to. Reading this property will cause the SYST command to be sent to the server and will only return a useful value after a connection has been established with the server.

By convention, the first whitespace separated token in the string identifies the general operating system platform. For example, here are some strings commonly returned by various FTP servers:

Examples	Description
UNIX Type: L8	A standard UNIX based server. This is the most common value returned by servers, and this indicates that the server supports UNIX file naming and directory listing conventions. This string may also include additional information such as the specific variant of UNIX and its version. The L8 portion of the string is a convention that lets the client know that a byte consists of 8 bits.
Windows_NT Version 5.0	A standard Windows based server, typically part of Internet Information Services (ISS). The server will use Windows file naming and directory listing conventions. The version identifies the specific release of Windows. For example, version 4.0 specifies Windows NT 4.0 and 5.0 specifies Windows 2000.
VMS V7.1 AlphaServer	A server running the VMS operating system. The server will use the standard file naming and directory listing conventions for that platform. Note that it is possible that a VMS system may also be configured to operate in a UNIX emulation mode, in which case it will return UNIX instead of VMS.
NetWare	A server running the NetWare operating system. The server will use the standard file naming and directory listing conventions for that platform. Note that it is possible that a NetWare system may be configured to operate in a UNIX emulation

	mode, in which case it return UNIX instead of NetWare.
WORLDGROUP Type: L8	A server running the WorldGroup software on the Windows platform. This server supports UNIX file naming and directory listing conventions. WorldGroup is a collaborative workgroup, email and file sharing service which includes an FTP server.

FtpClient Class | SocketTools Namespace

FtpClient.ThreadModel Property

Gets and sets a value which specifies the threading model for the class instance.

[Visual Basic]
```
Public Property ThreadModel As ThreadingModel
```

[C#]
```
public FtpClient.ThreadingModel ThreadModel {get; set;}
```

Property Value

Returns one or more ThreadingModel enumeration value which specifies the threading model for the client. The default value for this property is **modelSingleThread**.

Remarks

The **ThreadModel** property specifies the threading model that is used by the class instance when a connection is established. The default value for this property is **modelSingleThread**, which specifies that only the thread that established the connection should be permitted to invoke methods. It is important to note that this threading model does not limit the application to a single thread of execution. When a session is established using the **Connect** method, that session is attached to the thread that created it. From that point on, until the session is terminated, only the owner may invoke methods in that instance of the class. The ownership of the class instance may be transferred from one thread to another using the **AttachThread** method.

Setting this property to **modelFreeThread** disables certain internal safety checks that are performed by the class and may result in unexpected behavior unless you ensure that access to the class instance is synchronized across multiple threads. The application must ensure that no two threads will attempt to invoke a blocking method at the same time. In other words, if one thread invokes a method, the application must ensure that another thread will not attempt to invoke any other method at the same time using the same instance of the class.

Changing the value of this property will not affect an active client session. The threading model must be specified prior to invoking the **Connect** method.

See Also

FtpClient Class | SocketTools Namespace | AttachThread Method | ThreadingModel Enumeration | ThreadModel Attribute

FtpClient.TaskCount Property

Get the number of active background file transfers.

[Visual Basic]

```
Public ReadOnly Property TaskCount As Integer
```

[C#]

```
public int TaskCount {get;}
```

Property Value

An integer value that specifies the number of background file transfers that are currently in progress.

Remarks

The **TaskCount** property returns the number of background file transfers that are currently in progress. One common use for this property is to create a timer that periodically checks this value when a series of background transfers are started. When the property returns a value of zero, that indicates all of the background transfers have completed. This property can also be used to enumerate the active background tasks in conjunction with the **TaskList** property.

See Also

FtpClient Class | SocketTools Namespace

FtpClient.TaskId Property

Get the task identifier for the last background file transfer.

[Visual Basic]
```
Public ReadOnly Property TaskId As Integer
```

[C#]
```
public int TaskId {get;}
```

Property Value

An integer value the uniquely identifies the current background task.

Remarks

The **TaskId** property returns the task ID associated with the current background task. This identifies the last background file transfer that was initiated with a call to the **AsyncGetFile** or **AsyncPutFile** methods. This property value will change with each subsequent background transfer that is performed. If this property returns a value of zero, that indicates that no background tasks have been started for this instance of the class.

To enumerate the active background tasks, use the **TaskCount** property and the **TaskList** array.

See Also

FtpClient Class | SocketTools Namespace

FtpClient.TaskList Property

Get an array of active background task identifiers.

[Visual Basic]

```
Public ReadOnly Property TaskList As ArrayList
```

[C#]

```
public System.Collections.ArrayList TaskList {get;}
```

Property Value

An **ArrayList** object that contains a list of integer values that uniquely identify the active background tasks that have been started by this instance of the class.

Remarks

The **TaskList** property returns a read-only **ArrayList** object that is popularted with the task identifiers for all active background tasks that have been created by this instance of the class. The current number of active tasks can be determined using the **TaskCount** property.

As background tasks complete and additional tasks are started, the values stored in this array will change. The application should never make any assumptions about the numeric values stored in the array or the order they are returned. Task IDs should be considered opaque values that are unique to the process. When a background task completes, its corresponding ID is removed from the list of active tasks and this can potentially change the task ID values associated with each index into the array.

See Also

FtpClient Class | SocketTools Namespace

FtpClient.ThrowError Property

Gets and sets a value which specifies if method calls should throw exceptions when an error occurs.

[Visual Basic]

```
Public Property ThrowError As Boolean
```

[C#]

```
public bool ThrowError {get; set;}
```

Property Value

Returns **true** if method calls will generate exceptions when an error occurs; otherwise returns **false**. The default value is **false**.

Remarks

Error handling for when calling class methods can be done in either of two different styles, according to the value of this property.

If the **ThrowError** property is set to **false**, the application should check the return value of any method that is used, and report errors based upon the documented value of the return code. It is the responsibility of the application to interpret the error code, if it is desired to explain the error in addition to reporting it. This is the default behavior.

If the **ThrowError** property is set to **true**, then exceptions will be generated whenever a method call fails. The program must be written to catch these exceptions and take the appropriate action when an error occurs. Failure to handle an exception will cause the program to terminate abnormally.

Note that if an error occurs while a property is being read or modified, an exception will be raised regardless of the value of the **ThrowError** property.

FtpClient Class | SocketTools Namespace

FtpClient.Timeout Property

Gets and sets a value which specifies a timeout period in seconds.

[Visual Basic]

```
Public Property Timeout As Integer
```

[C#]

```
public int Timeout {get; set;}
```

Property Value

An integer value which specifies a timeout period in seconds.

Remarks

Setting the **Timeout** property specifies the number of seconds until a blocking operation fails and returns an error.

The timeout period is only used when the client is in blocking mode. Although this property can be changed when the client is in non-blocking mode, the value will be ignored until the client is returned to blocking mode.

For most applications it is recommended the timeout period be set between 10 and 20 seconds.

See Also

FtpClient Class | SocketTools Namespace

FtpClient.TimeZone Property

Gets and sets the current timezone offset in seconds.

[Visual Basic]
```
Public Property TimeZone As Integer
```

[C#]
```
public int TimeZone {get; set;}
```

Property Value

An integer value which specifies the current timezone offset in seconds.

Remarks

The **TimeZone** property returns the current offset from UTC in seconds. Setting the property changes the current timezone offset to the specified value. The value of this property is initially determined by the date and time settings on the local system.

This property value is used in conjunction with the **Localize** property to control how date and time localization is handled.

FtpClient Class | SocketTools Namespace

FtpClient.Trace Property

Gets and sets a value which indicates if network function logging is enabled.

[Visual Basic]

```
Public Property Trace As Boolean
```

[C#]

```
public bool Trace {get; set;}
```

Property Value

Returns **true** if network function tracing is enabled; otherwise returns **false**. The default value is **false**.

Remarks

The **Trace** property is used to enable (or disable) the tracing of network function calls. When enabled, each function call is logged to a file, including the function parameters, return value and error code if applicable. This facility can be enabled and disabled at run time, and the trace log file can be specified by setting the **TraceFile** property. All function calls that are being logged are appended to the trace file, if it exists. If no trace file exists when tracing is enabled, the trace file is created.

The tracing facility is available in all of the SocketTools networking classes and is enabled or disabled for an entire process. This means that once trace logging is enabled for a given component, all of the function calls made by the process using any of the SocketTools classes will be logged. For example, if you have an application using both the File Transfer Protocol and Post Office Protocol classes, and you set the **Trace** property to **true**, function calls made by both classes will be logged. Additionally, enabling a trace is cumulative, and tracing is not stopped until it is disabled for all classes used by the process.

If trace logging is not enabled, there is no negative impact on performance or throughput. Once enabled, application performance can degrade, especially in those situations in which multiple processes are being traced or the logfile is fairly large. Since logfiles can grow very quickly, even with modest applications, it is recommended that you delete the file when it is no longer needed.

When redistributing your application, make sure that you include the **SocketTools10.TraceLog.dll** module with your installation. If this library is not present, then no trace output will be generated and the value of the **Trace** property will be ignored. Only those function calls made by the SocketTools networking classes will be logged. Calls made directly to the Windows Sockets API, or calls made by other classes, will not be logged.

See Also

FtpClient Class | SocketTools Namespace

FtpClient.TraceFile Property

Gets and sets a value which specifies the name of the logfile.

[Visual Basic]
```
Public Property TraceFile As String
```

[C#]
```
public string TraceFile {get; set;}
```

Property Value

A string which specifies the name of the file.

Remarks

The **TraceFile** property is used to specify the name of the trace file that is created when network function tracing is enabled. If this property is set to an empty string (the default value), then a file named **SocketTools.log** is created in the system's temporary directory. If no temporary directory exists, then the file is created in the current working directory.

If the file exists, the trace output is appended to the file, otherwise the file is created. Since network function tracing is enabled per-process, the trace file is shared by all instances of the class being used. If multiple class instances have tracing enabled, the **TraceFile** property should be set to the same value for each instance. Since trace files can grow very quickly, even with modest applications, it is recommended that you delete the file when it is no longer needed.

The trace file has the following format:

```
 MyApp INF: WSAAsyncSelect(46, 0xcc4, 0x7e9, 0x27) returned 0 MyApp WRN:
connect(46, 192.0.0.1:1234, 16) returned -1 [10035] MyApp ERR: accept(46,
NULL, 0x0) returned -1 [10038]
```

The first column contains the name of the process that is being traced. The second column identifies if the trace record is reporting information, a warning, or an error. What follows is the name of the function being called, the arguments passed to the function and the function's return value. If a warning or error is reported, the error code is appended to the record (the value is placed inside brackets).

If parameters are passed as integer values, they are recorded in decimal. If the parameter or return value is a pointer (a memory address), it is recorded as a hexadecimal value preceded with "0x". A special type of pointer, called a null pointer, is recorded as NULL. Those functions which expect socket addresses are displayed in the following format:

```
aa.bb.cc.dd:nnnn
```

The first four numbers separated by periods represent the IP address, and the number following the colon represents the port number in host byte order. Note that in the second line of the above example, the control is attempting to connect to a system with the IP address 192.0.0.1 on port 1234.

Note that if the specified file cannot be created, or the user does not have permission to modify an existing file, the error is silently ignored and no trace output will be generated.

See Also

FtpClient Class | SocketTools Namespace

FtpClient.TraceFlags Property

Gets and sets a value which specifies the client function tracing flags.

[Visual Basic]

```
Public Property TraceFlags As TraceOptions
```

[C#]

```
public FtpClient.TraceOptions TraceFlags {get; set;}
```

Property Value

A TraceOptions enumeration which specifies the amount of detail written to the trace logfile.

Remarks

The **TraceFlags** property is used to specify the type of information written to the trace file when network function tracing is enabled.

Because network function tracing is enabled per-process, the trace flags are shared by all instances of the class being used. If multiple class instances have tracing enabled, the **TraceFlags** property should be set to the same value for each instance. Changing the trace flags for any one instance of the class will affect the logging performed for all SocketTools classes used by the application.

Warnings are generated when a non-fatal error is returned by a network function. For example, if data is being written and the error **errorOperationWouldBlock** occurs, a warning is generated because the application simply needs to attempt to write the data at a later time.

See Also

FtpClient Class | SocketTools Namespace

FtpClient.TransferBytes Property

Gets a value which specifies the number of bytes transferred to or from the remote server.

[Visual Basic]

```
Public ReadOnly Property TransferBytes As Long
```

[C#]

```
public long TransferBytes {get;}
```

Property Value

An integer value which specifies the number of bytes of data transferred to or from the server.

Remarks

The **TransferBytes** property returns the number of bytes that have been copied to or from the remote FTP server. If this property is read while a transfer is ongoing, the property returns the number of bytes that have been copied up to that point. If read after a transfer has completed, the total number of bytes copied is returned. This property value is reset with every data transfer.

See Also

FtpClient Class | SocketTools Namespace

FtpClient.TransferTime Property

Gets a value which specifies the number of seconds elapsed during a data transfer.

[Visual Basic]

```
Public ReadOnly Property TransferTime As Integer
```

[C#]

```
public int TransferTime {get;}
```

Property Value

An integer value which specifies the transfer time in seconds.

Remarks

The **TransferTime** property returns the number of seconds that have elapsed since the data connection was opened on the remote server. If the property is read while a transfer is ongoing, it returns the elapsed time. If the property is read after the transfer is complete, it returns the total number of seconds it took to transfer the data. This property value is reset with every data transfer.

See Also

FtpClient Class | SocketTools Namespace

FtpClient.URL Property

Gets and sets the current URL used to access a file on the server.

[Visual Basic]

```
Public Property URL As String
```

[C#]

```
public string URL {get; set;}
```

Property Value

A string which specifies the current URL.

Remarks

The **URL** property returns the current Uniform Resource Locator string which is used by the control to access a file on the server. URLs have a specific format which provides information about the remote host, port, path and file name, as well as optional information such as a username and password for authentication:

> `ftp://[`*`username`*` : [`*`password`*`] @] remotehost [:`*`remoteport`*`] / [`*`path/`*`...] filename [;`*`type=id`*`]`

The first part of the URL is the protocol and in this case will always be "ftp", or "ftps" if a secure connection is being used. If a username and password is required for authentication, then this will be included in the URL before the name of the remote host; otherwise an anonymous FTP session is assumed. Next, there is the name of the remote host to connect to, optionally followed by a port number. If no port number is given, then the default port for the protocol will be used. This is followed by the path, and then the name of the file on the server. An optional file type may be specified as well, with the type identifier being either "a" for text files or "i" for binary files.

One important consideration when using FTP URLs is that the path is relative to the user's home directory and should not be considered an absolute path from the root directory on the server. If no username and password is provided, then an anonymous session is used and the path is relative to the public directory used by the FTP server.

Here are some typical examples of URLs used to access files on an FTP server:

```
ftp://www.example.com/pub/financial/jan2020.xls
```

> In this example, the remote host is www.example.com, the path is "pub/financial" and the file name is "jan2020.xls". The default port will be used to access the file, and no username and password is provided for authentication so this file must be publicly available to anonymous users.

```
ftp://www.example.com:2121/employees/picnic.doc
```

> In this example, the remote host is www.example.com, the path is "employees" and the file name is "picnic.doc". However, the client should connect to an alternative port number, in this case 2121. This file must also be available to anonymous users because no username or password has been specified.

```
ftps://executive:secret@www.example.com/corporate/projections/sales2020.xls
```

In this example, the remote host is www.example.com and, the path is "corporate/projections" and the file name is "sales2020.xls". Because the protocol is ftps, a secure connection on port 990 will be established. The user name "executive" and password "secret" will be used to authenticate the session.

When setting the **URL** property, the class will parse the string and automatically update the **HostName**, **RemotePort**, **UserName**, **Password**, **RemotePath** and **RemoteFile** properties according to the values specified in the URL. This enables an application to simply provide the URL and then call the **Connect** method to establish the connection.

Note that if this property is assigned a value which cannot be parsed, an exception will be thrown that indicates that the property value is invalid. If the user enters an invalid URL and there is no exception handler, the unhandled exception will terminate the application.

See Also

FtpClient Class | SocketTools Namespace

FtpClient.UserName Property

Gets and sets the username used to authenticate the client session.

[Visual Basic]

```
Public Property UserName As String
```

[C#]

```
public string UserName {get; set;}
```

Property Value

A string which specifies the username.

Remarks

If a username is not specified when the **Connect** method is called, the value of this property will be used as the default username when establishing a connection with the server.

See Also

FtpClient Class | SocketTools Namespace

FtpClient.Version Property

Gets a value which returns the current version of the FtpClient class library.

[Visual Basic]

```
Public ReadOnly Property Version As String
```

[C#]

```
public string Version {get;}
```

Property Value

A string which specifies the version of the class library.

Remarks

The **Version** property returns a string which identifies the current version and build of the FtpClient class library. This value can be used by an application for validation and debugging purposes.

FtpClient Class | SocketTools Namespace

FtpClient Methods

The methods of the **FtpClient** class are listed below. For a complete list of **FtpClient** class members, see the FtpClient Members topic.

Public Static (Shared) Methods

ErrorText	Returns the description of an error code.

Public Instance Methods

AddFileType	Associate a file name extension with a specific file type.
AsyncGetFile	Overloaded. Download a file from the server to the local system in the background.
AsyncPutFile	Overloaded. Upload a file from the local system to the server in the background.
AttachThread	Attach an instance of the class to the current thread
Cancel	Cancel the current blocking client operation.
ChangeDirectory	Change the current working directory on the remote server.
CloseDirectory	Close the directory that was previously opened with the OpenDirectory method.
CloseFile	Close the file that was previously opened with the OpenFile method.
Command	Overloaded. Send a custom command to the server.
Connect	Overloaded. Establish a connection with a remote host.
CreateFile	Create a new file or overwrite an existing file.
DeleteFile	Delete a file on the remote server.
Disconnect	Terminate the connection with the remote server.
Dispose	Overloaded. Releases all resources used by FtpClient.
Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
FileList	Overloaded. Return a list of files on the remote host.
GetData	Overloaded. Transfers the contents of a file on the server and stores it in a byte array.
GetDirectory	Return the current working directory.
GetFile	Overloaded. Download a file from the server to the local system.

GetFileList	Overloaded. Returns an unparsed list of files in the specified directory.
GetFilePermissions	Return the access permissions for a file on the remote system.
GetFileSize	Overloaded. Returns the size of the specified file on the remote server.
GetFileStatus	Returns status information about the specified file.
GetFileTime	Overloaded. Returns the modification date and time for specified file on the remote server.
GetFirstFile	Overloaded. Get information about the first file in a directory listing returned by the server.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetMultipleFiles	Overloaded. Download multiple files from the server to the local system using a wildcard mask.
GetNextFile	Overloaded. Get information about the next file in a directory listing returned by the server.
GetType (inherited from Object)	Gets the Type of the current instance.
Initialize	Overloaded. Initialize an instance of the FtpClient class.
Login	Overloaded. Login to the remote server.
Logout	Log the current user off the server.
MakeDirectory	Create a new directory on the server.
OpenDirectory	Overloaded. Open the specified directory on the server.
OpenFile	Overloaded. Open an existing file or create a new file on the server.
PutData	Overloaded. Transfers data from a byte array and stores it in a file on the remote server.
PutFile	Overloaded. Upload a file from the local system to the server.
PutMultipleFiles	Overloaded. Upload multiple files from the local system to the server using a wildcard mask.
Read	Overloaded. Read file data from the server and store it in a byte array.
RemoveDirectory	Remove a directory on the server.
RenameFile	Change the name of a file on the server.
Reset	Reset the internal state of the object, resetting all properties to their default values.
SetFilePermissions	Change the access permissions for a file on the

	server.
SetFileTime	Changes the modification date and time for a file on the server.
TaskAbort	Overloaded. Abort the specified asynchronous task.
TaskDone	Overloaded. Determine if an asynchronous task has completed.
TaskResume	Overloaded. Resume execution of an asynchronous task.
TaskSuspend	Overloaded. Suspend execution of an asynchronous task.
TaskWait	Overloaded. Wait for an asynchronous task to complete.
ToString (inherited from Object)	Returns a String that represents the current Object.
Uninitialize	Uninitialize the class library and release any resources allocated for the current thread.
VerifyFile	Overloaded. Verify that the contents of a file on the local system are the same as the specified file on the server.
Write	Overloaded. Write one or more bytes of data to the server.

Protected Instance Methods

Dispose	Overloaded. Releases the unmanaged resources allocated by the FtpClient class and optionally releases the managed resources.
Finalize	Destroys an instance of the class, releasing the resources allocated for the session and unloading the networking library.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

FtpClient Class | SocketTools Namespace

FtpClient.AddFileType Method

Associate a file name extension with a specific file type.

```
[Visual Basic]
Public Function AddFileType( _
   ByVal fileExtension As String, _
   ByVal fileType As FtpFileType _
) As Boolean
```

```
[C#]
public bool AddFileType(
   string fileExtension,
   FtpFileType fileType
);
```

Parameters

fileExtension
A string value which specifies the file name extension.

fileType
A FtpFileType enumeration which specifies the type of file associated with the file extension.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

This method is used to associate specific file types with file name extensions. The class has an internal list of standard text file extensions which it automatically recognizes. This method can be used to extend or modify that list for the client session.

See Also

FtpClient Class | SocketTools Namespace | FtpFileType Enumeration

FtpClient.AsyncGetFile Method

Download a file from the server to the local system in the background.

Overload List

Download a file from the server to the local system in the background.

public bool AsyncGetFile(string);

Download a file from the server to the local system in the background.

public bool AsyncGetFile(string,string);

Download a file from the server to the local system in the background.

public bool AsyncGetFile(string,string,FtpTransferOptions);

Download a file from the server to the local system in the background.

public bool AsyncGetFile(string,string,FtpTransferOptions,long);

See Also

FtpClient Class | SocketTools Namespace | AsyncPutFile Method

FtpClient.AsyncGetFile Method (String)

Download a file from the server to the local system in the background.

[Visual Basic]

```
Overloads Public Function AsyncGetFile( _
   ByVal localFile As String _
) As Boolean
```

[C#]

```
public bool AsyncGetFile(
   string localFile
);
```

Parameters

localFile

A string that specifies the file on the local system that will be created, overwritten or appended to. The file pathing and name conventions must be that of the local host.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **AsyncGetFile** method will download the contents of a remote file to a file on the local system. It is similar to the **GetFile** method, however it retrieves the file using a background worker thread and does not block the current working thread. This enables the application to continue to perform other operations while the file is being downloaded from the server. This method requires that you explicitly establish a connection using the **Connect** method. All background tasks will duplicate the active connection and use it establish a secondary connection with the server to perform the file transfer. If you wish to perform multiple asynchronous file transfers from different servers, you must create a new instance of this class for each server.

After this method is called, the **OnTaskBegin** event will be fired, indicating that the background task has begun the process of connecting to the server and performing the file transfer. As the file is downloaded, the class will periodically invoke the **OnTaskRun** event handler. When the transfer has completed, the **OnTaskEnd** event will be fired. It is not required that you implement handlers for these events.

To determine when a transfer has completed without implementing any event handlers, periodically call the **TaskDone** method. If you wish to block the current thread and wait for the transfer to complete, call the **TaskWait** method. To stop a background file transfer that is in progress, call the **TaskAbort** method. This will signal the background worker thread to cancel the transfer and terminate the session.

This method can be called multiple times to download more than one file in the background; however, most servers limit the number of simultaneous connections that can originate from a single IP address. The application should not make any assumptions about the sequence in which background transfers are performed or the order in which they may complete.

See Also

FtpClient Class | SocketTools Namespace | FtpClient.AsyncGetFile Overload List | AsyncPutFile Method

FtpClient.AsyncGetFile Method (String, String)

Download a file from the server to the local system in the background.

[Visual Basic]

```
Overloads Public Function AsyncGetFile( _
   ByVal localFile As String, _
   ByVal remoteFile As String _
) As Boolean
```

[C#]

```
public bool AsyncGetFile(
   string localFile,
   string remoteFile
);
```

Parameters

localFile

A string that specifies the file on the local system that will be created, overwritten or appended to. The file pathing and name conventions must be that of the local host.

remoteFile

A string that specifies the file on the server that will be transferred to the local system. The file pathing and name conventions must be that of the server.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **AsyncGetFile** method will download the contents of a remote file to a file on the local system. It is similar to the **GetFile** method, however it retrieves the file using a background worker thread and does not block the current working thread. This enables the application to continue to perform other operations while the file is being downloaded from the server. This method requires that you explicitly establish a connection using the **Connect** method. All background tasks will duplicate the active connection and use it establish a secondary connection with the server to perform the file transfer. If you wish to perform multiple asynchronous file transfers from different servers, you must create a new instance of this class for each server.

After this method is called, the **OnTaskBegin** event will be fired, indicating that the background task has begun the process of connecting to the server and performing the file transfer. As the file is downloaded, the class will periodically invoke the **OnTaskRun** event handler. When the transfer has completed, the **OnTaskEnd** event will be fired. It is not required that you implement handlers for these events.

To determine when a transfer has completed without implementing any event handlers, periodically call the **TaskDone** method. If you wish to block the current thread and wait for the transfer to complete, call the **TaskWait** method. To stop a background file transfer that is in progress, call the **TaskAbort** method. This will signal the background worker thread to cancel the transfer and terminate the session.

This method can be called multiple times to download more than one file in the background; however, most servers limit the number of simultaneous connections that can originate from a single IP address. The application should not make any assumptions about the sequence in which background transfers are performed or the order in which they may complete.

FtpClient Class | SocketTools Namespace | FtpClient.AsyncGetFile Overload List | AsyncPutFile Method

FtpClient.AsyncGetFile Method (String, String, FtpTransferOptions)

Download a file from the server to the local system in the background.

[Visual Basic]

```
Overloads Public Function AsyncGetFile( _
   ByVal localFile As String, _
   ByVal remoteFile As String, _
   ByVal options As FtpTransferOptions _
) As Boolean
```

[C#]

```
public bool AsyncGetFile(
   string localFile,
   string remoteFile,
   FtpTransferOptions options
);
```

Parameters

localFile
A string that specifies the file on the local system that will be created, overwritten or appended to. The file pathing and name conventions must be that of the local host.

remoteFile
A string that specifies the file on the server that will be transferred to the local system. The file pathing and name conventions must be that of the server.

options
An FtpTransferOptions enumeration value which specifies one or more file transfer options.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **AsyncGetFile** method will download the contents of a remote file to a file on the local system. It is similar to the **GetFile** method, however it retrieves the file using a background worker thread and does not block the current working thread. This enables the application to continue to perform other operations while the file is being downloaded from the server. This method requires that you explicitly establish a connection using the **Connect** method. All background tasks will duplicate the active connection and use it establish a secondary connection with the server to perform the file transfer. If you wish to perform multiple asynchronous file transfers from different servers, you must create a new instance of this class for each server.

After this method is called, the **OnTaskBegin** event will be fired, indicating that the background task has begun the process of connecting to the server and performing the file transfer. As the file is downloaded, the class will periodically invoke the **OnTaskRun** event handler. When the transfer has completed, the **OnTaskEnd** event will be fired. It is not required that you implement handlers for these events.

To determine when a transfer has completed without implementing any event handlers, periodically call the **TaskDone** method. If you wish to block the current thread and wait for the transfer to complete, call the **TaskWait** method. To stop a background file transfer that is in progress, call the **TaskAbort** method. This will signal the background worker thread to cancel the transfer and terminate the session.

This method can be called multiple times to download more than one file in the background; however, most servers limit the number of simultaneous connections that can originate from a single IP address. The application should not make any assumptions about the sequence in which background transfers are performed or the order in which they may complete.

See Also

FtpClient Class | SocketTools Namespace | FtpClient.AsyncGetFile Overload List | AsyncPutFile Method

FtpClient.AsyncGetFile Method (String, String, FtpTransferOptions, Int64)

Download a file from the server to the local system in the background.

[Visual Basic]

```
Overloads Public Function AsyncGetFile( _
   ByVal localFile As String, _
   ByVal remoteFile As String, _
   ByVal options As FtpTransferOptions, _
   ByVal offset As Long _
) As Boolean
```

[C#]

```
public bool AsyncGetFile(
   string localFile,
   string remoteFile,
   FtpTransferOptions options,
   long offset
);
```

Parameters

localFile

A string that specifies the file on the local system that will be created, overwritten or appended to. The file pathing and name conventions must be that of the local host.

remoteFile

A string that specifies the file on the server that will be transferred to the local system. The file pathing and name conventions must be that of the server.

options

An FtpTransferOptions enumeration value which specifies one or more file transfer options.

offset

A byte offset which specifies where the file transfer should begin. The default value of zero specifies that the file transfer should start at the beginning of the file. A value greater than zero is typically used to restart a transfer that has not completed successfully. Note that specifying a non-zero offset requires that the server support the REST command to restart transfers.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **AsyncGetFile** method will download the contents of a remote file to a file on the local system. It is similar to the **GetFile** method, however it retrieves the file using a background worker thread and does not block the current working thread. This enables the application to continue to perform other operations while the file is being downloaded from the server. This method requires that you explicitly establish a connection using the **Connect** method. All background tasks will duplicate the active connection and use it establish a secondary connection with the server to perform the file transfer. If you wish to perform multiple asynchronous file transfers from different servers, you must create a new instance of this class for each server.

After this method is called, the **OnTaskBegin** event will be fired, indicating that the background task has begun the process of connecting to the server and performing the file transfer. As the file is downloaded, the class will periodically invoke the **OnTaskRun** event handler. When the transfer has completed, the **OnTaskEnd** event will be fired. It is not required that you implement handlers for these events.

To determine when a transfer has completed without implementing any event handlers, periodically call the **TaskDone** method. If you wish to block the current thread and wait for the transfer to complete, call the **TaskWait** method. To stop a background file transfer that is in progress, call the **TaskAbort** method. This will signal the background worker thread to cancel the transfer and terminate the session.

This method can be called multiple times to download more than one file in the background; however, most servers limit the number of simultaneous connections that can originate from a single IP address. The application should not make any assumptions about the sequence in which background transfers are performed or the order in which they may complete.

FtpClient Class | SocketTools Namespace | AsyncGetFile Method

FtpClient.AsyncPutFile Method (String)

Upload a file from the local system to the server in the background.

[Visual Basic]

```
Overloads Public Function AsyncPutFile( _
   ByVal localFile As String _
) As Boolean
```

[C#]

```
public bool AsyncPutFile(
   string localFile
);
```

Parameters

localFile

A string that specifies the file on the local system that will be transferred to the server. The file pathing and name conventions must be that of the local host.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **AsyncPutFile** method will upload the contents of a file on the local system to the server. It is similar to the **PutFile** method, however it retrieves the file using a background worker thread and does not block the current working thread. This enables the application to continue to perform other operations while the file is being uploaded to the server. This method requires that you explicitly establish a connection using the **Connect** method. All background tasks will duplicate the active connection and use it establish a secondary connection with the server to perform the file transfer. If you wish to perform multiple asynchronous file transfers from different servers, you must create an instance of the control for each server.

After this method is called, the **OnTaskBegin** event will be fired, indicating that the background task has begun the process of connecting to the server and performing the file transfer. As the file is uploaded, the control will periodically invoke the **OnTaskRun** event handler. When the transfer has completed, the **OnTaskEnd** event will be fired. It is not required that you implement handlers for these events.

To determine when a transfer has completed without implementing any event handlers, periodically call the **TaskDone** method. If you wish to block the current thread and wait for the transfer to complete, call the **TaskWait** method. To stop a background file transfer that is in progress, call the **TaskAbort** method. This will signal the background worker thread to cancel the transfer and terminate the session.

This method can be called multiple times to upload more than one file in the background; however, most servers limit the number of simultaneous connections that can originate from a single IP address. The application should not make any assumptions about the sequence in which background transfers are performed or the order in which they may complete.

FtpClient.AsyncPutFile Method (String, String, FtpTransferOptions)

Upload a file from the local system to the server in the background.

[Visual Basic]

```
Overloads Public Function AsyncPutFile( _
   ByVal localFile As String, _
   ByVal remoteFile As String, _
   ByVal options As FtpTransferOptions _
) As Boolean
```

[C#]

```
public bool AsyncPutFile(
   string localFile,
   string remoteFile,
   FtpTransferOptions options
);
```

Parameters

localFile
A string that specifies the file on the local system that will be transferred to the server. The file pathing and name conventions must be that of the local host.

remoteFile
A string that specifies the file on the server that will be created, overwritten or appended to. The file pathing and name conventions must be that of the server.

options
An FtpTransferOptions enumeration value which specifies one or more file transfer options.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **AsyncPutFile** method will upload the contents of a file on the local system to the server. It is similar to the **PutFile** method, however it retrieves the file using a background worker thread and does not block the current working thread. This enables the application to continue to perform other operations while the file is being uploaded to the server. This method requires that you explicitly establish a connection using the **Connect** method. FtpClient Class | SocketTools Namespace | FtpClient.AsyncPutFile Overload List | AsyncGetFile Method

FtpClient.AsyncPutFile Method (String, String, FtpTransferOptions, Int64)

Upload a file from the local system to the server in the background.

[Visual Basic]

```
Overloads Public Function AsyncPutFile( _
   ByVal localFile As String, _
   ByVal remoteFile As String, _
   ByVal options As FtpTransferOptions, _
   ByVal offset As Long _
) As Boolean
```

[C#]

```
public bool AsyncPutFile(
   string localFile,
   string remoteFile,
   FtpTransferOptions options,
   long offset
);
```

Parameters

localFile

A string that specifies the file on the local system that will be transferred to the server. The file pathing and name conventions must be that of the local host.

remoteFile

A string that specifies the file on the server that will be created, overwritten or appended to. The file pathing and name conventions must be that of the server.

options

An FtpTransferOptions enumeration value which specifies one or more file transfer options.

offset

A byte offset which specifies where the file transfer should begin. The default value of zero specifies that the file transfer should start at the beginning of the file. A value greater than zero is typically used to restart a transfer that has not completed successfully. Note that specifying a non-zero offset requires that the server support the REST command to restart transfers.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **AsyncPutFile** method will upload the contents of a file on the local system to the server. It is similar to the **PutFile** method, however it retrieves the file using a background worker thread and does not block the current working thread. This enables the application to continue to perform other operations while the file is being uploaded to the server. This method requires that you explicitly establish a connection using the **Connect** method. All background tasks will duplicate the active connection and use it establish a secondary connection with the server to perform the file transfer. If you wish to perform multiple asynchronous file transfers from different servers, you must create an instance of the control for each server.

After this method is called, the **OnTaskBegin** event will be fired, indicating that the background task has begun the process of connecting to the server and performing the file transfer. As the file is uploaded, the control will periodically invoke the **OnTaskRun** event handler. When the transfer has completed, the **OnTaskEnd** event will be fired. It is not required that you implement handlers for these events.

To determine when a transfer has completed without implementing any event handlers, periodically call the **TaskDone** method. If you wish to block the current thread and wait for the transfer to complete, call the **TaskWait** method. To stop a background file transfer that is in progress, call the **TaskAbort** method. This will signal the background worker thread to cancel the transfer and terminate the session.

This method can be called multiple times to upload more than one file in the background; however, most servers limit the number of simultaneous connections that can originate from a single IP address. The application should not make any assumptions about the sequence in which background transfers are performed or the order in which they may complete.

FtpClient.Cancel Method

Cancel the current blocking client operation.

[Visual Basic]

```
Public Sub Cancel()
```

[C#]

```
public void Cancel();
```

Remarks

When the **Cancel** method is called, the blocking client operation will not immediately fail. An internal flag is set which causes the blocking operation to exit with an error. This means that the application cannot cancel an operation and immediately perform some other blocking function. Instead it must allow the calling stack to unwind, returning back to the blocking operation before making any further function calls.

FtpClient.ChangeDirectory Method

Change the current working directory on the remote server.

[Visual Basic]

```
Public Function ChangeDirectory( _
   ByVal pathName As String _
) As Boolean
```

[C#]

```
public bool ChangeDirectory(
   string pathName
);
```

Parameters

pathName
A string which specifies the directory on the remote server. The file pathing and name conventions must be that of the remote host.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

FtpClient Class | SocketTools Namespace

FtpClient.Command Method (String)

Send a custom command to the server.

[Visual Basic]

```
Overloads Public Function Command( _
   ByVal command As String _
) As Boolean
```

[C#]

```
public bool Command(
   string command
);
```

Parameters

command

A string which specifies the command to send. Valid commands vary based on the Internet protocol and the type of server that the client is connected to. Consult the protocol standard and/or the technical reference documentation for the server to determine what commands may be issued by a client application.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **Command** method sends a command to the remote host and processes the result code sent back in response to that command. This method can be used to send custom commands to a server to take advantage of features or capabilities that may not be supported internally by the class library.

To determine the specific status code returned by the server, check the value of the **ResultCode** property after the method returns.

See Also

   ByVal command As String, _
   ByVal parameters As String _
) As Boolean
```

[C#]

```
public bool Command(
   string command,
   string parameters
);
```

Parameters

command

A string which specifies the command to send. Valid commands vary based on the Internet protocol and the type of server that the client is connected to. Consult the protocol standard and/or the technical reference documentation for the server to determine what commands may be issued by a client application.

parameters

An string which specifies one or more parameters to be sent along with the command. If more than one parameter is required, they must be separated by a single space character. Consult the protocol standard and/or technical reference documentation for the server to determine what parameters should be provided when issuing a specific command.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **Command** method sends a command to the remote host and processes the result code sent back in response to that command. This method can be used to send custom commands to a server to take advantage of features or capabilities that may not be supported internally by the class library.

To determine the specific status code returned by the server, check the value of the **ResultCode** property after the method returns.

FtpClient Class | SocketTools Namespace

FtpClient.Connect Method ()

Establish a connection with a remote host.

[Visual Basic]

```
Overloads Public Function Connect() As Boolean
```

[C#]

```
public bool Connect();
```

Return Value

A boolean value which specifies if the connection has been established. If the client is in blocking mode, a return value of **true** indicates that the connection has completed and the application may send and receive data from the remote host. If the client is in non-blocking mode, a return value of **true** indicates that the client has successfully created a socket and the connection is in progress.

When a non-blocking connection has completed, the OnConnect event will be fired. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

FtpClient Class | SocketTools Namespace | FtpClient.Connect Overload List

FtpClient.Connect Method (String)

Establish a connection with a remote host.

[Visual Basic]

```
Overloads Public Function Connect( _
   ByVal hostName As String _
) As Boolean
```

[C#]

```
public bool Connect(
   string hostName
);
```

Parameters

hostName

A string which specifies the remote host to establish a connection with. This may specify a host name or an Internet address in dot-notation.

Return Value

A boolean value which specifies if the connection has been established. If the client is in blocking mode, a return value of **true** indicates that the connection has completed and the application may send and receive data from the remote host. If the client is in non-blocking mode, a return value of **true** indicates that the client has successfully created a socket and the connection is in progress.

When a non-blocking connection has completed, the OnConnect event will be fired. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

FtpClient.Connect Method (String, Int32)

Establish a connection with a remote host.

[Visual Basic]

```
Overloads Public Function Connect( _
   ByVal hostName As String, _
   ByVal hostPort As Integer _
) As Boolean
```

[C#]

```
public bool Connect(
   string hostName,
   int hostPort
);
```

Parameters

hostName

A string which specifies the remote host to establish a connection with. This may specify a host name or an Internet address in dot-notation.

hostPort

An integer which specifies the port number for the connection. This value must be greater than zero and the maximum valid port number is 65535.

Return Value

A boolean value which specifies if the connection has been established. If the client is in blocking mode, a return value of **true** indicates that the connection has completed and the application may send and receive data from the remote host. If the client is in non-blocking mode, a return value of **true** indicates that the client has successfully created a socket and the connection is in progress.

When a non-blocking connection has completed, the OnConnect event will be fired. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

FtpClient.Connect Method (String, Int32, String, String)

Establish a connection with a remote host.

[Visual Basic]

```
Overloads Public Function Connect( _
   ByVal hostName As String, _
   ByVal hostPort As Integer, _
   ByVal userName As String, _
   ByVal userPassword As String _
) As Boolean
```

[C#]

```
public bool Connect(
   string hostName,
   int hostPort,
   string userName,
   string userPassword
);
```

Parameters

hostName

A string which specifies the remote host to establish a connection with. This may specify a host name or an Internet address in dot-notation.

hostPort

An integer which specifies the port number for the connection. This value must be greater than zero and the maximum valid port number is 65535.

userName

A string which specifies the user name which will be used to authenticate the client session. If the user name is specified as an empty string, then the login is considered to be anonymous.

userPassword

A string which specifies the password which will be used to authenticate the client session. This argument may be an empty string if no password is required for the specified user, or if no username has been specified.

Return Value

A boolean value which specifies if the connection has been established. If the client is in blocking mode, a return value of **true** indicates that the connection has completed and the application may send and receive data from the remote host. If the client is in non-blocking mode, a return value of **true** indicates that the client has successfully created a socket and the connection is in progress.

When a non-blocking connection has completed, the OnConnect event will be fired. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

FtpClient.Connect Method (String, Int32, String, String, Int32)

Establish a connection with a remote host.

[Visual Basic]

```
Overloads Public Function Connect( _
   ByVal hostName As String, _
   ByVal hostPort As Integer, _
   ByVal userName As String, _
   ByVal userPassword As String, _
   ByVal timeout As Integer _
) As Boolean
```

[C#]

```
public bool Connect(
   string hostName,
   int hostPort,
   string userName,
   string userPassword,
   int timeout
);
```

Parameters

hostName

A string which specifies the remote host to establish a connection with. This may specify a host name or an Internet address in dot-notation.

hostPort

An integer which specifies the port number for the connection. This value must be greater than zero and the maximum valid port number is 65535.

userName

A string which specifies the user name which will be used to authenticate the client session. If the user name is specified as an empty string, then the login is considered to be anonymous.

userPassword

A string which specifies the password which will be used to authenticate the client session. This argument may be an empty string if no password is required for the specified user, or if no username has been specified.

timeout

An integer value that specifies the number of seconds that the method will wait for the connection to complete before failing the operation and returning to the caller. This value is only meaningful for blocking connections.

Return Value

A boolean value which specifies if the connection has been established. If the client is in blocking mode, a return value of **true** indicates that the connection has completed and the application may send and receive data from the remote host. If the client is in non-blocking mode, a return value of **true** indicates that the client has successfully created a socket and the connection is in progress.

When a non-blocking connection has completed, the OnConnect event will be fired. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

```
public bool Connect(
   string hostName,
   int hostPort,
   string userName,
   string userPassword,
   int timeout,
   FtpOptions options
);
```

Parameters

hostName
A string which specifies the remote host to establish a connection with. This may specify a host name or an Internet address in dot-notation.

hostPort
An integer which specifies the port number for the connection. This value must be greater than zero and the maximum valid port number is 65535.

userName
A string which specifies the user name which will be used to authenticate the client session. If the user name is specified as an empty string, then the login is considered to be anonymous.

userPassword
A string which specifies the password which will be used to authenticate the client session. This argument may be an empty string if no password is required for the specified user, or if no username has been specified.

timeout
An integer value that specifies the number of seconds that the method will wait for the connection to complete before failing the operation and returning to the caller. This value is only meaningful for blocking connections.

options
One or more of the FtpOptions enumeration flags.

Return Value

A boolean value which specifies if the connection has been established. If the client is in blocking mode, a return value of **true** indicates that the connection has completed and the application may send and receive data from the remote host. If the client is in non-blocking mode, a return value of **true** indicates that the client has successfully created a socket and the connection is in progress.

When a non-blocking connection has completed, the OnConnect event will be fired. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

FtpClient.Connect Method (String, Int32, String, String, String)

Establish a connection with a remote host.

[Visual Basic]

```
Overloads Public Function Connect( _
   ByVal hostName As String, _
   ByVal hostPort As Integer, _
   ByVal userName As String, _
   ByVal userPassword As String, _
   ByVal userAccount As String _
) As Boolean
```

[C#]

```
public bool Connect(
   string hostName,
   int hostPort,
   string userName,
   string userPassword,
   string userAccount
);
```

Parameters

hostName

A string which specifies the remote host to establish a connection with. This may specify a host name or an Internet address in dot-notation.

hostPort

An integer which specifies the port number for the connection. This value must be greater than zero and the maximum valid port number is 65535.

userName

A string which specifies the user name which will be used to authenticate the client session. If the user name is specified as an empty string, then the login is considered to be anonymous.

userPassword

A string which specifies the password which will be used to authenticate the client session. This argument may be an empty string if no password is required for the specified user, or if no username has been specified.

userAccount

A string that specifies the account name to be used to authenticate the current client session. This parameter may be an empty string if no account name is required for the specified user.

Return Value

A boolean value which specifies if the connection has been established. If the client is in blocking mode, a return value of **true** indicates that the connection has completed and the application may send and receive data from the remote host. If the client is in non-blocking mode, a return value of **true** indicates that the client has successfully created a socket and the connection is in progress.

When a non-blocking connection has completed, the OnConnect event will be fired. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

Overloads Public Function Connect( _
   ByVal hostName As String, _
   ByVal hostPort As Integer, _
   ByVal userName As String, _
   ByVal userPassword As String, _
   ByVal userAccount As String, _
   ByVal timeout As Integer _
) As Boolean
```

[C#]

```
public bool Connect(
   string hostName,
   int hostPort,
   string userName,
   string userPassword,
   string userAccount,
   int timeout
);
```

Parameters

hostName

A string which specifies the remote host to establish a connection with. This may specify a host name or an Internet address in dot-notation.

hostPort

An integer which specifies the port number for the connection. This value must be greater than zero and the maximum valid port number is 65535.

userName

A string which specifies the user name which will be used to authenticate the client session. If the user name is specified as an empty string, then the login is considered to be anonymous.

userPassword

A string which specifies the password which will be used to authenticate the client session. This argument may be an empty string if no password is required for the specified user, or if no username has been specified.

userAccount

A string that specifies the account name to be used to authenticate the current client session. This parameter may be an empty string if no account name is required for the specified user.

timeout

An integer value that specifies the number of seconds that the method will wait for the connection to complete before failing the operation and returning to the caller. This value is only meaningful for blocking connections.

Return Value

A boolean value which specifies if the connection has been established. If the client is in blocking mode, a return value of **true** indicates that the connection has completed and the application may send and receive data from the remote host. If the client is in non-blocking mode, a return value of **true** indicates that the client has successfully created a socket and the connection is in progress.

When a non-blocking connection has completed, the OnConnect event will be fired. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

FtpClient.Connect Method (String, Int32, String, String, String, Int32, FtpOptions)

Establish a connection with a remote host.

[Visual Basic]

```
Overloads Public Function Connect( _
   ByVal hostName As String, _
   ByVal hostPort As Integer, _
   ByVal userName As String, _
   ByVal userPassword As String, _
   ByVal userAccount As String, _
   ByVal timeout As Integer, _
   ByVal options As FtpOptions _
) As Boolean
```

[C#]

```
public bool Connect(
   string hostName,
   int hostPort,
   string userName,
   string userPassword,
   string userAccount,
   int timeout,
   FtpOptions options
);
```

Parameters

hostName

A string which specifies the remote host to establish a connection with. This may specify a host name or an Internet address in dot-notation.

hostPort

An integer which specifies the port number for the connection. This value must be greater than zero and the maximum valid port number is 65535.

userName

A string which specifies the user name which will be used to authenticate the client session. If the user name is specified as an empty string, then the login is considered to be anonymous.

userPassword

A string which specifies the password which will be used to authenticate the client session. This argument may be an empty string if no password is required for the specified user, or if no username has been specified.

userAccount

A string that specifies the account name to be used to authenticate the current client session. This parameter may be an empty string if no account name is required for the specified user.

timeout

An integer value that specifies the number of seconds that the method will wait for the connection to complete before failing the operation and returning to the caller. This value is only meaningful for blocking connections.

options

One or more of the FtpOptions enumeration flags.

Return Value

A boolean value which specifies if the connection has been established. If the client is in blocking mode, a return value of **true** indicates that the connection has completed and the application may send and receive data from the remote host. If the client is in non-blocking mode, a return value of **true** indicates that the client has successfully created a socket and the connection is in progress.

When a non-blocking connection has completed, the OnConnect event will be fired. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

FtpClient Class | SocketTools Namespace | FtpClient.Connect Overload List

FtpClient.Connect Method (String, String, String)

Establish a connection with a remote host.

[Visual Basic]

```
Overloads Public Function Connect( _
   ByVal hostName As String, _
   ByVal userName As String, _
   ByVal userPassword As String _
) As Boolean
```

[C#]

```
public bool Connect(
   string hostName,
   string userName,
   string userPassword
);
```

Parameters

hostName

A string which specifies the remote host to establish a connection with. This may specify a host name or an Internet address in dot-notation.

userName

A string which specifies the user name which will be used to authenticate the client session. If the user name is specified as an empty string, then the login is considered to be anonymous.

userPassword

A string which specifies the password which will be used to authenticate the client session. This argument may be an empty string if no password is required for the specified user, or if no username has been specified.

Return Value

A boolean value which specifies if the connection has been established. If the client is in blocking mode, a return value of **true** indicates that the connection has completed and the application may send and receive data from the remote host. If the client is in non-blocking mode, a return value of **true** indicates that the client has successfully created a socket and the connection is in progress.

When a non-blocking connection has completed, the OnConnect event will be fired. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

FtpClient Class | SocketTools Namespace | FtpClient.Connect Overload List

FtpClient.CreateFile Method

Create a new file or overwrite an existing file.

[Visual Basic]

```
Public Function CreateFile( _
   ByVal remoteFile As String _
) As Boolean
```

[C#]

```
public bool CreateFile(
   string remoteFile
);
```

Parameters

remoteFile

A string which specifies the name of the file to create on the remote server. The file pathing and name conventions must be that of the remote host.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **CreateFile** method creates a new file on the remote server using the specified file name. The **Write** method may then be used to copy data to the open file. The user must have the appropriate permission to create the file on the server

See Also

FtpClient Class | SocketTools Namespace

FtpClient.DeleteFile Method

Delete a file on the remote server.

[Visual Basic]

```
Public Function DeleteFile( _
   ByVal remoteFile As String _
) As Boolean
```

[C#]

```
public bool DeleteFile(
   string remoteFile
);
```

Parameters

remoteFile

A string which specifies the name of the file on the remote server that is to be deleted. The file pathing and name conventions must be that of the remote host.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **DeleteFile** method deletes an existing file from the remote server. The user must have the appropriate permission to delete the specified file.

See Also

FtpClient Class | SocketTools Namespace

FtpClient.Disconnect Method

Terminate the connection with the remote server.

[Visual Basic]

```
Public Sub Disconnect()
```

[C#]

```
public void Disconnect();
```

Remarks

The **Disconnect** method terminates the connection with the remote host and closes the socket handle allocated by the class. Note that the socket is not immediately released when the connection is terminated and will enter a wait state for two minutes. After the time wait period has elapsed, the socket will be released by the operating system. This is a normal safety mechanism to handle any packets that may arrive after the connection has been closed.

FtpClient Class | SocketTools Namespace

FtpClient.Dispose Method (Boolean)

Releases the unmanaged resources allocated by the FtpClient class and optionally releases the managed resources.

[Visual Basic]

```
Overridable Overloads Protected Sub Dispose( _
   ByVal disposing As Boolean _
)
```

[C#]

```
protected virtual void Dispose(
   bool disposing
);
```

Parameters

disposing

A boolean value which should be specified as **true** to release both managed and unmanaged resources; **false** to release only unmanaged resources.

Remarks

The **Dispose** method terminates any active connection and explicitly releases the resources allocated for this instance of the class. In some cases, better performance can be achieved if the programmer explicitly releases resources when they are no longer being used. The **Dispose** method provides explicit control over these resources.

Unlike the **Uninitialize** method, once the **Dispose** method has been called, that instance of the class cannot be re-initialized and you should not attempt to access class properties or invoke any methods. Note that this method can be called even if other references to the object are active.

You should call **Dispose** in your derived class when you are finished using the derived class. The **Dispose** method leaves the derived class in an unusable state. After calling **Dispose**, you must release all references to the derived class and the **FtpClient** class so the memory they were occupying can be reclaimed by garbage collection.

FtpClient.GetData Method

Transfers the contents of a file on the server and stores it in a byte array.

Overload List

Transfers the contents of a file on the server and stores it in a byte array.

public bool GetData(string,byte[],ref int);

Transfers the contents of a file from the server and stores it in a MemoryStream.

public bool GetData(string,MemoryStream);

Transfers the contents of a file on the server and stores it in a string.

public bool GetData(string,ref string);

See Also

FtpClient Class | SocketTools Namespace

FtpClient.GetData Method (String, Byte[], Int32)

Transfers the contents of a file on the server and stores it in a byte array.

[Visual Basic]

```
Overloads Public Function GetData( _
   ByVal remoteFile As String, _
   ByVal buffer As Byte(), _
   ByRef length As Integer _
) As Boolean
```

[C#]

```
public bool GetData(
   string remoteFile,
   byte[] buffer,
   ref int length
);
```

Parameters

remoteFile

A string that specifies the file on the remote system that will be transferred to the local system. The file pathing and name conventions must be that of the remote host.

buffer

A byte array that the data will be stored in.

length

An integer value passed by reference which specifies the maximum number of bytes of data to read. This value cannot be larger than the size of the buffer specified by the caller. When the method returns, this value will be updated with the number of bytes actually stored in the byte array.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetData** method transfers data from a file on the server to the local system, storing it in the specified buffer . This method will cause the calling current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

See Also

FtpClient Class | SocketTools Namespace | FtpClient.GetData Overload List

FtpClient.GetData Method (String, String)

Transfers the contents of a file on the server and stores it in a string.

[Visual Basic]

```
Overloads Public Function GetData( _
   ByVal remoteFile As String, _
   ByRef buffer As String _
) As Boolean
```

[C#]

```
public bool GetData(
   string remoteFile,
   ref string buffer
);
```

Parameters

remoteFile

A string that specifies the file on the remote system that will be transferred to the local system. The file pathing and name conventions must be that of the remote host.

buffer

A string passed by reference that the data will be stored in. It is not recommended that binary files be stored in a string buffer. Only text files should be downloaded using this implementation of the method. For binary files, store the data in a byte array instead.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetData** method transfers data from a file on the server to the local system, storing it in the specified buffer . This method will cause the calling current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

FtpClient Class | SocketTools Namespace | FtpClient.GetData Overload List

FtpClient.GetData Method (String, MemoryStream)

Transfers the contents of a file from the server and stores it in a MemoryStream.

[Visual Basic]

```
Overloads Public Function GetData( _
   ByVal remoteFile As String, _
   ByVal memStream As MemoryStream _
) As Boolean
```

[C#]

```
public bool GetData(
   string remoteFile,
   MemoryStream memStream
);
```

Parameters

remoteFile

A string that specifies the file on the remote system that will be transferred to the local system. The file pathing and name conventions must be that of the remote host.

memStream

A System.IO.MemoryStream object that will contain the file data when the method returns. This stream must be open and writable.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetData** method transfers data from a file on the server to the local system, storing it in the specified MemoryStream. This method will cause the calling current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

The contents of the MemoryStream will be replaced by the contents of the file and the current position will be reset to the beginning of the stream. The stream must be open and writable, otherwise this method will throw **System.NotSupportedException**.

FtpClient.GetDirectory Method

Return the current working directory.

[Visual Basic]

```
Public Function GetDirectory( _
   ByRef pathName As String _
) As Boolean
```

[C#]

```
public bool GetDirectory(
   ref string pathName
);
```

Parameters

pathName

A string passed by reference which will contain the current working directory on the server when the method returns.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

FtpClient Class | SocketTools Namespace

FtpClient.GetFile Method (String)

Download a file from the server to the local system.

[Visual Basic]

```
Overloads Public Function GetFile( _
   ByVal localFile As String _
) As Boolean
```

[C#]

```
public bool GetFile(
   string localFile
);
```

Parameters

localFile

A string that specifies the file on the local system that will be created, overwritten or appended to. The file pathing and name conventions must be that of the local host.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetFile** method copies an existing file from the server to the local system. This method will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

This implementation of the **GetFile** method is most commonly used when the name of the remote file has already been specified, either by setting the **URL** property or by explicitly setting the **RemoteFile** property.

FtpClient.GetFile Method (String, String, FtpTransferOptions)

Download a file from the server to the local system.

[Visual Basic]

```
Overloads Public Function GetFile( _
   ByVal localFile As String, _
   ByVal remoteFile As String, _
   ByVal options As FtpTransferOptions _
) As Boolean
```

[C#]

```
public bool GetFile(
   string localFile,
   string remoteFile,
   FtpTransferOptions options
);
```

Parameters

localFile
A string that specifies the file on the local system that will be created, overwritten or appended to. The file pathing and name conventions must be that of the local host.

remoteFile
A string that specifies the file on the remote system that will be transferred to the local system. The file pathing and name conventions must be that of the remote host.

options
An FtpTransferOptions enumeration value which specifies one or more file transfer options.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetFile** method copies an existing file from the server to the local system. This method will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

See Also

FtpClient Class | SocketTools Namespace | FtpClient.GetFile Overload List

FtpClient.GetFile Method (String, String, FtpTransferOptions, Int64)

Download a file from the server to the local system.

[Visual Basic]

```
Overloads Public Function GetFile( _
   ByVal localFile As String, _
   ByVal remoteFile As String, _
   ByVal options As FtpTransferOptions, _
   ByVal offset As Long _
) As Boolean
```

[C#]

```
public bool GetFile(
   string localFile,
   string remoteFile,
   FtpTransferOptions options,
   long offset
);
```

Parameters

localFile
: A string that specifies the file on the local system that will be created, overwritten or appended to. The file pathing and name conventions must be that of the local host.

remoteFile
: A string that specifies the file on the remote system that will be transferred to the local system. The file pathing and name conventions must be that of the remote host.

options
: An FtpTransferOptions enumeration value which specifies one or more file transfer options.

offset
: A integer value which specifies the offset where the file transfer should begin. A value of zero specifies that the file transfer should start at the beginning of the file. A value greater than zero is typically used to restart a transfer that has not completed successfully. Note that specifying a non-zero offset requires that the server support the REST command to restart file transfers.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetFile** method copies an existing file from the server to the local system. This method will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

FtpClient.GetFileList Method

Returns an unparsed list of files in the specified directory.

Overload List

Returns an unparsed list of files in the specified directory.

public bool GetFileList(string,ref string);

Returns an unparsed list of files in the specified directory.

public bool GetFileList(string,ref string,bool);

Returns an unparsed list of files in the current working directory.

public bool GetFileList(ref string);

See Also

FtpClient Class | SocketTools Namespace

FtpClient.GetFileList Method (String)

Returns an unparsed list of files in the current working directory.

[Visual Basic]

```
Overloads Public Function GetFileList( _
   ByRef fileList As String _
) As Boolean
```

[C#]

```
public bool GetFileList(
   ref string fileList
);
```

Parameters

fileList

A string buffer passed by reference that will contain the file list data when the method returns.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetFileList** method returns a list of files in the current working directory on the server, copying the data to a string buffer. Unlike the **GetFirstFile** and **GetNextFile** methods that parses a directory listing, this method returns the unparsed file list data. The actual format of the data that is returned depends on the operating system and how the server implements file listings. For example, UNIX servers typically return the output from the **/bin/ls** command.

This method can be particularly useful when the client is connected to a server that returns file listings in a format that is not recognized by the component. The application can retrieve the unparsed file listing from the server and parse the contents.

This method is supported for both FTP and SFTP (SSH) connections, however the format of the data may differ depending on which protocol is used. Most UNIX based FTP servers will not list files and subdirectories that begin with a period, however most SFTP servers will return a list of all files, even those that begin with a period.

This method will cause the current thread to block until the file listing completes, a timeout occurs or the operation is canceled.

See Also

FtpClient Class | SocketTools Namespace | FtpClient.GetFileList Overload List

FtpClient.GetFileList Method (String, String)

Returns an unparsed list of files in the specified directory.

[Visual Basic]

```
Overloads Public Function GetFileList( _
   ByVal remotePath As String, _
   ByRef fileList As String _
) As Boolean
```

[C#]

```
public bool GetFileList(
   string remotePath,
   ref string fileList
);
```

Parameters

remotePath

A string value which specifies the name of a directory on the server. The list of files and subdirectories in that directory will be returned to the client. To obtain a list of files in the current working directory on the server, use an empty string.

fileList

A string buffer passed by reference that will contain the file list data when the method returns.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetFileList** method returns a list of files in the specified directory, copying the data to a string buffer. Unlike the **GetFirstFile** and **GetNextFile** methods that parses a directory listing, this method returns the unparsed file list data. The actual format of the data that is returned depends on the operating system and how the server implements file listings. For example, UNIX servers typically return the output from the **/bin/ls** command.

Some servers may not support file listings for any directory other than the current working directory. If an error is returned when specifying a directory name, try changing the current working directory using the **ChangeDirectory** method and then call this method again, an empty string as the ***remotePath*** parameter.

This method can be particularly useful when the client is connected to a server that returns file listings in a format that is not recognized by the component. The application can retrieve the unparsed file listing from the server and parse the contents.

This method is supported for both FTP and SFTP (SSH) connections, however the format of the data may differ depending on which protocol is used. Most UNIX based FTP servers will not list files and subdirectories that begin with a period, however most SFTP servers will return a list of all files, even those that begin with a period.

This method will cause the current thread to block until the file listing completes, a timeout occurs or the operation is canceled.

FtpClient Class | SocketTools Namespace | FtpClient.GetFileList Overload List

FtpClient.GetFileList Method (String, String, Boolean)

Returns an unparsed list of files in the specified directory.

[Visual Basic]

```
Overloads Public Function GetFileList( _
   ByVal remotePath As String, _
   ByRef fileList As String, _
   ByVal nameOnly As Boolean _
) As Boolean
```

[C#]

```
public bool GetFileList(
   string remotePath,
   ref string fileList,
   bool nameOnly
);
```

Parameters

remotePath

A string value which specifies the name of a directory on the server. The list of files and subdirectories in that directory will be returned to the client. To obtain a list of files in the current working directory on the server, use an empty string.

fileList

A string buffer passed by reference that will contain the file list data when the method returns.

nameOnly

A boolean value that specifies if the file listing should contain only the file name, or should include additional information about the file such as the size, ownership and permissions.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetFileList** method returns a list of files in the specified directory, copying the data to a string buffer. Unlike the **GetFirstFile** and **GetNextFile** methods that parses a directory listing, this method returns the unparsed file list data. The actual format of the data that is returned depends on the operating system and how the server implements file listings. For example, UNIX servers typically return the output from the **/bin/ls** command.

Some servers may not support file listings for any directory other than the current working directory. If an error is returned when specifying a directory name, try changing the current working directory using the **ChangeDirectory** method and then call this method again, an empty string as the *remotePath* parameter.

This method can be particularly useful when the client is connected to a server that returns file listings in a format that is not recognized by the component. The application can retrieve the unparsed file listing from the server and parse the contents. Note that if you specify the *nameOnly* parameter as true, the data will only contain a list of file names and there will be no way for the application to know if they represent a regular file or a subdirectory.

This method is supported for both FTP and SFTP (SSH) connections, however the format of the data may differ depending on which protocol is used. Most UNIX based FTP servers will not list files and subdirectories that begin with a period, however most SFTP servers will return a list of all files, even those that begin with a period.

This method will cause the current thread to block until the file listing completes, a timeout occurs or the operation is canceled.

FtpClient.GetFilePermissions Method

Return the access permissions for a file on the remote system.

[Visual Basic]

```
Public Function GetFilePermissions( _
   ByVal remoteFile As String, _
   ByRef filePerms As FtpPermissions _
) As Boolean
```

[C#]

```
public bool GetFilePermissions(
   string remoteFile,
   ref FtpPermissions filePerms
);
```

Parameters

remoteFile

A string that specifies the name of the file that the access permissions are to be returned for. The filename cannot contain any wildcard characters.

filePerms

An FtpPermissions enumeration value which is passed by reference and set to the file permissions when the method returns.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetFilePermissions** method returns information about the access permissions for a specific file on the server. This method uses the STAT command to retrieve information about the specified file. If the server does not support the use of this command, an error will be returned. You can use the **Features** property to determine what features are available and/or enabled on the server.

Note that on some systems, the STAT command will not return information on files that contain spaces or tabs in the filename. In this case, the method will fail.

FtpClient Class | SocketTools Namespace

FtpClient.GetFileSize Method

Returns the size of the specified file on the remote server.

Overload List

Returns the size of the specified file on the remote server.

public bool GetFileSize(string,ref int);

Returns the size of the specified file on the remote server.

public bool GetFileSize(string,ref long);

See Also

FtpClient Class | SocketTools Namespace

FtpClient.GetFileSize Method (String, Int64)

Returns the size of the specified file on the remote server.

[Visual Basic]

```
Overloads Public Function GetFileSize( _
   ByVal remoteFile As String, _
   ByRef fileSize As Long _
) As Boolean
```

[C#]

```
public bool GetFileSize(
   string remoteFile,
   ref long fileSize
);
```

Parameters

remoteFile

A string that specifies the name of the file on the server. The filename cannot contain any wildcard characters and must follow the naming conventions of the operating system the server is hosted on.

fileSize

A long integer value which is passed by reference and will specify the size of the file on the server when the method returns.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

This method uses the SIZE command to determine the length of the specified file. Not all servers implement this command, in which case the method will fail. You can use the **Features** property to determine what features are available and/or enabled on the server.

Note that if the file on the server is a text file, it is possible that the value returned by this method will not match the size of the file when it is downloaded to the local system. This is because different operating systems use different sequences of characters to mark the end of a line of text, and when a file is transferred in text mode, the end of line character sequence is automatically converted to a carriage return-linefeed, which is the convention used by the Windows platform.

FtpClient Class | SocketTools Namespace | FtpClient.GetFileSize Overload List

FtpClient.GetFileSize Method (String, Int32)

Returns the size of the specified file on the remote server.

[Visual Basic]

```
Overloads Public Function GetFileSize( _
   ByVal remoteFile As String, _
   ByRef fileSize As Integer _
) As Boolean
```

[C#]

```
public bool GetFileSize(
   string remoteFile,
   ref int fileSize
);
```

Parameters

remoteFile

A string that specifies the name of the file on the server. The filename cannot contain any wildcard characters and must follow the naming conventions of the operating system the server is hosted on.

fileSize

A long integer value which is passed by reference and will specify the size of the file on the server when the method returns.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

This method uses the SIZE command to determine the length of the specified file. Not all servers implement this command, in which case the method will fail. You can use the **Features** property to determine what features are available and/or enabled on the server.

Note that if the file on the server is a text file, it is possible that the value returned by this method will not match the size of the file when it is downloaded to the local system. This is because different operating systems use different sequences of characters to mark the end of a line of text, and when a file is transferred in text mode, the end of line character sequence is automatically converted to a carriage return-linefeed, which is the convention used by the Windows platform.

FtpClient Class | SocketTools Namespace | FtpClient.GetFileSize Overload List

FtpClient.GetFileStatus Method

Returns status information about the specified file.

[Visual Basic]

```
Public Function GetFileStatus( _
   ByVal remoteFile As String, _
   ByRef fileInfo As FileInformation _
) As Boolean
```

[C#]

```
public bool GetFileStatus(
   string remoteFile,
   ref FileInformation fileInfo
);
```

Parameters

remoteFile

A string which specifies the name of the file that status information is to be returned for.

fileInfo

A FileInformation structure that is passed by reference. When the method returns, the members of this structure will be populated with information about the file on the server.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetFileStatus** method returns information about the specified file. The filename must be specified using the remote host file naming conventions, and cannot include wildcard characters. The primary difference between using this method and using the **OpenDirectory, GetFirstFile** and **GetNextFile** methods to obtain file information is that the file status information is returned on the command channel. This method cannot be used while a file transfer is in progress or while a file listing is being returned by the server.

This method requires that the server return file status information in response to the STAT command. Some servers, for example on VMS platforms, do not provide this information. On some systems, the STAT command will not return information on files that contain spaces or tabs in the filename. In this case, the method will return an empty structure.

FtpClient Class | SocketTools Namespace

FtpClient.GetFileTime Method

Returns the modification date and time for specified file on the remote server.

Overload List

Returns the modification date and time for specified file on the remote server.

public bool GetFileTime(string,ref DateTime);

Returns the modification date and time for specified file on the remote server.

public bool GetFileTime(string,ref DateTime,bool);

See Also

FtpClient Class | SocketTools Namespace

FtpClient.GetFileTime Method (String, DateTime)

Returns the modification date and time for specified file on the remote server.

[Visual Basic]

```
Overloads Public Function GetFileTime( _
   ByVal remoteFile As String, _
   ByRef fileDate As Date _
) As Boolean
```

[C#]

```
public bool GetFileTime(
   string remoteFile,
   ref DateTime fileDate
);
```

Parameters

remoteFile

A string that specifies the name of the file on the server. The filename cannot contain any wildcard characters and must follow the naming conventions of the operating system the server is hosted on.

fileDate

A **System.DateTime** structure which is passed by reference. When the method returns, this object will be set to the date and time that the file was created or last modified.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

This method uses the MTDM command to determine the modification time for the file. If the server does not support this command, the method will attempt to use the STAT command to determine the file modification time. You can use the **Features** property to determine what features are available and/or enabled on the server.

The value of the Localize property determines if the date and time are adjusted for the local timezone.

See Also

FtpClient Class | SocketTools Namespace | FtpClient.GetFileTime Overload List

FtpClient.GetFileTime Method (String, DateTime, Boolean)

Returns the modification date and time for specified file on the remote server.

[Visual Basic]

```
Overloads Public Function GetFileTime( _
   ByVal remoteFile As String, _
   ByRef fileDate As Date, _
   ByVal localDate As Boolean _
) As Boolean
```

[C#]

```
public bool GetFileTime(
   string remoteFile,
   ref DateTime fileDate,
   bool localDate
);
```

Parameters

remoteFile

A string that specifies the name of the file on the server. The filename cannot contain any wildcard characters and must follow the naming conventions of the operating system the server is hosted on.

fileDate

A **System.DateTime** structure which is passed by reference. When the method returns, this object will be set to the date and time that the file was created or last modified.

localDate

A boolean flag which specifies if the date and time for the file should adjusted for the local timezone. A value of **true** specifies that the date and time should be adjusted for the local timezone. A value of **false** specifies that the date and time should be returned as a UTC (Coordinated Universal Time) value.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

This method uses the MTDM command to determine the modification time for the file. If the server does not support this command, the method will attempt to use the STAT command to determine the file modification time. You can use the **Features** property to determine what features are available and/or enabled on the server.

FtpClient Class | SocketTools Namespace

FtpClient.GetFirstFile Method (FileInformation)

Get information about the first file in a directory listing returned by the server.

[Visual Basic]

```
Overloads Public Function GetFirstFile( _
   ByRef fileInfo As FileInformation _
) As Boolean
```

[C#]

```
public bool GetFirstFile(
   ref FileInformation fileInfo
);
```

Parameters

fileInfo

A FileInformation structure that is passed by reference. When the method returns, the members of this structure will be populated with information about the file on the server.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

A file listing is initiated by calling the **OpenDirectory** method. Then, the application must call **GetFirstFile**, followed by calling **GetNextFile** in a loop until the method returns **false**. Once the complete directory listing has been returned, the **CloseDirectory** method must be called.

See Also

FtpClient Class | SocketTools Namespace | FtpClient.GetFirstFile Overload List

FtpClient.GetFirstFile Method (String)

Get the first file name in a directory listing returned by the server.

[Visual Basic]

```
Overloads Public Function GetFirstFile( _
   ByRef fileName As String _
) As Boolean
```

[C#]

```
public bool GetFirstFile(
   ref string fileName
);
```

Parameters

fileName

A string passed by reference which will contain a file name when the method returns.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

A file listing is initiated by calling the **OpenDirectory** method. Then, the application must call **GetFirstFile**, followed by calling **GetNextFile** in a loop until the method returns **false**. Once the complete directory listing has been returned, the **CloseDirectory** method must be called.

FtpClient.GetFirstFile Method (String, Boolean)

Get information about the first file in a directory listing returned by the server.

[Visual Basic]

```
Overloads Public Function GetFirstFile( _
   ByRef fileName As String, _
   ByRef isDirectory As Boolean _
) As Boolean
```

[C#]

```
public bool GetFirstFile(
   ref string fileName,
   ref bool isDirectory
);
```

Parameters

fileName
A string passed by reference which will contain a file name when the method returns.

isDirectory
A boolean passed by reference which will specify if the file is a regular file or a directory. A value of **true** indicates that the file is a directory. A value of **false** indicates that it is a regular file.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

A file listing is initiated by calling the **OpenDirectory** method. Then, the application must call **GetFirstFile**, followed by calling **GetNextFile** in a loop until the method returns **false**. Once the complete directory listing has been returned, the **CloseDirectory** method must be called.

FtpClient Class | SocketTools Namespace | FtpClient.GetFirstFile Overload List

FtpClient.GetFirstFile Method (String, Int64, Boolean)

Get information about the first file in a directory listing returned by the server.

[Visual Basic]

```
Overloads Public Function GetFirstFile( _
   ByRef fileName As String, _
   ByRef fileSize As Long, _
   ByRef isDirectory As Boolean _
) As Boolean
```

[C#]

```
public bool GetFirstFile(
   ref string fileName,
   ref long fileSize,
   ref bool isDirectory
);
```

Parameters

fileName
A string passed by reference which will contain a file name when the method returns.

fileSize
An integer passed by reference which will contain the size of the file when the method returns.

isDirectory
A boolean passed by reference which will specify if the file is a regular file or a directory. A value of **true** indicates that the file is a directory. A value of **false** indicates that it is a regular file.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

A file listing is initiated by calling the **OpenDirectory** method. Then, the application must call **GetFirstFile**, followed by calling **GetNextFile** in a loop until the method returns **false**. Once the complete directory listing has been returned, the **CloseDirectory** method must be called.

FtpClient.GetMultipleFiles Method

Download multiple files from the server to the local system using a wildcard mask.

Overload List

Download multiple files from the server to the local system using a wildcard mask.

public bool GetMultipleFiles(string,string);

Download multiple files from the server to the local system using a wildcard mask.

public bool GetMultipleFiles(string,string,string);

See Also

FtpClient Class | SocketTools Namespace

FtpClient.GetMultipleFiles Method (String, String, String)

Download multiple files from the server to the local system using a wildcard mask.

[Visual Basic]

```
Overloads Public Function GetMultipleFiles( _
   ByVal localPath As String, _
   ByVal remotePath As String, _
   ByVal fileMask As String _
) As Boolean
```

[C#]

```
public bool GetMultipleFiles(
   string localPath,
   string remotePath,
   string fileMask
);
```

Parameters

localPath

A string argument which specifies the name of the directory on the local system where the files will be stored. If a file by the same name already exists, it will be overwritten

remotePath

A string argument which specifies the name of the directory on the remote system where the files will be copied from. You must have permission to read the contents of the directory.

fileMask

An string argument which specifies the wildcard mask to be used when selecting what files should be transferred. Typically, this argument is a wildcard mask that limits the files downloaded from the server to those which match a specific extension.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetMultipleFiles** method copies multiple files from the remote system to the local system. If the local file already exists, it is overwritten. This method will cause the current thread to block until all of the files have been transferred, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

FtpClient.GetMultipleFiles Method (String, String)

Download multiple files from the server to the local system using a wildcard mask.

[Visual Basic]

```
Overloads Public Function GetMultipleFiles( _
   ByVal localPath As String, _
   ByVal remotePath As String _
) As Boolean
```

[C#]

```
public bool GetMultipleFiles(
   string localPath,
   string remotePath
);
```

Parameters

localPath

A string argument which specifies the name of the directory on the local system where the files will be stored. If a file by the same name already exists, it will be overwritten

remotePath

A string argument which specifies the name of the directory on the remote system where the files will be copied from. You must have permission to read the contents of the directory.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetMultipleFiles** method copies multiple files from the remote system to the local system. If the local file already exists, it is overwritten. This method will cause the current thread to block until all of the files have been transferred, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

FtpClient Class | SocketTools Namespace

FtpClient.GetNextFile Method (FileInformation)

Get information about the next file in a directory listing returned by the server.

[Visual Basic]

```
Overloads Public Function GetNextFile( _
   ByRef fileInfo As FileInformation _
) As Boolean
```

[C#]

```
public bool GetNextFile(
   ref FileInformation fileInfo
);
```

Parameters

fileInfo

A FileInformation structure that is passed by reference. When the method returns, the members of this structure will be populated with information about the file on the server.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

A file listing is initiated by calling the **OpenDirectory** method. Then, the application must call **GetFirstFile**, followed by calling **GetNextFile** in a loop until the method returns **false**. Once the complete directory listing has been returned, the **CloseDirectory** method must be called.

Get information about the next file in a directory listing returned by the server.

[Visual Basic]

```
Overloads Public Function GetNextFile( _
   ByRef fileName As String, _
   ByRef isDirectory As Boolean _
) As Boolean
```

[C#]

```
public bool GetNextFile(
   ref string fileName,
   ref bool isDirectory
);
```

Parameters

fileName

A string passed by reference which will contain a file name when the method returns.

isDirectory

A boolean passed by reference which will specify if the file is a regular file or a directory. A value of **true** indicates that the file is a directory. A value of **false** indicates that it is a regular file.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

A file listing is initiated by calling the **OpenDirectory** method. Then, the application must call **GetFirstFile**, followed by calling **GetNextFile** in a loop until the method returns **false**. Once the complete directory listing has been returned, the **CloseDirectory** method must be called.

FtpClient Class | SocketTools Namespace | FtpClient.GetNextFile Overload List

FtpClient.GetNextFile Method (String, Int64, Boolean)

Get information about the next file in a directory listing returned by the server.

[Visual Basic]

```
Overloads Public Function GetNextFile( _
   ByRef fileName As String, _
   ByRef fileSize As Long, _
   ByRef isDirectory As Boolean _
) As Boolean
```

[C#]

```
public bool GetNextFile(
   ref string fileName,
   ref long fileSize,
   ref bool isDirectory
);
```

Parameters

fileName
A string passed by reference which will contain a file name when the method returns.

fileSize
An integer passed by reference which will contain the size of the file when the method returns.

isDirectory
A boolean passed by reference which will specify if the file is a regular file or a directory. A value of **true** indicates that the file is a directory. A value of **false** indicates that it is a regular file.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

A file listing is initiated by calling the **OpenDirectory** method. Then, the application must call **GetFirstFile**, followed by calling **GetNextFile** in a loop until the method returns **false**. Once the complete directory listing has been returned, the **CloseDirectory** method must be called.

FtpClient.Initialize Method

Initialize an instance of the FtpClient class.

Overload List

Initialize an instance of the FtpClient class.

public bool Initialize();

Initialize an instance of the FtpClient class.

public bool Initialize(string);

See Also

FtpClient Class | SocketTools Namespace

FtpClient.Initialize Method ()

Initialize an instance of the FtpClient class.

[Visual Basic]

```
Overloads Public Function Initialize() As Boolean
```

[C#]

```
public bool Initialize();
```

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **Initialize** method can be used to explicitly initialize an instance of the **FtpClient** class, loading the networking library and allocating resources for the current thread. Typically an application would define the license key as a custom attribute, however this method can be used to initialize the class directly.

The runtime license key for your copy of SocketTools can be generated using the License Manager utility that is included with the product. Note that if you have installed an evaluation license, you will not have a runtime license key and cannot redistribute any applications which use the **FtpClient** class

See Also

FtpClient Class | SocketTools Namespace | FtpClient.Initialize Overload List

FtpClient.Initialize Method (String)

Initialize an instance of the FtpClient class.

[Visual Basic]

```
Overloads Public Function Initialize( _
   ByVal licenseKey As String _
) As Boolean
```

[C#]

```
public bool Initialize(
   string licenseKey
);
```

Parameters

licenseKey

A string argument which specifies the runtime license key which will be used to initialize the class library.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **Initialize** method can be used to explicitly initialize an instance of the **FtpClient** class, loading the networking library and allocating resources for the current thread. Typically an application would define the license key as a custom attribute, however this method can be used to initialize the class directly.

The runtime license key for your copy of SocketTools can be generated using the License Manager utility that is included with the product. Note that if you have installed an evaluation license, you will not have a runtime license key and cannot redistribute any applications which use the **FtpClient** class

FtpClient.Login Method

Login to the remote server.

Overload List

Login to the remote server.

public bool Login();

Login to the remote server.

public bool Login(string,string);

Login to the remote server.

public bool Login(string,string,string);

See Also

FtpClient Class | SocketTools Namespace

FtpClient.Login Method ()

Login to the remote server.

[Visual Basic]

```
Overloads Public Function Login() As Boolean
```

[C#]

```
public bool Login();
```

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **Login** method identifies the user to the remote server. The value of the **UserName** and **Password** properties will be used to authenticate the client session. If the user name or password is invalid, an error will occur. By default, when a connection is established, the user is automatically authenticated. This method is typically used if you wish to log in as another user during the same session.

See Also

FtpClient Class | SocketTools Namespace | FtpClient.Login Overload List

FtpClient.Login Method (String, String)

Login to the remote server.

[Visual Basic]

```
Overloads Public Function Login( _
   ByVal userName As String, _
   ByVal userPassword As String _
) As Boolean
```

[C#]

```
public bool Login(
   string userName,
   string userPassword
);
```

Parameters

userName
A string that specifies the name of the user logging into the server.

userPassword
A string that specifies the password used to authenticate the user.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **Login** method identifies the user to the remote server. If the user name or password is invalid, an error will occur. By default, when a connection is established, the **UserName** and **Password** properties are used to automatically log the user in to the server. This method is typically used if you wish to log in as another user during the same session.

FtpClient.Login Method (String, String, String)

Login to the remote server.

[Visual Basic]

```
Overloads Public Function Login( _
   ByVal userName As String, _
   ByVal userPassword As String, _
   ByVal userAccount As String _
) As Boolean
```

[C#]

```
public bool Login(
   string userName,
   string userPassword,
   string userAccount
);
```

Parameters

userName
A string that specifies the name of the user logging into the server.

userPassword
A string that specifies the password used to authenticate the user.

userAccount
A string that specifies the account name to be used when authenticating the user.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **Login** method identifies the user to the remote server. If the user name or password is invalid, an error will occur. By default, when a connection is established, the **UserName**, **Password** and **Account** properties are used to automatically log the user in to the server. This method is typically used if you wish to log in as another user during the same session.

```

[C#]

```
public bool Logout();
```

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **Logout** method logs the current user off the server. The **Login** method may then be used to login as another user during the same session. Note that this method will not terminate the connection with the server.

FtpClient.MakeDirectory Method

Create a new directory on the server.

[Visual Basic]

```
Public Function MakeDirectory( _
   ByVal pathName As String _
) As Boolean
```

[C#]

```
public bool MakeDirectory(
   string pathName
);
```

Parameters

pathName

A string that specifies the name of the directory to create on the server. The naming and pathing conventions used for the directory must be compatible with what is used on the operating system that hosts the server.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

Servers may not support creating multiple subdirectories in a single call, so applications should not assume that this can be done. For example, an error may be returned by the server if the new directory name "/Projects/Today" is specified, but the "/Projects" directory does not already exist.

It is also important to note that files and directories on UNIX based systems are case sensitive, so the directory names "Projects" and "projects" refer to two different directories. This is not the case on Windows systems, where either name would refer to the same directory.

FtpClient Class | SocketTools Namespace

FtpClient.OpenDirectory Method

Open the current working directory on the server.

Overload List

Open the current working directory on the server.

public bool OpenDirectory();

Open the specified directory on the server.

public bool OpenDirectory(string);

See Also

FtpClient Class | SocketTools Namespace

FtpClient.OpenDirectory Method ()

Open the current working directory on the server.

[Visual Basic]

```
Overloads Public Function OpenDirectory() As Boolean
```

[C#]

```
public bool OpenDirectory();
```

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **OpenDirectory** method opens the current working directory on the server so that the list of files in that directory may be obtained using the **GetFirstFile** and **GetNextFile** methods. Once all of the files in the directory have been read, the application must call the **CloseDirectory** method in order to close the data channel to the server. Failure to do this will result in an error the next time the application attempts to transfer a file or open another directory.

See Also

FtpClient Class | SocketTools Namespace | FtpClient.OpenDirectory Overload List

FtpClient.OpenDirectory Method (String)

Open the specified directory on the server.

[Visual Basic]

```
Overloads Public Function OpenDirectory( _
   ByVal pathName As String _
) As Boolean
```

[C#]

```
public bool OpenDirectory(
   string pathName
);
```

Parameters

pathName

A string that specifies the name of the directory to open on the server. The naming and pathing conventions used for the directory must be compatible with what is used on the operating system that hosts the server.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **OpenDirectory** method opens the specified directory on the server so that the list of files in that directory may be obtained using the **GetFirstFile** and **GetNextFile** methods. Once all of the files in the directory have been read, the application must call the **CloseDirectory** method in order to close the data channel to the server. Failure to do this will result in an error the next time the application attempts to transfer a file or open another directory.

Note that files and directories on UNIX based systems are case sensitive, so the directory names "Projects" and "projects" refer to two different directories. This is not the case on Windows systems, where either name would refer to the same directory.

FtpClient.OpenFile Method

Open an existing file for reading on the server.

Overload List

Open an existing file for reading on the server.

public bool OpenFile(string);

Open an existing file or create a new file on the server.

public bool OpenFile(string,FtpOpenMode);

Open an existing file or create a new file on the server.

public bool OpenFile(string,FtpOpenMode,long);

See Also

FtpClient Class | SocketTools Namespace

FtpClient.OpenFile Method (String)

Open an existing file for reading on the server.

[Visual Basic]

```
Overloads Public Function OpenFile( _
   ByVal remoteFile As String _
) As Boolean
```

[C#]

```
public bool OpenFile(
   string remoteFile
);
```

Parameters

remoteFile

A string that specifies the name of the file on the server. The filename cannot contain any wildcard characters and must follow the naming conventions of the operating system the server is hosted on.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **OpenFile** method opens an existing file on the server for reading. The **Read** method may then be used to read data from the file. Once the all of the data has been read, the **CloseFile** method must be called to close the data channel.

It is strongly recommended that most applications use the **GetFile** or **PutFile** methods to perform file transfers. These methods are easier to use, and have internal optimizations that improves the overall data transfer rate when compared to implementing the file transfer code in your own application.

See Also

FtpClient Class | SocketTools Namespace | FtpClient.OpenFile Overload List

FtpClient.OpenFile Method (String, FtpOpenMode)

Open an existing file or create a new file on the server.

[Visual Basic]

```
Overloads Public Function OpenFile( _
   ByVal remoteFile As String, _
   ByVal openMode As FtpOpenMode _
) As Boolean
```

[C#]

```
public bool OpenFile(
   string remoteFile,
   FtpOpenMode openMode
);
```

Parameters

remoteFile

A string that specifies the name of the file on the server. The filename cannot contain any wildcard characters and must follow the naming conventions of the operating system the server is hosted on.

openMode

An FtpOpenMode enumeration which specifies how the file should be accessed on the server.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **OpenFile** method opens an existing file or creates a new file on the remote server using the specified file name. The **Read** method may then be used to read data from the file and the **Write** method may be used to write data to the file. Once the all of the data has been read or written, the **CloseFile** method must be called to close the data channel.

It is strongly recommended that most applications use the **GetFile** or **PutFile** methods to perform file transfers. These methods are easier to use, and have internal optimizations that improves the overall data transfer rate when compared to implementing the file transfer code in your own application.

When a file is created on the remote server, the file ownership and access rights are determined by the server. Some servers may provide a method to change these attributes through site-specific commands. Refer to the server's operating system documentation for more information about what commands may be available.

See Also

FtpClient Class | SocketTools Namespace | FtpClient.OpenFile Overload List

FtpClient.OpenFile Method (String, FtpOpenMode, Int64)

Open an existing file or create a new file on the server.

[Visual Basic]

```
Overloads Public Function OpenFile( _
   ByVal remoteFile As String, _
   ByVal openMode As FtpOpenMode, _
   ByVal offset As Long _
) As Boolean
```

[C#]

```
public bool OpenFile(
   string remoteFile,
   FtpOpenMode openMode,
   long offset
);
```

Parameters

remoteFile
: A string that specifies the name of the file on the server. The filename cannot contain any wildcard characters and must follow the naming conventions of the operating system the server is hosted on.

openMode
: An FtpOpenMode enumeration which specifies how the file should be accessed on the server.

offset
: An integer value which specifies the byte offset where the file transfer should begin. If this argument is omitted, this specifies that the file transfer should start at the beginning of the file. A value greater than zero is typically used to restart a transfer that has not completed successfully. Note that specifying a non-zero offset requires that the server support the REST command to restart transfers.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **OpenFile** method opens an existing file or creates a new file on the remote server using the specified file name. The **Read** method may then be used to read data from the file and the **Write** method may be used to write data to the file. Once the all of the data has been read or written, the **CloseFile** method must be called to close the data channel.

It is strongly recommended that most applications use the **GetFile** or **PutFile** methods to perform file transfers. These methods are easier to use, and have internal optimizations that improves the overall data transfer rate when compared to implementing the file transfer code in your own application.

When a file is created on the remote server, the file ownership and access rights are determined by the server. Some servers may provide a method to change these attributes through site-specific commands. Refer to the server's operating system documentation for more information about what commands may be available.

FtpClient.PutData Method

Transfers data from a byte array and stores it in a file on the remote server.

Overload List

Transfers data from a byte array and stores it in a file on the remote server.

public bool PutData(string,byte[],int);

Transfers data from a MemoryStream and stores it in a file on the remote server.

public bool PutData(string,MemoryStream);

Transfers data from a string buffer and stores it in a file on the remote server.

public bool PutData(string,string);

Transfers data from a string buffer and stores it in a file on the remote server.

public bool PutData(string,string,int);

See Also

FtpClient Class | SocketTools Namespace

FtpClient.PutData Method (String, Byte[], Int32)

Transfers data from a byte array and stores it in a file on the remote server.

[Visual Basic]

```
Overloads Public Function PutData( _
   ByVal remoteFile As String, _
   ByVal buffer As Byte(), _
   ByVal length As Integer _
) As Boolean
```

[C#]

```
public bool PutData(
   string remoteFile,
   byte[] buffer,
   int length
);
```

Parameters

remoteFile
A string that specifies the file on the remote system that will contain the data being transferred. If the file already exists, it will be overwritten. The file pathing and name conventions must be that of the remote host.

buffer
A byte array that contains the data to be written to the file.

length
An integer value which specifies the maximum number of bytes of data to write. This value cannot be larger than the size of the byte array specified by the caller.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **PutData** method transfers data from a local buffer and stores it on a file on the server. This method will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

See Also

FtpClient Class | SocketTools Namespace | FtpClient.PutData Overload List

FtpClient.PutData Method (String, String)

Transfers data from a string buffer and stores it in a file on the remote server.

[Visual Basic]

```
Overloads Public Function PutData( _
   ByVal remoteFile As String, _
   ByVal buffer As String _
) As Boolean
```

[C#]

```
public bool PutData(
   string remoteFile,
   string buffer
);
```

Parameters

remoteFile

A string that specifies the file on the remote system that will contain the data being transferred. If the file already exists, it will be overwritten. The file pathing and name conventions must be that of the remote host.

buffer

A string that contains the data to be written to the file.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **PutData** method transfers data from a local buffer and stores it on a file on the server. This method will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

This implementation of the method should only be used with text files.

FtpClient.PutData Method (String, String, Int32)

Transfers data from a string buffer and stores it in a file on the remote server.

[Visual Basic]

```
Overloads Public Function PutData( _
   ByVal remoteFile As String, _
   ByVal buffer As String, _
   ByVal length As Integer _
) As Boolean
```

[C#]

```
public bool PutData(
   string remoteFile,
   string buffer,
   int length
);
```

Parameters

remoteFile

A string that specifies the file on the remote system that will contain the data being transferred. If the file already exists, it will be overwritten. The file pathing and name conventions must be that of the remote host.

buffer

A string that contains the data to be written to the file.

length

An integer value which specifies the maximum number of bytes of data to write. This value cannot be larger than the size of the byte array specified by the caller.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **PutData** method transfers data from a local buffer and stores it on a file on the server. This method will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

This implementation of the method should only be used with text files.

See Also

FtpClient Class | SocketTools Namespace | FtpClient.PutData Overload List

FtpClient.PutData Method (String, MemoryStream)

Transfers data from a MemoryStream and stores it in a file on the remote server.

[Visual Basic]

```
Overloads Public Function PutData( _
   ByVal remoteFile As String, _
   ByVal memStream As MemoryStream _
) As Boolean
```

[C#]

```
public bool PutData(
   string remoteFile,
   MemoryStream memStream
);
```

Parameters

remoteFile
A string that specifies the file on the remote system that will contain the data being transferred. If the file already exists, it will be overwritten. The file pathing and name conventions must be that of the remote host.

memStream
A MemoryStream that contains the data to be uploaded to the server. This stream must be open and readable.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **PutData** method transfers data from a MemoryStream and stores it on a file on the server. This method will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

The complete contents of the stream will be uploaded to the server, and when the method returns, the current position will be at the end of the stream. The stream must be open and readable, otherwise this method will throw **System.NotSupportedException**.

FtpClient Class | SocketTools Namespace | RemoteFile Property | URL Property

FtpClient.PutFile Method (String)

Upload a file from the local system to the server.

[Visual Basic]

```
Overloads Public Function PutFile( _
   ByVal localFile As String _
) As Boolean
```

[C#]

```
public bool PutFile(
   string localFile
);
```

Parameters

localFile

A string that specifies the file on the local system that will be transferred to the server. The file pathing and name conventions must be that of the local host.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **PutFile** method copies an existing file from the local system to the server. This method will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

This implementation of the **PutFile** method is most commonly used when the name of the remote file has already been specified, either by setting the **URL** property or by explicitly setting the **RemoteFile** property.

   ByVal remoteFile As String _
) As Boolean
```

[C#]

```
public bool PutFile(
   string localFile,
   string remoteFile
);
```

Parameters

localFile

A string that specifies the file on the local system that will be transferred to the server. The file pathing and name conventions must be that of the local host.

remoteFile

A string that specifies the file on the server that will be created. If the file already exists on the server, it will be overwritten. The file pathing and name conventions must be that of the remote host.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **PutFile** method copies an existing file from the local system to the server. This method will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

Upload a file from the local system to the server.

[Visual Basic]

```
Overloads Public Function PutFile( _
   ByVal localFile As String, _
   ByVal remoteFile As String, _
   ByVal options As FtpTransferOptions, _
   ByVal offset As Long _
) As Boolean
```

[C#]

```
public bool PutFile(
   string localFile,
   string remoteFile,
   FtpTransferOptions options,
   long offset
);
```

Parameters

localFile
: A string that specifies the file on the local system that will be transferred to the server. The file pathing and name conventions must be that of the local host.

remoteFile
: A string that specifies the file on the server that will be created, overwritten or appended to. The file pathing and name conventions must be that of the remote host.

options
: An FtpTransferOptions enumeration which specifies how the file should be uploaded to the server.

offset
: A numeric value which specifies the byte offset where the file transfer should begin. The default value of zero specifies that the file transfer should start at the beginning of the file. A value greater than zero is typically used to restart a transfer that has not completed successfully. Note that specifying a non-zero offset requires that the server support the REST command to restart transfers.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **PutFile** method copies an existing file from the local system to the server. FtpClient Class | SocketTools Namespace

FtpClient.PutMultipleFiles Method (String, String, String)

Upload multiple files from the local system to the server using a wildcard mask.

[Visual Basic]

```
Overloads Public Function PutMultipleFiles( _
   ByVal localPath As String, _
   ByVal remotePath As String, _
   ByVal fileMask As String _
) As Boolean
```

[C#]

```
public bool PutMultipleFiles(
   string localPath,
   string remotePath,
   string fileMask
);
```

Parameters

localPath
A string argument which specifies the name of the directory on the local system where the files will be copied from. You must have permission to read the contents of the directory.

remotePath
A string argument which specifies the name of the directory on the remote system where the files will be stored. You must have permission to modify the contents of the directory and create files.

fileMask
A string argument which specifies the wildcard mask to be used when selecting what files should be transferred. An empty string indicates that all files in the specified directory should be uploaded. Typically, this argument is a wildcard mask that limits the files uploaded to the server to those which match a specific extension.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **PutMultipleFiles** method copies multiple files from the local system to the remote server. If the remote file already exists, it is overwritten. This method will cause the current thread to block until all of the files have been transferred, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

FtpClient.PutMultipleFiles Method (String, String)

Upload multiple files from the local system to the server using a wildcard mask.

[Visual Basic]

```
Overloads Public Function PutMultipleFiles( _
   ByVal localPath As String, _
   ByVal remotePath As String _
) As Boolean
```

[C#]

```
public bool PutMultipleFiles(
   string localPath,
   string remotePath
);
```

Parameters

localPath
A string argument which specifies the name of the directory on the local system where the files will be copied from. You must have permission to read the contents of the directory.

remotePath
A string argument which specifies the name of the directory on the remote system where the files will be stored. You must have permission to modify the contents of the directory and create files.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **PutMultipleFiles** method copies multiple files from the local system to the remote server. If the remote file already exists, it is overwritten. This method will cause the current thread to block until all of the files have been transferred, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

FtpClient.Read Method

Read file data from the server and store it in a byte array.

Overload List

Read file data from the server and store it in a byte array.

public int Read(byte[]);

Read file data from the server and store it in a byte array.

public int Read(byte[],int);

Read file data from the server and store it in a string.

public int Read(ref string);

Read file data from the server and store it in a string.

public int Read(ref string,int);

See Also

FtpClient Class | SocketTools Namespace

FtpClient.Read Method (Byte[])

Read file data from the server and store it in a byte array.

[Visual Basic]

```
Overloads Public Function Read( _
   ByVal buffer As Byte() _
) As Integer
```

[C#]

```
public int Read(
   byte[] buffer
);
```

Parameters

buffer

A byte array that the data will be stored in.

Return Value

An integer value which specifies the number of bytes actually read from the server. A return value of zero specifies that the remote host has closed the connection and there is no more data available to be read. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Read** method returns data that has been read from the server, up to the number of bytes specified. If no data is available to be read, an error will be generated if the client is in non-blocking mode. If the client is in blocking mode, the program will stop until data is received from the server or the connection is closed.

See Also

FtpClient Class | SocketTools Namespace | FtpClient.Read Overload List

FtpClient.Read Method (Byte[], Int32)

Read file data from the server and store it in a byte array.

[Visual Basic]

```
Overloads Public Function Read( _
   ByVal buffer As Byte(), _
   ByVal length As Integer _
) As Integer
```

[C#]

```
public int Read(
   byte[] buffer,
   int length
);
```

Parameters

buffer

A byte array that the data will be stored in.

length

An integer value which specifies the maximum number of bytes of data to read. This value cannot be larger than the size of the buffer specified by the caller.

Return Value

An integer value which specifies the number of bytes actually read from the server. A return value of zero specifies that the remote host has closed the connection and there is no more data available to be read. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Read** method returns data that has been read from the server, up to the number of bytes specified. If no data is available to be read, an error will be generated if the client is in non-blocking mode. If the client is in blocking mode, the program will stop until data is received from the server or the connection is closed.

FtpClient Class | SocketTools Namespace | FtpClient.Read Overload List

FtpClient.Read Method (String)

Read file data from the server and store it in a string.

[Visual Basic]

```
Overloads Public Function Read( _
   ByRef buffer As String _
) As Integer
```

[C#]

```
public int Read(
   ref string buffer
);
```

Parameters

buffer

A string that is passed by reference. When the method returns, it will contain the data read from the server.

Return Value

An integer value which specifies the number of bytes actually read from the server. A return value of zero specifies that the remote host has closed the connection and there is no more data available to be read. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Read** method returns data that has been read from the server, up to the number of bytes specified. If no data is available to be read, an error will be generated if the client is in non-blocking mode. If the client is in blocking mode, the program will stop until data is received from the server or the connection is closed.

See Also

FtpClient Class | SocketTools Namespace | FtpClient.Read Overload List

FtpClient.Read Method (String, Int32)

Read file data from the server and store it in a string.

[Visual Basic]

```
Overloads Public Function Read( _
   ByRef buffer As String, _
   ByVal length As Integer _
) As Integer
```

[C#]

```
public int Read(
   ref string buffer,
   int length
);
```

Parameters

buffer

A string that is passed by reference. When the method returns, it will contain the data read from the server.

length

An integer value which specifies the maximum number of bytes of data to read.

Return Value

An integer value which specifies the number of bytes actually read from the server. A return value of zero specifies that the remote host has closed the connection and there is no more data available to be read. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Read** method returns data that has been read from the server, up to the number of bytes specified. If no data is available to be read, an error will be generated if the client is in non-blocking mode. If the client is in blocking mode, the program will stop until data is received from the server or the connection is closed.

FtpClient Class | SocketTools Namespace | FtpClient.Read Overload List

FtpClient.RemoveDirectory Method

Remove a directory on the server.

[Visual Basic]

```
Public Function RemoveDirectory( _
   ByVal pathName As String _
) As Boolean
```

[C#]

```
public bool RemoveDirectory(
   string pathName
);
```

Parameters

pathName

A string that specifies the name of the directory to remove from the server. The naming and pathing conventions used for the directory must be compatible with what is used on the operating system that hosts the server.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **RemoveDirectory** method removes an existing directory on the remote host. You must have the appropriate permission to remove the directory, or an error will occur. Note that most operating systems will not permit you to remove a directory that contains files or other subdirectories.

See Also

FtpClient Class | SocketTools Namespace

FtpClient.RenameFile Method

Change the name of a file on the server.

[Visual Basic]

```
Public Function RenameFile( _
   ByVal oldName As String, _
   ByVal newName As String _
) As Boolean
```

[C#]

```
public bool RenameFile(
   string oldName,
   string newName
);
```

Parameters

oldName
: A string that specifies the name of the file to be renamed on the server. The file must exist on the server, otherwise an error will be returned.

newName
: A string that specifies the new name for the file on the server. The naming conventions used for the file must be compatible with what is used on the operating system that hosts the server. Note that some servers may not permit you to rename the file if a file with the new name already exists.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **RenameFile** method changes the name of an existing file on the server to a new name. Note that you must have permission to rename the file or an error will occur. On UNIX based systems this means that you must have write permission to the directory where the file is being renamed.

See Also

FtpClient Class | SocketTools Namespace

FtpClient.Reset Method

Reset the internal state of the object, resetting all properties to their default values.

[Visual Basic]

```
Public Sub Reset()
```

[C#]

```
public void Reset();
```

Remarks

The **Reset** method returns the object to its default state. If a connection to a server has been established, it will be terminated the resources allocated for the client session will be released. All properties will be reset to their default values.

The **Reset** and **Uninitialize** methods will abort all active background transfers and wait for those tasks to complete before returning to the caller. It is recommended that your application explicitly wait for background transfers to complete or abort them using this method before allowing the program to terminate. This will ensure that your program can perform any necessary cleanup operations. If there are active background tasks running at the time that the class instance is disposed, it can force the instance to stop those worker threads immediately without waiting for them to terminate gracefully.

FtpClient Class | SocketTools Namespace

FtpClient.SetFilePermissions Method

Change the access permissions for a file on the server.

[Visual Basic]

```
Public Function SetFilePermissions( _
   ByVal remoteFile As String, _
   ByVal filePerms As FtpPermissions _
) As Boolean
```

[C#]

```
public bool SetFilePermissions(
   string remoteFile,
   FtpPermissions filePerms
);
```

Parameters

remoteFile

A string that specifies the name of the file that the access permissions are to be returned for. The filename cannot contain any wildcard characters.

filePerms

An FtpPermissions enumeration which specifies the new permissions for the file.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

This method uses the SITE CHMOD command to set the permissions for the file. This command is typically only supported on servers that are hosted on UNIX based systems. If the command is not supported, an error will be returned. You can use the **Features** property to determine what features are available and/or enabled on the server.

Users who are familiar with the UNIX operating system will recognize the **chmod** command used to change the file permissions. However, it should be noted that the numeric value used as an argument to the command is in octal, not decimal. For example, issuing the command **chmod 644 filename.txt** on a UNIX based system will make the file readable and writable by the owner, and readable by other users in the owner's group as well as all other users. The value 644 is an octal value, which is equivalent to the decimal value 420. If you were to mistakenly specify 644 as the value for the *Permissions* argument, rather than the decimal value of 420, the permissions on the file would be incorrect. It is strongly recommended that you use the enumeration values and do not cast a numeric value as the argument.

Note that Visual Basic allows you to specify an integer value in octal by prefixing it with &O. For example, &O644 could be used as the file permissions value. C# and C++ consider any integer with a preceding 0 to be an octal number, so 0644 would be a valid permissions value.

See Also

FtpClient Class | SocketTools Namespace

FtpClient.SetFileTime Method

Changes the modification date and time for a file on the server.

[Visual Basic]

```
Public Function SetFileTime( _
   ByVal remoteFile As String, _
   ByVal fileDate As Date _
) As Boolean
```

[C#]

```
public bool SetFileTime(
   string remoteFile,
   DateTime fileDate
);
```

Parameters

remoteFile

A string that specifies the name of the file on the server. The filename cannot contain any wildcard characters and must follow the naming conventions of the operating system the server is hosted on.

fileDate

A **System.DateTime** value that specifies the new date and time for the file.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **SetFileTime** method changes the modification date and time for the specified file on the remote server. This method uses the MTDM command to change the modification time for the file. If the server does not support this command, the method will return an error. Note that some servers only support the MDTM command to return, but not change, the file modification time.

FtpClient.TaskAbort Method

Abort all asynchronous tasks that are currently active.

Overload List

Abort all asynchronous tasks that are currently active.

public bool TaskAbort();

Abort the specified asynchronous task.

public bool TaskAbort(int);

Abort the specified asynchronous task.

public bool TaskAbort(int,int);

See Also

FtpClient Class | SocketTools Namespace

FtpClient.TaskAbort Method ()

Abort all asynchronous tasks that are currently active.

[Visual Basic]

```
Overloads Public Function TaskAbort() As Boolean
```

[C#]

```
public bool TaskAbort();
```

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **TaskAbort** method signals all background worker threads created by this instance of the class to abort their current operation and terminate as soon as possible. This version of the method will signal each active task and return immediately to the caller.

The **Reset** and **Uninitialize** methods will abort all active background transfers and wait for those tasks to complete before returning to the caller. It is recommended that your application explicitly wait for background transfers to complete or abort them using this method before allowing the program to terminate. This will ensure that your program can perform any necessary cleanup operations. If there are active background tasks running at the time that the class instance is disposed, it can force the instance to stop those worker threads immediately without waiting for them to terminate gracefully.

See Also

FtpClient Class | SocketTools Namespace | FtpClient.TaskAbort Overload List

FtpClient.TaskAbort Method (Int32)

Abort the specified asynchronous task.

[Visual Basic]

```
Overloads Public Function TaskAbort( _
   ByVal taskId As Integer _
) As Boolean
```

[C#]

```
public bool TaskAbort(
   int taskId
);
```

Parameters

taskId

An integer value that specifies the unique identifier associated with a background task.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **TaskAbort** method signals the background worker thread associated with the task ID to abort the current operation and terminate as soon as possible. This version of the method returns immediately after the background thread has been signaled.

See Also

FtpClient Class | SocketTools Namespace | FtpClient.TaskAbort Overload List

FtpClient.TaskAbort Method (Int32, Int32)

Abort the specified asynchronous task.

[Visual Basic]

```
Overloads Public Function TaskAbort( _
   ByVal taskId As Integer, _
   ByVal timeWait As Integer _
) As Boolean
```

[C#]

```
public bool TaskAbort(
   int taskId,
   int timeWait
);
```

Parameters

taskId
An integer value that specifies the unique identifier associated with a background task.

timeWait
An integer value that specifies the number of milliseconds to wait for the background task to abort.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **TaskAbort** method signals the background worker thread associated with the task ID to abort the current operation and terminate as soon as possible. If the ***timeWait*** parameter has a value of zero, the method returns immediately after the background thread has been signaled. If the ***timeWait*** parameter is non-zero, the method will wait that amount of time for the background thread to terminate.

The **Reset** and **Uninitialize** methods will abort all active background transfers and wait for those tasks to complete before returning to the caller. It is recommended that your application explicitly wait for background transfers to complete or abort them using this method before allowing the program to terminate. This will ensure that your program can perform any necessary cleanup operations. If there are active background tasks running at the time that the class instance is disposed, it can force the instance to stop those worker threads immediately without waiting for them to terminate gracefully.

FtpClient Class | SocketTools Namespace | FtpClient.TaskAbort Overload List

FtpClient.TaskDone Method

Determine if the current asynchronous task has completed.

Overload List

Determine if the current asynchronous task has completed.

public bool TaskDone();

Determine if an asynchronous task has completed.

public bool TaskDone(int);

See Also

FtpClient Class | SocketTools Namespace

FtpClient.TaskDone Method ()

Determine if the current asynchronous task has completed.

[Visual Basic]

```
Overloads Public Function TaskDone() As Boolean
```

[C#]

```
public bool TaskDone();
```

Return Value

This method returns a Boolean value. If the task has finished, the return value is **true**. If the background task is still active, the return value is **false**.

Remarks

The **TaskDone** method is used to determine if the current asynchronous task has completed. This overloaded version of the method is functionally equivalent to providing the value of the **TaskId** property as the unique task identifier.

If you use this method to poll the status of a background task from within the main UI thread, you must ensure that Windows messages are processed so that the application remains responsive to the end-user. To check if a background transfer has completed, it is recommended that you use a timer to periodically call this method rather than calling it repeatedly within a loop.

To determine if the task completed successfully, the **TaskWait** method will provide the last error code associated with the task. Note that if this method returns **true**, it is guaranteed that calling **TaskWait** using the same task ID will return the error code to the caller immediately without causing the current thread to block.

See Also

FtpClient Class | SocketTools Namespace | FtpClient.TaskDone Overload List

FtpClient.TaskDone Method (Int32)

Determine if an asynchronous task has completed.

[Visual Basic]

```
Overloads Public Function TaskDone( _
   ByVal taskId As Integer _
) As Boolean
```

[C#]

```
public bool TaskDone(
   int taskId
);
```

Parameters

taskId

An optional integer value that specifies the unique identifier associated with a background task.

Return Value

This method returns a Boolean value. If the task has finished, the return value is **true**. If the background task is still active, the return value is **false**.

Remarks

The **TaskDone** method is used to determine if the specified asynchronous task has completed.

If you use this method to poll the status of a background task from within the main UI thread, you must ensure that Windows messages are processed so that the application remains responsive to the end-user. To check if a background transfer has completed, it is recommended that you use a timer to periodically call this method rather than calling it repeatedly within a loop.

To determine if the task completed successfully, the **TaskWait** method will provide the last error code associated with the task. Note that if this method returns **true**, it is guaranteed that calling **TaskWait** using the same task ID will return the error code to the caller immediately without causing the current thread to block.

FtpClient Class | SocketTools Namespace

FtpClient.TaskResume Method ()

Resume execution of the current asynchronous task.

[Visual Basic]

```
Overloads Public Function TaskResume() As Boolean
```

[C#]

```
public bool TaskResume();
```

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **TaskResume** method resumes execution of the current background task that was previously suspended using the **TaskSuspend** method. This overloaded version of the method is functionally equivalent to providing the value of the **TaskId** property as the unique task identifier.

See Also

FtpClient Class | SocketTools Namespace | FtpClient.TaskResume Overload List

FtpClient.TaskResume Method (Int32)

Resume execution of an asynchronous task.

[Visual Basic]

```
Overloads Public Function TaskResume( _
   ByVal taskId As Integer _
) As Boolean
```

[C#]

```
public bool TaskResume(
   int taskId
);
```

Parameters

taskId

An integer value that specifies the unique identifier associated with a background task.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **TaskResume** method resumes execution of the background worker thread that was previously suspended using the **TaskSuspend** method.

FtpClient Class | SocketTools Namespace

FtpClient.TaskSuspend Method ()

Suspend execution of the current asynchronous task.

[Visual Basic]

```
Overloads Public Function TaskSuspend() As Boolean
```

[C#]

```
public bool TaskSuspend();
```

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **TaskSuspend** method will suspend execution of the background worker thread associated with the current task. This overloaded version of the method is functionally equivalent to providing the value of the **TaskId** property as the unique task identifier.

Once the task has been suspended, it will no longer be scheduled for execution, however the client session will remain active and the task may be resumed using the **TaskResume** method. Note that if a task is suspended for a long period of time, the background operation may fail because it has exceeded the timeout period imposed by the server.

See Also

FtpClient Class | SocketTools Namespace | FtpClient.TaskSuspend Overload List

FtpClient.TaskSuspend Method (Int32)

Suspend execution of an asynchronous task.

[Visual Basic]

```
Overloads Public Function TaskSuspend( _
   ByVal taskId As Integer _
) As Boolean
```

[C#]

```
public bool TaskSuspend(
   int taskId
);
```

Parameters

taskId

An integer value that specifies the unique identifier associated with a background task.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **TaskSuspend** method will suspend execution of the background worker thread associated with the task.

Once the task has been suspended, it will no longer be scheduled for execution, however the client session will remain active and the task may be resumed using the **TaskResume** method. Note that if a task is suspended for a long period of time, the background operation may fail because it has exceeded the timeout period imposed by the server.

FtpClient Class | SocketTools Namespace

FtpClient.TaskWait Method ()

Wait for all asynchronous tasks to complete.

[Visual Basic]

```
Overloads Public Function TaskWait() As Boolean
```

[C#]

```
public bool TaskWait();
```

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

This overloaded version of the **TaskWait** method will cause the current working thread to block until all background tasks created by this instance of the class have completed. If there are no active background tasks, this method will return to the caller immediately.

You should not call this version of the method from the main UI thread. Windows messages will not be processed while this method is blocked waiting for the background tasks to complete, and this can cause your application to appear non-responsive to the end-user. If you have a GUI application and you need to determine if all tasks have completed, create a timer to periodically check the value of the **TaskCount** property. When it returns zero, there are no active background tasks executing.

See Also

FtpClient Class | SocketTools Namespace | FtpClient.TaskWait Overload List

FtpClient.TaskWait Method (Int32)

Wait for an asynchronous task to complete.

[Visual Basic]

```
Overloads Public Function TaskWait( _
   ByVal taskId As Integer _
) As Boolean
```

[C#]

```
public bool TaskWait(
   int taskId
);
```

Parameters

taskId

An integer value that specifies the unique identifier associated with a background task.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **TaskWait** method waits for the specified task to complete. This method will cause the current working thread to block for an indefinite period of time until the task completes. If the specified task has already completed at the time this method is called, the method will return immediately without causing the current thread to block.

You should not call this overloaded version of the method from the main UI thread. Windows messages will not be processed while this method is blocked waiting for the background task to complete, and this can cause your application to appear non-responsive to the end-user. If you have a GUI application and you need to determine if a background task has finished, create a timer to periodically call the **TaskDone** method. When it returns **true** (indicating that the task has completed), you can safely call **TaskWait** to obtain the elapsed time and last error code without blocking the current thread.

See Also

FtpClient.TaskWait Method (Int32, Int32)

Wait for an asynchronous task to complete.

[Visual Basic]

```
Overloads Public Function TaskWait( _
   ByVal taskId As Integer, _
   ByVal timeWait As Integer _
) As Boolean
```

[C#]

```
public bool TaskWait(
   int taskId,
   int timeWait
);
```

Parameters

taskId

An integer value that specifies the unique identifier associated with a background task.

timeWait

An integer value that specifies the number of milliseconds to wait for the background task to complete.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **TaskWait** method waits for the specified task to complete. This method will cause the current working thread to block until the task completes or the amount of time exceeds the number of milliseconds specified by the caller. If the *timeWait* parameter is zero, then this method will poll the status of the task and return immediately to the caller. If the specified task has already completed at the time this method is called, the method will return immediately without causing the current thread to block.

You should not call this method from the main UI thread with a long timeout period to wait for a background task to complete. Windows messages will not be processed while this method is blocked waiting for the background task to complete, and this can cause your application to appear non-responsive to the end-user. If you have a GUI application and you need to determine if a background task has finished, create a timer to periodically call the **TaskDone** method. When it returns **true** (indicating that the task has completed), you can safely call **TaskWait** to obtain the elapsed time and last error code without blocking the current thread.

FtpClient.TaskWait Method (Int32, Int32, ErrorCode)

Wait for an asynchronous task to complete.

[Visual Basic]

```
Overloads Public Function TaskWait( _
   ByVal taskId As Integer, _
   ByVal timeWait As Integer, _
   ByRef taskError As ErrorCode _
) As Boolean
```

[C#]

```
public bool TaskWait(
   int taskId,
   int timeWait,
   ref ErrorCode taskError
);
```

Parameters

taskId

An integer value that specifies the unique identifier associated with a background task.

timeWait

An integer value that specifies the number of milliseconds to wait for the background task to complete.

taskError

An ErrorCode value passed by reference that will contain the last error code set by the asynchronous task.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **TaskWait** method waits for the specified task to complete. This method will cause the current working thread to block until the task completes or the amount of time exceeds the number of milliseconds specified by the caller. If the *timeWait* parameter is zero, then this method will poll the status of the task and return immediately to the caller.

If the specified task has already completed at the time this method is called, the method will return immediately without causing the current thread to block. The ***taskError*** parameter will contain the last error code value that was set by the worker thread before it terminated. If the ***taskError*** value is zero, that means that the background task was successful and no error occurred. A non-zero value will indicate that the background task has failed.

You should not call this method from the main UI thread with a long timeout period to wait for a background task to complete. Windows messages will not be processed while this method is blocked waiting for the background task to complete, and this can cause your application to appear non-responsive to the end-user. If you have a GUI application and you need to determine if a background task has finished, create a timer to periodically call the **TaskDone** method. When it returns **true** (indicating that the task has completed), you can safely call **TaskWait** to obtain the elapsed time and last error code without blocking the current thread.

Wait for an asynchronous task to complete.

[Visual Basic]

```
Overloads Public Function TaskWait( _
   ByVal taskId As Integer, _
   ByVal timeWait As Integer, _
   ByRef timeElapsed As Integer, _
   ByRef taskError As ErrorCode _
) As Boolean
```

[C#]

```
public bool TaskWait(
   int taskId,
   int timeWait,
   ref int timeElapsed,
   ref ErrorCode taskError
);
```

Parameters

taskId
An integer value that specifies the unique identifier associated with a background task.

timeWait
An integer value that specifies the number of milliseconds to wait for the background task to complete.

timeElapsed
An integer value passed by reference that will contain the elapsed time for the task in milliseconds when the method returns.

taskError
An ErrorCode value passed by reference that will contain the last error code set by the asynchronous task.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **TaskWait** method waits for the specified task to complete. This method will cause the current working thread to block until the task completes or the amount of time exceeds the number of milliseconds specified by the caller. If the *timeWait* parameter is zero, then this method will poll the status of the task and return immediately to the caller.

If the specified task has already completed at the time this method is called, the method will return immediately without causing the current thread to block. The *timeElapsed* parameter contain the number of milliseconds that it took for the task to complete. The *taskError* parameter will contain the last error code value that was set by the worker thread before it terminated. If the *taskError* value is zero, that means that the background task was successful and no error occurred. A non-zero value will indicate that the background task has failed.

You should not call this method from the main UI thread with a long timeout period to wait for a background task to complete. Windows messages will not be processed while this method is blocked

waiting for the background task to complete, and this can cause your application to appear non-responsive to the end-user. If you have a GUI application and you need to determine if a background task has finished, create a timer to periodically call the **TaskDone** method. When it returns **true** (indicating that the task has completed), you can safely call **TaskWait** to obtain the elapsed time and last error code without blocking the current thread.

FtpClient Class | SocketTools Namespace | FtpClient.TaskWait Overload List

FtpClient.Uninitialize Method

Uninitialize the class library and release any resources allocated for the current thread.

[Visual Basic]

```
Public Sub Uninitialize()
```

[C#]

```
public void Uninitialize();
```

Remarks

The **Uninitialize** method terminates any active connection, releases resources allocated for the current thread and unloads the networking library. After this method has been called, no further network operations may be performed until the class instance has been re-initialized.

If the **Initialize** method is explicitly called by the application, it should be matched by a call to the **Uninitialize** method when that instance of the class is no longer needed.

The **Reset** and **Uninitialize** methods will abort all active background transfers and wait for those tasks to complete before returning to the caller. It is recommended that your application explicitly wait for background transfers to complete or abort them using this method before allowing the program to terminate. This will ensure that your program can perform any necessary cleanup operations. If there are active background tasks running at the time that the class instance is disposed, it can force the instance to stop those worker threads immediately without waiting for them to terminate gracefully.

[C#]

```
public bool VerifyFile(
   string localFile,
   string remoteFile
);
```

Parameters

localFile
A string value which specifies the name of the local file.

remoteFile
A string value which specifies the name of the file on the server.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **VerifyFile** method will attempt to verify that the contents of the local and remote files are identical using one of several methods, based on the features that the server supports. Preference will be given to the most reliable method available, using either an MD5 hash, a CRC32 checksum or comparing the size of the file, in that order.

See Also

FtpClient Class | SocketTools Namespace | FtpClient.VerifyFile Overload List

FtpClient.VerifyFile Method (String, String, FtpVerifyOptions)

Verify that the contents of a file on the local system are the same as the specified file on the server.

[Visual Basic]

```
Overloads Public Function VerifyFile( _
   ByVal localFile As String, _
   ByVal remoteFile As String, _
   ByVal options As FtpVerifyOptions _
) As Boolean
```

[C#]

```
public bool VerifyFile(
   string localFile,
   string remoteFile,
   FtpVerifyOptions options
);
```

Parameters

localFile
A string value which specifies the name of the local file.

remoteFile
A string value which specifies the name of the file on the server.

options
An FtpVerifyOptions enumeration which specifies one or more options that should be used when comparing the files.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **VerifyFile** method will attempt to verify that the contents of the local and remote files are identical using one of several methods, based on the features that the server supports. Preference will be given to the most reliable method available, using either an MD5 hash, a CRC32 checksum or comparing the size of the file, in that order.

FtpClient Class | SocketTools Namespace | FtpClient.VerifyFile Overload List

FtpClient.Write Method

Write one or more bytes of data to the server.

Overload List

Write one or more bytes of data to the server.

public int Write(byte[]);

Write one or more bytes of data to the server.

public int Write(byte[],int);

Write a string of characters to the server.

public int Write(string);

Write a string of characters to the server.

public int Write(string,int);

See Also

FtpClient Class | SocketTools Namespace

FtpClient.Write Method (Byte[])

Write one or more bytes of data to the server.

[Visual Basic]

```
Overloads Public Function Write( _
   ByVal buffer As Byte() _
) As Integer
```

[C#]

```
public int Write(
   byte[] buffer
);
```

Parameters

buffer
    A byte array that contains the data to be written to the server.

Return Value

An integer value which specifies the number of bytes actually written to the server. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Write** method sends one or more bytes of data to the server. If there is enough room in the socket's internal send buffer to accommodate all of the data, it is copied to the send buffer and control immediately returns to the caller. If amount of data exceeds the available buffer space and the socket is in blocking mode, then the method will block until the data can be sent. If the socket is in non-blocking mode and the send buffer is full, an error will occur.

See Also

FtpClient Class | SocketTools Namespace | FtpClient.Write Overload List

FtpClient.Write Method (Byte[], Int32)

Write one or more bytes of data to the server.

[Visual Basic]

```
Overloads Public Function Write( _
   ByVal buffer As Byte(), _
   ByVal length As Integer _
) As Integer
```

[C#]

```
public int Write(
   byte[] buffer,
   int length
);
```

Parameters

buffer

A byte array that contains the data to be written to the server.

length

An integer value which specifies the maximum number of bytes of data to write. This value cannot be larger than the size of the buffer specified by the caller.

Return Value

An integer value which specifies the number of bytes actually written to the server. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Write** method sends one or more bytes of data to the server. If there is enough room in the socket's internal send buffer to accommodate all of the data, it is copied to the send buffer and control immediately returns to the caller. If amount of data exceeds the available buffer space and the socket is in blocking mode, then the method will block until the data can be sent. If the socket is in non-blocking mode and the send buffer is full, an error will occur.

See Also

FtpClient Class | SocketTools Namespace | FtpClient.Write Overload List

FtpClient.Write Method (String)

Write a string of characters to the server.

[Visual Basic]

```
Overloads Public Function Write( _
   ByVal buffer As String _
) As Integer
```

[C#]

```
public int Write(
   string buffer
);
```

Parameters

buffer
A string which contains the data to be written to the server.

Return Value

An integer value which specifies the number of characters actually written to the server. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Write** method sends a string of characters to the server. If there is enough room in the socket's internal send buffer to accommodate all of the data, it is copied to the send buffer and control immediately returns to the caller. If amount of data exceeds the available buffer space and the socket is in blocking mode, then the method will block until the data can be sent. If the socket is in non-blocking mode and the send buffer is full, an error will occur.

See Also

FtpClient Class | SocketTools Namespace | FtpClient.Write Overload List

FtpClient.Write Method (String, Int32)

Write a string of characters to the server.

[Visual Basic]

```
Overloads Public Function Write( _
   ByVal buffer As String, _
   ByVal length As Integer _
) As Integer
```

[C#]

```
public int Write(
   string buffer,
   int length
);
```

Parameters

buffer

A string which contains the data to be written to the server.

length

An integer value which specifies the maximum number of characters to write. This value cannot be larger than the length of the string specified by the caller.

Return Value

An integer value which specifies the number of characters actually written to the server. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Write** method sends a string of characters to the server. If there is enough room in the socket's internal send buffer to accommodate all of the data, it is copied to the send buffer and control immediately returns to the caller. If amount of data exceeds the available buffer space and the socket is in blocking mode, then the method will block until the data can be sent. If the socket is in non-blocking mode and the send buffer is full, an error will occur.

FtpClient Events

The events of the **FtpClient** class are listed below. For a complete list of **FtpClient** class members, see the FtpClient Members topic.

Public Instance Events

⚡ OnCancel	Occurs when a blocking client operation is canceled.
⚡ OnCommand	Occurs when the client sends a command to the remote host and receives a reply indicating the result of that command.
⚡ OnConnect	Occurs when a connection is established with the remote host.
⚡ OnDisconnect	Occurs when the remote host disconnects from the local system.
⚡ OnError	Occurs when an socket operation fails.
⚡ OnFileList	Occurs when a directory listing is parsed by the class.
⚡ OnGetFile	Occurs when a file download has been initiated.
⚡ OnLastFile	Occurs when the last file in a directory listing has been processed.
⚡ OnProgress	Occurs as a data stream is being read or written to the socket.
⚡ OnPutFile	Occurs when a file upload is initiated.
⚡ OnRead	Occurs when data is available to be read from the socket.
⚡ OnTaskBegin	Occurs when an asynchronous task begins execution.
⚡ OnTaskEnd	Occurs when an asynchronous task completes.
⚡ OnTaskRun	Occurs while a background task is active.
⚡ OnTimeout	Occurs when a blocking operation fails to complete before the timeout period elapses.
⚡ OnWrite	Occurs when data can be written to the socket.

See Also

FtpClient Class | SocketTools Namespace

FtpClient.OnCancel Event

Occurs when a blocking client operation is canceled.

[Visual Basic]
```
Public Event OnCancel As EventHandler
```

[C#]
```
public event EventHandler OnCancel;
```

Remarks

The **OnCancel** event is generated when a blocking client operation, such as sending or receiving data, is canceled with the **Cancel** method. To assist in determining which operation was canceled, check the value of the **Status** property.

See Also

FtpClient Class | SocketTools Namespace

FtpClient.OnCommand Event

Occurs when the client sends a command to the remote host and receives a reply indicating the result of that command.

[Visual Basic]

```
Public Event OnCommand As OnCommandEventHandler
```

[C#]

```
public event OnCommandEventHandler OnCommand;
```

Event Data

The event handler receives an argument of type FtpClient.CommandEventArgs containing data related to this event. The following **FtpClient.CommandEventArgs** properties provide information specific to this event.

Property	Description
ResultCode	Gets a value which specifies the last result code returned by the server.
ResultString	Gets a string value which describes the result of the previous command.

Remarks

The **OnCommand** event is generated when the client receives a reply from the server after some action has been taken.

See Also

FtpClient Class | SocketTools Namespace

FtpClient.CommandEventArgs Class

Provides data for the OnCommand event.

For a list of all members of this type, see FtpClient.CommandEventArgs Members.

System.Object
  System.EventArgs
    SocketTools.FtpClient.CommandEventArgs

[Visual Basic]

```
Public Class FtpClient.CommandEventArgs
    Inherits EventArgs
```

[C#]

```
public class FtpClient.CommandEventArgs : EventArgs
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

CommandEventArgs specifies the result code and result string for the last command executed by the server.

The OnCommand event occurs whenever a command is executed on the server.

Requirements

Namespace: SocketTools

Assembly: SocketTools.FtpClient (in SocketTools.FtpClient.dll)

See Also

FtpClient.CommandEventArgs Members | SocketTools Namespace

FtpClient.CommandEventArgs Members

FtpClient.CommandEventArgs overview

Public Instance Constructors

FtpClient.CommandEventArgs Constructor	Initializes a new instance of the FtpClient.CommandEventArgs class.

Public Instance Properties

ResultCode	Gets a value which specifies the last result code returned by the server.
ResultString	Gets a string value which describes the result of the previous command.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString (inherited from Object)	Returns a String that represents the current Object.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

FtpClient.CommandEventArgs Class | SocketTools Namespace

FtpClient.CommandEventArgs Constructor

Initializes a new instance of the FtpClient.CommandEventArgs class.

[Visual Basic]

```
Public Sub New()
```

[C#]

```
public FtpClient.CommandEventArgs();
```

See Also

FtpClient.CommandEventArgs Class | SocketTools Namespace

FtpClient.CommandEventArgs Properties

The properties of the **FtpClient.CommandEventArgs** class are listed below. For a complete list of **FtpClient.CommandEventArgs** class members, see the FtpClient.CommandEventArgs Members topic.

Public Instance Properties

ResultCode	Gets a value which specifies the last result code returned by the server.
ResultString	Gets a string value which describes the result of the previous command.

See Also

FtpClient.CommandEventArgs Class | SocketTools Namespace

FtpClient.CommandEventArgs.ResultCode Property

Gets a value which specifies the last result code returned by the server.

[Visual Basic]

```
Public ReadOnly Property ResultCode As Integer
```

[C#]

```
public int ResultCode {get;}
```

Property Value

An integer value which specifies the last result code returned by the server.

Remarks

This property should be checked after the **Command** method is used to execute a command on the server to determine if the operation was successful. Result codes are three-digit numeric values returned by the remote server and may be broken down into the following ranges:

ResultCode	Description
100-199	Positive preliminary result. This indicates that the requested action is being initiated, and the client should expect another reply from the server before proceeding.
200-299	Positive completion result. This indicates that the server has successfully completed the requested action.
300-399	Positive intermediate result. This indicates that the requested action cannot complete until additional information is provided to the server.
400-499	Transient negative completion result. This indicates that the requested action did not take place, but the error condition is temporary and may be attempted again.
500-599	Permanent negative completion result. This indicates that the requested action did not take place.

It is important to note that while some result codes have become standardized, not all servers respond to commands using the same result codes. For example, one server may respond with a result code of 221 to indicate success, while another may respond with a value of 235. It is recommended that applications check for ranges of values to determine if a command was successful, not a specific value.

See Also

FtpClient.CommandEventArgs Class | SocketTools Namespace

FtpClient.CommandEventArgs.ResultString Property

Gets a string value which describes the result of the previous command.

[Visual Basic]

```
Public ReadOnly Property ResultString As String
```

[C#]

```
public string ResultString {get;}
```

Property Value

A string which describes the result of the previous command executed on the server.

Remarks

This string is generated by the remote server, and typically is used to describe the result code. For example, if an error is indicated by the result code, the result string may describe the condition that caused the error.

See Also

FtpClient.CommandEventArgs Class | SocketTools Namespace

FtpClient.OnConnect Event

Occurs when a connection is established with the remote host.

[Visual Basic]
```
Public Event OnConnect As EventHandler
```

[C#]
```
public event EventHandler OnConnect;
```

Remarks

The **OnConnect** event occurs when a connection is made with a remote host as a result of a **Connect** method call. When the **Connect** method is called and the **Blocking** property is set to **false**, a socket is created but the connection is not actually established until after this event occurs. Between the time connection process is started and this event fires, no operation may be performed by the client other than calling the **Disconnect** method.

This event is only generated if the client is in non-blocking mode.

See Also

FtpClient Class | SocketTools Namespace

FtpClient.OnDisconnect Event

Occurs when the remote host disconnects from the local system.

[Visual Basic]

```
Public Event OnDisconnect As EventHandler
```

[C#]

```
public event EventHandler OnDisconnect;
```

Remarks

The **OnDisconnect** event occurs when the remote host closes its socket, terminating its connection with the application. Because there may still be data in the socket receive buffers, you should continue to read data from the socket until the **Read** method returns a value of 0. Once all of the data has been read, you should call the **Disconnect** method to close the local socket and terminate the session.

This event is only generated if the client is in non-blocking mode.

See Also

FtpClient Class | SocketTools Namespace

FtpClient.OnError Event

Occurs when an socket operation fails.

[Visual Basic]

```
Public Event OnError As OnErrorEventHandler
```

[C#]

```
public event OnErrorEventHandler OnError;
```

Event Data

The event handler receives an argument of type FtpClient.ErrorEventArgs containing data related to this event. The following **FtpClient.ErrorEventArgs** properties provide information specific to this event.

Property	Description
Description	Gets a value which describes the last error that has occurred.
Error	Gets a value which specifies the last error that has occurred.

Remarks

The **OnError** event occurs when a client operation fails.

See Also

FtpClient Class | SocketTools Namespace

FtpClient.ErrorEventArgs Class

Provides data for the OnError event.

For a list of all members of this type, see FtpClient.ErrorEventArgs Members.

System.Object
  System.EventArgs
    SocketTools.FtpClient.ErrorEventArgs

[Visual Basic]

```
Public Class FtpClient.ErrorEventArgs
    Inherits EventArgs
```

[C#]

```
public class FtpClient.ErrorEventArgs : EventArgs
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

ErrorEventArgs specifies the numeric error code and a description of the error that has occurred.

An OnError event occurs when a method fails.

Requirements

Namespace: SocketTools

Assembly: SocketTools.FtpClient (in SocketTools.FtpClient.dll)

See Also

FtpClient.ErrorEventArgs Properties

The properties of the **FtpClient.ErrorEventArgs** class are listed below. For a complete list of **FtpClient.ErrorEventArgs** class members, see the FtpClient.ErrorEventArgs Members topic.

Public Instance Properties

Description	Gets a value which describes the last error that has occurred.
Error	Gets a value which specifies the last error that has occurred.

See Also

FtpClient.ErrorEventArgs Class | SocketTools Namespace

FtpClient.ErrorEventArgs.Description Property

Gets a value which describes the last error that has occurred.

[Visual Basic]

```
Public ReadOnly Property Description As String
```

[C#]

```
public string Description {get;}
```

Property Value

A string which describes the last error that has occurred.

See Also

FtpClient.ErrorEventArgs Class | SocketTools Namespace | Error Property

FtpClient.ErrorEventArgs.Error Property

Gets a value which specifies the last error that has occurred.

[Visual Basic]
```
Public ReadOnly Property Error As ErrorCode
```

[C#]
```
public FtpClient.ErrorCode Error {get;}
```

Property Value

ErrorCode enumeration which specifies the error.

See Also

FtpClient.OnGetFile Event

Occurs when a file download has been initiated.

[Visual Basic]

```
Public Event OnGetFile As OnGetFileEventHandler
```

[C#]

```
public event OnGetFileEventHandler OnGetFile;
```

Event Data

The event handler receives an argument of type FtpClient.GetFileEventArgs containing data related to this event. The following **FtpClient.GetFileEventArgs** properties provide information specific to this event.

Property	Description
LocalFile	Gets a value which specifies the name of the local file.
RemoteFile	Gets a value which specifies the name of the remote file.

Remarks

The **OnGetFile** event is generated when a file transfer is initiated by calling the **GetFile** or **GetMultipleFiles** methods. This will be followed by one or more **OnProgress** events which will indicate the progress of the transfer. If multiple files are being downloaded, this event will fire for each file as it is transferred.

See Also

```
public class FtpClient.GetFileEventArgs : EventArgs
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

GetFileEventArgs specifies information about the start of a file transfer from the server to the local system.

The OnGetFile event occurs when either the **GetFile** or **GetMultipleFiles** methods are called.

Requirements

Namespace: SocketTools

Assembly: SocketTools.FtpClient (in SocketTools.FtpClient.dll)

FtpClient.OnProgress Event

Occurs as a data stream is being read or written to the socket.

[Visual Basic]
```
Public Event OnProgress As OnProgressEventHandler
```

[C#]
```
public event OnProgressEventHandler OnProgress;
```

Event Data

The event handler receives an argument of type FtpClient.ProgressEventArgs containing data related to this event. The following **FtpClient.ProgressEventArgs** properties provide information specific to this event.

Property	Description
BytesCopied	Gets a value which specifies the number of bytes of data that has been read or written.
BytesTotal	Gets a value which specifies the total number of bytes in the data stream.
FileName	Gets a value which specifies a file name.
Percent	Gets a value which specifies the percentage of data that has been read or written.

Remarks

The **OnProgress** event occurs as a data stream is being read or written to the socket. If large amounts of data are being read or written, this event can be used to update a progress bar or other user-interface component to provide the user with some visual feedback on the progress of the operation.

See Also

FtpClient Class | SocketTools Namespace

FtpClient.ProgressEventArgs Class

Provides data for the OnProgress event.

For a list of all members of this type, see FtpClient.ProgressEventArgs Members.

System.Object
  System.EventArgs
    SocketTools.FtpClient.ProgressEventArgs

[Visual Basic]

```
Public Class FtpClient.ProgressEventArgs
    Inherits EventArgs
```

[C#]

```
public class FtpClient.ProgressEventArgs : EventArgs
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

ProgressEventArgs specifies the number of bytes copied from the data stream, the total number of bytes in the data stream and a completion percentage.

The OnProgress event occurs as a data stream is being read or written to the socket.

Requirements

Namespace: SocketTools

Assembly: SocketTools.FtpClient (in SocketTools.FtpClient.dll)

FtpClient.ProgressEventArgs Properties

The properties of the **FtpClient.ProgressEventArgs** class are listed below. For a complete list of **FtpClient.ProgressEventArgs** class members, see the FtpClient.ProgressEventArgs Members topic.

Public Instance Properties

BytesCopied	Gets a value which specifies the number of bytes of data that has been read or written.
BytesTotal	Gets a value which specifies the total number of bytes in the data stream.
FileName	Gets a value which specifies a file name.
Percent	Gets a value which specifies the percentage of data that has been read or written.

See Also

FtpClient.ProgressEventArgs Class | SocketTools Namespace

FtpClient.ProgressEventArgs.BytesCopied Property

Gets a value which specifies the number of bytes of data that has been read or written.

[Visual Basic]

```
Public ReadOnly Property BytesCopied As Long
```

[C#]

```
public long BytesCopied {get;}
```

Property Value

An integer value which specifies the number of bytes of data.

Remarks

The **BytesCopied** property specifies the number of bytes that have been read from the socket and stored in the local stream buffer, or written from the stream buffer to the socket.

See Also

FtpClient.ProgressEventArgs Class | SocketTools Namespace | BytesTotal Property | Percent Property

FtpClient.ProgressEventArgs.BytesTotal Property

Gets a value which specifies the total number of bytes in the data stream.

[Visual Basic]

```
Public ReadOnly Property BytesTotal As Long
```

[C#]

```
public long BytesTotal {get;}
```

Property Value

An integer value which specifies the number of bytes of data.

Remarks

The **BytesTotal** property specifies the total amount of data being read from the socket and stored in the data stream, or written from the data stream to the socket. If the amount of data was unknown or unspecified at the time the method call was made, then this value will always be the same as the **BytesCopied** property.

FtpClient.ProgressEventArgs Class | SocketTools Namespace

FtpClient.ProgressEventArgs.Percent Property

Gets a value which specifies the percentage of data that has been read or written.

[Visual Basic]

```
Public ReadOnly Property Percent As Integer
```

[C#]

```
public int Percent {get;}
```

Property Value

An integer value which specifies a percentage.

Remarks

The **Percent** property specifies the percentage of data that has been transmitted, expressed as an integer value between 0 and 100, inclusive. If the maximum size of the data stream was not specified by the caller, this value will always be 100.

FtpClient.OnPutFile Event

Occurs when a file upload is initiated.

[Visual Basic]
```
Public Event OnPutFile As OnPutFileEventHandler
```

[C#]
```
public event OnPutFileEventHandler OnPutFile;
```

Event Data

The event handler receives an argument of type FtpClient.PutFileEventArgs containing data related to this event. The following **FtpClient.PutFileEventArgs** properties provide information specific to this event.

Property	Description
LocalFile	Gets a value which specifies the name of the local file.
RemoteFile	Gets a value which specifies the name of the remote file.

Remarks

The **OnPutFile** event is generated when a file transfer is initiated by calling the **PutFile** or **PutMultipleFiles** methods. This will be followed by one or more **OnProgress** events which will indicate the progress of the transfer. If multiple files are being uploaded, this event will fire for each file as it is transferred.

FtpClient Class | SocketTools Namespace

FtpClient.PutFileEventArgs Class

Provides data for the OnPutFile event.

For a list of all members of this type, see FtpClient.PutFileEventArgs Members.

System.Object
  System.EventArgs
    SocketTools.FtpClient.PutFileEventArgs

[Visual Basic]

```
Public Class FtpClient.PutFileEventArgs
    Inherits EventArgs
```

[C#]

```
public class FtpClient.PutFileEventArgs : EventArgs
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

PutFileEventArgs specifies information about the start of a file transfer from the local system to the server.

The OnPutFile event occurs when either the **PutFile** or **PutMultipleFiles** methods are called.

Requirements

Namespace: SocketTools

Assembly: SocketTools.FtpClient (in SocketTools.FtpClient.dll)

FtpClient.PutFileEventArgs overview

Public Instance Constructors

FtpClient.PutFileEventArgs Constructor	Initializes a new instance of the FtpClient.PutFileEventArgs class.

Public Instance Properties

LocalFile	Gets a value which specifies the name of the local file.
RemoteFile	Gets a value which specifies the name of the remote file.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString (inherited from Object)	Returns a String that represents the current Object.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

FtpClient.OnRead Event

Occurs when data is available to be read from the socket.

[Visual Basic]

```
Public Event OnRead As EventHandler
```

[C#]

```
public event EventHandler OnRead;
```

Remarks

The **OnRead** event occurs when data is available to be read from the server. This event is level-triggered, which means that once this event fires, it will not occur again until some data has been read from the server. This design prevents an application from being flooded with event notifications. It is recommended that your application read all of the available data from the server and store it in a local buffer for processing. See the example below.

This event is only generated if the client is in non-blocking mode.

Example

```
Private Sub FtpClient1_OnRead(ByVal sender As Object, ByVal e As System.EventArgs)
Handles FtpClient1.OnRead
    Dim strBuffer As String
    Dim nRead As Integer

    Do
        ' Read up to m_nBufferSize bytes of data from the socket
        nRead = FtpClient1.Read(strBuffer, m_nBufferSize)

        If nRead > 0 Then
            ' Append the data to an internal buffer for processing
            m_dataBuffer = m_dataBuffer + strBuffer
        End If
    Loop Until nRead < 1

    ProcessData()
End Sub
```

FtpClient.OnTaskBegin Event

Occurs when an asynchronous task begins execution.

[Visual Basic]
```
Public Event OnTaskBegin As OnTaskBeginEventHandler
```

[C#]
```
public event OnTaskBeginEventHandler OnTaskBegin;
```

Event Data

The event handler receives an argument of type FtpClient.TaskBeginEventArgs containing data related to this event. The following **FtpClient.TaskBeginEventArgs** property provides information specific to this event.

Property	Description
TaskId	Get the unique task identifier associated with the event.

Remarks

The **OnTaskBegin** event occurs when a background task associated with an asynchronous file transfer begins executing. This event can be used in conjunction with the **OnTaskEnd** event to monitor one or more background tasks that are created to perform asynchronous file transfers.

This event and the related asynchronous task events are invoked from the context of the thread that is managing the background task, and not the thread that created the class instance. If a handler is implemented for this event, its code will be executing in a different thread than the main UI thread. You should never attempt to update your application's user interface directly from within this event handler. Instead, you must create a delegate and use the **Invoke** method to ensure that any changes to the user interface are done within the context of the main UI thread.

Because background tasks are managed in separate threads, this has the effect of making your application multi-threaded, even if you do not explicitly create any worker threads in your own code. If the code in your event handler modifies a public member variable or shared object, you must ensure that access to that object is synchronized. For example, if your event handler updates a shared instance of a **Hashtable** object, you should ensure that all operations are performed through the thread-safe wrapper returned by the **Synchronized** method for that class. Refer to the MSDN documentation for more information about creating thread-safe applications.

FtpClient.OnTaskEnd Event

Occurs when an asynchronous task completes.

[Visual Basic]

```
Public Event OnTaskEnd As OnTaskEndEventHandler
```

[C#]

```
public event OnTaskEndEventHandler OnTaskEnd;
```

Event Data

The event handler receives an argument of type FtpClient.TaskEndEventArgs containing data related to this event. The following **FtpClient.TaskEndEventArgs** properties provide information specific to this event.

Property	Description
Error	Get the last error code for the background task.
TaskId	Get the unique task identifier associated with the event.
TimeElapsed	Gets the amount of time that has elapsed in milliseconds.

Remarks

The **OnTaskEnd** event occurs when a file transfer completes and the background task has terminated. Refer to the **OnTaskBegin** event for additional information about implementing a handler for this event.

The properties of the **FtpClient.TaskEndEventArgs** class are listed below. For a complete list of **FtpClient.TaskEndEventArgs** class members, see the FtpClient.TaskEndEventArgs Members topic.

Public Instance Properties

Error	Get the last error code for the background task.
TaskId	Get the unique task identifier associated with the event.
TimeElapsed	Gets the amount of time that has elapsed in milliseconds.

See Also

FtpClient.TaskEndEventArgs Class | SocketTools Namespace

FtpClient.TaskEndEventArgs.Error Property

Get the last error code for the background task.

[Visual Basic]

```
Public ReadOnly Property Error As ErrorCode
```

[C#]

```
public FtpClient.ErrorCode Error {get;}
```

Property Value

An **ErrorCode** enumeration that specifies the last error code set by the background task.

See Also

FtpClient.TaskEndEventArgs Class | SocketTools Namespace

FtpClient.TaskEndEventArgs.TaskId Property

Get the unique task identifier associated with the event.

[Visual Basic]

```
Public ReadOnly Property TaskId As Integer
```

[C#]

```
public int TaskId {get;}
```

Property Value

An integer value that uniquely identifies the task that invoked the event handler.

See Also

FtpClient.TaskEndEventArgs Class | SocketTools Namespace

FtpClient.TaskEndEventArgs.TimeElapsed Property

Gets the amount of time that has elapsed in milliseconds.

[Visual Basic]

```
Public ReadOnly Property TimeElapsed As Integer
```

[C#]

```
public int TimeElapsed {get;}
```

Property Value

An integer value that specifies the number of milliseconds that the background task has executed.

See Also

FtpClient.TaskEndEventArgs Class | SocketTools Namespace

FtpClient.OnTaskRun Event

Occurs while a background task is active.

[Visual Basic]
```
Public Event OnTaskRun As OnTaskRunEventHandler
```

[C#]
```
public event OnTaskRunEventHandler OnTaskRun;
```

Event Data

The event handler receives an argument of type FtpClient.TaskRunEventArgs containing data related to this event. The following **FtpClient.TaskRunEventArgs** properties provide information specific to this event.

Property	Description
Completed	Gets an estimate of the progress of the background task.
TaskId	Get the unique task identifier associated with the event.
TimeElapsed	Gets the amount of time that has elapsed in milliseconds.

Remarks

The **OnTaskRun** event is generated periodically during a file transfer while the background task is active. The rate and number of times that this event will be generated depends on the task being performed. This event is generally analogous to the **OnProgress** event for file transfers that are performed in the current working thread, however the **OnTaskRun** event will occur for each individual background task that is active.

Refer to the **OnTaskBegin** event for additional information about implementing a handler for this event.

FtpClient.TaskRunEventArgs.Completed Property

Gets an estimate of the progress of the background task.

[Visual Basic]

```
Public ReadOnly Property Completed As Integer
```

[C#]

```
public int Completed {get;}
```

Property Value

An integer value that returns a number between 0 and 100 inclusive that specifies the estimated percentage of completion for the task. A value of zero indicates that the task has just begun executing, while a value of 100 indicates that the task is at or near completion.

See Also

FtpClient.TaskRunEventArgs Class | SocketTools Namespace

FtpClient.TaskRunEventArgs.TaskId Property

Get the unique task identifier associated with the event.

[Visual Basic]

```
Public ReadOnly Property TaskId As Integer
```

FtpClient.TaskRunEventArgs Class | SocketTools Namespace

FtpClient.OnTimeout Event

Occurs when a blocking operation fails to complete before the timeout period elapses.

[Visual Basic]

```
Public Event OnTimeout As EventHandler
```

[C#]

```
public event EventHandler OnTimeout;
```

Remarks

The **OnTimeout** event occurs when a blocking operation, such as sending or receiving data on the socket, fails to complete before the specified timeout period elapses. The timeout period for a blocking operation can be adjusted by setting the **Timeout** property.

This event is only generated if the client is in blocking mode.

See Also

FtpClient Class | SocketTools Namespace

FtpClient.OnWrite Event

Occurs when data can be written to the socket.

[Visual Basic]

```
Public Event OnWrite As EventHandler
```

[C#]

```
public event EventHandler OnWrite;
```

Remarks

The **OnWrite** event occurs when the application can write data to the server. This event will typically occur when a connection is first established with the remote host, and after the **Write** method has failed because there was insufficient memory available in the socket send buffers. In the second case, when some of the buffered data has been successfully sent to the remote host and there is space available in the send buffers, this event is used to signal the application that it may attempt to send more data.

This event is only generated if the client is in non-blocking mode.

See Also

FtpClient Class | SocketTools Namespace

FtpClient.ErrorCode Enumeration

Specifies the error codes returned by the FtpClient class.

[Visual Basic]
```
Public Enum FtpClient.ErrorCode
```

[C#]
```
public enum FtpClient.ErrorCode
```

Remarks

The FtpClient class uses the **ErrorCode** enumeration to specify what error has occurred when a method fails. The current error code may be determined by checking the value of the **LastError** property.

Note that the last error code is only meaningful if the previous operation has failed.

Members

Member Name	Description
errorNone	No error.
errorNotHandleOwner	Handle not owned by the current thread.
errorFileNotFound	The specified file or directory does not exist.
errorFileNotCreated	The specified file could not be created.
errorOperationCanceled	The blocking operation has been canceled.
errorInvalidFileType	The specified file is a block or character device, not a regular file.
errorInvalidDevice	The specified file type is invalid or not a regular file.
errorTooManyParameters	The maximum number of function parameters has been exceeded.
errorInvalidFileName	The specified file name contains invalid characters or is too long.
errorInvalidFileHandle	Invalid file handle passed to function.
errorFileReadFailed	Unable to read data from the specified file.
errorFileWriteFailed	Unable to write data to the specified file.
errorOutOfMemory	Out of memory.
errorAccessDenied	Access denied.
errorInvalidParameter	Invalid argument passed to function.
errorClipboardUnavailable	The system clipboard is currently unavailable.
errorClipboardEmpty	The system clipboard is empty or does not contain any text data.
errorFileEmpty	The specified file does not contain any data.
errorFileExists	The specified file already exists.

errorEndOfFile	End of file.
errorDeviceNotFound	The specified device could not be found.
errorDirectoryNotFound	The specified directory could not be found.
errorInvalidbuffer	Invalid memory address passed to function.
errorBufferTooSmall	The specified buffer is not large enough to contain the data.
errorNoHandles	No more handles are available to this process.
errorOperationWouldBlock	The specified operation would block the current thread.
errorOperationInProgress	A blocking operation is currently in progress.
errorAlreadyInProgress	The specified operation is already in progress.
errorInvalidHandle	Invalid handle passed to function.
errorInvalidAddress	Invalid network address specified.
errorInvalidSize	Datagram is too large to fit in specified buffer.
errorInvalidProtocol	Invalid network protocol specified.
errorProtocolNotAvailable	The specified network protocol is not available.
errorProtocolNotSupported	The specified protocol is not supported.
errorSocketNotSupported	The specified socket type is not supported.
errorInvalidOption	The specified option is invalid.
errorProtocolFamily	Specified protocol family is not supported.
errorProtocolAddress	The specified address is invalid for this protocol family.
errorAddressInUse	The specified address is in use by another process.
errorAddressUnavailable	The specified address cannot be assigned.
errorNetworkUnavailable	The networking subsystem is unavailable.
errorNetworkUnreachable	The specified network is unreachable.
errorNetworkReset	Network dropped connection on remote reset.
errorConnectionAborted	Connection was aborted due to timeout or other failure.
errorConnectionReset	Connection was reset by remote network.
errorOutOfBuffers	No buffer space is available.
errorAlreadyConnected	Connection already established with remote host.
errorNotConnected	No connection established with remote host.
errorConnectionShutdown	Unable to send or receive data after connection shutdown.
errorOperationTimeout	The specified operation has timed out.
errorConnectionRefused	The connection has been refused by the remote host.

errorHostUnavailable	The specified host is unavailable.
errorHostUnreachable	Remote host is unreachable.
errorTooManyProcesses	Too many processes are using the networking subsystem.
errorTooManyThreads	Too many threads have been created by the current process.
errorTooManySessions	Too many client sessions have been created by the current process.
errorInternalFailure	An unexpected internal error has occurred.
errorNetworkNotReady	Network subsystem is not ready for communication.
errorInvalidVersion	This version of the operating system is not supported.
errorNetworkNotInitialized	The networking subsystem has not been initialized.
errorRemoteShutdown	The remote host has initiated a graceful shutdown sequence.
errorInvalidHostName	The specified hostname is invalid or could not be resolved.
errorHostNameNotFound	The specified hostname could not be found.
errorHostNameRefused	Unable to resolve hostname, request refused.
errorHostNameNotResolved	Unable to resolve hostname, no address for specified host.
errorInvalidLicense	The license for this product is invalid.
errorProductNotLicensed	This product is not licensed to perform this operation.
errorNotImplemented	This function has not been implemented on this platform.
errorUnknownLocalhost	Unable to determine local host name.
errorInvalidHostAddress	Invalid host address specified.
errorInvalidServicePort	Invalid service port number specified.
errorInvalidServiceName	Invalid or unknown service name specified.
errorInvalidEventId	Invalid event identifier specified.
errorOperationNotBlocking	No blocking operation in progress on this socket.
errorSecurityNotInitialized	Unable to initialize security interface for this process.
errorSecurityContext	Unable to establish security context for this session.
errorSecurityCredentials	Unable to open certificate store or establish security credentials.
errorSecurityCertificate	Unable to validate the certificate chain for this

	session.
errorSecurityDecryption	Unable to decrypt data stream.
errorSecurityEncryption	Unable to encrypt data stream.
errorOperationNotSupported	The specified operation is not supported.
errorInvalidProtocolVersion	Invalid application protocol version specified.
errorNoServerResponse	No data returned from server.
errorInvalidServerResponse	Invalid data returned from server.
errorUnexpectedServerResponse	Unexpected response code returned from server.
errorServerTransactionFailed	Server transaction failed.
errorServiceUnavailable	The service is currently unavailable.
errorServiceNotReady	The service is not ready, try again later.
errorServerResyncFailed	Unable to resynchronize with server.
errorInvalidProxyType	Invalid proxy server type specified.
errorProxyRequired	Resource must be accessed through specified proxy.
errorInvalidProxyLogin	Unable to login to proxy server using specified credentials.
errorProxyResyncFailed	Unable to resynchronize with proxy server.
errorInvalidCommand	Invalid command specified.
errorInvalidCommandParameter	Invalid command parameter specified.
errorInvalidCommandSequence	Invalid command sequence specified.
errorCommandNotImplemented	Specified command not implemented on this server.
errorCommandNotAuthorized	Specified command not authorized for the current user.
errorCommandAborted	Specified command was aborted by the remote host.
errorOptionNotSupported	The specified option is not supported on this server.
errorRequestNotCompleted	The current client request has not been completed.
errorInvalidUserName	The specified username is invalid.
errorInvalidPassword	The specified password is invalid.
errorInvalidAccount	The specified account name is invalid.
errorAccountRequired	Account name has not been specified.
errorInvalidAuthenticationType	Invalid authentication protocol specified.
errorAuthenticationRequired	User authentication is required.
errorProxyAuthenticationRequired	Proxy authentication required.

errorAlreadyAuthenticated	User has already been authenticated.
errorAuthenticationFailed	Unable to authenticate the specified user.
errorNetworkAdapter	Unable to determine network adapter configuration.
errorInvalidRecordType	Invalid record type specified.
errorInvalidRecordName	Invalid record name specified.
errorInvalidRecordData	Invalid record data specified.
errorConnectionOpen	Data connection already established.
errorConnectionClosed	Server closed data connection.
errorConnectionPassive	Data connection is passive.
errorConnectionFailed	Unable to open data connection to server.
errorInvalidSecurityLevel	Data connection cannot be opened with this security setting.
errorCachedTLSRequired	Data connection requires cached TLS session.
errorDataReadOnly	Data connection is read-only.
errorDataWriteOnly	Data connection is write-only.
errorEndOfData	End of data.
errorRemoteFileUnavailable	Remote file is unavailable.
errorInsufficientStorage	Insufficient storage on server.
errorStorageallocation	File exceeded storage allocation on server.
errorDirectoryExists	The specified directory already exists.
errorDirectoryEmpty	No files returned by the server for the specified directory.
errorEndOfDirectory	End of directory listing.
errorUnknownDirectoryFormat	Unknown directory format.
errorInvalidResource	Invalid resource name specified.
errorResourceRedirected	The specified resource has been redirected.
errorResourceRestricted	Access to this resource has been restricted.
errorResourceNotModified	The specified resource has not been modified.
errorResourceNotFound	The specified resource cannot be found.
errorResourceConflict	Request could not be completed due to the current state of the resource.
errorResourceRemoved	The specified resource has been permanently removed from this server.
errorContentLengthRequired	Request must include the content length.
errorRequestPrecondition	Request could not be completed due to server precondition.
errorUnsupportedMediaType	Request specified an unsupported media type.

errorInvalidContentRange	Content range specified for this resource is invalid.
errorInvalidMessagePart	Message is not multipart or an invalid message part was specified.
errorInvalidMessageHeader	The specified message header is invalid or has not been defined.
errorInvalidMessageBoundary	The multipart message boundary has not been defined.
errorNoFileAttachment	The current message part does not contain a file attachment.
errorUnknownFileType	The specified file type could not be determined.
errorDataNotEncoded	The specified data block could not be encoded.
errorDataNotDecoded	The specified data block could not be decoded.
errorFileNotEncoded	The specified file could not be encoded.
errorFileNotDecoded	The specified file could not be decoded.
errorNoMessageText	No message text.
errorInvalidCharacterSet	Invalid character set specified.
errorInvalidEncodingType	Invalid encoding type specified.
errorInvalidMessageNumber	Invalid message number specified.
errorNoReturnAddress	No valid return address specified.
errorNoValidRecipients	No valid recipients specified.
errorInvalidRecipient	The specified recipient address is invalid.
errorRelayNotAuthorized	The specified domain is invalid or server will not relay messages.
errorMailboxUnavailable	Specified mailbox is currently unavailable.
errorMailboxReadOnly	The selected mailbox cannot be modified.
errorMailboxNotSelected	No mailbox has been selected.
errorInvalidMailbox	Specified mailbox is invalid.
errorInvalidDomain	The specified domain name is invalid or not recognized.
errorInvalidSender	The specified sender address is invalid or not recognized.
errorMessageNotDelivered	Message not delivered to any of the specified recipients.
errorEndOfMessageData	No more message data available to be read
errorInvalidmessageSize	The specified message size is invalid.
errorMessageNotCreated	The message could not be created in the specified mailbox.
errorNoMoreMailboxes	No more mailboxes exist on this server.

errorInvalidEmulationType	The specified terminal emulation type is invalid.
errorInvalidFontHandle	The specified font handle is invalid.
errorInvalidFontName	The specified font name is invalid or unavailable.
errorInvalidPacketSize	The specified packet size is invalid.
errorInvalidPacketData	The specified packet data is invalid.
errorInvalidPacketId	The unique packet identifier is invalid.
errorPacketTTLExpired	The specified packet time-to-live period has expired.
errorInvalidNewsGroup	Invalid newsgroup specified.
errorNoNewsgroupSelected	No newsgroup selected.
errorEmptyNewsgroup	No articles in specified newsgroup.
errorInvalidArticle	Invalid article number specified.
errorNoArticleSelected	No article selected in the current newsgroup.
errorFirstArticle	First article in current newsgroup.
errorLastArticle	Last article in current newsgroup.
errorArticleExists	Unable to transfer article, article already exists.
errorArticleRejected	Unable to transfer article, article rejected.
errorArticleTransferFailed	Article transfer failed.
errorArticlePostingDenied	Posting is not permitted on this server.
errorArticlePostingFailed	Unable to post article on this server.
errorInvalidDateFormat	The specified date format is not recognized.
errorFeatureNotSupported	The specified feature is not supported on this server.
errorInvalidFormHandle	The specified form handle is invalid or a form has not been created.
errorInvalidFormAction	The specified form action is invalid or has not been specified.
errorInvalidFormMethod	The specified form method is invalid or not supported.
errorInvalidFormType	The specified form type is invalid or not supported.
errorInvalidFormField	The specified form field name is invalid or does not exist.
errorEmptyForm	The specified form does not contain any field values.
errorMaximumConnections	The maximum number of client connections exceeded.
errorThreadCreationFailed	Unable to create a new thread for the current process.
errorInvalidThreadHandle	The specified thread handle is no longer valid.

errorThreadTerminated	The specified thread has been terminated.
errorThreadDeadlock	The operation would result in the current thread becoming deadlocked.
errorInvalidClientMoniker	The specified moniker is not associated with any client session.
errorClientMonikerExists	The specified moniker has been assigned to another client session.
errorServerInactive	The specified server is not listening for client connections.
errorServerSuspended	The specified server is suspended and not accepting client connections.
errorNoMessageStore	No message store has been specified.
errorMessageStoreChanged	The message store has changed since it was last accessed.
errorMessageNotFound	No message was found that matches the specified criteria.
errorMessageDeleted	The specified message has been deleted.
errorFileChecksumMismatch	The local and remote file checksums do not match.
errorFileSizeMismatch	The local and remote file sizes do not match.
errorInvalidFeedUrl	The news feed URL is invalid or specifies an unsupported protocol.
errorInvalidFeedFormat	The internal format of the news feed is invalid.
errorInvalidFeedVersion	This version of the news feed is not supported.
errorChannelEmpty	There are no valid items found in this news feed.
errorInvalidItemNumber	The specified channel item identifier is invalid.
errorItemNotFound	The specified channel item could not be found.
errorItemEmpty	The specified channel item does not contain any data.
errorInvalidItemProperty	The specified item property name is invalid.
errorItemPropertyNotFound	The specified item property has not been defined.
errorInvalidChannelTitle	The channel title is invalid or has not been defined.
errorInvalidChannelLink	The channel hyperlink is invalid or has not been defined.
errorInvalidChannelDescription	The channel description is invalid or has not been defined.
errorInvalidItemText	The description for an item is invalid or has not been defined.
errorInvalidItemLink	The hyperlink for an item is invalid or has not been defined.

errorInvalidServiceType	The specified service type is invalid.
errorServiceSuspended	Access to the specified service has been suspended.
errorServiceRestricted	Access to the specified service has been restricted.
errorInvalidProviderName	The specified provider name is invalid or unknown.
errorInvalidPhoneNumber	The specified phone number is invalid or not supported in this region.
errorGatewayNotFound	A message gateway cannot be found for the specified provider.
errorMessageTooLong	The message exceeds the maximum number of characters permitted.
errorInvalidProviderData	The request returned invalid or incomplete service provider data.
errorInvalidGatewayData	The request returned invalid or incomplete message gateway data.
errorMultipleProviders	The request has returned multiple service providers.
errorProviderNotFound	The specified service provider could not be found.
errorInvalidMessageService	The specified message is not supported with this service type.
errorInvalidMessageFormat	The specified message format is invalid.
errorInvalidConfiguration	The specified configuration options are invalid.
errorServerActive	The requested action is not permitted while the server is active.
errorServerPortBound	Unable to obtain exclusive use of the specified local port.
errorInvalidClientSession	The specified client identifier is invalid for this session.
errorClientNotIdentified	The specified client has not provided user credentials.
errorInvalidClientState	The requested action cannot be performed at this time.
errorInvalidResultCode	The specified result code is not valid for this protocol
errorCommandRequired	The specified command is required and cannot be disabled.
errorCommandDisabled	The specified command has been disabled.
errorCommandSequence	The command cannot be processed at this time.
errorCommandCompleted	The previous command has completed.
errorInvalidProgramName	The specified program name is invalid or unrecognized.

errorInvalidRequestHeader	The request header contains one or more invalid values.
errorInvalidVirtualHost	The specified virtual host name is invalid.
errorVirtualHostNotFound	The specified virtual host does not exist.
errorTooManyVirtualHosts	Too many virtual hosts created for this server.
errorInvalidVirtualPath	The specified virtual path name is invalid.
errorVirtualPathNotFound	The specified virtual path does not exist.
errorTooManyVirtualPaths	Too many virtual paths created for this server.
errorInvalidTask	The asynchronous task identifier is invalid.
errorTaskActive	The asynchronous task has not finished.
errorTaskQueued	The asynchronous task has been queued.
errorTaskSuspended	The asynchronous task has been suspended.
errorTaskFinished	The asynchronous task has finished.

FtpClient.FtpChannelMode Enumeration

Specifies the channel mode specified by setting the ChannelMode property.

[Visual Basic]

```
Public Enum FtpClient.FtpChannelMode
```

[C#]

```
public enum FtpClient.FtpChannelMode
```

Members

Member Name	Description
channelClear	Data sent and received on this channel should not be encrypted.
channelSecure	Data sent and received on this channel should be encrypted. Specifying this option requires that a secure connection has already been established with the server.

Requirements

Namespace: SocketTools

Assembly: SocketTools.FtpClient (in SocketTools.FtpClient.dll)

SocketTools Namespace

FtpClient.FtpChannelType Enumeration

Specifies the channel used by the ChannelMode property.

[Visual Basic]

```
Public Enum FtpClient.FtpChannelType
```

[C#]

```
public enum FtpClient.FtpChannelType
```

Members

Member Name	Description
channelCommand	The communication channel used to send commands to the server and receive command result and status information from the server.
channelData	The communication channel used to send or receive data during a file transfer.

Requirements

Namespace: SocketTools

Assembly: SocketTools.FtpClient (in SocketTools.FtpClient.dll)

FtpClient.FtpDirectoryFormat Enumeration

A value which specifies the format of a directory listing returned by the server.

[Visual Basic]
```
Public Enum FtpClient.FtpDirectoryFormat
```

[C#]
```
public enum FtpClient.FtpDirectoryFormat
```

Remarks

Values other than **formatAuto** should only be set if the class library cannot automatically determine the directory format returned by the server. The default directory format is determined both by the server's operating system and by analyzing the format of the data returned by the server. If the class is unable to automatically determine the format, it will attempt to parse the list of files as though it is a UNIX style listing.

Members

Member Name	Description
formatAuto	This value specifies that the control should automatically determine the format of the file lists returned by the server. It is recommended that most applications use this value and allow the control to automatically determine the appropriate file listing format used by the server.
formatUnix	This value specifies that the server returns file lists in the format commonly used by UNIX servers. Note that many servers can be configured to return file listings in this format, even if they are not actually a UNIX based platform. Consult the technical reference documentation for your server for more information.
formatMsdos	This value specifies that the server returns file lists in the format commonly used by MS-DOS based systems. This includes Windows NT servers. Long file names will be returned if supported by the underlying filesystem, such as NTFS or FAT32.
formatVms	This value specifies that the server returns file lists in the format commonly used by VMS servers. Note that VMS servers can be configured to return a standard UNIX style listing in additional to the default VMS format.
formatSterling1	This value specifies that the server returns file listings in a proprietary format used by the Sterling server, which is used for EDI (Electronic Data Interchange) applications. This format uses a 13 byte status code.
formatSterling2	This value specifies that the server returns file

	listings in a proprietary format used by the Sterling server, which is used for EDI (Electronic Data Interchange) applications. This format uses a 10 byte status code.
formatNetware	This value specifies that the server returns file listings in a proprietary format used by NetWare servers. The format is similar to UNIX style listings except that file access and permissions are indicated by letter codes enclosed in brackets. This is the default format selected if the server identifies itself as a NetWare system.
formatMlsd	This value specifies that the server should return file listings in a machine-independent format as defined by RFC 3659. This format specifies file information as a sequence of name and value pairs, with the same format being used regardless of the operating system that the server is hosted on. Note that not all servers support this format, and some proxy servers may reject the command even if the remote server supports its use.

SocketTools Namespace

FtpClient.FtpFeatures Enumeration

Specifies the server features that are available for the current client session.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

```
[Visual Basic]
<Flags>
Public Enum FtpClient.FtpFeatures
```

```
[C#]
[Flags]
public enum FtpClient.FtpFeatures
```

Remarks

When a client connection is first established, all features are enabled by default. However, as the client issues commands to the server, if the server reports that the command is unrecognized that feature will automatically be disabled in the client.

For example, the first time an application calls the **GetFileSize** method to determine the size of a file, the class library will try to use the SIZE command. If the server reports that the SIZE command is not available, that feature will be disabled and the class will not use the command again during the session unless it is explicitly re-enabled. This is designed to prevent the class from repeatedly sending invalid commands to a server, which may result in the server aborting the connection.

Members

Member Name	Description	Value
featureSIZE	The server supports the SIZE command to determine the size of a file. If this feature is not enabled, the library will attempt to use the STAT command to determine the file size.	1
featureSTAT	The server supports using the STAT command to return information about a specific file. If this feature is not enabled, the client may not be able to obtain information about a specific file such as its size, permissions or modification time.	2
featureMDTM	The server supports the MDTM command to obtain information about the modification time for a specific file. This command may also be used to set the file time on the server.	4
featureREST	The server supports restarting file transfers using the REST command. If this feature is not enabled, the client will not be able to restart file transfers and must upload or download the complete file.	8

featureSITE	The server supports site specific commands using the SITE command. If this feature is not enabled, no site specific commands will be sent to the server.	16
featureIDLE	The server supports setting the idle timeout period using the SITE IDLE command to specify the number of seconds that the client may idle before the server terminates the connection.	32
featureCHMOD	The server supports modifying the permissions of a specific file using the SITE CHMOD command. If this feature is not enabled, the client will not be able to set the permissions for a file.	64
featureAUTH	The server supports explicit SSL sessions using the AUTH command. If this feature is not enabled, the client will only be able to connect to a secure server that uses implicit SSL connections. Changing this feature has no effect on standard, non-secure connections.	128
featurePBSZ	The server supports the PBSZ command which specifies the buffer size used with secure data connections. If this feature is disabled, it may prevent the client from changing the protection level on the data channel. Changing this feature has no effect on standard, non-secure connections.	256
featurePROT	The server supports the PROT command which specifies the protection level for the data channel. If this feature is disabled, the client will be unable to change the protection level on the data channel. Changing this feature has no effect on standard, non-secure connections.	512
featureCCC	The server supports the CCC command which returns the command channel to a non-secure mode. Changing this feature has no effect on standard, non-secure connections.	1024
featureHOST	The server supports the HOST command which enables a client to specify the hostname after establishing a connection with a server that supports virtual hosting.	2048

featureMLST	The server supports the MLST command which returns status information for files. If this feature is enabled, the MLST command will be used instead of the STAT command.	4096
featureMFMT	The server supports the MFMT command which is used to change the last modification time for a file. If this command is supported, it is used instead of the MDTM command to change the modification time for a file.	8192
featureXCRC	The server supports the XCRC command which returns the CRC32 checksum for the contents of a specified file. This command is used for file verification.	16384
featureXMD5	The server supports the XMD5 command which returns an MD5 hash for the contents of a specified file. This command is used for file verification.	32768
featureLANG	The server supports the LANG command which sets the language used for the current client session. Command responses and file naming conventions will use the specified language.	65536
featureUTF8	The server supports the OPTS UTF-8 command which specifies UTF-8 encoding when specifying filenames. This feature is typically used in conjunction with setting the default language for the client session.	131072
featureXQUOTA	The server supports the XQUOTA command which returns quota information for the current client session.	262144
featureUTIME	The server supports the UTIME command which is used to change the last modification time for a specified file.	524288

FtpClient.FtpFileType Enumeration

Specifies the type of file being transferred.

[Visual Basic]

```
Public Enum FtpClient.FtpFileType
```

[C#]

```
public enum FtpClient.FtpFileType
```

Members

Member Name	Description
fileAuto	The file type should be automatically determined based on the file name extension. If the file extension is unknown, the file type should be determined based on the contents of the file. The class has an internal list of common text file extensions, and additional file extensions can be registered using the **AddFileType** method.
fileAscii	The file being transferred is an ASCII text file. The characters the mark the end of a line (for example, a carriage return/linefeed pair under MS-DOS) are automatically converted to the format used by the target operating system.
fileEbcdic	The file being transferred is a text file created using the EBCDIC character set. If a file is being copied to a remote system, the ASCII characters are automatically converted to EBCDIC. If the file is being retrieved from a remote system, the EBCDIC characters are automatically converted to ASCII.
fileImage	The file is transferred without any modification. This is the default file transfer type, and should be used when transferring binary (non-text) data.
fileText	The same value as **fileAscii**.
fileBinary	The same value as **fileImage**.

Requirements

Namespace: SocketTools

Assembly: SocketTools.FtpClient (in SocketTools.FtpClient.dll)

SocketTools Namespace | AddFileType Method (SocketTools.FtpClient)

FtpClient.FtpOpenMode Enumeration

Specifies how a file is opened on the server.

[Visual Basic]

```
Public Enum FtpClient.FtpOpenMode
```

[C#]

```
public enum FtpClient.FtpOpenMode
```

Members

Member Name	Description
fileRead	The file is opened for read access. If the file does not exist, an error will occur.
fileWrite	The file is opened for write access. If the file does not exist, it will be created. If it does exist, it will be overwritten.
fileAppend	The file is opened for write access. If the file does not exist, it will be created. If it does exist, the data will be appended to the end of the file.
fileUnique	The file is opened for write access and created using a file name that is guaranteed to be unique. This option is not supported on all servers.

Requirements

Namespace: SocketTools

Assembly: SocketTools.FtpClient (in SocketTools.FtpClient.dll)

SocketTools Namespace

FtpClient.FtpOptions Enumeration

Specifies the options that the FtpClient class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]

```
<Flags>
Public Enum FtpClient.FtpOptions
```

[C#]

```
[Flags]
public enum FtpClient.FtpOptions
```

Remarks

The FtpClient class uses the **FtpOptions** enumeration to specify one or more options to be used when establishing a connection with a remote host. Multiple options may be specified if necessary.

Members

Member Name	Description	Value
optionNone	No option specified.	0
optionDefault	The default connection option. This is the same as specifying **optionPassive**.	1
optionPassive	This option specifies the client should attempt to establish a passive connection to the server. This means that instead of the client opening a port on the local system and waiting for the server to establish a connection back to the client, the client will establish a second data connection to the server. This mode is recommended for most systems that are behind a NAT router or firewall.	1
optionFirewall	This option specifies the client should always use the host IP address to establish the data connection with the server, not the address returned by the server in response to the PASV command. This option may be necessary if the server is behind a router that performs Network Address Translation (NAT) and it returns an unreachable IP address for the data connection. If this option is specified, it will also enable passive mode data transfers.	2
optionNoAuth	This option specifies the server does not require authentication, or that it	4

	requires an alternate authentication method. When this option is used, the client connection is flagged as authenticated as soon as the connection to the server has been established. Note that using this option to bypass authentication may result in subsequent errors when attempting to retrieve a directory listing or transfer a file. It is recommended that you consult the technical reference documentation for the server to determine its specific authentication requirements.	
optionKeepAlive	This option specifies the client should attempt to keep the connection with the server active for an extended period of time. It is important to note that regardless of this option, the server may still choose to disconnect client sessions that are holding the command channel open but are not performing file transfers.	8
optionNoAuthRSA	This option specifies that RSA authentication should not be used with SSH-1 connections. This option is ignored with SSH-2 connections and should only be specified if required by the remote host. This option has no effect on standard or secure connections using SSL.	16
optionNoPwdNul	This option specifies that the user password cannot be terminated with a null byte. This option is ignored with SSH-2 connections and should only be specified if required by the remote host. This option has no effect on standard or secure connections using SSL.	32
optionNoRekey	This option specifies the client should never attempt a repeat key exchange with the server. Some SSH servers do not support rekeying the session, and this can cause the client to become non-responsive or abort the connection after being connected for an hour. This option has no effect on standard or secure connections using SSL.	64
optionCompatSID	This compatibility option changes how the session ID is handled during public key authentication with older SSH servers. This option should only be	128

	specified when connecting to servers that use OpenSSH 2.2.0 or earlier versions. This option has no effect on standard or secure connections using SSL.	
optionCompatHMAC	This compatibility option changes how the HMAC authentication codes are generated. This option should only be specified when connecting to servers that use OpenSSH 2.2.0 or earlier versions. This option has no effect on standard or secure connections using SSL.	256
optionVirtualHost	This option specifies the server supports virtual hosting, where multiple domains are hosted by a server using the same external IP address. If this option is enabled, the client will send the HOST command to the server upon establishing a connection.	512
optionVerify	This option specifies that file transfers should be automatically verified after the transfer has completed. If the server supports the XMD5 command, the transfer will be verified by calculating an MD5 hash of the file contents. If the server does not support the XMD5 command, but does support the XCRC command, the transfer will be verified by calculating a CRC32 checksum of the file contents. If neither the XMD5 or XCRC commands are supported, the transfer is verified by comparing the size of the file. Automatic file verification is only performed for binary mode transfers because of the end-of-line conversion that may occur when text files are uploaded or downloaded.	1024
optionTunnel	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established. This option also forces all connections to be outbound and enables the firewall compatibility features in the client.	65536

optionTrustedSite	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using either the SSL or TLS protocols.	2048
optionSecure	This option specifies the client should attempt to establish a secure connection with the server. The server must support secure connections using either the SSL or TLS protocol.	4096
optionImplicitSSL	This option specifies the client should attempt to establish a secure implicit SSL session. The SSL handshake is initiated immediately after the connection to the server has been established.	4096
optionExplicitSSL	This option specifies the client should attempt to establish a secure explicit SSL session. The initial connection to the server is not encrypted, and the client will attempt to negotiate a secure connection by sending a command to the server. Some servers may require this option when connecting to the server on ports other than the default secure port of 990.	8192
optionSecureShell	This option specifies the client should attempt to establish a secure connection using the Secure Shell (SSH) protocol. This option is automatically selected if the connection is established on port 22, the standard port for SSH connections. It is only necessary to specify this option if the SSH connection must be established on a non-standard port.	16384
optionSecureFallback	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will permit connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.	32768
optionPreferIPv6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not	262144

	have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.	
optionFreeThread	This option specifies that class methods may be called from any thread, and not only the thread that established the connection. Using this option disables certain internal safety checks that are made by the class and may result in unexpected behavior unless you ensure that access to the class instance is synchronized across multiple threads.	524288
optionHiResTimer	This option specifies that elapsed time values should be returned in milliseconds rather than seconds. This option is intended to provide greater accuracy with smaller file transfers over a high speed network connection.	1048576
optionTLSReuse	This option specifies that TLS session reuse should be enabled when establishing a secure data connection. This option is only supported on Windows 8.1 or Windows Server 2012 R2 and later platforms, and it should only be used when explicitly required by the server. This option is not compatible with servers built using OpenSSL 1.0.2 and earlier versions which do not provide Extended Master Secret (EMS) support as outlined in RFC7627.	2097152

FtpClient.FtpPermissions Enumeration

Specifies the access permissions for a file on the server.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

```
[Visual Basic]
<Flags>
Public Enum FtpClient.FtpPermissions
```

```
[C#]
[Flags]
public enum FtpClient.FtpPermissions
```

Members

Member Name	Description	Value
symbolicLink	The file is a symbolic link to another file. Symbolic links are special types of files found on UNIX based systems which are similar to Windows shortcuts.	4096
ownerRead	The owner has permission to open the file for reading. If the current user is the owner of the file, this grants the user the right to download the file to the local system.	1024
ownerWrite	The owner has permission to open the file for writing. If the current user is the owner of the file, this grants the user the right to replace the file. If this permission is set for a directory, this grants the user the right to create and delete files.	512
ownerExecute	The owner has permission to execute the contents of the file. The file is typically either a binary executable, script or batch file. If this permission is set for a directory, this may also grant the user the right to open that directory and search for files in that directory.	256
groupRead	Users in the specified group have permission to open the file for reading. If the current user is in the same group as the file owner, this grants the user the right to download the file.	64
groupWrite	Users in the specified group have permission to open the file for writing. On some platforms, this may also imply permission to delete the file. If the current user is in the same group as the	32

	file owner, this grants the user the right to replace the file. If this permission is set for a directory, this grants the user the right to create and delete files.	
groupExecute	Users in the specified group have permission to execute the contents of the file. If this permission is set for a directory, this may also grant the user the right to open that directory and search for files in that directory.	16
worldRead	All users have permission to open the file for reading. This permission grants any user the right to download the file to the local system.	4
worldWrite	All users have permission to open the file for writing. This permission grants any user the right to replace the file. If this permission is set for a directory, this grants any user the right to create and delete files.	2
worldExecute	All users have permission to execute the contents of the file. If this permission is set for a directory, this may also grant all users the right to open that directory and search for files in that directory.	1

FtpClient.FtpProxyType Enumeration

Specifies the type of proxy server that is being used by the FtpClient class.

[Visual Basic]
```
Public Enum FtpClient.FtpProxyType
```

[C#]
```
public enum FtpClient.FtpProxyType
```

Members

Member Name	Description
proxyNone	No proxy server is being used. This is the default value.
proxyUser	The client is not logged into the proxy server. The USER command is sent in the format username@ftpsite followed by the password. This is the format used with the Gauntlet proxy server.
proxyLogin	The client is logged into the proxy server. The USER command is then sent in the format username@ftpsite followed by the password. This is the format used by the InterLock proxy server.
proxyOpen	The client is not logged into the proxy server. The OPEN command is sent specifying the host name, followed by the username and password.
proxySite	The client is logged into the server. The SITE command is sent, specifying the host name, followed by the username and the password.
proxyOther	This special proxy type specifies that another, undefined proxy server is being used. The client connects to the proxy host, but does not attempt to authenticate the client. The application is responsible for negotiating with the proxy server, typically using the Command property to send specific command sequences.

Requirements

SocketTools Namespace

FtpClient.FtpServerType Enumeration

Specifies the type of server that the client is connected to.

[Visual Basic]
```
Public Enum FtpClient.FtpServerType
```

[C#]
```
public enum FtpClient.FtpServerType
```

Members

Member Name	Description
serverUnknown	The server type could not be determined by issuing the SYST command. The server may not support the command, or the command may only allowed when issued by an authenticated user.
serverUNIX	The server is running on a UNIX based operating system. This can include Linux and other variants, as well as operating systems which emulate UNIX style file pathing and directory listings.
serverMSDOS	The server is running on an MS-DOS based operating system. The server expects file pathing and naming conventions according to the standard MS-DOS format and returns directory listings similar to the output of the DIR command.
serverWindows	The server is running on a Windows based operating system. The server expects file pathing and naming conventions according to the standard Windows long filename format, and returns directory listings similar to the output of the DIR command. Note that Windows servers may be configured to return file and directory information in a format similar to UNIX systems, in which case the system may be identified as UNIX even though it is actually running on a Windows platform.
serverVMS	The server is running on a DEC VMS based operating system. The server expects file pathing and naming conventions specific to that operating system. Note that VMS servers may be configured to return file and directory information in a format similar to UNIX systems, in which case the system may be identified as UNIX even though it is actually running on a VMS platform.
serverNetware	The server is running on a NetWare based operating system. The server expects file pathing and naming conventions similar to the standard Windows long filename format, and returns

	directory listings that are similar to UNIX systems with the exception of the access and permissions flags for the file. Note that a NetWare system may return listings in different formats based on the filesystem and site specific options specified.
serverOther	The server type was not recognized. An attempt will be made to automatically determine the correct file pathing and naming conventions used by the server. To obtain a list of files on the server, it may be necessary to explicitly set the DirectoryFormat property to specify the directory listing format.

```
Public Enum FtpClient.FtpStatus
```

[C#]

```
public enum FtpClient.FtpStatus
```

Members

Member Name	Description
statusUnused	A client connection has not been established. Attempts to perform any network operations, such as sending or receiving data, will generate an error.
statusIdle	A client connection has been created, but is not currently in use. A blocking socket operation can be executed at this point.
statusConnect	The client is in the process of establishing a connection with a remote host.
statusRead	The client is in the process of receiving data from a remote host.
statusWrite	The client is in the process of sending data to a remote host.
statusDisconnect	The client connection is being closed and subsequent attempts to access that session will result in an error.
statusOpenFile	A file on the remote host is being opened.
statusCloseFile	A file on the remote host is being closed.
statusGetFile	A file is being downloaded from the remote host to the local system. No other blocking operation may be performed in the current thread while the file transfer is in progress.
statusPutFile	A file is being uploaded from the local system to the remote host. No other blocking operation may be performed in the current thread while the file transfer is in progress.
statusFileList	A file listing is being returned from the remote host. No other blocking operation may be performed in the current thread while the file listing is in progress, including downloading or uploading files.

Requirements

SocketTools Namespace

FtpClient.FtpTransferOptions Enumeration

Specifies the file transfer options that the FtpClient class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]

```
<Flags>
Public Enum FtpClient.FtpTransferOptions
```

[C#]

```
[Flags]
public enum FtpClient.FtpTransferOptions
```

Members

Member Name	Description	Value
transferDefault	This option specifies the default transfer mode should be used. If the file exists, it will be overwritten.	0
transferAppend	This option specifies that if the file exists, data will be appended to the end of the file. If the file does not exist, it will be created.	1

Requirements

Namespace: SocketTools

Assembly: SocketTools.FtpClient (in SocketTools.FtpClient.dll)

SocketTools Namespace

FtpClient.SecurityCertificate Enumeration

Specifies the security certificate status values that may be returned by the FtpClient class.

[Visual Basic]
```
Public Enum FtpClient.SecurityCertificate
```

[C#]
```
public enum FtpClient.SecurityCertificate
```

Remarks

The FtpClient class uses the **SecurityCertificate** enumeration to identify the current status of the certificate that was provided by the remote host when a secure connection was established.

Members

Member Name	Description
certificateNone	No certificate information is available. A secure connection was not established with the server.
certificateValid	The certificate is valid.
certificateNoMatch	The certificate is valid, however the domain name specified in the certificate does not match the domain name of the remote host. The application can examine the **CertificateSubject** property to determine the site the certificate was issued to.
certificateExpired	The certificate has expired and is no longer valid. The application can examine the **CertificateExpires** property to determine when the certificate expired.
certificateRevoked	The certificate has been revoked and is no longer valid. It is recommended that the application immediately terminate the connection if this status is returned.
certificateUntrusted	The certificate has not been issued by a trusted authority, or the certificate is not trusted on the local host. It is recommended that the application immediately terminate the connection if this status is returned.
certificateInvalid	The certificate is invalid. This typically indicates that the internal structure of the certificate is damaged. It is recommended that the application immediately terminate the connection if this status is returned.

FtpClient.SecureCipherAlgorithm Enumeration

Specifies the encryption algorithms that the FtpClient class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]
```
<Flags>
Public Enum FtpClient.SecureCipherAlgorithm
```

[C#]
```
[Flags]
public enum FtpClient.SecureCipherAlgorithm
```

Remarks

The FtpClient class uses the **SecureCipherAlgorithm** enumeration to identify which encryption algorithm was selected when a secure connection was established with the remote host.

Members

Member Name	Description	Value
cipherNone	No cipher has been selected. A secure connection has not been established with the remote host.	0
cipherRC2	The RC2 block cipher was selected. This is a variable key length cipher which supports keys between 40- and 128-bits in length, in 8-bit increments.	1
cipherRC4	The RC4 stream cipher was selected. This is a variable key length cipher which supports keys between 40- and 128-bits in length, in 8-bit increments.	2
cipherRC5	The RC5 block cipher was selected. This is a variable key length cipher which supports keys up to 2040 bits, in 8-bit increments.	4
cipherDES	The DES (Data Encryption Standard) block cipher was selected. This is a fixed key length cipher using 56-bit keys.	8
cipherDES3	The Triple DES block cipher was selected. This cipher encrypts the data three times using different keys, effectively using a 168-bit key length.	16
cipherDESX	A variant of the DES block cipher which XORs an extra 64-bits of the key before and after the plaintext has been encrypted, increasing the key size to 184 bits.	32
cipherAES	The Advanced Encryption Standard	64

	cipher (also known as the Rijndael cipher) is a fixed block size cipher which use a key size of 128, 192 or 256 bits. This cipher is supported on Windows XP SP3 SP3 and later versions of the operating system.	
cipherSkipjack	The Skipjack block cipher was selected. This is a fixed key length cipher, using 80-bit keys.	128
cipherBlowfish	The Blowfish block cipher was selected. This is a variable key length cipher up to 448 bits, using a 64-bit block size.	256

FtpClient.SecureHashAlgorithm Enumeration

Specifies the hash algorithms that the FtpClient class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]

```
<Flags>
Public Enum FtpClient.SecureHashAlgorithm
```

[C#]

```
[Flags]
public enum FtpClient.SecureHashAlgorithm
```

Remarks

The FtpClient class uses the **SecureHashAlgorithm** enumeration to identify the message digest (hash) algorithm that was selected when a secure connection was established with the remote host.

Members

Member Name	Description	Value
hashNone	No hash algorithm has been selected. This is not a secure connection with the server.	0
hashMD5	The MD5 algorithm was selected. This algorithm produces a 128-bit message digest. This algorithm is no longer considered to be cryptographically secure.	1
hashSHA	The SHA-1 algorithm was selected. This algorithm produces a 160-bit message digest. This algorithm is no longer considered to be cryptographically secure.	2
hashSHA256	The SHA-256 algorithm was selected. This algorithm produces a 256-bit message digest.	4
hashSHA384	The SHA-384 algorithm was selected. This algorithm produces a 384-bit message digest.	8
hashSHA512	The SHA-512 algorithm was selected. This algorithm produces a 512-bit message digest.	16

FtpClient.SecureKeyAlgorithm Enumeration

Specifies the key exchange algorithms that the FtpClient class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]

```
<Flags>
Public Enum FtpClient.SecureKeyAlgorithm
```

[C#]

```
[Flags]
public enum FtpClient.SecureKeyAlgorithm
```

Remarks

The FtpClient class uses the **SecureKeyAlgorithm** enumeration to identify the key exchange algorithm that was selected when a secure connection was established with the remote host.

Members

Member Name	Description	Value
keyExchangeNone	No key exchange algorithm has been selected. This is not a secure connection with the server.	0
keyExchangeRSA	The RSA public key exchange algorithm has been selected.	1
keyExchangeKEA	The KEA public key exchange algorithm has been selected. This is an improved version of the Diffie-Hellman public key algorithm.	2
keyExchangeDH	The Diffie-Hellman public key exchange algorithm has been selected.	4
keyExchangeECDH	The Elliptic Curve Diffie-Hellman key exchange algorithm was selected. This is a variant of the Diffie-Hellman algorithm which uses elliptic curve cryptography. This key exchange algorithm is only supported on Windows XP SP3 SP3 and later versions of the operating system.	8

Requirements

Namespace: SocketTools

Assembly: SocketTools.FtpClient (in SocketTools.FtpClient.dll)

SocketTools Namespace

FtpClient.SecurityProtocols Enumeration

Specifies the security protocols that the FtpClient class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]
```
<Flags>
Public Enum FtpClient.SecurityProtocols
```

[C#]
```
[Flags]
public enum FtpClient.SecurityProtocols
```

Remarks

The FtpClient class uses the **SecurityProtocols** enumeration to specify one or more security protocols to be used when establishing a connection with a remote host. Multiple protocols may be specified if necessary and the actual protocol used will be negotiated with the remote host. It is recommended that most applications use **protocolDefault** when creating a secure connection.

Members

Member Name	Description	Value
protocolNone	No security protocol will be used, a secure connection will not be established.	0
protocolSSL2	The SSL 2.0 protocol has been selected. This protocol has been deprecated and is no longer widely used. It is not recommended that this protocol be used when establishing secure connections.	1
protocolSSL3	The SSL 3.0 protocol has been selected. This protocol has been deprecated and is no longer widely used. It is not recommended that this protocol be used when establishing secure connections. In most cases, this protocol is only selected if TLS is not supported by the server.	2
protocolTLS10	The TLS 1.0 protocol has been selected. This version of the protocol is commonly used by older servers and is the only version of TLS supported on Windows platforms prior to Windows 7 SP1 and Windows Server 2008 R2.	4
protocolTLS11	The TLS 1.1 protocol has been selected. This version of TLS is supported on Windows 7 SP1 and Windows Server 2008 R2 and later versions of the	8

	operating system.	
protocolTLS12	The TLS 1.2 protocol has been selected. This is the default version of the protocol and is supported on Windows 7 SP1 and Windows Server 2008 R2 and later versions of Windows. It is recommended that you use this version of TLS.	16
protocolSSH1	The Secure Shell 1.0 protocol has been selected. This version of the protocol has been deprecated and is no longer widely used. It is not recommended that this version of the protocol be used to establish a connection.	256
protocolSSH2	The Secure Shell 2.0 protocol has been selected. This is the most commonly used version of the protocol. It is recommended that this version of the protocol be used unless the server explicitly requires the client to use an earlier version.	512
protocolSSL	Any version of the Secure Sockets Layer (SSL) protocol should be used. The actual protocol version used will be negotiated with the remote host.	3
protocolTLS	Any version of the the Transport Layer Security (TLS) protocol should be used. The actual protocol version used will be negotiated with the remote host, with with preference for TLS 1.2.	28
protocolTLS1	Version 1.0, 1.1 or 1.2 of the the Transport Layer Security (TLS) protocol should be used. The actual protocol version used will be negotiated with the remote host, with preference for TLS 1.2.	28
protocolSSH	Any version of the the Secure Shell (SSH) protocol should be used. The actual protocol version used will be negotiated with the remote host.	768
protocolDefault	The default selection of security protocols will be used when establishing a connection. The TLS 1.2, 1.1 and 1.0 protocols will be negotiated with the host, in that order of preference. This option will always request the latest version of the preferred security protocols and is the recommended	16

	value.	
protocolUnknown	An unknown or unsupported security protocol has been specified. This value indicates an error condition.	4096

FtpClient.TraceOptions Enumeration

Specifies the logging options that the FtpClient class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]

```
<Flags>
Public Enum FtpClient.TraceOptions
```

[C#]

```
[Flags]
public enum FtpClient.TraceOptions
```

Remarks

The FtpClient class uses the **TraceOptions** enumeration to specify what kind of debugging information is written to the trace logfile. These options are only meaningful when trace logging is enabled by setting the **Trace** property to **true**.

Members

Member Name	Description	Value
traceDefault	The default trace logging option. This is the same as specifying the **traceInfo** option.	0
traceInfo	All network function calls are written to the trace file. This is the default value.	0
traceError	Only those network function calls which fail are recorded in the trace file.	1
traceWarning	Only those network function calls which fail, or return values which indicate a warning, are recorded in the trace file.	2
traceHexDump	All network function calls are written to the trace file, plus all the data that is sent or received is displayed, in both ASCII and hexadecimal format.	4
traceProcess	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for multithreaded applications that are using worker threads.	4096

SocketTools Namespace

FtpClient.OnCommandEventHandler Delegate

Represents the method that will handle the OnCommand event.

[Visual Basic]

```
Public Delegate Sub FtpClient.OnCommandEventHandler( _
   ByVal sender As Object, _
   ByVal e As CommandEventArgs _
)
```

[C#]

```
public delegate void FtpClient.OnCommandEventHandler(
      object sender,
      CommandEventArgs e
   );
```

Parameters

sender

The source of the event.

e

A CommandEventArgs object that contains the event data.

Remarks

When you create an **OnCommandEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnCommandEventHandler** delegate declaration.

Requirements

Namespace: SocketTools

Assembly: SocketTools.FtpClient (in SocketTools.FtpClient.dll)

See Also

SocketTools Namespace

FtpClient.OnErrorEventHandler Delegate

Represents the method that will handle the OnError event.

[Visual Basic]

```
Public Delegate Sub FtpClient.OnErrorEventHandler( _
   ByVal sender As Object, _
   ByVal e As ErrorEventArgs _
)
```

[C#]

```
public delegate void FtpClient.OnErrorEventHandler(
      object sender,
      ErrorEventArgs e
   );
```

Parameters

sender

The source of the event.

e

An ErrorEventArgs object that contains the event data.

Remarks

When you create an **OnErrorEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnErrorEventHandler** delegate declaration.

Requirements

Namespace: SocketTools

Assembly: SocketTools.FtpClient (in SocketTools.FtpClient.dll)

See Also

SocketTools Namespace

FtpClient.OnFileListEventHandler Delegate

Represents the method that will handle the OnFileList event.

[Visual Basic]

```
Public Delegate Sub FtpClient.OnFileListEventHandler( _
   ByVal sender As Object, _
   ByVal e As FileListEventArgs _
)
```

[C#]

```
public delegate void FtpClient.OnFileListEventHandler(
      object sender,
      FileListEventArgs e
   );
```

Parameters

sender

The source of the event.

e

A FileListEventArgs object which contains the event data.

Remarks

When you create an **OnFileListEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnFileListEventHandler** delegate declaration.

Requirements

Namespace: SocketTools

Assembly: SocketTools.FtpClient (in SocketTools.FtpClient.dll)

See Also

SocketTools Namespace

FtpClient.OnGetFileEventHandler Delegate

Represents the method that will handle the OnGetFile event.

[Visual Basic]

```
Public Delegate Sub FtpClient.OnGetFileEventHandler( _
   ByVal sender As Object, _
   ByVal e As GetFileEventArgs _
)
```

[C#]

```
public delegate void FtpClient.OnGetFileEventHandler(
      object sender,
      GetFileEventArgs e
   );
```

Parameters

sender

The source of the event.

e

A GetFileEventArgs object which contains the event data.

Remarks

When you create an **OnGetFileEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnGetFileEventHandler** delegate declaration.

Requirements

Namespace: SocketTools

Assembly: SocketTools.FtpClient (in SocketTools.FtpClient.dll)

See Also

SocketTools Namespace

FtpClient.OnProgressEventHandler Delegate

Represents the method that will handle the OnProgress event.

[Visual Basic]

```
Public Delegate Sub FtpClient.OnProgressEventHandler( _
   ByVal sender As Object, _
   ByVal e As ProgressEventArgs _
)
```

[C#]

```
public delegate void FtpClient.OnProgressEventHandler(
      object sender,
      ProgressEventArgs e
   );
```

Parameters

sender

The source of the event.

e

A ProgressEventArgs object that contains the event data.

Remarks

When you create an **OnProgressEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnProgressEventHandler** delegate declaration.

Requirements

Namespace: SocketTools

Assembly: SocketTools.FtpClient (in SocketTools.FtpClient.dll)

See Also

SocketTools Namespace

FtpClient.OnPutFileEventHandler Delegate

Represents the method that will handle the OnPutFile event.

[Visual Basic]

```
Public Delegate Sub FtpClient.OnPutFileEventHandler( _
   ByVal sender As Object, _
   ByVal e As PutFileEventArgs _
)
```

[C#]

```
public delegate void FtpClient.OnPutFileEventHandler(
      object sender,
      PutFileEventArgs e
   );
```

Parameters

sender

The source of the event.

e

A PutFileEventArgs object that contains the event data.

Remarks

When you create an **OnPutFileEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnPutFileEventHandler** delegate declaration.

Requirements

Namespace: SocketTools

Assembly: SocketTools.FtpClient (in SocketTools.FtpClient.dll)

See Also

SocketTools Namespace

FtpClient.OnTaskBeginEventHandler Delegate

Represents the method that will handle the OnTaskBegin event.

[Visual Basic]
```
Public Delegate Sub FtpClient.OnTaskBeginEventHandler( _
   ByVal sender As Object, _
   ByVal e As TaskBeginEventArgs _
)
```

[C#]
```
public delegate void FtpClient.OnTaskBeginEventHandler(
      object sender,
      TaskBeginEventArgs e
   );
```

Parameters

sender
The source of the event.

e
A TaskBeginEventArgs object that contains the event data.

Remarks

When you create an **OnTaskBeginEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnTaskBeginEventHandler** delegate declaration.

This event handler will be invoked in the context of the worker thread that is managing the background task, not the thread that created an instance of the class. Because UI components should only be modified by the thread that created them, the event handler should never attempt to update the user interface directly.

Requirements

Namespace: SocketTools

Assembly: SocketTools.FtpClient (in SocketTools.FtpClient.dll)

SocketTools Namespace

FtpClient.OnTaskEndEventHandler Delegate

Represents the method that will handle the OnTaskEnd event.

[Visual Basic]

```
Public Delegate Sub FtpClient.OnTaskEndEventHandler( _
   ByVal sender As Object, _
   ByVal e As TaskEndEventArgs _
)
```

[C#]

```
public delegate void FtpClient.OnTaskEndEventHandler(
      object sender,
      TaskEndEventArgs e
   );
```

Parameters

sender

The source of the event.

e

A TaskEndEventArgs object that contains the event data.

Remarks

When you create an **OnTaskEndEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnTaskEndEventHandler** delegate declaration.

This event handler will be invoked in the context of the worker thread that is managing the background task, not the thread that created an instance of the class. Because UI components should only be modified by the thread that created them, the event handler should never attempt to update the user interface directly.

Requirements

Namespace: SocketTools

Assembly: SocketTools.FtpClient (in SocketTools.FtpClient.dll)

SocketTools Namespace

FtpClient.OnTaskRunEventHandler Delegate

Represents the method that will handle the OnTaskRun event.

[Visual Basic]

```
Public Delegate Sub FtpClient.OnTaskRunEventHandler( _
   ByVal sender As Object, _
   ByVal e As TaskRunEventArgs _
)
```

[C#]

```
public delegate void FtpClient.OnTaskRunEventHandler(
      object sender,
      TaskRunEventArgs e
   );
```

Parameters

sender

The source of the event.

e

A TaskRunEventArgs object that contains the event data.

Remarks

When you create an **OnTaskRunEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnTaskRunEventHandler** delegate declaration.

This event handler will be invoked in the context of the worker thread that is managing the background task, not the thread that created an instance of the class. Because UI components should only be modified by the thread that created them, the event handler should never attempt to update the user interface directly.

Requirements

Namespace: SocketTools

Assembly: SocketTools.FtpClient (in SocketTools.FtpClient.dll)

SocketTools Namespace

FtpClient.RuntimeLicenseAttribute Class

Attribute that defines the runtime license key for the class.

For a list of all members of this type, see FtpClient.RuntimeLicenseAttribute Members.

System.Object
  System.Attribute
    SocketTools.FtpClient.RuntimeLicenseAttribute

[Visual Basic]
```
<AttributeUsage(ValidOn:=AttributeTargets.Assembly, AllowMultiple:=False,
   Inherited:=True)>
Public Class FtpClient.RuntimeLicenseAttribute
    Inherits Attribute
```

[C#]
```
[AttributeUsage(ValidOn=AttributeTargets.Assembly, AllowMultiple=False,
   Inherited=True)]
public class FtpClient.RuntimeLicenseAttribute : Attribute
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

The RuntimeLicense attribute is used to define the runtime license key that will be used when an instance of the class is created. This attribute is defined in the assembly information module for the language, such as AssemblyInfo.cs when programming C#. The runtime license key must be defined if you wish to redistribute your application.

The runtime license key for your copy of SocketTools can be generated using the License Manager utility that is included with the product. Note that if you have installed an evaluation license, you will not have a runtime license key and cannot redistribute any applications which use the FtpClient class.

Example

```
<Assembly: SocketTools.FtpClient.RuntimeLicense("abcdefghijklmnop")>
```

```
[assembly: SocketTools.FtpClient.RuntimeLicense("abcdefghijklmnop")]
```

Requirements

Namespace: SocketTools

Assembly: SocketTools.FtpClient (in SocketTools.FtpClient.dll)

See Also

FtpClient.RuntimeLicenseAttribute Members | SocketTools Namespace

FtpClient.RuntimeLicenseAttribute Members

FtpClient.RuntimeLicenseAttribute overview

Public Instance Constructors

FtpClient.RuntimeLicenseAttribute Constructor	Constructor for the RuntimeLicense attribute which defines the runtime license key.

Public Instance Properties

LicenseKey	Returns the value of the runtime license key.
TypeId (inherited from Attribute)	When implemented in a derived class, gets a unique identifier for this Attribute.

Public Instance Methods

Equals (inherited from Attribute)	
GetHashCode (inherited from Attribute)	Returns the hash code for this instance.
GetType (inherited from Object)	Gets the Type of the current instance.
IsDefaultAttribute (inherited from Attribute)	When overridden in a derived class, returns an indication whether the value of this instance is the default value for the derived class.
Match (inherited from Attribute)	When overridden in a derived class, returns a value indicating whether this instance equals a specified object.
ToString (inherited from Object)	Returns a String that represents the current Object.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

FtpClient.RuntimeLicenseAttribute Class | SocketTools Namespace

FtpClient.RuntimeLicenseAttribute Constructor

Constructor for the RuntimeLicense attribute which defines the runtime license key.

[Visual Basic]

```
Public Sub New( _
   ByVal licenseKey As String _
)
```

[C#]

```
public FtpClient.RuntimeLicenseAttribute(
   string licenseKey
);
```

Parameters

licenseKey

A string argument which specifies the runtime license key which will be used to initialize the class library.

Remarks

The runtime license key for your copy of SocketTools can be generated using the License Manager utility that is included with the product. Note that if you have installed an evaluation license, you will not have a runtime license key and cannot redistribute any applications which use the FtpClient class.

See Also

FtpClient.RuntimeLicenseAttribute Class | SocketTools Namespace

FtpClient.RuntimeLicenseAttribute Properties

The properties of the **FtpClient.RuntimeLicenseAttribute** class are listed below. For a complete list of **FtpClient.RuntimeLicenseAttribute** class members, see the FtpClient.RuntimeLicenseAttribute Members topic.

Public Instance Properties

LicenseKey	Returns the value of the runtime license key.
TypeId (inherited from Attribute)	When implemented in a derived class, gets a unique identifier for this Attribute.

See Also

FtpClient.RuntimeLicenseAttribute Class | SocketTools Namespace

FtpClient.RuntimeLicenseAttribute.LicenseKey Property

Returns the value of the runtime license key.

[Visual Basic]

```
Public Property LicenseKey As String
```

[C#]

```
public string LicenseKey {get; set;}
```

Property Value

A string which contains the runtime license key.

See Also

FtpClient.RuntimeLicenseAttribute Class | SocketTools Namespace

FtpClientException Class

The exception that is thrown when a client error occurs.

For a list of all members of this type, see FtpClientException Members.

System.Object
  System.Exception
    System.ApplicationException
      SocketTools.FtpClientException

[Visual Basic]
```
Public Class FtpClientException
    Inherits ApplicationException
```

[C#]
```
public class FtpClientException : ApplicationException
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

A FtpClientException is thrown by the FtpClient class when an error occurs.

The default constructor for the FtpClientException class sets the **ErrorCode** property to the last error that occurred.

Requirements

Namespace: SocketTools

Assembly: SocketTools.FtpClient (in SocketTools.FtpClient.dll)

See Also

FtpClientException Members | SocketTools Namespace

FtpClientException Members

FtpClientException overview

Public Instance Constructors

FtpClientException	Overloaded. Initializes a new instance of the FtpClientException class.

Public Instance Properties

HelpLink (inherited from Exception)	Gets or sets a link to the help file associated with this exception.
InnerException (inherited from Exception)	Gets the Exception instance that caused the current exception.
Message	Gets a value which describes the error that caused the exception.
Number	Gets a value which specifies the numeric value of the error that caused the exception.
Source (inherited from Exception)	Gets or sets the name of the application or the object that causes the error.
StackTrace (inherited from Exception)	Gets a string representation of the frames on the call stack at the time the current exception was thrown.
TargetSite (inherited from Exception)	Gets the method that throws the current exception.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetBaseException (inherited from Exception)	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetObjectData (inherited from Exception)	When overridden in a derived class, sets the SerializationInfo with information about the exception.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString	Creates and returns a string representation of the current exception.

Protected Instance Properties

HResult (inherited from Exception)	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

FtpClientException Class | SocketTools Namespace

FtpClientException Constructor

Initializes a new instance of the FtpClientException class with the last client error code.

Overload List

Initializes a new instance of the FtpClientException class with the last client error code.

public FtpClientException();

Initializes a new instance of the FtpClientException class with a specified error number.

public FtpClientException(int);

Initializes a new instance of the FtpClientException class with a specified error message.

public FtpClientException(string);

Initializes a new instance of the FtpClientException class with a specified error message and a reference to the inner exception that is the cause of this exception.

public FtpClientException(string,Exception);

See Also

FtpClientException Class | SocketTools Namespace

FtpClientException Constructor ()

Initializes a new instance of the FtpClientException class with the last client error code.

[Visual Basic]

```
Overloads Public Sub New()
```

[C#]

```
public FtpClientException();
```

Remarks

The ctor constructor sets the **ErrorCode** property to the last client error that occurred. For more information about the errors that may occur, refer to the FtpClient.ErrorCode enumeration.

See Also

FtpClientException Class | SocketTools Namespace | FtpClientException Constructor Overload List

FtpClientException Constructor (String)

Initializes a new instance of the FtpClientException class with a specified error message.

[Visual Basic]

```
Overloads Public Sub New( _
   ByVal message As String _
)
```

[C#]

```
public FtpClientException(
   string message
);
```

Parameters

message

The error message that explains the reason for the exception.

Remarks

The content of the ***message*** parameter is intended to be understood by humans. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

See Also

FtpClientException Class | SocketTools Namespace | FtpClientException Constructor Overload List

FtpClientException Constructor (String, Exception)

Initializes a new instance of the FtpClientException class with a specified error message and a reference to the inner exception that is the cause of this exception.

[Visual Basic]

```
Overloads Public Sub New( _
   ByVal message As String, _
   ByVal inner As Exception _
)
```

[C#]

```
public FtpClientException(
   string message,
   Exception inner
);
```

Parameters

message

The error message that explains the reason for the exception.

inner

The exception that is the cause of the current exception. If the ***innerException*** parameter is not a null reference, the current exception is raised in a **catch** block that handles the inner exception.

Remarks

The content of the message parameter is intended to be understood by humans. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

An exception that is thrown as a direct result of a previous exception should include a reference to the previous exception in the **InnerException** property. The **InnerException** property returns the same value that is passed into the constructor, or a null reference if the **InnerException** property does not supply the inner exception value to the constructor.

See Also

FtpClientException Class | SocketTools Namespace | FtpClientException Constructor Overload List

FtpClientException Constructor (Int32)

Initializes a new instance of the FtpClientException class with a specified error number.

[Visual Basic]

```
Overloads Public Sub New( _
   ByVal code As Integer _
)
```

[C#]

```
public FtpClientException(
   int code
);
```

Parameters

code

An integer value which specifies an error code.

Remarks

This constructor sets the **ErrorCode** property to the specified error code. For more information about the errors that may occur, refer to the FtpClient.ErrorCode enumeration.

FtpClientException Class | SocketTools Namespace | FtpClientException Constructor Overload List

FtpClientException Properties

The properties of the **FtpClientException** class are listed below. For a complete list of **FtpClientException** class members, see the FtpClientException Members topic.

Public Instance Properties

HelpLink (inherited from Exception)	Gets or sets a link to the help file associated with this exception.
InnerException (inherited from Exception)	Gets the Exception instance that caused the current exception.
Message	Gets a value which describes the error that caused the exception.
Number	Gets a value which specifies the numeric value of the error that caused the exception.
Source (inherited from Exception)	Gets or sets the name of the application or the object that causes the error.
StackTrace (inherited from Exception)	Gets a string representation of the frames on the call stack at the time the current exception was thrown.
TargetSite (inherited from Exception)	Gets the method that throws the current exception.

Protected Instance Properties

HResult (inherited from Exception)	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception.

See Also

FtpClientException Class | SocketTools Namespace

FtpClientException.Message Property

Gets a value which describes the error that caused the exception.

[Visual Basic]

```
Overrides Public ReadOnly Property Message As String
```

[C#]

```
public override string Message {get;}
```

Property Value

A string which describes the error that caused the exception.

Remarks

The **Message** property returns a string which describes the error that caused the exception.

See Also

FtpClientException Class | SocketTools Namespace

FtpClientException.Number Property

Gets a value which specifies the numeric value of the error that caused the exception.

[Visual Basic]

```
Public ReadOnly Property Number As Integer
```

[C#]

```
public int Number {get;}
```

Property Value

An integer value that specifies the error that caused the exception.

Remarks

The **Number** property returns an integer value which specifies the numeric value of the error that caused the exception. If a network error occurs, this value is the same as the values returned by the Windows Sockets API. For more information about socket error codes, see the Windows Socket Version 2 API error code documentation in MSDN.

FtpClientException Class | SocketTools Namespace

FtpClientException Methods

The methods of the **FtpClientException** class are listed below. For a complete list of **FtpClientException** class members, see the FtpClientException Members topic.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetBaseException (inherited from Exception)	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetObjectData (inherited from Exception)	When overridden in a derived class, sets the SerializationInfo with information about the exception.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString	Creates and returns a string representation of the current exception.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

FtpClientException Class | SocketTools Namespace

FtpClientException.ToString Method

Creates and returns a string representation of the current exception.

[Visual Basic]
```
Overrides Public Function ToString() As String
```

[C#]
```
public override string ToString();
```

Return Value

A string representation of the current exception.

Remarks

The **ToString** method returns a representation of the current exception that is intended to be understood by humans. Where the exception contains culture-sensitive data, the string representation returned by **ToString** is required to take into account the current system culture. Although there are no exact requirements for the format of the returned string, it should attempt to reflect the value of the object as perceived by the user.

This implementation of **ToString** obtains the numeric error code value and a description of the error that caused the current exception. If there is no error message or it is an empty string, then no error message is returned.

This method overrides **ApplicationException.ToString**.

FtpClientException Class | SocketTools Namespace

FtpServer Class

Implements a server that enables the application to send and receive files using the File Transfer Protocol.

For a list of all members of this type, see FtpServer Members.

System.Object
  SocketTools.FtpServer

[Visual Basic]
```
Public Class FtpServer
    Implements IDisposable
```

[C#]
```
public class FtpServer : IDisposable
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

The **SocketTools.FtpServer** class provides an interface for implementing an embedded, lightweight server that can be used to exchange files with a client using the standard File Transfer Protocol. The server can accept connections from any third-party application or a program developed using the **SocketTools.FtpClient** class.

The application specifies an initial server configuration by setting the relevant properties and can implement event handlers to monitor the activities of the clients that have connected to the server. The class automatically handles the standard FTP commands and requires minimal coding on the part of the application that is hosting the control. However, the application may also use event mechanism to filter specific commands or to extend the protocol by providing custom implementations of existing commands or add entirely new commands.

The server supports active and passive mode file transfers, has compatibility options for NAT router and firewall support, and provides support for secure file transfers using explicit TLS sessions. Secure connections require that a valid server certificate be installed on the system.

Requirements

Namespace: SocketTools

Assembly: SocketTools.FtpServer (in SocketTools.FtpServer.dll)

FtpServer Members

FtpServer overview

Public Static (Shared) Methods

ErrorText	Returns the description of an error code.

Public Instance Constructors

FtpServer Constructor	Initializes a new instance of the FtpServer class.

Public Instance Fields

AdapterAddress	Returns the IP address associated with the specified network adapter.

Public Instance Properties

AdapterCount	Get the number of available local and remote network adapters.
AuthFail	Gets and sets the maximum number of authentication attempts permitted.
AuthTime	Gets and sets the amount of time a client has to authenticate the session.
CertificateName	Gets and sets a value that specifies the name of the server certificate.
CertificatePassword	Gets and sets the password associated with the server certificate.
CertificateStore	Gets and sets a value that specifies the name of the local certificate store.
CertificateUser	Gets and sets the user that owns the server certificate.
ClientAccess	Gets and sets the access rights that have been granted to the client session.
ClientAddress	Return the Internet address of the current client connection.
ClientCount	Return the number of active client sessions connected to the server.
ClientDirectory	Return the current working directory for the active client session.
ClientHome	Return the home directory for the active client session.
ClientHost	Return the host name that the client used to establish the connection.
ClientId	Gets the unique client identifier for the current client session.

ClientIdle	Gets and sets the maximum number of seconds a client can be idle before the server terminates the session.
ClientPort	Gets a value that specifies the port number used by the current client session.
ClientThread	Gets the thread ID for the current client session.
ClientUser	Return the user name associated with the specified client session.
CommandLine	Return the complete command line issued by the client.
Directory	Get and set the full path to the root directory assigned to the server.
ExecTime	Get and set maximum number of seconds that the server will permit an external command to execute.
ExternalAddress	Get and set the external IP address used for passive mode data transfers.
HiddenFiles	Determine if the server should permit access to hidden files.
Identity	Gets and sets a string that identifies the server to the client.
IdleTime	Gets and sets the maximum number of seconds a client can be idle before the server terminates the session.
IsActive	Gets a value which indicates if the server is active.
IsAnonymous	Determine if the active client session has authenticated as an anonymous user.
IsAuthenticated	Determine if the active client session has been authenticated.
IsInitialized	Gets a value which indicates if the current instance of the class has been initialized successfully.
IsListening	Gets a value which indicates if the server is listening for client connections.
LastError	Gets and sets a value which specifies the last error that has occurred.
LastErrorString	Gets a value which describes the last error that has occurred.
LocalPath	Return the full path to the local file or directory that is the target of the current command.
LocalTime	Determines if the server should return file and directory times adjusted for the local timezone.
LocalUser	Determines if the server should perform user authentication using the Windows local account

	database.
LockFiles	Determines if files should be exclusively locked when a client attempts to upload or download a file.
LogFile	Gets and sets the name of the server log file.
LogFormat	Gets and sets the format used when updating the server log file.
LogLevel	Gets and sets the level of detail included in the server log file.
MaxClients	Gets and sets the maximum number of clients that can connect to the server.
MaxGuests	Gets and sets the maximum number of anonymous users that are permitted to connect to the server.
MaxPort	Gets and sets the maximum port number used by the server for passive data connections.
MemoryUsage	Gets the amount of unmanaged memory currently allocated by the server.
MinPort	Gets and sets the maximum port number used by the server for passive data connections.
MultiUser	Determine if the server should be started in multi-user mode.
Options	Gets and sets the options that may be specified for the server instance.
Priority	Gets and sets a value which specifies the server priority.
ReadOnly	Determine if the server should prevent clients from uploading files.
Restricted	Determine if the server should be started in restricted mode, limiting client access to the server.
Secure	Determine if the server should accept secure client connections.
ServerAddress	Gets and sets the address that will be used by the server to listen for connections.
ServerHandle	Gets the handle to the server created to listen for client connections.
ServerName	Gets a value which specifies the host name for the local system.
ServerPort	Gets and sets the port number that will be used by the server to listen for connections.
ServerThread	Gets the thread ID for the current server.
ServerUuid	Gets and sets the Universally Unique Identifier

	(UUID) associated with the server.
StackSize	Gets and sets the size of the stack allocated for threads created by the server.
ThrowError	Gets and sets a value which specifies if method calls should throw exceptions when an error occurs.
Trace	Gets and sets a value which indicates if network function logging is enabled.
TraceFile	Gets and sets a value which specifies the name of the network function tracing logfile.
TraceFlags	Gets and sets a value which specifies the network function tracing flags.
UnixMode	Determine if the server should impersonate a UNIX-based operating system.
Version	Gets a value which returns the current version of the FtpServer class library.
VirtualPath	Return the virtual path to the local file or directory that is the target of the current command.

Public Instance Methods

AddUser	Overloaded. Add a new virtual user to the server.
Authenticate	Overloaded. Authenticate the client and assign access rights for the session.
DeleteUser	Remove a virtual user from the server.
Disconnect	Overloaded. Disconnect the specified client session from the server.
Dispose	Overloaded. Releases all resources used by FtpServer.
Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from Object)	Gets the Type of the current instance.
Initialize	Overloaded. Initialize an instance of the FtpServer class.
RegisterProgram	Overloaded. Register a program for use with the SITE EXEC command.
Reset	Reset the internal state of the object, resetting all properties to their default values.
ResolvePath	Overloaded. Resolve a path to its full virtual or local file name.

Restart	Restarts the server and terminates all active client connections.
Resume	Resume accepting new client connections.
SendResponse	Overloaded. Send a result code and message to the client in response to a command.
Start	Overloaded. Start listening for client connections on the specified IP address and port number.
Stop	Stop listening for new client connections and terminate all active clients already connected to the server.
Suspend	Suspend accepting new client connections.
Throttle	Overloaded. Limit the maximum number of client connections, connections per IP address and connection rate.
ToString (inherited from Object)	Returns a String that represents the current Object.
Uninitialize	Uninitialize the class library and release any resources allocated for the server.

Public Instance Events

OnAuthenticate	Occurs when the client has requested authentication with the specified username and password.
OnCommand	Occurs when a client has issued a command to the server.
OnConnect	Occurs when a connection is established with the remote host.
OnDisconnect	Occurs when the remote host disconnects from the local system.
OnDownload	Occurs when a connection is established with the remote host.
OnError	Occurs when an network operation fails.
OnExecute	Occurs when the client has executed an external program on the server.
OnIdle	Occurs when the there are no clients connected to the server.
OnLogin	Occurs when the client has successfully authenticated the session.
OnLogout	Occurs when the client has logged out or reinitialized the session.
OnResult	Occurs when the command issued by the client has been processed by the server.
OnStart	Occurs when the server starts accepting connections.

OnStop	Occurs when the server stops accepting connections.
OnTimeout	Occurs when the client has exceeded the maximum allowed idle time.
OnUpload	Occurs when the client has successfully uploaded a file to the server.

Protected Instance Methods

Dispose	Overloaded. Releases the unmanaged resources allocated by the FtpServer class and optionally releases the managed resources.
Finalize	Destroys an instance of the class, releasing the resources allocated for the session and unloading the networking library.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

FtpServer Class | SocketTools Namespace

FtpServer Constructor

Initializes a new instance of the FtpServer class.

[Visual Basic]

```
Public Sub New()
```

[C#]

```
public FtpServer();
```

See Also

FtpServer Class | SocketTools Namespace

FtpServer Fields

The fields of the **FtpServer** class are listed below. For a complete list of **FtpServer** class members, see the FtpServer Members topic.

Public Instance Fields

◆ AdapterAddress	Returns the IP address associated with the specified network adapter.

See Also

FtpServer Class | SocketTools Namespace

FtpServer.AdapterAddress Field

Returns the IP address associated with the specified network adapter.

[Visual Basic]
```
Public ReadOnly AdapterAddress As AdapterAddressArray
```

[C#]
```
public readonly AdapterAddressArray AdapterAddress;
```

Remarks

The **AdapterAddress** array returns the IP addresses that are associated with the local network or remote dial-up network adapters configured on the system. The **AdapterCount** property can be used to determine the number of adapters that are available.

Multihomed systems with more than one local network adapter, or a combination of local and dial-up adapters will not be listed in a specific order. An application should not make the assumption that the first address returned by **AdapterAddress** always refers to a local network adapter.

Note that it is possible that the **AdapterCount** property will return 0, and **AdapterAddress** will return an empty string. This indicates that the system does not have a physical network adapter with an assigned IP address, and there are no dial-up networking connections currently active. If a dial-up networking connection is established at some later point, the **AdapterCount** property will change to 1, and the **AdapterAddress** property will return the IP address allocated for that connection.

See Also

FtpServer Class | SocketTools Namespace | AdapterAddressArray Class | AdapterCount Property

FtpServer Properties

The properties of the **FtpServer** class are listed below. For a complete list of **FtpServer** class members, see the FtpServer Members topic.

Public Instance Properties

AdapterCount	Get the number of available local and remote network adapters.
AuthFail	Gets and sets the maximum number of authentication attempts permitted.
AuthTime	Gets and sets the amount of time a client has to authenticate the session.
CertificateName	Gets and sets a value that specifies the name of the server certificate.
CertificatePassword	Gets and sets the password associated with the server certificate.
CertificateStore	Gets and sets a value that specifies the name of the local certificate store.
CertificateUser	Gets and sets the user that owns the server certificate.
ClientAccess	Gets and sets the access rights that have been granted to the client session.
ClientAddress	Return the Internet address of the current client connection.
ClientCount	Return the number of active client sessions connected to the server.
ClientDirectory	Return the current working directory for the active client session.
ClientHome	Return the home directory for the active client session.
ClientHost	Return the host name that the client used to establish the connection.
ClientId	Gets the unique client identifier for the current client session.
ClientIdle	Gets and sets the maximum number of seconds a client can be idle before the server terminates the session.
ClientPort	Gets a value that specifies the port number used by the current client session.
ClientThread	Gets the thread ID for the current client session.
ClientUser	Return the user name associated with the specified client session.

CommandLine	Return the complete command line issued by the client.
Directory	Get and set the full path to the root directory assigned to the server.
ExecTime	Get and set maximum number of seconds that the server will permit an external command to execute.
ExternalAddress	Get and set the external IP address used for passive mode data transfers.
HiddenFiles	Determine if the server should permit access to hidden files.
Identity	Gets and sets a string that identifies the server to the client.
IdleTime	Gets and sets the maximum number of seconds a client can be idle before the server terminates the session.
IsActive	Gets a value which indicates if the server is active.
IsAnonymous	Determine if the active client session has authenticated as an anonymous user.
IsAuthenticated	Determine if the active client session has been authenticated.
IsInitialized	Gets a value which indicates if the current instance of the class has been initialized successfully.
IsListening	Gets a value which indicates if the server is listening for client connections.
LastError	Gets and sets a value which specifies the last error that has occurred.
LastErrorString	Gets a value which describes the last error that has occurred.
LocalPath	Return the full path to the local file or directory that is the target of the current command.
LocalTime	Determines if the server should return file and directory times adjusted for the local timezone.
LocalUser	Determines if the server should perform user authentication using the Windows local account database.
LockFiles	Determines if files should be exclusively locked when a client attempts to upload or download a file.
LogFile	Gets and sets the name of the server log file.
LogFormat	Gets and sets the format used when updating the server log file.
LogLevel	Gets and sets the level of detail included in the

	server log file.
MaxClients	Gets and sets the maximum number of clients that can connect to the server.
MaxGuests	Gets and sets the maximum number of anonymous users that are permitted to connect to the server.
MaxPort	Gets and sets the maximum port number used by the server for passive data connections.
MemoryUsage	Gets the amount of unmanaged memory currently allocated by the server.
MinPort	Gets and sets the maximum port number used by the server for passive data connections.
MultiUser	Determine if the server should be started in multi-user mode.
Options	Gets and sets the options that may be specified for the server instance.
Priority	Gets and sets a value which specifies the server priority.
ReadOnly	Determine if the server should prevent clients from uploading files.
Restricted	Determine if the server should be started in restricted mode, limiting client access to the server.
Secure	Determine if the server should accept secure client connections.
ServerAddress	Gets and sets the address that will be used by the server to listen for connections.
ServerHandle	Gets the handle to the server created to listen for client connections.
ServerName	Gets a value which specifies the host name for the local system.
ServerPort	Gets and sets the port number that will be used by the server to listen for connections.
ServerThread	Gets the thread ID for the current server.
ServerUuid	Gets and sets the Universally Unique Identifier (UUID) associated with the server.
StackSize	Gets and sets the size of the stack allocated for threads created by the server.
ThrowError	Gets and sets a value which specifies if method calls should throw exceptions when an error occurs.
Trace	Gets and sets a value which indicates if network function logging is enabled.

TraceFile	Gets and sets a value which specifies the name of the network function tracing logfile.
TraceFlags	Gets and sets a value which specifies the network function tracing flags.
UnixMode	Determine if the server should impersonate a UNIX-based operating system.
Version	Gets a value which returns the current version of the FtpServer class library.
VirtualPath	Return the virtual path to the local file or directory that is the target of the current command.

See Also

FtpServer Class | SocketTools Namespace

FtpServer.AdapterCount Property

Get the number of available local and remote network adapters.

[Visual Basic]

```
Public ReadOnly Property AdapterCount As Integer
```

[C#]

```
public int AdapterCount {get;}
```

Property Value

Returns the number of available local and remote network adapters.

Remarks

The **AdapterCount** property returns the number of local and remote dial-up networking adapters available on the local system. This value can be used in conjunction with the **AdapterAddress** array to enumerate the IP addresses assigned to the various network adapters.

Note that it is possible that the **AdapterCount** property will return 0, and **AdapterAddress** will return an empty string. This indicates that the system does not have a physical network adapter with an assigned IP address, and there are no dial-up networking connections currently active. If a dial-up networking connection is established at some later point, the **AdapterCount** property will change to 1, and the **AdapterAddress** property will return the IP address allocated for that connection.

See Also

FtpServer Class | SocketTools Namespace | AdapterAddress Field

FtpServer.AuthFail Property

Gets and sets the maximum number of authentication attempts permitted.

[Visual Basic]

```
Public Property AuthFail As Integer
```

[C#]

```
public int AuthFail {get; set;}
```

Property Value

An integer value that specifies the maximum number of user authentication attempts permitted.

Remarks

The **AuthFail** property value specifies the maximum number of user authentication attempts that are permitted until the server terminates the client connection. A value of zero specifies that the default configuration limit of 3 authentication attempts per login should be allowed. The maximum number of authentication attempts is 10.

See Also

FtpServer Class | SocketTools Namespace

FtpServer.AuthTime Property

Gets and sets the amount of time a client has to authenticate the session.

[Visual Basic]

```
Public Property AuthTime As Integer
```

[C#]

```
public int AuthTime {get; set;}
```

Property Value

An integer value that specifies the user authentication time in seconds.

Remarks

The **AuthTime** property value specifies the maximum number of user authentication attempts that are permitted until the server terminates the client connection. A value of zero specifies the default value of 60 seconds. If the value is non-zero, the minimum value is 20 seconds and the maximum value is 300 seconds (5 minutes). This value is used to ensure that a client has successfully authenticated itself within a limited period of time. This prevents a potential denial-of-service attack against the server where clients establish connections and hold them open without authentication. In conjunction with the **AuthFail** property, this also limits the ability of a client to attempt to probe the server for valid username and password combinations.

See Also

FtpServer Class | SocketTools Namespace

FtpServer.CertificateName Property

Gets and sets a value that specifies the name of the server certificate.

[Visual Basic]

```
Public Property CertificateName As String
```

[C#]

```
public string CertificateName {get; set;}
```

Property Value

A string which specifies the server certificate name.

Remarks

The **CertificateName** property sets the common name or friendly name of the certificate that should be used when starting a secure server. If the **Secure** property is set to True, this property must be specify a valid certificate name. The certificate must have a private key associated with it, otherwise client connections will fail because the class will be unable to create a security context for the session.

When the certificate store is searched for a matching certificate, it will first search for any certificate with a friendly name that matches the property value. If no valid certificate is found, it will then search for a certificate with a matching common name.

Certificates may be installed and viewed on the local system using the Certificate Manager that is included with the Windows operating system. For more information, refer to the documentation for the Microsoft Management Console.

See Also

FtpServer Class | SocketTools Namespace | CertificateStore Property | Secure Property

FtpServer.CertificateStore Property

Gets and sets a value that specifies the name of the local certificate store.

[Visual Basic]

```
Public Property CertificateStore As String
```

[C#]

```
public string CertificateStore {get; set;}
```

Property Value

A string which specifies the certificate store name. The default value is the current user's personal certificate store.

Remarks

The **CertificateStore** property is used to specify the name of the certificate store which contains the security certificate to use when security is enabled for the server. The certificate may either be stored in the registry or in a file. If the certificate is stored in the registry, then this property should be set to one of the following predefined values:

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as VeriSign and Thawte act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. If a certificate store is not specified, this is the default value that is used.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as VeriSign and Thawte are installed as part of the operating system and periodically updated by Microsoft.

In most cases the server certificate will be installed in the user's personal certificate store, and therefore it is not necessary to set this property value because that is the default location that will be used to search for the certificate. This property is only used if the **CertificateName** property is also set to a valid certificate name.

If you are using a local certificate store, with the certificate and private key stored in the registry, you can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU" for the current user, or "HKLM" for the local machine. For example, a certificate store name of "HKLM:MY" would specify the personal certificate store for the local machine, rather than the current user. If neither prefix is specified, it will default to the certificate store for the current user.

This property may also be used to specify a file that contains the server certificate. In this case, the property should specify the full path to the file and must contain both the certificate and private key in

PKCS12 format. If the file is protected by a password, the **CertificatePassword** property must also be set to specify the password.

See Also

FtpServer Class | SocketTools Namespace | CertificatePassword Property | Secure Property

FtpServer.ClientAccess Property

Gets and sets the access rights that have been granted to the client session.

[Visual Basic]
```
Public Property ClientAccess As UserAccess
```

[C#]
```
public FtpServer.UserAccess ClientAccess {get; set;}
```

Property Value

A UserAccess enumeration that specifies on or more user access permissions.

Remarks

The **ClientAccess** property is used to determine all of the access permissions that are currently granted to an authenticated client session and optionally change those permissions. For a list of user access rights that can be granted to the client, see the UserAccess enumeration.

When modifying the value of this property, it is recommended that you use bitwise OR and AND operands to set and clear specific bitflags. The exception is when using the **ftpAccessDefault** permission. If you wish to reset the client session to use the default permissions based on the server configuration and client authentication, then you should assign this value directly to the **ClientAccess** property.

This property should only be accessed within an event handler such as **OnCommand** because its value is specific to the client session that raised the event. This property will always return a value of zero outside of an event handler, and an exception will be raised if you attempt to modify this property outside of an event handler.

FtpServer Class | SocketTools Namespace

FtpServer.ClientAddress Property

Return the Internet address of the current client connection.

[Visual Basic]

```
Public ReadOnly Property ClientAddress As String
```

[C#]

```
public string ClientAddress {get;}
```

Property Value

A string that specifies the client Internet Protocol address.

Remarks

The **ClientAddress** property returns the address of the current client session which has connected to the server. This property should only be accessed within an event handler such as **OnConnect** because its value is specific to the client session that raised the event. This property will always return an empty string when accessed outside of an event handler.

See Also

FtpServer Class | SocketTools Namespace

FtpServer.ClientCount Property

Return the number of active client sessions connected to the server.

[Visual Basic]
```
Public ReadOnly Property ClientCount As Integer
```

[C#]
```
public int ClientCount {get;}
```

Property Value

An integer value that specifies the number of active client sessions.

Remarks

The **ClientCount** read-only property returns the number of active client sessions that have been established with the server. The value includes both authenticated and unauthenticated client sessions.

See Also

FtpServer Class | SocketTools Namespace

FtpServer.ClientDirectory Property

Return the current working directory for the active client session.

[Visual Basic]

```
Public ReadOnly Property ClientDirectory As String
```

[C#]

```
public string ClientDirectory {get;}
```

Property Value

A string that specifies the full path to a local directory on the server.

Remarks

The **ClientDirectory** property returns the current working directory for the active client session. Initially this value will be the absolute path on the local system that maps to an authenticated client's home directory. The client can change its current working directory using the CWD command. The **ClientHome** property will return the home directory that has been assigned to the client.

It is important to note that the current working directory for client sessions is virtual, and does not reflect the current working directory for the server process. This property should only be accessed within an event handler after the client session has been authenticated. Unauthenticated clients are not assigned a current working directory. This property will always return an empty string when accessed outside of an event handler.

See Also

FtpServer Class | SocketTools Namespace

FtpServer.ClientHome Property

Return the home directory for the active client session.

[Visual Basic]

```
Public ReadOnly Property ClientHome As String
```

[C#]

```
public string ClientHome {get;}
```

Property Value

A string that specifies the full path to a local directory on the server.

Remarks

The **ClientHome** property returns the home directory for the active client session. This will be the same path to the home directory specified when the **Authenticate** method was used to authenticate the client session. If a home directory was not explicitly assigned when the client was authenticated, then this property returns the default home directory that was created for the client, or the server root directory if the **MultiUser** property was set to **False** when the server was started. The **ClientDirectory** property will return the current working directory for the client.

This property should only be accessed within an event handler after the client session has been authenticated. Unauthenticated clients are not assigned a home directory. This property will always return an empty string when accessed outside of an event handler.

See Also

FtpServer Class | SocketTools Namespace

FtpServer.ClientHost Property

Return the host name that the client used to establish the connection.

[Visual Basic]

```
Public ReadOnly Property ClientHost As String
```

[C#]

```
public string ClientHost {get;}
```

Property Value

A string that specifies the host name used by the client to connect to the server.

Remarks

The **ClientHost** property returns the host name that the client used to establish the connection. If the client sends the HOST command, this property will return the value specified by the client. If the client does not explicitly specify the host name, then this property will return the same host name that was assigned to the server when it started.

See Also

FtpServer Class | SocketTools Namespace

FtpServer.ClientId Property

Gets the unique client identifier for the current client session.

[Visual Basic]

```
Public ReadOnly Property ClientId As Integer
```

[C#]

```
public int ClientId {get;}
```

Property Value

An integer value which uniquely identifies the client session.

Remarks

Each client connection that is accepted by the server is assigned a unique numeric value. This value can be used by the application to identify that client session, and is different than the socket handle allocated for the client. While it is possible for a client socket handle to be reused by the operating system, client IDs are unique throughout the life of the server session and are never duplicated.

It is important to note that the actual value of the client ID should be considered opaque. It is only guaranteed that the value will be greater than zero, and that it will be unique to the client session.

This property only returns a meaningful value when accessed from within a class event handler, or a method that has been invoked from within an event handler.

See Also

FtpServer Class | SocketTools Namespace

FtpServer.ClientIdle Property

Gets and sets the maximum number of seconds a client can be idle before the server terminates the session.

[Visual Basic]
```
Public Property ClientIdle As Integer
```

[C#]
```
public int ClientIdle {get; set;}
```

Property Value

An integer value that specifies the idle timeout period in seconds.

Remarks

The **ClientIdle** property returns the maximum number of seconds that the active client session may be idle before the server closes the control connection. The idle timeout period for each client session is based on the value of the **IdleTime** property when the server was started, with the default value of 300 seconds (5 minutes). Changing this value inside an event handler will change the timeout period for the active client session. Clients may also use the SITE IDLE command to request that the server change the idle timeout period.

This property should only be accessed within an event handler such as **OnConnect** or **OnLogin** because its value is specific to the client session that raised the event. This property will always return a value of zero outside of an event handler, and an exception will be raised if you attempt to modify this property outside of an event handler.

When the timeout period for the client has elapsed, the **OnTimeout** event will fire prior to the client being disconnected from the server.

See Also

FtpServer Class | SocketTools Namespace

FtpServer.ClientPort Property

Gets a value that specifies the port number used by the current client session.

[Visual Basic]

```
Public ReadOnly Property ClientPort As Integer
```

[C#]

```
public int ClientPort {get;}
```

Property Value

An integer value which specifies the peer port number.

Remarks

The **ClientPort** property returns the port number that the current client has used when establishing a connection with the server. This property value is only meaningful when accessed within an event handler such as the **OnConnect** event.

See Also

FtpServer Class | SocketTools Namespace

FtpServer.ClientThread Property

Gets the thread ID for the current client session.

[Visual Basic]
```
Public ReadOnly Property ClientThread As Integer
```

[C#]
```
public int ClientThread {get;}
```

Property Value

An integer value which identifies the client thread that was created to manage the client session.

Remarks

Until the thread terminates, the thread identifier uniquely identifies the thread throughout the system.

This property only returns a meaningful value when accessed from within a class event handler, or a method that has been invoked from within an event handler.

See Also

FtpServer Class | SocketTools Namespace

FtpServer.ClientUser Property

Return the user name associated with the specified client session.

[Visual Basic]

```
Public ReadOnly Property ClientUser As String
```

[C#]

```
public string ClientUser {get;}
```

Property Value

A string that specifies the user name associated with the active client session.

Remarks

The **ClientUser** property returns the user name that the client used to authenticate the client session. This property should only be accessed within an event handler after the client session has been authenticated. Unauthenticated clients are not assigned a user name. This property will always return an empty string when accessed outside of an event handler.

See Also

FtpServer Class | SocketTools Namespace

FtpServer.Directory Property

Get and set the full path to the root directory assigned to the server.

[Visual Basic]

```
Public Property Directory As String
```

[C#]

```
public string Directory {get; set;}
```

Property Value

A string that specifies the full path to a local directory on the server.

Remarks

The **Directory** property returns the path to the root directory for the server. If this property is set to the name of a valid directory before the server is started, that directory will be considered the root directory for the server. If this property is not set, or is set to an empty string, then the server will use the current working directory as its root directory, however this is not recommended. It is recommended that you specify an absolute path to the directory, otherwise the path will be relative to the current working directory. You may include environment variables in the path surrounded by percent (%) symbols and they will be expanded.

If you have configured the server to permit clients to upload files, you must ensure that your application has permission to create files in the directory that you specify. A recommended location for the server root directory would be a subdirectory of the %ALLUSERSPROFILE% directory. Using the environment variable ensures that your server will work correctly on different versions of Windows. If the root directory does not exist at the time that the server is started, it will be created.

If the **MultiUser** property is **False**, all authenticated clients will have their current working directory initialized to the server root directory. If the **MultiUser** property is **True**, then the Public and User subdirectories will be created in the root directory, and each authenticated client will have their current working directory initialized to their individual home directory.

This property can be read after the server has started and it will return the full path to the root directory. However, attempting to change the value of this property after the server has started will cause an exception to be raised. To change the root directory for the server, you must first call the **Stop** method which will terminate all active client connections.

See Also

FtpServer Class | SocketTools Namespace

FtpServer.ExternalAddress Property

Get and set the external IP address used for passive mode data transfers.

[Visual Basic]
```
Public Property ExternalAddress As String
```

[C#]
```
public string ExternalAddress {get; set;}
```

Property Value

A string that specifies an Internet Protocol address.

Remarks

When using passive mode file transfers, the server creates a second listening (passive) socket that is used to exchange data between the client and server. The client sends the PASV command, and the server responds with its IP address and the ephemeral port number that was selected for the transfer. If the server is located behind a router that performs Network Address Translation (NAT), the address that the server will return will typically be a non-routable IP address assigned to the local system on the LAN side of the network. Setting the **ExternalAddress** property will instruct the server to return a different IP address in response to the PASV command sent by the client. Typically you would use the address assigned to the router on the Internet side of the connection.

If the **ExternalAddresss** property is not assigned a specific address, reading this property value will cause the control to automatically determine its external IP address. This requires that you have an active connection to the Internet; checking the value of this property on a system that uses dial-up networking may cause the operating system to automatically connect to the Internet service provider. The control may be unable to determine the external IP address for the local host for a number of reasons, particularly if the system is behind a firewall or uses a proxy server that restricts access to external sites on the Internet. If the external address for the local host cannot be determined, the property will return an empty string.

This property will not change the IP address the server is using to listen for client connections. The only way to change the listening IP address is to stop and restart the server using the new address. This property only changes the IP address that is reported to clients when a passive data connection is used. Incorrect use of this property can prevent the client from establishing a data connection to the server. The address must be in the same address family as the local address that the server was started with. For example, if the server was started using an IPv4 address, the IP address assigned to this property cannot be an IPv6 address.

See Also

FtpServer Class | SocketTools Namespace

FtpServer.HiddenFiles Property

Determine if the server should permit access to hidden files.

[Visual Basic]

```
Public Property HiddenFiles As Boolean
```

[C#]

```
public bool HiddenFiles {get; set;}
```

Property Value

A Boolean value that specifies if hidden files can be accessed by clients.

Remarks

The **HiddenFiles** property determines if the server should allow clients to access files with the hidden and/or system attribute. If this property is **True**, then hidden files are included in directory listings and clients may download or replace hidden files. If the property is **False**, hidden files are not included in directory listings and any attempt to access, delete or modify a hidden file will result in an error.

The default value for this property is **False.**

See Also

FtpServer Class | SocketTools Namespace

FtpServer.Identity Property

Gets and sets a string that identifies the server to the client.

[Visual Basic]
```
Public Property Identity As String
```

[C#]
```
public string Identity {get; set;}
```

Property Value

A string that identifies the server instance.

Remarks

The **Identity** property returns a string that is used to identify the server. It is used for informational purposes only and does not affect the operation of the server. Typically the string specifies the name of the application and a version number, and is displayed whenever a client establishes its initial connection to the server. This property can be set to assign an identity to the server, however after the server has started this property becomes read-only.

See Also

FtpServer Class | SocketTools Namespace

FtpServer.IdleTime Property

Gets and sets the maximum number of seconds a client can be idle before the server terminates the session.

[Visual Basic]

```
Public Property IdleTime As Integer
```

[C#]

```
public int IdleTime {get; set;}
```

Property Value

An integer value that specifies the idle timeout period in seconds.

Remarks

The **IdleTime** property specifies the maximum number of seconds that a client session may be idle before the server closes the control connection to the client. A value of zero specifies the default value of 300 seconds (5 minutes). If the value is non-zero, the minimum value is 60 seconds and the maximum value is 7200 seconds (2 hours). This value is used to initialize the default idle timeout period for each client session. A client may request that the server change the idle timeout period for its session by sending the SITE IDLE command. The server determines if a client is idle based on the time the last command was issued and whether or not a file transfer is in progress.

The **ClientIdle** property can be used to determine the idle timeout period for a specific client. When the timeout period for the client has elapsed, the **OnTimeout** event will fire prior to the client being disconnected from the server.

See Also

FtpServer Class | SocketTools Namespace

FtpServer.IsActive Property

Gets a value which indicates if the server is active.

[Visual Basic]

```
Public ReadOnly Property IsActive As Boolean
```

[C#]

```
public bool IsActive {get;}
```

Property Value

A Boolean value that specifies if the server instance is currently active.

Remarks

The **IsActive** property returns **True** if the server has been started using the **Start** method. If the server has not been started, the property will return **False**.

To determine if the server is accepting client connections, use the **IsListening** property. This property will only indicate if the server has been started. For example, if the server has been suspended using the **Suspend** method, this property will return a value of **True**, while the **IsListening** property will return a value of **False**.

An application should not depend on this property returning **False** immediately after the **Stop** method has been called to shutdown the server. This property will continue to return **True** until all clients have disconnected from the server and the server thread has terminated. To determine when the server has stopped, implement a handler for the **OnStop** event.

See Also

FtpServer Class | SocketTools Namespace

FtpServer.IsAnonymous Property

Determine if the active client session has authenticated as an anonymous user.

[Visual Basic]

```
Public ReadOnly Property IsAnonymous As Boolean
```

[C#]

```
public bool IsAnonymous {get;}
```

Property Value

A Boolean value that specifies if the active client session is anonymous.

Remarks

The **IsAnonymous** property returns **True** if the active client session has authenticated as an anonymous (guest) user. This property should only be accessed within an event handler such as **OnCommand** because its value is specific to the client session that raised the event. This property will always return a value of **False** outside of an event handler.

See Also

FtpServer Class | SocketTools Namespace

FtpServer.IsAuthenticated Property

Determine if the active client session has been authenticated.

[Visual Basic]

```
Public ReadOnly Property IsAuthenticated As Boolean
```

[C#]

```
public bool IsAuthenticated {get;}
```

Property Value

A Boolean value that specifies if the active client session has been authenticated.

Remarks

The **IsAuthenticated** property returns **True** if the active client session has successfully authenticated with a valid username and password. This property should only be accessed within an event handler such as **OnCommand** because its value is specific to the client session that raised the event. This property will always return a value of **False** outside of an event handler.

See Also

FtpServer Class | SocketTools Namespace

FtpServer.IsInitialized Property

Gets a value which indicates if the current instance of the class has been initialized successfully.

[Visual Basic]
```
Public ReadOnly Property IsInitialized As Boolean
```

[C#]
```
public bool IsInitialized {get;}
```

Property Value

Returns **true** if the class instance has been initialized; otherwise returns **false**.

Remarks

The **IsInitialized** property is used to determine if the current instance of the class has been initialized properly. Normally this is done automatically by the class constructor, however there are circumstances where the class may not be able to initialize itself.

The most common reasons that a class instance may not initialize correctly is that no runtime license key has been defined in the assembly or the license key provided is invalid. It may also indicate a problem with the system configuration or user access rights, such as not being able to load the required networking libraries or not being able to access the system registry.

See Also

FtpServer Class | SocketTools Namespace

FtpServer.IsListening Property

Gets a value which indicates if the server is listening for client connections.

[Visual Basic]

```
Public ReadOnly Property IsListening As Boolean
```

[C#]

```
public bool IsListening {get;}
```

Property Value

Returns **true** if the server is listening for client connections; otherwise returns **false**.

Remarks

The **IsListening** property will return **true** if the **Start** method was called and the server is currently accepting incoming client connections. In all other situations, this property will return **false**.

See Also

FtpServer Class | SocketTools Namespace

FtpServer.LastError Property

Gets and sets a value which specifies the last error that has occurred.

[Visual Basic]

```
Public Property LastError As ErrorCode
```

[C#]

```
public FtpServer.ErrorCode LastError {get; set;}
```

Property Value

Returns an ErrorCode enumeration value which specifies the last error code.

Remarks

The **LastError** property returns the error code associated with the last error that occurred for the current instance of the class. It is important to note that this value only has meaning if the previous method indicates that an error has actually occurred.

It is possible to explicitly clear the last error code by assigning the property to the value **ErrorCode.errorNone**.

The error code value can be cast to an integer value for display purposes if required. For a description of the error that can be displayed using a message box or some other similar mechanism, get the value of the **LastErrorString** property.

See Also

FtpServer Class | SocketTools Namespace

FtpServer.LastErrorString Property

Gets a value which describes the last error that has occurred.

[Visual Basic]

```
Public ReadOnly Property LastErrorString As String
```

[C#]

```
public string LastErrorString {get;}
```

Property Value

A string which describes the last error that has occurred.

Remarks

The **LastErrorString** property can be used to obtain a description of the last error that occurred for the current instance of the class. It is important to note that this value only has meaning if the previous method indicates that an error has actually occurred.

See Also

FtpServer Class | SocketTools Namespace

FtpServer.LocalPath Property

Return the full path to the local file or directory that is the target of the current command.

[Visual Basic]

```
Public Property LocalPath As String
```

[C#]

```
public string LocalPath {get; set;}
```

Property Value

A string that specifies the full path to a local file or directory on the server.

Remarks

The **LocalPath** property returns the full path to a local file name or directory specified by the client as an argument to a standard FTP command. For example, if the client sends the RETR command to the server, this property will return the complete path to the local file that the client wants to download. This property will only return a value for those standard commands that perform some action on a file or directory, otherwise it will return an empty string.

Setting this property allows you to effectively redirect the client to use a different file than the one that was actually requested. If the path is absolute, then it will be used as-is. If the path is relative, it will be relative to the current working directory for the active client session. The full path to this file is not limited to the server root directory or its subdirectory, it can specify a file anywhere on the local system. If this property is set to an empty string, then the server will revert to using the actual file or directory name specified by the command.

This property should only be set within an **OnCommand** event handler, and only for those commands that perform an action on a file or directory. If the current command does not target a file or directory, setting this property will cause an exception to be raised by the control. Exercise caution when using this property to redirect the server to use a different file than the one requested by the client; changing the target file may cause the client to behave in unexpected ways.

See Also

FtpServer Class | SocketTools Namespace

FtpServer.LocalTime Property

Determines if the server should return file and directory times adjusted for the local timezone.

[Visual Basic]

```
Public Property LocalTime As Boolean
```

[C#]

```
public bool LocalTime {get; set;}
```

Property Value

A Boolean value that specifies of files should be listed using the local timezone on the server.

Remarks

The **LocalTime** property determines if the server should return file and directory times adjusted for the local timezone. By default, the server will return all file times as UTC values. This option affects the time information sent to a client when a list of files is requested, as well as when status information is requested for a specific file. This property value will not affect the MDTM and MFMT commands which always use file times as UTC values.

The default value for this property is **False**.

See Also

FtpServer Class | SocketTools Namespace

FtpServer.LocalUser Property

Determines if the server should perform user authentication using the Windows local account database.

[Visual Basic]

```
Public Property LocalUser As Boolean
```

[C#]

```
public bool LocalUser {get; set;}
```

Property Value

A Boolean value that specifies if the server should authenticate local users.

Remarks

The **LocalUser** property determines if the server should perform user authentication using the Windows local account database. If this option is not specified, the application is responsible for creating virtual users using the **AddUser** method or implementing an **OnAuthenticate** event handler and authenticating client sessions individually.

If this property is set to **True**, a client can authenticate as a local user, however the session will not inherit that user's access rights. All files that are accessed or created by the server will continue to use the permissions of the process that started the server. For example, consider a server application that was started by local user ***A***. Next, a client connects to the server and authenticates itself as local user ***B***. When that client uploads a file to the server, the file that is created will be owned by user ***A***, not user ***B***. This ensures that the server application retains ownership and control of the files that have been created or modified.

The default value for this property is **False**.

See Also

FtpServer Class | SocketTools Namespace

FtpServer.LockFiles Property

Determines if files should be exclusively locked when a client attempts to upload or download a file.

[Visual Basic]

```
Public Property LockFiles As Boolean
```

[C#]

```
public bool LockFiles {get; set;}
```

Property Value

A Boolean value that specifies if files should be locked during file transfers.

Remarks

The **LocalTime** property determines if files should be exclusively locked when a client attempts to upload or download a file. If another client attempts to access the same file, the operation will fail. By default, the server will permit multiple clients to access the same file, although it will still write-lock files that are in the process of being uploaded..

The default value for this property is **False**.

See Also

FtpServer Class | SocketTools Namespace

FtpServer.LogFile Property

Gets and sets the name of the server log file.

[Visual Basic]

```
Public Property LogFile As String
```

[C#]

```
public string LogFile {get; set;}
```

Property Value

A string that specifies the full path to a local log file.

Remarks

The **LogFile** property is used to specify the name of a file that will contain a log of all client activity. The **LogFormat** and **LogLevel** properties affect the specific format for the file and the level of detail included in the log. It is recommended that you specify an absolute path to the log file, otherwise the path will be relative to the current working directory. You may include environment variables in the path surrounded by percent (%) symbols and they will be expanded.

If the log file does not exist it will be created when the server is started. If file already exists, the server will append the new logging data to the file. The server must have permission to create and/or modify the specified file.

Setting this property to an empty string after the server has been started will have the effect of disabling logging, setting the logging level to 0 and the logging format to **FormatType.formatNone**.

See Also

FtpServer Class | SocketTools Namespace

FtpServer.LogFormat Property

Gets and sets the format used when updating the server log file.

[Visual Basic]

```
Public Property LogFormat As FormatType
```

[C#]

```
public FtpServer.FormatType LogFormat {get; set;}
```

Property Value

A FormatType enumeration that specifies the log file format.

See Also

FtpServer Class | SocketTools Namespace

FtpServer.LogLevel Property

Gets and sets the level of detail included in the server log file.

[Visual Basic]

```
Public Property LogLevel As Integer
```

[C#]

```
public int LogLevel {get; set;}
```

Property Value

An integer value that specifies the amount of information the server writes to the log file.

Remarks

The **LogLevel** property is used to specify the level of detail that should generated in the log file. The minimum value is 1 and the maximum value is 10. If this parameter is zero, it is the same as specifying a log file format of **ftpLogNone** and will disable logging by the server.

See Also

FtpServer Class | SocketTools Namespace

FtpServer.MaxClients Property

Gets and sets the maximum number of clients that can connect to the server.

[Visual Basic]

```
Public Property MaxClients As Integer
```

[C#]

```
public int MaxClients {get; set;}
```

Property Value

An integer value which specifies the maximum number of client sessions that will be accepted by the server. A value of zero specifies that there is no fixed limit to the maximum number of clients.

Remarks

The **MaxClients** property specifies the maximum number of client connections that will be accepted by the server. Once the maximum number of connections has been established, the server will reject any subsequent connections until the number of active client connections drops below the specified value. A value of zero specifies that there should be no limit on the number of clients.

Changing the value of this property while a server is actively listening for connections will modify the maximum number of client connections permitted, but it will not affect connections that have already been established.

By default, there are no limits on the number of client connections or the connection rate when a server is started. Use the **Throttle** method to change the maximum number of client connections per IP address or the overall connection rate threshold for the server.

It is important to note that regardless of the maximum number of clients specified by this property, the actual number of client connections that can be managed by the server depends on the number of sockets that can be allocated from the operating system. The amount of physical memory installed on the system affects the number of connections that can be maintained because each connection allocates memory for the socket context from the non-paged memory pool.

See Also

FtpServer Class | SocketTools Namespace

FtpServer.MaxGuests Property

Gets and sets the maximum number of anonymous users that are permitted to connect to the server.

[Visual Basic]

```
Public Property MaxGuests As Integer
```

[C#]

```
public int MaxGuests {get; set;}
```

Property Value

An integer value that specifies the maximum number of anonymous (guest) users.

Remarks

The **MaxGuests** property specifies the maximum number of guest users that will be accepted by the server. Once the maximum number of connections has been established, the server will reject any subsequent connections until the number of active guest users drops below the specified value. A guest user is one that authenticates with the username "anonymous" and their email address as the password.

Changing the value of this property while a server is actively listening for connections will modify the maximum number of guest logins permitted, but it will not affect connections that have already been established. You can also use the **Throttle** method to change the maximum number of clients, the maximum number of clients per IP address and the rate at which clients can connect to the server.

The default value for this property is zero, disabling guest logins. If your server is accessible to the public and you decide to allow guest users, it is recommended that you set the **Restricted** property to True, and you should not grant permission for guests to upload files or execute registered programs using the SITE EXEC command.

See Also

FtpServer Class | SocketTools Namespace

FtpServer.MaxPort Property

Gets and sets the maximum port number used by the server for passive data connections.

[Visual Basic]

```
Public Property MaxPort As Integer
```

[C#]

```
public int MaxPort {get; set;}
```

Property Value

An integer value that specifies the maximum port number.

Remarks

The **MaxPort** property specifies the maximum range of port numbers that will be used with passive data connections. A value of zero specifies the default value of 65535 should be used. The minimum value of this member is 10000 and the maximum value is 65535. If the value is non-zero, it must be greater than the value of the **MinPort** property.

Attempting to change the value of this property after the server has started will cause an exception to be raised. To change the maximum port number for the server, you must first call the **Stop** method which will terminate all active client connections.

See Also

FtpServer Class | SocketTools Namespace

FtpServer.MinPort Property

Gets and sets the maximum port number used by the server for passive data connections.

[Visual Basic]

```
Public Property MinPort As Integer
```

[C#]

```
public int MinPort {get; set;}
```

Property Value

An integer value that specifies the minimum port number.

Remarks

The **MinPort** property specifies the minimum range of port numbers that will be used with passive data connections. A value of zero specifies that the default value of 30000 should be used. The minimum value of this member is 10000 and the maximum value is 65535. If the value is non-zero, it must be less than the value of the **MaxPort** property.

Attempting to change the value of this property after the server has started will cause an exception to be raised. To change the minimum port number for the server, you must first call the **Stop** method which will terminate all active client connections.

FtpServer.MemoryUsage Property

Gets the amount of unmanaged memory currently allocated by the server.

[Visual Basic]

```
Public ReadOnly Property MemoryUsage As Long
```

[C#]

```
public long MemoryUsage {get;}
```

Property Value

A long integer which specifies the number of bytes of memory allocated.

Remarks

This read-only property returns the amount of memory allocated by the server and all active client sessions. It enumerates all unmanaged memory allocations made by the server process and client session threads, returning the total number of bytes allocated for the server. This value reflects the amount of memory explicitly allocated by the class and does not reflect the total working set size of the process, or the memory allocated on the managed heap which is used by the .NET garbage collector.

Getting the value of this property forces the server into a locked state, and all client sessions will block while the memory usage is being calculated. Because this enumerates all unmanaged heaps allocated for the server process, it can be an expensive operation, particularly when there are a large number of active clients connected to the server. Frequently checking the value of this property can significantly degrade the performance of the server. It is primarily intended for use as a debugging tool to determine if memory usage is the result of an increase in active client sessions. If the value returned by this property remains reasonably constant, but the amount of memory allocated for the process continues to grow, it could indicate a memory leak in some other area of the application.

FtpServer Class | SocketTools Namespace | StackSize Property

FtpServer.MultiUser Property

Determine if the server should be started in multi-user mode.

[Visual Basic]

```
Public Property MultiUser As Boolean
```

[C#]

```
public bool MultiUser {get; set;}
```

Property Value

A Boolean value that specifies if the server should be started in multi-user mode.

Remarks

The **MultiUser** property determines if the server should be started in multi-user mode. If this property is set to **True**, each user will be assigned their own home directory which will be based on their user name. When a client authenticates as that user, its current working directory is set to the user's home directory. If this property is set to **False**, then all users will share the server root directory by default. This property does not affect the maximum number of simultaneous client connections to the server. To isolate users to their own individual home directory, set the **Restricted** property to **True**.

Setting this property to **True** will cause the server to create two subdirectories under the server root directory named Public and Users. The Public subdirectory is where public files should be stored, and also serves as the home directory for anonymous (guest) users. The Users subdirectory is where the home directories for each user will be created.

Attempting to change the value of this property after the server has started will cause an exception to be raised. To change this property value, you must first call the **Stop** method which will terminate all active client connections.

The default value for this property is **False**.

See Also

FtpServer Class | SocketTools Namespace

FtpServer.Options Property

Gets and sets the options that may be specified for the server instance.

[Visual Basic]

```
Public Property Options As ServerOptions
```

[C#]

```
public FtpServer.ServerOptions Options {get; set;}
```

Property Value

A ServerOptions enumeration that specifies one or more server options.

Remarks

The **Options** property is used to specify one or more server options as bitflags using the ServerOptions enumeration. Each option has a corresponding property, and it is recommended that you use those properties, such as **LocalUser** and **UnixMode**, to specify whether a particular server option should be enabled or disabled. Using the class properties will make your code more readable and ensure forward compatibility.

See Also

FtpServer Class | SocketTools Namespace

FtpServer.Priority Property

Gets and sets a value which specifies the server priority.

[Visual Basic]
```
Public Property Priority As ServerPriority
```

[C#]
```
public FtpServer.ServerPriority Priority {get; set;}
```

Property Value

Returns a ServerPriority enumeration value which specifies the current server priority. The default value for this property is **priorityNormal**.

Remarks

The **Priority** property can be used to control the processor usage, memory and network bandwidth allocated by the server for client sessions. The default priority balances resource utilization and client throughput while ensuring that the user interface remains responsive to the user. Lower priorities reduce the overall resource utilization at the expense of throughput.

Higher priority values increases the thread priority and processor utilization for the client sessions. It is not recommended that you increase the server priority unless you understand the implications of doing so and have thoroughly tested your application. Raising the priority of the server can have a negative impact on the responsiveness of the user interface.

See Also

FtpServer Class | SocketTools Namespace | ServerPriority Enumeration

FtpServer.ReadOnly Property

Determine if the server should prevent clients from uploading files.

[Visual Basic]

```
Public Property ReadOnly As Boolean
```

[C#]

```
public bool ReadOnly {get; set;}
```

Property Value

A Boolean value that specifies if clients have read-only access to the server.

Remarks

The **ReadOnly** property determines if the server should only allow read-only access to files by default, changing the default permissions granted to authenticated users. If this property is set to **True**, anonymous users will not be able to upload, rename or delete files and cannot create subdirectories. This is recommended if the server is publicly accessible over the Internet and guest logins are permitted.

Attempting to change the value of this property after the server has started will cause an exception to be raised. To change this property value, you must first call the **Stop** method which will terminate all active client connections.

The default value for this property is **False**.

See Also

FtpServer Class | SocketTools Namespace

FtpServer.Restricted Property

Determine if the server should be started in restricted mode, limiting client access to the server.

[Visual Basic]

```
Public Property Restricted As Boolean
```

[C#]

```
public bool Restricted {get; set;}
```

Property Value

A Boolean value that specifies if client access to the server is restricted.

Remarks

The **Restricted** property determines if the server should be initialized in a restricted mode that isolates the server and limits the ability for clients to access files on the host system. If this property is set to **True**, all file transfers are limited to the user's home directory and certain site-specific commands are disabled. This is recommended for general purpose applications designed to accept connections from clients over the Internet. This property value is only meaningful if the **MultiUser** property has also been set to **True**.

Attempting to change the value of this property after the server has started will cause an exception to be raised. To change this property value, you must first call the **Stop** method which will terminate all active client connections.

The default value for this property is **False**.

See Also

FtpServer Class | SocketTools Namespace

FtpServer.Secure Property

Determine if the server should accept secure client connections.

[Visual Basic]
```
Public Property Secure As Boolean
```

[C#]
```
public bool Secure {get; set;}
```

Property Value

A Boolean value that specifies if the server should accept secure connections.

Remarks

The **Secure** property determines if client connections are encrypted using the standard SSL or TLS security protocols. The default value for this property is **False**, which specifies that clients will use a standard, unencrypted connection to the server. To enable secure connections, the application should set this property value to **True** prior to calling the **Start** method.

When secure connections are enabled, the server will accept the client connection and then wait for the client to initiate the handshake where both the client and server negotiate the various encryption options available. This process is handled automatically by the server, and all that is required is that the application specify the server certificate which should be used. This is done by setting the **CertificateName** property, and optionally the **CertificateStore** property if required.

See Also

FtpServer Class | SocketTools Namespace

FtpServer.ServerAddress Property

Gets and sets the address that will be used by the server to listen for connections.

[Visual Basic]

```
Public Property ServerAddress As String
```

[C#]

```
public string ServerAddress {get; set;}
```

Property Value

A string which specifies the IP address that the server will use to listen for incoming client connections. An empty string indicates that the server will accept connections on any valid network interface configured for the local system.

Remarks

The **ServerAddress** property is used to specify the default address that the server will use when listening for connections. Setting this property to the value 0.0.0.0 or an empty string indicates that the server should listen for client connections using any valid network interface. If an address is specified, it must be a valid Internet address that is bound to a network adapter configured on the local system. Clients will only be able to connect to the server using that specific address.

It is common to set this property to the value 127.0.0.1 for testing purposes. It is a non-routable address that specifies the local system, and most software firewalls are configured so they do not block applications using this address.

See Also

FtpServer Class | SocketTools Namespace | ServerName Property | ServerPort Property

FtpServer.ServerName Property

Gets a value which specifies the host name for the local system.

[Visual Basic]

```
Public Property ServerName As String
```

[C#]

```
public string ServerName {get; set;}
```

Property Value

A string which specifies the local host name.

Remarks

The **ServerName** property returns the fully-qualified host name assigned to the local system. This consists of the local computer name and its domain name. The actual value returned depends on the system configuration. If no domain has been specified for the system, then only the machine name will be returned.

See Also

FtpServer Class | SocketTools Namespace

FtpServer.ServerPort Property

Gets and sets the port number that will be used by the server to listen for connections.

[Visual Basic]

```
Public Property ServerPort As Integer
```

[C#]

```
public int ServerPort {get; set;}
```

Property Value

An integer value which specifies the port number.

Remarks

The **ServerPort** property is used to set the port number that server will use to listen for incoming client connections. Valid port numbers are in the range of 1 to 65535. It is recommended that most custom servers specify a port number larger than 5000 to avoid potential conflicts with standard Internet services and ephemeral ports used by client applications.

If a port number is specified that is already in use by another application, the **OnError** event will fire and the background server thread will terminate. To enable a server to be stopped and immediately restarted using the same address and port number, make sure that the **ReuseAddress** property is set to a value of **true**.

See Also

FtpServer Class | SocketTools Namespace | ServerAddress Property | ServerName Property

FtpServer.ServerThread Property

Gets the thread ID for the current server.

[Visual Basic]

```
Public ReadOnly Property ServerThread As Integer
```

[C#]

```
public int ServerThread {get;}
```

Property Value

An integer value which identifies the server thread that was created. A return value of zero specifies that no server has been started.

Remarks

Until the thread terminates, the thread identifier uniquely identifies the thread throughout the system.

See Also

FtpServer Class | SocketTools Namespace

FtpServer.ServerUuid Property

Gets and sets the Universally Unique Identifier (UUID) associated with the server.

[Visual Basic]

```
Public Property ServerUuid As String
```

[C#]

```
public string ServerUuid {get; set;}
```

Property Value

A string that specifies the UUID assigned to the server instance.

Remarks

The **ServerUuid** property returns the UUID that uniquely identifies this instance of the server. If the application does not set this property, a temporary UUID will be assigned to the server. If a value is assigned to this property, it must be a valid UUID string. A permanent UUID can be generated using a utility such as **uuidgen** which is included with Visual Studio.

Attempting to change the value of this property after the server has started will cause an exception to be raised. To change this property value, you must first call the **Stop** method which will terminate all active client connections.

See Also

FtpServer Class | SocketTools Namespace

FtpServer.StackSize Property

Gets and sets the size of the stack allocated for threads created by the server.

[Visual Basic]

```
Public Property StackSize As Integer
```

[C#]

```
public int StackSize {get; set;}
```

Property Value

An integer value that specifies the initial amount of memory that is committed to the stack for each thread created by the server.

Remarks

The default stack size for each thread is set to 256K for 32-bit processes and 512K for 64-bit processes. Increasing or decreasing the stack size will only affect new threads that are created by the server, it will not affect those threads that have already been created to manage active client sessions. It is recommended that most applications use the default stack size.

See Also

FtpServer Class | SocketTools Namespace

FtpServer.ThrowError Property

Gets and sets a value which specifies if method calls should throw exceptions when an error occurs.

[Visual Basic]

```
Public Property ThrowError As Boolean
```

[C#]

```
public bool ThrowError {get; set;}
```

Property Value

Returns **true** if method calls will generate exceptions when an error occurs; otherwise returns **false**. The default value is **false**.

Remarks

Error handling for when calling class methods can be done in either of two different styles, according to the value of this property.

If the **ThrowError** property is set to **false**, the application should check the return value of any method that is used, and report errors based upon the documented value of the return code. It is the responsibility of the application to interpret the error code, if it is desired to explain the error in addition to reporting it. This is the default behavior.

If the **ThrowError** property is set to **true**, then exceptions will be generated whenever a method call fails. The program must be written to catch these exceptions and take the appropriate action when an error occurs. Failure to handle an exception will cause the program to terminate abnormally.

Note that if an error occurs while a property is being read or modified, an exception will be raised regardless of the value of the **ThrowError** property.

See Also

FtpServer Class | SocketTools Namespace

FtpServer.Trace Property

Gets and sets a value which indicates if network function logging is enabled.

[Visual Basic]

```
Public Property Trace As Boolean
```

[C#]

```
public bool Trace {get; set;}
```

Property Value

Returns **true** if network function tracing is enabled; otherwise returns **false**. The default value is **false**.

Remarks

The **Trace** property is used to enable (or disable) the tracing of network function calls. When enabled, each function call is logged to a file, including the function parameters, return value and error code if applicable. This facility can be enabled and disabled at run time, and the trace log file can be specified by setting the **TraceFile** property. All function calls that are being logged are appended to the trace file, if it exists. If no trace file exists when tracing is enabled, the trace file is created.

The tracing facility is available in all of the SocketTools networking classes and is enabled or disabled for an entire process. This means that once trace logging is enabled for a given component, all of the function calls made by the process using any of the SocketTools classes will be logged. For example, if you have an application using both the File Transfer Protocol and Post Office Protocol classes, and you set the **Trace** property to **true**, function calls made by both classes will be logged. Additionally, enabling a trace is cumulative, and tracing is not stopped until it is disabled for all classes used by the process.

If trace logging is not enabled, there is no negative impact on performance or throughput. Once enabled, application performance can degrade, especially in those situations in which multiple processes are being traced or the logfile is fairly large. Since logfiles can grow very quickly, even with modest applications, it is recommended that you delete the file when it is no longer needed.

When redistributing your application, make sure that you include the **SocketTools10.TraceLog.dll** module with your installation. If this library is not present, then no trace output will be generated and the value of the **Trace** property will be ignored. Only those function calls made by the SocketTools networking classes will be logged. Calls made directly to the Windows Sockets API, or calls made by other classes, will not be logged.

See Also

FtpServer Class | SocketTools Namespace

FtpServer.TraceFile Property

Gets and sets a value which specifies the name of the network function tracing logfile.

[Visual Basic]

```
Public Property TraceFile As String
```

[C#]

```
public string TraceFile {get; set;}
```

Property Value

A string which specifies the name of the file.

Remarks

The **TraceFile** property is used to specify the name of the trace file that is created when network function tracing is enabled. If this property is set to an empty string (the default value), then a file named **SocketTools.log** is created in the system's temporary directory. If no temporary directory exists, then the file is created in the current working directory.

If the file exists, the trace output is appended to the file, otherwise the file is created. Since network function tracing is enabled per-process, the trace file is shared by all instances of the class being used. If multiple class instances have tracing enabled, the **TraceFile** property should be set to the same value for each instance. Since trace files can grow very quickly, even with modest applications, it is recommended that you delete the file when it is no longer needed.

The trace file has the following format:

```
 MyApp INF: WSAAsyncSelect(46, 0xcc4, 0x7e9, 0x27) returned 0 MyApp WRN:
connect(46, 192.0.0.1:1234, 16) returned -1 [10035] MyApp ERR: accept(46,
NULL, 0x0) returned -1 [10038]
```

The first column contains the name of the process that is being traced. The second column identifies if the trace record is reporting information, a warning, or an error. What follows is the name of the function being called, the arguments passed to the function and the function's return value. If a warning or error is reported, the error code is appended to the record (the value is placed inside brackets).

If parameters are passed as integer values, they are recorded in decimal. If the parameter or return value is a pointer (a memory address), it is recorded as a hexadecimal value preceded with "0x". A special type of pointer, called a null pointer, is recorded as NULL. Those functions which expect socket addresses are displayed in the following format:

```
aa.bb.cc.dd:nnnn
```

The first four numbers separated by periods represent the IP address, and the number following the colon represents the port number in host byte order. Note that in the second line of the above example, the control is attempting to connect to a system with the IP address 192.0.0.1 on port 1234.

Note that if the specified file cannot be created, or the user does not have permission to modify an existing file, the error is silently ignored and no trace output will be generated.

See Also

FtpServer Class | SocketTools Namespace

FtpServer.TraceFlags Property

Gets and sets a value which specifies the network function tracing flags.

[Visual Basic]

```
Public Property TraceFlags As TraceOptions
```

[C#]

```
public FtpServer.TraceOptions TraceFlags {get; set;}
```

Property Value

A TraceOptions enumeration which specifies the amount of detail written to the trace logfile.

Remarks

The **TraceFlags** property is used to specify the type of information written to the trace file when network function tracing is enabled.

Because network function tracing is enabled per-process, the trace flags are shared by all instances of the class being used. If multiple class instances have tracing enabled, the **TraceFlags** property should be set to the same value for each instance. Changing the trace flags for any one instance of the class will affect the logging performed for all SocketTools classes used by the application.

Warnings are generated when a non-fatal error is returned by a network function. For example, if data is being written and the error **errorOperationWouldBlock** occurs, a warning is generated because the application simply needs to attempt to write the data at a later time.

See Also

FtpServer Class | SocketTools Namespace

FtpServer.UnixMode Property

Determine if the server should impersonate a UNIX-based operating system.

[Visual Basic]

```
Public Property UnixMode As Boolean
```

[C#]

```
public bool UnixMode {get; set;}
```

Property Value

A Boolean value that specifies if the server should impersonate a UNIX based server.

Remarks

The **UnixMode** property determines if the server should impersonate a UNIX-based operating system. If this property is set to a value of **True**, the server will identify itself as running on a UNIX system and directory listings will be in a format commonly used by UNIX. If this property value is **False**, the server will identify itself as running on Windows NT and directory listings will be in the same format used by the Microsoft IIS FTP server. Note that this option does not affect the path delimiter used with file and directory names.

Attempting to change the value of this property after the server has started will cause an exception to be raised. To change this property value, you must first call the **Stop** method which will terminate all active client connections.

The default value for this property is **False**.

See Also

FtpServer Class | SocketTools Namespace

FtpServer.Version Property

Gets a value which returns the current version of the FtpServer class library.

[Visual Basic]

```
Public ReadOnly Property Version As String
```

[C#]

```
public string Version {get;}
```

Property Value

A string which specifies the version of the class library.

Remarks

The **Version** property returns a string which identifies the current version and build of the FtpServer class library. This value can be used by an application for validation and debugging purposes.

See Also

FtpServer Class | SocketTools Namespace

FtpServer.VirtualPath Property

Return the virtual path to the local file or directory that is the target of the current command.

[Visual Basic]

```
Public Property VirtualPath As String
```

[C#]

```
public string VirtualPath {get; set;}
```

Property Value

A string that specifies the virtual path to the local file accessed by the active client session.

Remarks

The **VirtualPath** property returns the virtual path to a local file name or directory specified by the client as an argument to a standard FTP command. For example, if the client sends the RETR command to the server, this property will return the complete virtual path to the file that the client wants to download. This property will only return a value for those standard commands that perform some action on a file or directory, otherwise it will return an empty string.

Setting this property allows you to effectively redirect the client to use a different file than the one that was actually requested. If the path is absolute, then it will be used as-is. If the path is relative, it will be relative to the current working directory for the active client session. If this property is set to an empty string, then the server will revert to using the actual file or directory name specified by the command.

This property should only be set within an **OnCommand** event handler, and only for those commands that perform an action on a file or directory. If the current command does not target a file or directory, setting this property will cause an exception to be raised by the control. Exercise caution when using this property to redirect the server to use a different file than the one requested by the client; changing the target file may cause the client to behave in unexpected ways.

FtpServer Class | SocketTools Namespace

FtpServer Methods

The methods of the **FtpServer** class are listed below. For a complete list of **FtpServer** class members, see the FtpServer Members topic.

Public Static (Shared) Methods

ErrorText	Returns the description of an error code.

Public Instance Methods

AddUser	Overloaded. Add a new virtual user to the server.
Authenticate	Overloaded. Authenticate the client and assign access rights for the session.
DeleteUser	Remove a virtual user from the server.
Disconnect	Overloaded. Disconnect the specified client session from the server.
Dispose	Overloaded. Releases all resources used by FtpServer.
Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from Object)	Gets the Type of the current instance.
Initialize	Overloaded. Initialize an instance of the FtpServer class.
RegisterProgram	Overloaded. Register a program for use with the SITE EXEC command.
Reset	Reset the internal state of the object, resetting all properties to their default values.
ResolvePath	Overloaded. Resolve a path to its full virtual or local file name.
Restart	Restarts the server and terminates all active client connections.
Resume	Resume accepting new client connections.
SendResponse	Overloaded. Send a result code and message to the client in response to a command.
Start	Overloaded. Start listening for client connections on the specified IP address and port number.
Stop	Stop listening for new client connections and terminate all active clients already connected to the server.
Suspend	Suspend accepting new client connections.

Throttle	Overloaded. Limit the maximum number of client connections, connections per IP address and connection rate.
ToString (inherited from Object)	Returns a String that represents the current Object.
Uninitialize	Uninitialize the class library and release any resources allocated for the server.

Protected Instance Methods

Dispose	Overloaded. Releases the unmanaged resources allocated by the FtpServer class and optionally releases the managed resources.
Finalize	Destroys an instance of the class, releasing the resources allocated for the session and unloading the networking library.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

FtpServer.AddUser Method

Add a new virtual user to the server.

Overload List

Add a new virtual user to the server.

public bool AddUser(string,string);

Add a new virtual user to the server.

public bool AddUser(string,string,UserAccess,string);

Add a new virtual user to the server.

public bool AddUser(string,string,string);

See Also

FtpServer Class | SocketTools Namespace

FtpServer.AddUser Method (String, String, UserAccess, String)

Add a new virtual user to the server.

[Visual Basic]

```
Overloads Public Function AddUser( _
   ByVal userName As String, _
   ByVal userPassword As String, _
   ByVal accessFlags As UserAccess, _
   ByVal homeDirectory As String _
) As Boolean
```

[C#]

```
public bool AddUser(
   string userName,
   string userPassword,
   UserAccess accessFlags,
   string homeDirectory
);
```

Parameters

userName

A string which specifies the user name. The maximum length of a username is 63 characters and it is recommended that names be limited to alphanumeric characters. Whitespace, control characters and certain symbols such as path delimiters and wildcard characters are not permitted. If an invalid character is included in the name, the method will fail with an error indicating the username is invalid. The username must be at least three characters in length. Usernames are not case sensitive.

userPassword

A string which specifies the user password. The maximum length of a password is 63 characters and is limited to printable characters. Whitespace and control characters are not permitted. If an invalid character is included in the password, the function will fail with an error indicating the password is invalid. The password must be at least one character in length. Passwords are case sensitive.

accessFlags

A UserAccess enumeration which specifies the access clients will be given when authenticated as this user.

homeDirectory

A string which specifies the directory that will be the virtual user's home directory. If the server was started in multi-user mode, this directory will be relative to the user directory created by the server, otherwise it will be relative to the server root directory. If the directory does not exist, it will be created the first time that the virtual user successfully logs in to the server. If this parameter is an empty string, a default home directory will be created for the virtual user.

Return Value

A boolean value which specifies if the virtual user was added to the server. A return value of **true** specifies that the operation was successful. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **AddUser** method creates a virtual user that is associated with the server. When a client connects with the server and provides authentication credentials, the server will check if the username has been created using this method. If a match is found, the client access rights will be updated.

If you wish to modify the information for an existing user, it is not necessary to delete the username first. If this method is called with a username that already exists, that record is replaced with the values passed to this method. You cannot use this method to create a virtual user named "anonymous".

The virtual users created by this method exist only as long as the server is active. If you wish to maintain a persistent database of users and passwords, you are responsible for its implementation based on the requirements of your specific application. For example, a simple implementation would be to store the user information in a local XML or INI file and then read that configuration file after the server has started, calling this method for each user that is listed.

See Also

FtpServer Class | SocketTools Namespace | FtpServer.AddUser Overload List

FtpServer.AddUser Method (String, String, String)

Add a new virtual user to the server.

[Visual Basic]

```
Overloads Public Function AddUser( _
   ByVal userName As String, _
   ByVal userPassword As String, _
   ByVal homeDirectory As String _
) As Boolean
```

[C#]

```
public bool AddUser(
   string userName,
   string userPassword,
   string homeDirectory
);
```

Parameters

userName

A string which specifies the user name. The maximum length of a username is 63 characters and it is recommended that names be limited to alphanumeric characters. Whitespace, control characters and certain symbols such as path delimiters and wildcard characters are not permitted. If an invalid character is included in the name, the method will fail with an error indicating the username is invalid. The username must be at least three characters in length. Usernames are not case sensitive.

userPassword

A string which specifies the user password. The maximum length of a password is 63 characters and is limited to printable characters. Whitespace and control characters are not permitted. If an invalid character is included in the password, the function will fail with an error indicating the password is invalid. The password must be at least one character in length. Passwords are case sensitive.

homeDirectory

A string which specifies the directory that will be the virtual user's home directory. If the server was started in multi-user mode, this directory will be relative to the user directory created by the server, otherwise it will be relative to the server root directory. If the directory does not exist, it will be created the first time that the virtual user successfully logs in to the server. If this parameter is an empty string, a default home directory will be created for the virtual user.

Return Value

A boolean value which specifies if the virtual user was added to the server. A return value of **true** specifies that the operation was successful. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **AddUser** method creates a virtual user that is associated with the server. When a client connects with the server and provides authentication credentials, the server will check if the username has been created using this method. If a match is found, the client access rights will be updated.

If you wish to modify the information for an existing user, it is not necessary to delete the username first. If this method is called with a username that already exists, that record is replaced with the values passed to this method. You cannot use this method to create a virtual user named "anonymous".

The virtual users created by this method exist only as long as the server is active. If you wish to maintain a persistent database of users and passwords, you are responsible for its implementation based on the requirements of your specific application. For example, a simple implementation would be to store the user information in a local XML or INI file and then read that configuration file after the server has started, calling this method for each user that is listed.

FtpServer Class | SocketTools Namespace | FtpServer.AddUser Overload List

FtpServer.AddUser Method (String, String)

Add a new virtual user to the server.

[Visual Basic]

```
Overloads Public Function AddUser( _
   ByVal userName As String, _
   ByVal userPassword As String _
) As Boolean
```

[C#]

```
public bool AddUser(
   string userName,
   string userPassword
);
```

Parameters

userName

A string which specifies the user name. The maximum length of a username is 63 characters and it is recommended that names be limited to alphanumeric characters. Whitespace, control characters and certain symbols such as path delimiters and wildcard characters are not permitted. If an invalid character is included in the name, the method will fail with an error indicating the username is invalid. The username must be at least three characters in length. Usernames are not case sensitive.

userPassword

A string which specifies the user password. The maximum length of a password is 63 characters and is limited to printable characters. Whitespace and control characters are not permitted. If an invalid character is included in the password, the function will fail with an error indicating the password is invalid. The password must be at least one character in length. Passwords are case sensitive.

Return Value

A boolean value which specifies if the virtual user was added to the server. A return value of **true** specifies that the operation was successful. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **AddUser** method creates a virtual user that is associated with the server. When a client connects with the server and provides authentication credentials, the server will check if the username has been created using this method. If a match is found, the client access rights will be updated.

If you wish to modify the information for an existing user, it is not necessary to delete the username first. If this method is called with a username that already exists, that record is replaced with the values passed to this method. You cannot use this method to create a virtual user named "anonymous".

The virtual users created by this method exist only as long as the server is active. If you wish to maintain a persistent database of users and passwords, you are responsible for its implementation based on the requirements of your specific application. For example, a simple implementation would be to store the user information in a local XML or INI file and then read that configuration file after the server has started, calling this method for each user that is listed.

FtpServer Class | SocketTools Namespace

FtpServer.Authenticate Method (Int32, UserAccess, String)

Authenticate the client and assign access rights for the session.

[Visual Basic]

```
Overloads Public Function Authenticate( _
   ByVal clientId As Integer, _
   ByVal accessFlags As UserAccess, _
   ByVal homeDirectory As String _
) As Boolean
```

[C#]

```
public bool Authenticate(
   int clientId,
   UserAccess accessFlags,
   string homeDirectory
);
```

Parameters

clientId

An integer that identifies the client session.

accessFlags

A UserAccess enumeration which specifies the access clients will be given when authenticated as this user.

homeDirectory

A string which specifies the directory that will be the client's home directory. If the server was started in multi-user mode, this directory will be relative to the user directory created by the server, otherwise it will be relative to the server root directory. If the directory does not exist, it will be created. If this parameter is an empty string, a default home directory will be created for the client.

Return Value

A boolean value which specifies if the virtual user has been authenticated. A return value of **true** specifies that the operation was successful. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Authenticate** method authenticates a client session, typically in response to an **OnAuthenticate** event that indicates a client has requested authentication. It is recommended that most applications specify **accessDefault** as the *accessFlags* parameter for a client session, since this allows the server automatically grant the appropriate access based on the server configuration options for normal and anonymous users. If the server is going to be publicly accessible or third-party FTP clients will be used to access the server, you should always grant the **ftpAccessList** permission to clients. Many client applications will not function correctly if they are unable to obtain a list of files in the user's home directory.

If the server was started with the **MultiUser** and **Restricted** properties set to a value of **true**, the client session will be effectively locked to its home directory and cannot navigate to the server root directory. By default, restricted client sessions are also limited to only downloading files and requesting directory listings. If a client session is not restricted, the client can access files outside of its home directory. Regardless of this option, a client cannot access files outside of the server root directory.

If the **Restricted** property is **true** or the **accessAnonymous** permission is specified, the client session will be authenticated in a restricted mode and the access rights for the session will persist until the client disconnects from the server. Unlike regular users, the access rights for a restricted client cannot be changed by the server at a later point. This restriction is designed to prevent the inadvertent granting of rights to an untrusted client that could compromise the security of the server.

If the ***homeDirectory*** parameter is an empty string and the server has been started in multi-user mode, each user is assigned their own home directory based on their username. If the server has not been started in multi-user mode, then the default home directory will be the server root directory and is shared by all users. The **ClientHome** property will return the full path to the home directory for an authenticated client.

If the **accessExecute** permission is granted to the client session, it can execute external programs using the SITE EXEC command. Because the program is executed in the context of the server process, it is recommended that you limit access to this functionality and ensure that the programs being executed do not introduce any security risks to the operating system. This permission is never granted by default, and the SITE EXEC command will return an error if the client session is anonymous, regardless of whether this permission is granted or not.

This method is should only be used for custom authentication schemes and is not necessary if you have used the **AddUser** method to create virtual users.

FtpServer Class | SocketTools Namespace | FtpServer.Authenticate Overload List

FtpServer.Authenticate Method (UserAccess, String)

Authenticate the client and assign access rights for the session.

[Visual Basic]

```
Overloads Public Function Authenticate( _
   ByVal accessFlags As UserAccess, _
   ByVal homeDirectory As String _
) As Boolean
```

[C#]

```
public bool Authenticate(
   UserAccess accessFlags,
   string homeDirectory
);
```

Parameters

accessFlags

A UserAccess enumeration which specifies the access clients will be given when authenticated as this user.

homeDirectory

A string which specifies the directory that will be the client's home directory. If the server was started in multi-user mode, this directory will be relative to the user directory created by the server, otherwise it will be relative to the server root directory. If the directory does not exist, it will be created. If this parameter is an empty string, a default home directory will be created for the client.

Return Value

A boolean value which specifies if the virtual user has been authenticated. A return value of **true** specifies that the operation was successful. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Authenticate** method authenticates the active client session, typically in response to an **OnAuthenticate** event that indicates a client has requested authentication. It is recommended that most applications specify **accessDefault** as the *accessFlags* parameter for a client session, since this allows the server automatically grant the appropriate access based on the server configuration options for normal and anonymous users. If the server is going to be publicly accessible or third-party FTP clients will be used to access the server, you should always grant the **ftpAccessList** permission to clients. Many client applications will not function correctly if they are unable to obtain a list of files in the user's home directory.

If the server was started with the **MultiUser** and **Restricted** properties set to a value of **true**, the client session will be effectively locked to its home directory and cannot navigate to the server root directory. By default, restricted client sessions are also limited to only downloading files and requesting directory listings. If a client session is not restricted, the client can access files outside of its home directory. Regardless of this option, a client cannot access files outside of the server root directory.

If the **Restricted** property is **true** or the **accessAnonymous** permission is specified, the client session will be authenticated in a restricted mode and the access rights for the session will persist until the client disconnects from the server. Unlike regular users, the access rights for a restricted client cannot be changed by the server at a later point. This restriction is designed to prevent the inadvertent granting of rights to an untrusted client that could compromise the security of the server.

If the *homeDirectory* parameter is an empty string and the server has been started in multi-user mode, each user is assigned their own home directory based on their username. If the server has not been started in multi-user mode, then the default home directory will be the server root directory and is shared by all users. The **ClientHome** property will return the full path to the home directory for an authenticated client.

If the **accessExecute** permission is granted to the client session, it can execute external programs using the SITE EXEC command. Because the program is executed in the context of the server process, it is recommended that you limit access to this functionality and ensure that the programs being executed do not introduce any security risks to the operating system. This permission is never granted by default, and the SITE EXEC command will return an error if the client session is anonymous, regardless of whether this permission is granted or not.

This method is should only be used for custom authentication schemes and is not necessary if you have used the **AddUser** method to create virtual users.

FtpServer.DeleteUser Method

Remove a virtual user from the server.

[Visual Basic]

```
Public Function DeleteUser( _
   ByVal userName As String _
) As Boolean
```

[C#]

```
public bool DeleteUser(
   string userName
);
```

Parameters

userName

A string which specifies the user name to be deleted. Usernames are not case sensitive.

Return Value

A boolean value which specifies if the virtual user has been deleted. A return value of **true** specifies that the operation was successful. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **DeleteUser** method removes a virtual user that was created by a previous call to the **AddUser** method. This method will not match partial usernames and wildcard characters cannot be used to delete multiple users. Usernames are not case sensitive. You cannot use this method to delete the "anonymous" user.

FtpServer.Disconnect Method

Disconnect the specified client session from the server.

Overload List

Disconnect the specified client session from the server.

public void Disconnect();

Disconnect the specified client session from the server.

public void Disconnect(int);

See Also

FtpServer Class | SocketTools Namespace

FtpServer.Disconnect Method (Int32)

Disconnect the specified client session from the server.

[Visual Basic]

```
Overloads Public Sub Disconnect( _
   ByVal clientId As Integer _
)
```

[C#]

```
public void Disconnect(
   int clientId
);
```

Parameters

clientId

An integer that identifies the client session.

Return Value

A boolean value which specifies if the client has been signaled to disconnect from the server. A return value of **true** specifies that the operation was successful. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Disconnect** method terminates the specified client session, releasing the socket handle other resources that were allocated for the session. It is only necessary to use this method if you want the server to explicitly terminate a client connection. Normally the client will close its connection to the server, the **OnDisconnect** event will fire and the server will automatically disconnect the client.

This method signals the thread that is managing the client that it should disconnect from the server, and it will begin the process of terminating the session. This is an asynchronous process and it is not guaranteed that the client will have actually disconnected from the server at the time that this method returns to the caller.

See Also

FtpServer Class | SocketTools Namespace | FtpServer.Disconnect Overload List

FtpServer.Disconnect Method ()

Disconnect the specified client session from the server.

[Visual Basic]
```
Overloads Public Sub Disconnect()
```

[C#]
```
public void Disconnect();
```

Return Value

A boolean value which specifies if the client has been signaled to disconnect from the server. A return value of **true** specifies that the operation was successful. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Disconnect** method terminates the active client session, releasing the socket handle other resources that were allocated for the session. It is only necessary to use this method if you want the server to explicitly terminate a client connection. Normally the client will close its connection to the server, the **OnDisconnect** event will fire and the server will automatically disconnect the client.

This method signals the thread that is managing the client that it should disconnect from the server, and it will begin the process of terminating the session. This is an asynchronous process and it is not guaranteed that the client will have actually disconnected from the server at the time that this method returns to the caller.

FtpServer.Dispose Method

Releases all resources used by FtpServer.

Overload List

Releases all resources used by FtpServer.

public void Dispose();

Releases the unmanaged resources allocated by the FtpServer class and optionally releases the managed resources.

protected void Dispose(bool);

See Also

FtpServer Class | SocketTools Namespace

FtpServer.Dispose Method (Boolean)

Releases the unmanaged resources allocated by the FtpServer class and optionally releases the managed resources.

[Visual Basic]

```
Overloads Protected Sub Dispose( _
   ByVal disposing As Boolean _
)
```

[C#]

```
protected void Dispose(
   bool disposing
);
```

Parameters

disposing

A boolean value which should be specified as **true** to release both managed and unmanaged resources; **false** to release only unmanaged resources.

Remarks

The **Dispose** method terminates any active connection and explicitly releases the resources allocated for this instance of the class. In some cases, better performance can be achieved if the programmer explicitly releases resources when they are no longer being used. The **Dispose** method provides explicit control over these resources.

Unlike the **Uninitialize** method, once the **Dispose** method has been called, that instance of the class cannot be re-initialized and you should not attempt to access class properties or invoke any methods. Note that this method can be called even if other references to the object are active.

You should call **Dispose** in your derived class when you are finished using the derived class. The **Dispose** method leaves the derived class in an unusable state. After calling **Dispose**, you must release all references to the derived class and the **FtpServer** class so the memory they were occupying can be reclaimed by garbage collection.

See Also

FtpServer Class | SocketTools Namespace | FtpServer.Dispose Overload List

FtpServer.Dispose Method ()

Releases all resources used by FtpServer.

[Visual Basic]

```
NotOverridable Overloads Public Sub Dispose() _
    Implements IDisposable.Dispose
```

[C#]

```
public void Dispose();
```

Implements

IDisposable.Dispose

Remarks

The **Dispose** method stops the server, terminates all active client sessions and explicitly releases the resources allocated for this instance of the class. In some cases, better performance can be achieved if the programmer explicitly releases resources when they are no longer being used. The **Dispose** method provides explicit control over these resources.

Unlike the **Uninitialize** method, once the **Dispose** method has been called, that instance of the class cannot be re-initialized and you should not attempt to access class properties or invoke any methods. Note that this method can be called even if other references to the object are active.

FtpServer Class | SocketTools Namespace | FtpServer.Dispose Overload List

FtpServer.Finalize Method

Destroys an instance of the class, releasing the resources allocated for the session and unloading the networking library.

[Visual Basic]

```
Overrides Protected Sub Finalize()
```

[C#]

```
protected override void Finalize();
```

See Also

FtpServer Class | SocketTools Namespace

FtpServer.Initialize Method

Initialize an instance of the FtpServer class.

Overload List

Initialize an instance of the FtpServer class.

public bool Initialize();

Initialize an instance of the FtpServer class.

public bool Initialize(string);

See Also

FtpServer Class | SocketTools Namespace | Uninitialize Method

FtpServer.Initialize Method (String)

Initialize an instance of the FtpServer class.

[Visual Basic]

```
Overloads Public Function Initialize( _
   ByVal licenseKey As String _
) As Boolean
```

[C#]

```
public bool Initialize(
   string licenseKey
);
```

Return Value

A boolean value which specifies if the class was initialized successfully.

Remarks

The Initialize method can be used to explicitly initialize an instance of the FtpServer class, loading the networking library and allocating resources for the current thread. Typically an application would define the license key as a custom attribute, however this method can be used to initialize the class directly.

The runtime license key for your copy of FtpServer can be generated using the License Manager utility that is included with the product. Note that if you have installed an evaluation license, you will not have a runtime license key and cannot redistribute any applications which use the FtpServer class.

Example

The following example shows how to use the Initialize method to initialize an instance of the class. This example assumes that the license key string has been defined in code.

```
SocketTools.FtpServer server = new SocketTools.FtpServer();

if (server.Initialize(strLicenseKey) == false)
{
    MessageBox.Show(server.LastErrorString, "Error",
                    MessageBoxButtons.OK, MessageBoxIcon.Exclamation);
    return;
}
```

```
Dim Server As New SocketTools.FtpServer

If Server.Initialize(strLicenseKey) = False Then
    MsgBox(Server.LastErrorString, vbIconExclamation)
    Exit Sub
End If
```

See Also

FtpServer Class | SocketTools Namespace | FtpServer.Initialize Overload List | RuntimeLicenseAttribute Class | Uninitialize Method

FtpServer.Initialize Method ()

Initialize an instance of the FtpServer class.

[Visual Basic]

```
Overloads Public Function Initialize() As Boolean
```

[C#]

```
public bool Initialize();
```

Return Value

A boolean value which specifies if the class was initialized successfully.

Remarks

The Initialize method can be used to explicitly initialize an instance of the FtpServer class, loading the networking library and allocating resources for the current thread. Typically it is not necessary to explicitly call this method because the instance of the class is initialized by the class constructor. However, if the **Uninitialize** method is called, the class must be re-initialized before any other methods are called.

See Also

FtpServer Class | SocketTools Namespace | FtpServer.Initialize Overload List | Uninitialize Method

FtpServer.Reset Method

Reset the internal state of the object, resetting all properties to their default values.

[Visual Basic]

```
Public Sub Reset()
```

[C#]

```
public void Reset();
```

Remarks

The **Reset** method returns the object to its default state. If a server has been started, it will be stopped and any active client connections will be terminated. All properties will be reset to their default values.

See Also

FtpServer Class | SocketTools Namespace

FtpServer.Restart Method

Restarts the server and terminates all active client connections.

[Visual Basic]

```
Public Function Restart() As Boolean
```

[C#]

```
public bool Restart();
```

Return Value

A boolean value which specifies if the server was restarted. A return value of **true** specifies that the server has been successfully restarted. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Restart** method terminates all active client connections, recreates a new listening socket bound to the same address and port number, and then resumes accepting new client connections.

Register a program for use with the SITE EXEC command.

Overload List

Register a program for use with the SITE EXEC command.

public bool RegisterProgram(string,string);

Register a program for use with the SITE EXEC command.

public bool RegisterProgram(string,string,string);

Register a program for use with the SITE EXEC command.

public bool RegisterProgram(string,string,string,string);

See Also

FtpServer Class | SocketTools Namespace

FtpServer.RegisterProgram Method (String, String, String, String)

Register a program for use with the SITE EXEC command.

[Visual Basic]

```
Overloads Public Function RegisterProgram( _
   ByVal command As String, _
   ByVal program As String, _
   ByVal parameters As String, _
   ByVal directory As String _
) As Boolean
```

[C#]

```
public bool RegisterProgram(
   string command,
   string program,
   string parameters,
   string directory
);
```

Parameters

command

A string which identifies the external program. This is the name that is passed to the SITE EXEC command and does not need to match the actual name of the executable file on the local system. The maximum length of the command name is 31 characters and this parameter cannot be an empty string.

program

A string which specifies the full path to the executable program on the local system.

parameters

A string that specifies additional parameters for the program. This value will be passed to the program as command line arguments. If the program does not require any command line parameters, this value may be an empty string.

directory

A string that specifies the current working directory for the program. If this value is an empty string, the server will use the root document directory assigned to the server.

Return Value

A boolean value which specifies if the external program has been registered with the server. A return value of **true** specifies that the operation was successful. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **RegisterProgram** method registers an executable program for use with the SITE EXEC command. Because this can present a significant security risk to the server, clients are not given permission to use this command by default. A client must be explicitly granted permission to use SITE EXEC by including **accessExecute** as one of the permissions when authenticating the client session with the **Authenticate** method or creating a virtual user using the **AddUser** method.

To give the server complete control over what programs can be executed using SITE EXEC, the program must be registered with the server and referenced by an alias specified by the *CommandName* parameter. The maximum length of a program name is 31 characters and it must be at least 3 characters in length. The name must only consist of alphanumeric characters and the first character of the program name cannot be numeric. The program name is not case-sensitive, however convention is to use uppercase characters. If a program name is specified that already has been registered, it will be updated with the new information provided by this method.

The ***ProgramFile*** string specifies file name of the program that will be executed. You should not install any executable programs in the server root directory or its subdirectories. A client should never have the ability to directly access the executable file itself. It is permitted to have multiple command names that reference the same executable file. The only requirement is that the command names be unique. The program name may contain environment variables surrounded by % symbols. For example, %ProgramFiles% would be expanded to the C:\Program Files folder.

It is important to note that the program specified by ***ProgramFile*** must be an executable file, not a script or batch file. If the program name does not contain a directory path, then the standard Windows pathing rules will be used when searching for an executable file that matches the given name. It is recommended that you always provide a full path to the executable file.

The ***Parameters*** string is used to define optional command line parameters that will be included with the command. This string can contain placeholders that are replaced by additional parameters specified by the client when it sends the SITE EXEC command. First replacement parameter is %1, the second is %2 and so on.

The executable program that is registered using this method must be a console application that writes to standard output. Programs that write directly to a console, or programs written to use a Windows user interface are not supported and will yield unpredictable results. In most cases, those programs that do not use standard input and output will be forcibly terminated by the server. If the program attempts to read from standard input, it will immediately encounter an end-of-file condition. Programs executed by the SITE EXEC command have no input; it is similar to a program that has its input redirected from the NUL: device. If the program must process a file on the server, the local file name should be passed as a command line parameter.

The output from the program will be redirected back to the client control channel. The output should be textual, with each line of text terminated by a carriage return and linefeed (CRLF). Programs that write binary data to standard output, particular data with embedded nulls, will yield unpredictable results and are not supported. To ensure that the program output conforms to the protocol standard, any non-printable characters will be replaced with a space and each line of output will be prefixed by a single space.

If the server is running on a system with User Account Control (UAC) enabled and does not have elevated privileges, do not register a program that requires elevated privileges or has a manifest that specifies the requestedExecutionLevel as requiring administrative privileges.

FtpServer Class | SocketTools Namespace | FtpServer.RegisterProgram Overload List

FtpServer.RegisterProgram Method (String, String, String)

Register a program for use with the SITE EXEC command.

[Visual Basic]

```
Overloads Public Function RegisterProgram( _
   ByVal command As String, _
   ByVal program As String, _
   ByVal parameters As String _
) As Boolean
```

[C#]

```
public bool RegisterProgram(
   string command,
   string program,
   string parameters
);
```

Parameters

command

A string which identifies the external program. This is the name that is passed to the SITE EXEC command and does not need to match the actual name of the executable file on the local system. The maximum length of the command name is 31 characters and this parameter cannot be an empty string.

program

A string which specifies the full path to the executable program on the local system.

parameters

A string that specifies additional parameters for the program. This value will be passed to the program as command line arguments. If the program does not require any command line parameters, this value may be an empty string.

Return Value

A boolean value which specifies if the external program has been registered with the server. A return value of **true** specifies that the operation was successful. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **RegisterProgram** method registers an executable program for use with the SITE EXEC command. Because this can present a significant security risk to the server, clients are not given permission to use this command by default. A client must be explicitly granted permission to use SITE EXEC by including **accessExecute** as one of the permissions when authenticating the client session with the **Authenticate** method or creating a virtual user using the **AddUser** method.

To give the server complete control over what programs can be executed using SITE EXEC, the program must be registered with the server and referenced by an alias specified by the *CommandName* parameter. The maximum length of a program name is 31 characters and it must be at least 3 characters in length. The name must only consist of alphanumeric characters and the first character of the program name cannot be numeric. The program name is not case-sensitive, however convention is to use upper-case characters. If a program name is specified that already has been registered, it will be updated with the new information provided by this method.

The *ProgramFile* string specifies file name of the program that will be executed. You should not install any executable programs in the server root directory or its subdirectories. A client should never have the ability to directly access the executable file itself. It is permitted to have multiple command names that reference the same executable file. The only requirement is that the command names be unique. The program name may contain environment variables surrounded by % symbols. For example, %ProgramFiles% would be expanded to the C:\Program Files folder.

It is important to note that the program specified by ***ProgramFile*** must be an executable file, not a script or batch file. If the program name does not contain a directory path, then the standard Windows pathing rules will be used when searching for an executable file that matches the given name. It is recommended that you always provide a full path to the executable file.

The ***Parameters*** string is used to define optional command line parameters that will be included with the command. This string can contain placeholders that are replaced by additional parameters specified by the client when it sends the SITE EXEC command. First replacement parameter is %1, the second is %2 and so on.

The executable program that is registered using this method must be a console application that writes to standard output. Programs that write directly to a console, or programs written to use a Windows user interface are not supported and will yield unpredictable results. In most cases, those programs that do not use standard input and output will be forcibly terminated by the server. FtpServer Class | SocketTools Namespace | FtpServer.RegisterProgram Overload List

FtpServer.RegisterProgram Method (String, String)

Register a program for use with the SITE EXEC command.

[Visual Basic]

```
Overloads Public Function RegisterProgram( _
   ByVal command As String, _
   ByVal program As String _
) As Boolean
```

[C#]

```
public bool RegisterProgram(
   string command,
   string program
);
```

Parameters

command
A string which identifies the external program. This is the name that is passed to the SITE EXEC command and does not need to match the actual name of the executable file on the local system. The maximum length of the command name is 31 characters and this parameter cannot be an empty string.

program
A string which specifies the full path to the executable program on the local system.

Return Value

A boolean value which specifies if the external program has been registered with the server. A return value of **true** specifies that the operation was successful. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **RegisterProgram** method registers an executable program for use with the SITE EXEC command. Because this can present a significant security risk to the server, clients are not given permission to use this command by default. A client must be explicitly granted permission to use SITE EXEC by including **accessExecute** as one of the permissions when authenticating the client session with the **Authenticate** method or creating a virtual user using the **AddUser** method.

To give the server complete control over what programs can be executed using SITE EXEC, the program must be registered with the server and referenced by an alias specified by the *CommandName* parameter. The maximum length of a program name is 31 characters and it must be at least 3 characters in length. The name must only consist of alphanumeric characters and the first character of the program name cannot be numeric. The program name is not case-sensitive, however convention is to use upper-case characters. If a program name is specified that already has been registered, it will be updated with the new information provided by this method.

The *ProgramFile* string specifies file name of the program that will be executed. You should not install any executable programs in the server root directory or its subdirectories. A client should never have the ability to directly access the executable file itself. It is permitted to have multiple command names that reference the same executable file. The only requirement is that the command names be unique. The program name may contain environment variables surrounded by % symbols. For example, %ProgramFiles% would be expanded to the C:\Program Files folder.

It is important to note that the program specified by *ProgramFile* must be an executable file, not a script or batch file. If the program name does not contain a directory path, then the standard Windows pathing rules will be used when searching for an executable file that matches the given name. It is recommended that you always provide a full path to the executable file.

The ***Parameters*** string is used to define optional command line parameters that will be included with the command. This string can contain placeholders that are replaced by additional parameters specified by the client when it sends the SITE EXEC command. First replacement parameter is %1, the second is %2 and so on.

The executable program that is registered using this method must be a console application that writes to standard output. Programs that write directly to a console, or programs written to use a Windows user interface are not supported and will yield unpredictable results. In most cases, those programs that do not use standard input and output will be forcibly terminated by the server. If the program attempts to read from standard input, it will immediately encounter an end-of-file condition. Programs executed by the SITE EXEC command have no input; it is similar to a program that has its input redirected from the NUL: device. If the program must process a file on the server, the local file name should be passed as a command line parameter.

The output from the program will be redirected back to the client control channel. The output should be textual, with each line of text terminated by a carriage return and linefeed (CRLF). Programs that write binary data to standard output, particular data with embedded nulls, will yield unpredictable results and are not supported. To ensure that the program output conforms to the protocol standard, any non-printable characters will be replaced with a space and each line of output will be prefixed by a single space.

If the server is running on a system with User Account Control (UAC) enabled and does not have elevated privileges, do not register a program that requires elevated privileges or has a manifest that specifies the requestedExecutionLevel as requiring administrative privileges.

FtpServer Class | SocketTools Namespace

FtpServer.ResolvePath Method (Int32, String, String, Boolean)

Resolve a path to its full virtual or local file name.

[Visual Basic]

```
Overloads Public Function ResolvePath( _
   ByVal clientId As Integer, _
   ByVal sourcePath As String, _
   ByRef resolvedPath As String, _
   ByVal isVirtual As Boolean _
) As Boolean
```

[C#]

```
public bool ResolvePath(
   int clientId,
   string sourcePath,
   ref string resolvedPath,
   bool isVirtual
);
```

Parameters

clientId
An integer that identifies the client session.

sourcePath
A string that specifies the name of the path to resolve. This may either be a virtual path, or a path to a local file name or directory.

resolvedPath
A string that will contain the resolved path when the method returns.

isVirtual
A Boolean parameter that specifies if the source path is a virtual path or local path.

Return Value

A boolean value which specifies if the source path could be resolved. A return value of **true** specifies that the operation was successful. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **ResolvePath** method is used to resolve a local file name or directory to obtain its virtual path name, or obtain the full path name of a file or directory that is mapped to a virtual path. If the ***isVirtual*** parameter is **false**, the ***sourcePath*** parameter is considered to be a path to a local file or directory and the ***resolvedPath*** parameter will contain the virtual path. If the ***isVirtual*** parameter is **true**, then the s***ourcePath*** parameter is considered to be a virtual path and the ***resolvedPath*** parameter will contain the full path to the local file or directory that the virtual path is mapped to

A virtual path for the client is either relative to the server root directory, or the client home directory if the client was authenticated as a restricted user. These virtual paths are what the client will see as an absolute path on the server. For example, if the server was configured to use "C:\ProgramData\MyServer" as the root directory, and the ***SourcePath*** parameter was specified as "C:\ProgramData\MyServer\Documents\Research", this method would return the virtual path to that directory as "/Documents/Research".

If the client session was authenticated as a restricted user, then the virtual path is always relative to the client home directory instead of the server root directory. This is because restricted users are isolated to their own home directory and any subdirectories. For example, if restricted user "John" has a home directory of "C:\ProgramData\MyServer\Users\John" and the ***SourcePath*** parameter was specified as "C:\ProgramData\MyServer\Users\John\Accounting\Projections.pdf" this method would return the virtual path as "/Accounting/Projections.pdf".

If the ***sourcePath*** parameter specifies a file or directory outside of the server root directory, this method will fail and the last error code will be set to **errorInvalidFileName**. This method can only be used with authenticated clients. If the ***clientId*** parameter specifies a client session that has not been authenticated, this method will fail and the last error code will be **errorAuthenticationRequired**.

FtpServer Class | SocketTools Namespace | FtpServer.ResolvePath Overload List

FtpServer.ResolvePath Method (String, String, Boolean)

Resolve a path to its full virtual or local file name.

[Visual Basic]

```
Overloads Public Function ResolvePath( _
   ByVal sourcePath As String, _
   ByRef resolvedPath As String, _
   ByVal isVirtual As Boolean _
) As Boolean
```

[C#]

```
public bool ResolvePath(
   string sourcePath,
   ref string resolvedPath,
   bool isVirtual
);
```

Parameters

sourcePath
A string that specifies the name of the path to resolve. This may either be a virtual path, or a path to a local file name or directory.

resolvedPath
A string that will contain the resolved path when the method returns.

isVirtual
A Boolean parameter that specifies if the source path is a virtual path or local path.

Return Value

A boolean value which specifies if the source path could be resolved. A return value of **true** specifies that the operation was successful. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **ResolvePath** method is used to resolve a local file name or directory to obtain its virtual path name, or obtain the full path name of a file or directory that is mapped to a virtual path. If the ***isVirtual*** parameter is **false**, the ***sourcePath*** parameter is considered to be a path to a local file or directory and the ***resolvedPath*** parameter will contain the virtual path. If the ***isVirtual*** parameter is **true**, then the s***ourcePath*** parameter is considered to be a virtual path and the ***resolvedPath*** parameter will contain the full path to the local file or directory that the virtual path is mapped to

A virtual path for the client is either relative to the server root directory, or the client home directory if the client was authenticated as a restricted user. These virtual paths are what the client will see as an absolute path on the server. For example, if the server was configured to use "C:\ProgramData\MyServer" as the root directory, and the ***SourcePath*** parameter was specified as "C:\ProgramData\MyServer\Documents\Research", this method would return the virtual path to that directory as "/Documents/Research".

If the client session was authenticated as a restricted user, then the virtual path is always relative to the client home directory instead of the server root directory. This is because restricted users are isolated to their own home directory and any subdirectories. For example, if restricted user "John" has a home directory of "C:\ProgramData\MyServer\Users\John" and the ***SourcePath*** parameter was specified as "C:\ProgramData\MyServer\Users\John\Accounting\Projections.pdf" this method would return the virtual path as "/Accounting/Projections.pdf".

If the ***sourcePath*** parameter specifies a file or directory outside of the server root directory, this method will fail and the last error code will be set to **errorInvalidFileName**. This method can only be used with authenticated clients. If the ***clientId*** parameter specifies a client session that has not been authenticated, this method will fail and the last error code will be **errorAuthenticationRequired**.

FtpServer.Resume Method

Resume accepting new client connections.

[Visual Basic]

```
Public Function Resume() As Boolean
```

[C#]

```
public bool Resume();
```

Return Value

A boolean value which specifies if the server has resumed accepting client connections. A return value of **true** specifies that the operation was successful. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Resume** method instructs the server to resume accepting new client connections. Any pending client connections that were requested while the server was suspended will be accepted.

FtpServer.SendResponse Method

Send a result code and message to the client in response to a command.

Overload List

Send a result code and message to the client in response to a command.

public bool SendResponse(int);

Send a result code and message to the client in response to a command.

public bool SendResponse(int,int);

Send a result code and message to the client in response to a command.

public bool SendResponse(int,int,string);

Send a result code and message to the client in response to a command.

public bool SendResponse(int,string);

See Also

FtpServer Class | SocketTools Namespace

FtpServer.SendResponse Method (Int32, Int32, String)

Send a result code and message to the client in response to a command.

[Visual Basic]

```
Overloads Public Function SendResponse( _
   ByVal clientId As Integer, _
   ByVal resultCode As Integer, _
   ByVal message As String _
) As Boolean
```

[C#]

```
public bool SendResponse(
   int clientId,
   int resultCode,
   string message
);
```

Parameters

clientId
An integer that identifies the client session.

resultCode
An integer value that specifies the command result code to be returned to the client.

message
A string value that specifies a message to be sent to the client. If this parameter is an empty string, a default message associated with the result code will be used.

Return Value

A boolean value which specifies if the response was sent to the client. A return value of **true** specifies that the operation was successful. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **SendResponse** method is used to respond to a command issued by the client from within an **OnCommand** event handler. Command responses are normally handled by the server as a normal part of processing a command and this method is only used if the application has implemented custom commands or wishes to modify the standard responses sent by the server. The message may be a maximum of 2048 characters and may include embedded carriage-return and linefeed characters. If no message is specified, then a default message will be sent based on the result code.

Result codes must be three digits (in the range of 100 through 999) and although this method will support the use of non-standard result codes, it is recommended that the client application use the standard codes defined in RFC 959 whenever possible. The use of non-standard result codes may cause problems with FTP clients that expect specific result codes in response to a particular command.

This method should only be called once in response to a command sent by the client. If a result code has already been sent in response to a command and this method is called, it will fail and return a value of zero. This is necessary because sending multiple result codes in response to a single command may cause unpredictable behavior by the client.

FtpServer Class | SocketTools Namespace | FtpServer.SendResponse Overload List

FtpServer.SendResponse Method (Int32, Int32)

Send a result code and message to the client in response to a command.

[Visual Basic]

```
Overloads Public Function SendResponse( _
   ByVal clientId As Integer, _
   ByVal resultCode As Integer _
) As Boolean
```

[C#]

```
public bool SendResponse(
   int clientId,
   int resultCode
);
```

Parameters

clientId

An integer that identifies the client session.

resultCode

An integer value that specifies the command result code to be returned to the client.

Return Value

A boolean value which specifies if the response was sent to the client. A return value of **true** specifies that the operation was successful. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **SendResponse** method is used to respond to a command issued by the client from within an **OnCommand** event handler. Command responses are normally handled by the server as a normal part of processing a command and this method is only used if the application has implemented custom commands or wishes to modify the standard responses sent by the server. The message may be a maximum of 2048 characters and may include embedded carriage-return and linefeed characters. If no message is specified, then a default message will be sent based on the result code.

Result codes must be three digits (in the range of 100 through 999) and although this method will support the use of non-standard result codes, it is recommended that the client application use the standard codes defined in RFC 959 whenever possible. The use of non-standard result codes may cause problems with FTP clients that expect specific result codes in response to a particular command.

This method should only be called once in response to a command sent by the client. If a result code has already been sent in response to a command and this method is called, it will fail and return a value of zero. This is necessary because sending multiple result codes in response to a single command may cause unpredictable behavior by the client.

Send a result code and message to the client in response to a command.

[Visual Basic]

```
Overloads Public Function SendResponse( _
   ByVal resultCode As Integer, _
   ByVal message As String _
) As Boolean
```

[C#]

```
public bool SendResponse(
   int resultCode,
   string message
);
```

Parameters

resultCode

An integer value that specifies the command result code to be returned to the client.

message

A string value that specifies a message to be sent to the client. If this parameter is an empty string, a default message associated with the result code will be used.

Return Value

A boolean value which specifies if the response was sent to the client. A return value of **true** specifies that the operation was successful. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **SendResponse** method is used to respond to a command issued by the client from within an **OnCommand** event handler. Command responses are normally handled by the server as a normal part of processing a command and this method is only used if the application has implemented custom commands or wishes to modify the standard responses sent by the server. The message may be a maximum of 2048 characters and may include embedded carriage-return and linefeed characters. If no message is specified, then a default message will be sent based on the result code.

Result codes must be three digits (in the range of 100 through 999) and although this method will support the use of non-standard result codes, it is recommended that the client application use the standard codes defined in RFC 959 whenever possible. The use of non-standard result codes may cause problems with FTP clients that expect specific result codes in response to a particular command.

This method should only be called once in response to a command sent by the client. If a result code has already been sent in response to a command and this method is called, it will fail and return a value of zero. This is necessary because sending multiple result codes in response to a single command may cause unpredictable behavior by the client.

FtpServer Class | SocketTools Namespace

FtpServer.Start Method (String, Int32, String, Int32, Int32, ServerOptions)

Start listening for client connections on the specified IP address and port number.

[Visual Basic]
```
Overloads Public Function Start( _
   ByVal localAddress As String, _
   ByVal localPort As Integer, _
   ByVal rootDirectory As String, _
   ByVal maxClients As Integer, _
   ByVal idleTime As Integer, _
   ByVal options As ServerOptions _
) As Boolean
```

[C#]
```
public bool Start(
   string localAddress,
   int localPort,
   string rootDirectory,
   int maxClients,
   int idleTime,
   ServerOptions options
);
```

Parameters

localAddress

A string which specifies the local hostname or IP address address that the server should be bound to. If this parameter is an empty string, then an appropriate address will automatically be used. If a specific address is used, the server will only accept client connections on the network interface that is bound to that address.

localPort

An integer that specifies the port number the server should use to listen for client connections. If a value of zero is specified, the server will use the standard port number 21 to listen for connections, or port 990 if the server is configured to use implicit SSL. The port number used by the application must be unique and multiple instances of a server cannot use the same port number. It is recommended that a port number greater than 5000 be used for private, application-specific implementations.

rootDirectory

A string that specifies the path to the root directory for the server. If this value is an empty string, the server will use the current working directory as the root directory.

maxClients

An integer value that specifies the maximum number of clients that may connect to the server.

idleTime

An integer value that specifies the number of seconds a client can be idle before the server terminates the session.

options

A ServerOptions enumeration that specifies one or more server options.

Return Value

A boolean value which specifies if the server was started. A return value of **true** specifies that the server has been successfully started. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure

Remarks

The **Start** method begins listening for client connections on the specified local address and port number. The server is started in its own thread and manages the client sessions independently of the calling thread.

To listen for connections on any suitable IPv4 interface, specify the special dotted-quad address "0.0.0.0". You can accept connections from clients using either IPv4 or IPv6 on the same socket by specifying the special IPv6 address "::0", however this is only supported on Windows 7 SP1 and Windows Server 2008 R2 or later platforms. If no local address is specified, then the server will only listen for connections from clients using IPv4. This behavior is by design for backwards compatibility with systems that do not have an IPv6 TCP/IP stack installed.

It is recommended that you always specify an absolute path for the server root directory, either by passing the full pathname as an argument to this method or by setting the **Directory** property. If the path includes environment variables surrounded by percent (%) symbols, they will be automatically expanded.

If you have configured the server to permit clients to upload files, you must ensure that your application has permission to create files in the directory that you specify. A recommended location for the server root directory would be a subdirectory of the %ALLUSERSPROFILE% directory. Using the environment variable ensures that your server will work correctly on different versions of Windows. If the root directory does not exist at the time that the server is started, it will be created.

localAddress

A string which specifies the local hostname or IP address address that the server should be bound to. If this parameter is an empty string, then an appropriate address will automatically be used. If a specific address is used, the server will only accept client connections on the network interface that is bound to that address.

localPort

An integer that specifies the port number the server should use to listen for client connections. If a value of zero is specified, the server will use the standard port number 21 to listen for connections, or port 990 if the server is configured to use implicit SSL. The port number used by the application must be unique and multiple instances of a server cannot use the same port number. It is recommended that a port number greater than 5000 be used for private, application-specific implementations.

rootDirectory

A string that specifies the path to the root directory for the server. If this value is an empty string, the server will use the current working directory as the root directory.

Return Value

A boolean value which specifies if the server was started. A return value of **true** specifies that the server has been successfully started. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure

Remarks

The **Start** method begins listening for client connections on the specified local address and port number. The server is started in its own thread and manages the client sessions independently of the calling thread.

To listen for connections on any suitable IPv4 interface, specify the special dotted-quad address "0.0.0.0". You can accept connections from clients using either IPv4 or IPv6 on the same socket by specifying the special IPv6 address "::0", however this is only supported on Windows 7 SP1 and Windows Server 2008 R2 or later platforms. If no local address is specified, then the server will only listen for connections from clients using IPv4. This behavior is by design for backwards compatibility with systems that do not have an IPv6 TCP/IP stack installed.

It is recommended that you always specify an absolute path for the server root directory, either by passing the full pathname as an argument to this method or by setting the **Directory** property. If the path includes environment variables surrounded by percent (%) symbols, they will be automatically expanded.

If you have configured the server to permit clients to upload files, you must ensure that your application has permission to create files in the directory that you specify. A recommended location for the server root directory would be a subdirectory of the %ALLUSERSPROFILE% directory. Using the environment variable ensures that your server will work correctly on different versions of Windows. If the root directory does not exist at the time that the server is started, it will be created.

FtpServer.Start Method (String, Int32)

Start listening for client connections on the specified IP address and port number.

[Visual Basic]

```
Overloads Public Function Start( _
   ByVal localAddress As String, _
   ByVal localPort As Integer _
) As Boolean
```

[C#]

```
public bool Start(
   string localAddress,
   int localPort
);
```

Parameters

localAddress

A string which specifies the local hostname or IP address address that the server should be bound to. If this parameter is an empty string, then an appropriate address will automatically be used. If a specific address is used, the server will only accept client connections on the network interface that is bound to that address.

localPort

An integer that specifies the port number the server should use to listen for client connections. If a value of zero is specified, the server will use the standard port number 21 to listen for connections, or port 990 if the server is configured to use implicit SSL. The port number used by the application must be unique and multiple instances of a server cannot use the same port number. It is recommended that a port number greater than 5000 be used for private, application-specific implementations.

Return Value

A boolean value which specifies if the server was started. A return value of **true** specifies that the server has been successfully started. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure

Remarks

The **Start** method begins listening for client connections on the specified local address and port number. The server is started in its own thread and manages the client sessions independently of the calling thread.

To listen for connections on any suitable IPv4 interface, specify the special dotted-quad address "0.0.0.0". You can accept connections from clients using either IPv4 or IPv6 on the same socket by specifying the special IPv6 address "::0", however this is only supported on Windows 7 SP1 and Windows Server 2008 R2 or later platforms. If no local address is specified, then the server will only listen for connections from clients using IPv4. This behavior is by design for backwards compatibility with systems that do not have an IPv6 TCP/IP stack installed.

It is recommended that you always specify an absolute path for the server root directory, either by passing the full pathname as an argument to this method or by setting the **Directory** property. If the path includes environment variables surrounded by percent (%) symbols, they will be automatically expanded.

If you have configured the server to permit clients to upload files, you must ensure that your application has permission to create files in the directory that you specify. A recommended location for the server root directory would be a subdirectory of the %ALLUSERSPROFILE% directory. Using the environment variable ensures that your server will work correctly on different versions of Windows. FtpServer.Start Method ()

Start listening for client connections on the specified IP address and port number.

[Visual Basic]
```
Overloads Public Function Start() As Boolean
```

[C#]
```
public bool Start();
```

Return Value

A boolean value which specifies if the server was started. A return value of **true** specifies that the server has been successfully started. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure

Remarks

The **Start** method begins listening for client connections on the specified local address and port number. The server is started in its own thread and manages the client sessions independently of the calling thread.

To listen for connections on any suitable IPv4 interface, specify the special dotted-quad address "0.0.0.0". You can accept connections from clients using either IPv4 or IPv6 on the same socket by specifying the special IPv6 address "::0", however this is only supported on Windows 7 SP1 and Windows Server 2008 R2 or later platforms. If no local address is specified, then the server will only listen for connections from clients using IPv4. FtpServer Class | SocketTools Namespace | FtpServer.Start Overload List

FtpServer.Stop Method

Stop listening for new client connections and terminate all active clients already connected to the server.

[Visual Basic]
```
Public Function Stop() As Boolean
```

[C#]
```
public bool Stop();
```

Return Value

A boolean value which specifies if the server was stopped. A return value of **true** specifies that the server has been successfully stopped. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Stop** method instructs the server to stop accepting client connections, disconnects all active client connections and terminates the thread that is managing the server session. If this method is called when there is one or more clients connected to the server, it will signal each client thread to terminate and then wait for the server thread to terminate.

See Also

FtpServer Class | SocketTools Namespace | Restart Method | Resume Method | Start Method | Throttle Method

FtpServer.Suspend Method

Suspend accepting new client connections.

[Visual Basic]

```
Public Function Suspend() As Boolean
```

[C#]

```
public bool Suspend();
```

Return Value

A boolean value which specifies if the server has been suspended. A return value of **true** specifies that the server has been successfully stopped. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Suspend** method instructs the server to suspend accepting new client connections. All new clients that attempt to connect to the server will be sent a 421 "service unavailable" error code and the connection will be immediately closed. To resume accepting new client connections, call the **Resume** method. This method will not affect those clients that have already established a connection with the server before the **Suspend** method was called.

FtpServer.Throttle Method

Limit the maximum number of client connections.

Overload List

Limit the maximum number of client connections.

public bool Throttle(int);

Limit the maximum number of client connections and connections per IP address.

public bool Throttle(int,int);

Limit the maximum number of client connections, connections per IP address and connection rate.

public bool Throttle(int,int,int);

Limit the maximum number of client connections, connections per IP address and connection rate.

public bool Throttle(int,int,int,int);

See Also

FtpServer Class | SocketTools Namespace

FtpServer.Throttle Method (Int32, Int32, Int32, Int32)

Limit the maximum number of client connections, connections per IP address and connection rate.

[Visual Basic]

```
Overloads Public Function Throttle( _
   ByVal maxClients As Integer, _
   ByVal maxClientsPerAddress As Integer, _
   ByVal maxGuests As Integer, _
   ByVal connectionRate As Integer _
) As Boolean
```

[C#]

```
public bool Throttle(
   int maxClients,
   int maxClientsPerAddress,
   int maxGuests,
   int connectionRate
);
```

Parameters

maxClients

An integer value that specifies the maximum number of clients that may connect to the server. A value of zero specifies that there is no fixed limit to the number of client connections.

maxClientsPerAddress

An integer value that specifies the maximum number of clients that may connect to the server from the same IP address. A value of zero specifies that there is no fixed limit to the number of client connections per address. By default, there is no limit on the number of client connections per address.

maxGuests

An integer value that specifies the maximum number of anonymous (guest) users that may be logged in at any one time.

connectionRate

An integer value that specifies a restriction on the rate of client connections, limiting the number of connections that will be accepted within that period of time. A value of zero specifies that there is no restriction on the rate of client connections. The higher this value, the fewer the number of connections that will be accepted within a specific period of time. By default, there is no limit on the client connection rate.

Return Value

A boolean value which specifies if the method was successful. A return value of **true** indicates success. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

If the maximum number of client connections or maximum number of connections per address is exceeded, the server will reject subsequent connection attempts until the number of active client sessions drops below the specified threshold. Note that adjusting these values lower than the current connection limits will not affect clients that have already connected to the server. For example, if the **Start** method is called with the maximum number of clients set to 100, and then the **Throttle** method is called lowering that value to 75, no existing client connections will be affected by the change. However, the server will not accept any new connections until the number of active clients drops below 75.

If the value of the ***maxGuests*** parameter is greater than zero, then anonymous logins will be enabled and clients can authenticate with the username "anonymous" and their email address as the password. If the parameter is set to zero, then anonymous logins will be disabled. Note that this will not affect any clients that are currently logged in, it only affects those clients that connect after the **Throttle** method has been called.

Increasing the connection rate value will force the server to slow down the rate at which it will accept incoming client connection requests. For example, setting this parameter to a value of 1000 would limit the server to accepting one client connection every second, while a value of 250 would allow the server to accept four client connections per second. Note that significantly increasing the amount of time the server must wait to accept client connections can exceed the connection backlog queue, resulting in client connections being rejected.

See Also

FtpServer Class | SocketTools Namespace | FtpServer.Throttle Overload List

FtpServer.Throttle Method (Int32, Int32, Int32)

Limit the maximum number of client connections, connections per IP address and connection rate.

[Visual Basic]

```
Overloads Public Function Throttle( _
   ByVal maxClients As Integer, _
   ByVal maxClientsPerAddress As Integer, _
   ByVal maxGuests As Integer _
) As Boolean
```

[C#]

```
public bool Throttle(
   int maxClients,
   int maxClientsPerAddress,
   int maxGuests
);
```

Parameters

maxClients

An integer value that specifies the maximum number of clients that may connect to the server. A value of zero specifies that there is no fixed limit to the number of client connections.

maxClientsPerAddress

An integer value that specifies the maximum number of clients that may connect to the server from the same IP address. A value of zero specifies that there is no fixed limit to the number of client connections per address. By default, there is no limit on the number of client connections per address.

maxGuests

An integer value that specifies the maximum number of anonymous (guest) users that may be logged in at any one time.

Return Value

A boolean value which specifies if the method was successful. A return value of **true** indicates success. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

If the maximum number of client connections or maximum number of connections per address is exceeded, the server will reject subsequent connection attempts until the number of active client sessions drops below the specified threshold. Note that adjusting these values lower than the current connection limits will not affect clients that have already connected to the server. For example, if the **Start** method is called with the maximum number of clients set to 100, and then the **Throttle** method is called lowering that value to 75, no existing client connections will be affected by the change. However, the server will not accept any new connections until the number of active clients drops below 75.

If the value of the *maxGuests* parameter is greater than zero, then anonymous logins will be enabled and clients can authenticate with the username "anonymous" and their email address as the password. If the parameter is set to zero, then anonymous logins will be disabled. Note that this will not affect any clients that are currently logged in, it only affects those clients that connect after the **Throttle** method has been called.

Increasing the connection rate value will force the server to slow down the rate at which it will accept incoming client connection requests. For example, setting this parameter to a value of 1000 would limit the server to accepting one client connection every second, while a value of 250 would allow the server to accept four client connections per second. Note that significantly increasing the amount of time the server must wait to accept client connections can exceed the connection backlog queue, resulting in client connections being rejected.

   ByVal maxClients As Integer, _
   ByVal maxClientsPerAddress As Integer _
) As Boolean
```

[C#]

```
public bool Throttle(
   int maxClients,
   int maxClientsPerAddress
);
```

Parameters

maxClients

An integer value that specifies the maximum number of clients that may connect to the server. A value of zero specifies that there is no fixed limit to the number of client connections.

maxClientsPerAddress

An integer value that specifies the maximum number of clients that may connect to the server from the same IP address. A value of zero specifies that there is no fixed limit to the number of client connections per address. By default, there is no limit on the number of client connections per address.

Return Value

A boolean value which specifies if the method was successful. A return value of **true** indicates success. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

If the maximum number of client connections or maximum number of connections per address is exceeded, the server will reject subsequent connection attempts until the number of active client sessions drops below the specified threshold. Note that adjusting these values lower than the current connection limits will not affect clients that have already connected to the server. For example, if the **Start** method is called with the maximum number of clients set to 100, and then the **Throttle** method is called lowering that value to 75, no existing client connections will be affected by the change. FtpServer.Uninitialize Method

Uninitialize the class library and release any resources allocated for the server.

[Visual Basic]

```
Public Sub Uninitialize()
```

[C#]

```
public void Uninitialize();
```

Remarks

The **Uninitialize** method terminates any active connection, releases resources allocated for the server and unloads the networking library. After this method has been called, no further network operations may be performed until the class instance has been re-initialized.

If the **Initialize** method is explicitly called by the application, it should be matched by a call to the **Uninitialize** method when that instance of the class is no longer needed.

FtpServer Events

The events of the **FtpServer** class are listed below. For a complete list of **FtpServer** class members, see the FtpServer Members topic.

Public Instance Events

⚡ OnAuthenticate	Occurs when the client has requested authentication with the specified username and password.
⚡ OnCommand	Occurs when a client has issued a command to the server.
⚡ OnConnect	Occurs when a connection is established with the remote host.
⚡ OnDisconnect	Occurs when the remote host disconnects from the local system.
⚡ OnDownload	Occurs when a connection is established with the remote host.
⚡ OnError	Occurs when an network operation fails.
⚡ OnExecute	Occurs when the client has executed an external program on the server.
⚡ OnIdle	Occurs when the there are no clients connected to the server.
⚡ OnLogin	Occurs when the client has successfully authenticated the session.
⚡ OnLogout	Occurs when the client has logged out or reinitialized the session.
⚡ OnResult	Occurs when the command issued by the client has been processed by the server.
⚡ OnStart	Occurs when the server starts accepting connections.
⚡ OnStop	Occurs when the server stops accepting connections.
⚡ OnTimeout	Occurs when the client has exceeded the maximum allowed idle time.
⚡ OnUpload	Occurs when the client has successfully uploaded a file to the server.

See Also

FtpServer Class | SocketTools Namespace

FtpServer.OnAuthenticate Event

Occurs when the client has requested authentication with the specified username and password.

[Visual Basic]
```
Public Event OnAuthenticate As OnAuthenticateEventHandler
```

[C#]
```
public event OnAuthenticateEventHandler OnAuthenticate;
```

Event Data

The event handler receives an argument of type FtpServer.AuthenticateEventArgs containing data related to this event. The following **FtpServer.AuthenticateEventArgs** properties provide information specific to this event.

Property	Description
ClientId	Gets a value that uniquely identifies the client session.
HostName	Gets the host name used by the client to establish the connection to the server.
Password	Gets the password provided by the client for authentication.
UserName	Gets the password provided by the client for authentication.

Remarks

The **OnAuthenticate** event occurs when the client has requested authentication by sending the USER and PASS command to the server. The event handler can call the **Authenticate** method to authenticate the client session. If the client is not authenticated, the server will send an error message to the client and terminate the session.

If the application has created one or more virtual users using the **AddUser** method and/or the **LocalUser** property has been set to **True**, it is not necessary to implement an **OnAuthenticate** handler unless you also wish to perform custom authentication for specific users.

This event handler will be invoked in the context of the worker thread that is managing the client session, not the thread that created an instance of the class. Because UI components should only be modified by the thread that created them, the event handler should never attempt to update the user interface directly.

FtpServer.AuthenticateEventArgs overview

Public Instance Constructors

FtpServer.AuthenticateEventArgs Constructor	Initializes a new instance of the FtpServer.AuthenticateEventArgs class.

Public Instance Properties

ClientId	Gets a value that uniquely identifies the client session.
HostName	Gets the host name used by the client to establish the connection to the server.
Password	Gets the password provided by the client for authentication.
UserName	Gets the password provided by the client for authentication.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString (inherited from Object)	Returns a String that represents the current Object.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

FtpServer.AuthenticateEventArgs Class | SocketTools Namespace

FtpServer.AuthenticateEventArgs.ClientId Property

Gets a value that uniquely identifies the client session.

[Visual Basic]

```
Public ReadOnly Property ClientId As Integer
```

[C#]

```
public int ClientId {get;}
```

Property Value

An integer value which identifies the client session.

Remarks

The **ClientId** property returns a unique integer value that identifies the client session that generated the event.

See Also

FtpServer.AuthenticateEventArgs Class | SocketTools Namespace

FtpServer.AuthenticateEventArgs.HostName Property

Gets the host name used by the client to establish the connection to the server.

[Visual Basic]

```
Public ReadOnly Property HostName As String
```

[C#]

```
public string HostName {get;}
```

Property Value

A string that specifies a host name.

See Also

FtpServer.AuthenticateEventArgs Class | SocketTools Namespace

FtpServer.AuthenticateEventArgs.Password Property

Gets the password provided by the client for authentication.

[Visual Basic]
```
Public ReadOnly Property Password As String
```

[C#]
```
public string Password {get;}
```

Property Value

A string that specifies the password provided by the client when it requests authentication.

FtpServer.AuthenticateEventArgs Class | SocketTools Namespace

FtpServer.AuthenticateEventArgs.UserName Property

Gets the password provided by the client for authentication.

[Visual Basic]

```
Public ReadOnly Property UserName As String
```

[C#]

```
public string UserName {get;}
```

Property Value

A string that specifies the username provided by the client when it requests authentication.

See Also

FtpServer.AuthenticateEventArgs Class | SocketTools Namespace

FtpServer.OnCommand Event

Occurs when a client has issued a command to the server.

[Visual Basic]
```
Public Event OnCommand As OnCommandEventHandler
```

[C#]
```
public event OnCommandEventHandler OnCommand;
```

Event Data

The event handler receives an argument of type FtpServer.CommandEventArgs containing data related to this event. The following **FtpServer.CommandEventArgs** properties provide information specific to this event.

Property	Description
ClientId	Gets a value that uniquely identifies the client session.
Command	Gets a value that specifies the command issued by the client.
Parameters	Gets a value that specifies the command parameters issued by the client.

Remarks

The **OnCommand** event occurs after the client has sent a command to the server, but before the command has been processed. This event occurs for all commands issued by the client, including invalid or disabled commands. If the application wishes to handle the command itself, it must perform any processing and then call the **SendResponse** method to send the success or error code to the client. If the **SendResponse** method is not called, then the server will perform its default processing for the command.

After the command has been processed, the **OnResult** event handler will be invoked.

This event handler will be invoked in the context of the worker thread that is managing the client session, not the thread that created an instance of the class. Because UI components should only be modified by the thread that created them, the event handler should never attempt to update the user interface directly.

FtpServer.CommandEventArgs Members

FtpServer.CommandEventArgs overview

Public Instance Constructors

FtpServer.CommandEventArgs Constructor	Initializes a new instance of the FtpServer.CommandEventArgs class.

Public Instance Properties

ClientId	Gets a value that uniquely identifies the client session.
Command	Gets a value that specifies the command issued by the client.
Parameters	Gets a value that specifies the command parameters issued by the client.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString (inherited from Object)	Returns a String that represents the current Object.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

FtpServer.CommandEventArgs Properties

The properties of the **FtpServer.CommandEventArgs** class are listed below. For a complete list of **FtpServer.CommandEventArgs** class members, see the FtpServer.CommandEventArgs Members topic.

Public Instance Properties

ClientId	Gets a value that uniquely identifies the client session.
Command	Gets a value that specifies the command issued by the client.
Parameters	Gets a value that specifies the command parameters issued by the client.

See Also

FtpServer.CommandEventArgs Class | SocketTools Namespace

FtpServer.CommandEventArgs.ClientId Property

Gets a value that uniquely identifies the client session.

[Visual Basic]

```
Public ReadOnly Property ClientId As Integer
```

[C#]

```
public int ClientId {get;}
```

Property Value

An integer value which identifies the client session.

Remarks

The **ClientId** property returns a unique integer value that identifies the client session that generated the event.

See Also

FtpServer.CommandEventArgs Class | SocketTools Namespace

FtpServer.CommandEventArgs.Command Property

Gets a value that specifies the command issued by the client.

[Visual Basic]

```
Public ReadOnly Property Command As String
```

[C#]

```
public string Command {get;}
```

Property Value

A string that specifies the command sent by the client.

See Also

FtpServer.CommandEventArgs Class | SocketTools Namespace

FtpServer.CommandEventArgs.Parameters Property

Gets a value that specifies the command parameters issued by the client.

[Visual Basic]

```
Public ReadOnly Property Parameters As String
```

[C#]

```
public string Parameters {get;}
```

Property Value

A string that specifies the command parameters sent by the client.

See Also

FtpServer.CommandEventArgs Class | SocketTools Namespace

FtpServer.OnConnect Event

Occurs when a connection is established with the remote host.

[Visual Basic]

```
Public Event OnConnect As OnConnectEventHandler
```

[C#]

```
public event OnConnectEventHandler OnConnect;
```

Event Data

The event handler receives an argument of type FtpServer.ConnectEventArgs containing data related to this event. The following **FtpServer.ConnectEventArgs** properties provide information specific to this event.

Property	Description
ClientAddress	Gets the address of the client establishing the connection.
ClientId	Gets a value that uniquely identifies the client session.

Remarks

The **OnConnect** event occurs after the client has established its initial connection to the server, after the server has checked the active client limits and the TLS handshake has been performed if required. If the server has been suspended, or the limit on the maximum number of client sessions has been exceeded, the server will terminate the client session prior to this event handler being invoked.

If no event handler is implemented, the server will perform the default action of accepting the connection and sending a standard greeting to the client. If you want your application to send a custom greeting to the client when it connects, call the **SendResponse** method, specifying a result code of 220 and a message of your choice.

To reject a connection, call the **SendResponse** method to send an error response to the client. Typically the result code value would be 421 to indicate that the server will not accept the connection. Next, call the **DisconnectClient** method to terminate the client session.

This event handler will be invoked in the context of the worker thread that is managing the client session, not the thread that created an instance of the class. Because UI components should only be modified by the thread that created them, the event handler should never attempt to update the user interface directly.

FtpServer.ConnectEventArgs Properties

The properties of the **FtpServer.ConnectEventArgs** class are listed below. For a complete list of **FtpServer.ConnectEventArgs** class members, see the FtpServer.ConnectEventArgs Members topic.

Public Instance Properties

ClientAddress	Gets the address of the client establishing the connection.
ClientId	Gets a value that uniquely identifies the client session.

See Also

FtpServer.ConnectEventArgs Class | SocketTools Namespace | OnConnect Event (SocketTools.FtpServer)

FtpServer.ConnectEventArgs.ClientAddress Property

Gets the address of the client establishing the connection.

[Visual Basic]

```
Public ReadOnly Property ClientAddress As String
```

[C#]

```
public string ClientAddress {get;}
```

Property Value

A string that specifies the Internet Protocol address of the client.

See Also

FtpServer.ConnectEventArgs Class | SocketTools Namespace

FtpServer.ConnectEventArgs.ClientId Property

Gets a value that uniquely identifies the client session.

[Visual Basic]

```
Public ReadOnly Property ClientId As Integer
```

[C#]

```
public int ClientId {get;}
```

Property Value

An integer value which identifies the client session.

Remarks

The **ClientId** property returns a unique integer value that identifies the client session that generated the event.

FtpServer.OnDownload Event

Occurs when a connection is established with the remote host.

[Visual Basic]
```
Public Event OnDownload As OnDownloadEventHandler
```

[C#]
```
public event OnDownloadEventHandler OnDownload;
```

Event Data

The event handler receives an argument of type FtpServer.DownloadEventArgs containing data related to this event. The following **FtpServer.DownloadEventArgs** properties provide information specific to this event.

Property	Description
ClientId	Gets a value that uniquely identifies the client session.
FileName	Gets a value that specifies the file being downloaded.
FileSize	Gets a value that specifies the size of the file.

Remarks

The **OnDownload** event occurs after the client has successfully downloaded a file from the server using the RETR command. If the file transfer fails or is aborted, this event will not occur.

This event handler will be invoked in the context of the worker thread that is managing the client session, not the thread that created an instance of the class. Because UI components should only be modified by the thread that created them, the event handler should never attempt to update the user interface directly.

FtpServer.DownloadEventArgs Properties

The properties of the **FtpServer.DownloadEventArgs** class are listed below. For a complete list of **FtpServer.DownloadEventArgs** class members, see the FtpServer.DownloadEventArgs Members topic.

Public Instance Properties

ClientId	Gets a value that uniquely identifies the client session.
FileName	Gets a value that specifies the file being downloaded.
FileSize	Gets a value that specifies the size of the file.

See Also

FtpServer.DownloadEventArgs Class | SocketTools Namespace

FtpServer.DownloadEventArgs.ClientId Property

Gets a value that uniquely identifies the client session.

[Visual Basic]

```
Public ReadOnly Property ClientId As Integer
```

[C#]

```
public int ClientId {get;}
```

Property Value

An integer value which identifies the client session.

Remarks

The **ClientId** property returns a unique integer value that identifies the client session that generated the event.

See Also

FtpServer.DownloadEventArgs Class | SocketTools Namespace

FtpServer.DownloadEventArgs.FileName Property

Gets a value that specifies the file being downloaded.

[Visual Basic]

```
Public ReadOnly Property FileName As String
```

[C#]

```
public string FileName {get;}
```

Property Value

A string that specifies the full path to a file on the local system.

See Also

FtpServer.DownloadEventArgs Class | SocketTools Namespace

FtpServer.DownloadEventArgs.FileSize Property

Gets a value that specifies the size of the file.

[Visual Basic]

```
Public ReadOnly Property FileSize As Long
```

[C#]

```
public long FileSize {get;}
```

Property Value

A long integer value that specifies the size of the file in bytes.

See Also

FtpServer.DownloadEventArgs Class | SocketTools Namespace

FtpServer.OnDisconnect Event

Occurs when the remote host disconnects from the local system.

[Visual Basic]

```
Public Event OnDisconnect As OnDisconnectEventHandler
```

[C#]

```
public event OnDisconnectEventHandler OnDisconnect;
```

Event Data

The event handler receives an argument of type FtpServer.DisconnectEventArgs containing data related to this event. The following **FtpServer.DisconnectEventArgs** property provides information specific to this event.

Property	Description
ClientId	Gets a value that uniquely identifies the client session.

Remarks

The **OnDisconnect** event is generated when the connection is terminated by the client and there is no more data available to be read.

It is not necessary to call the **Disconnect** method inside the **OnDisconnect** event handler because the client session is already in the process of disconnecting from the server.

This event handler will be invoked in the context of the worker thread that is managing the client session, not the thread that created an instance of the class. Because UI components should only be modified by the thread that created them, the event handler should never attempt to update the user interface directly.

FtpServer.DisconnectEventArgs.ClientId Property

Gets a value that uniquely identifies the client session.

[Visual Basic]
```
Public ReadOnly Property ClientId As Integer
```

[C#]
```
public int ClientId {get;}
```

Property Value

An integer value which identifies the client session.

Remarks

The **ClientId** property returns a unique integer value that identifies the client session that generated the event.

See Also

FtpServer.DisconnectEventArgs Class | SocketTools Namespace

FtpServer.OnError Event

Occurs when an network operation fails.

[Visual Basic]
```
Public Event OnError As OnErrorEventHandler
```

[C#]
```
public event OnErrorEventHandler OnError;
```

Event Data

The event handler receives an argument of type FtpServer.ErrorEventArgs containing data related to this event. The following **FtpServer.ErrorEventArgs** properties provide information specific to this event.

Property	Description
ClientId	Gets a value that uniquely identifies the client session.
Description	Gets a value which describes the last error that has occurred.
Error	Gets a value which specifies the last error that has occurred.

Remarks

The **OnError** event occurs when a network operation fails.

This event handler may be invoked in the context of the worker thread that is managing the client session, not the thread that created an instance of the class. Because UI components should only be modified by the thread that created them, the event handler should never attempt to update the user interface directly.

FtpServer.ErrorEventArgs Properties

The properties of the **FtpServer.ErrorEventArgs** class are listed below. For a complete list of **FtpServer.ErrorEventArgs** class members, see the FtpServer.ErrorEventArgs Members topic.

Public Instance Properties

ClientId	Gets a value that uniquely identifies the client session.
Description	Gets a value which describes the last error that has occurred.
Error	Gets a value which specifies the last error that has occurred.

See Also

FtpServer.ErrorEventArgs Class | SocketTools Namespace

FtpServer.ErrorEventArgs.ClientId Property

Gets a value that uniquely identifies the client session.

[Visual Basic]

```
Public ReadOnly Property ClientId As Integer
```

[C#]

```
public int ClientId {get;}
```

Property Value

An integer value which identifies the client session.

Remarks

The **ClientId** property returns a unique integer value that identifies the client session that generated the event.

See Also

FtpServer.ErrorEventArgs Class | SocketTools Namespace

FtpServer.ErrorEventArgs.Description Property

Gets a value which describes the last error that has occurred.

[Visual Basic]
```
Public ReadOnly Property Description As String
```

[C#]
```
public string Description {get;}
```

Property Value

A string which describes the last error that has occurred.

See Also

FtpServer.ErrorEventArgs Class | SocketTools Namespace | Error Property

FtpServer.ErrorEventArgs.Error Property

Gets a value which specifies the last error that has occurred.

[Visual Basic]

```
Public ReadOnly Property Error As ErrorCode
```

[C#]

```
public FtpServer.ErrorCode Error {get;}
```

Property Value

ErrorCode enumeration which specifies the error.

See Also

FtpServer.ErrorEventArgs Class | SocketTools Namespace | Description Property

FtpServer.OnExecute Event

Occurs when the client has executed an external program on the server.

[Visual Basic]
```
Public Event OnExecute As OnExecuteEventHandler
```

[C#]
```
public event OnExecuteEventHandler OnExecute;
```

Event Data

The event handler receives an argument of type FtpServer.ExecuteEventArgs containing data related to this event. The following **FtpServer.ExecuteEventArgs** properties provide information specific to this event.

Property	Description
ClientId	Gets a value that uniquely identifies the client session.
ExitCode	Gets a value that specifies the exit code for the external program.
Output	Gets the output of the external command executed by the client.
Program	Gets the name of the external program executed by the client.

Remarks

The **OnExecute** event occurs after the client has successfully executed an external program using the SITE EXEC command.

This event will only be generated if the client has the **ftpAccessExecute** permission. Clients are not granted this permission by default, and must be explicitly permitted to execute external programs. If the client does have this permission, it can only execute specific programs that have been registered by the server application using the **RegisterProgram** method.

This event handler will be invoked in the context of the worker thread that is managing the client session, not the thread that created an instance of the class. Because UI components should only be modified by the thread that created them, the event handler should never attempt to update the user interface directly.

FtpServer.ExecuteEventArgs.Program Property

Gets the name of the external program executed by the client.

[Visual Basic]

```
Public ReadOnly Property Program As String
```

[C#]

```
public string Program {get;}
```

Property Value

A string that identifies the external program executed by the client.

See Also

FtpServer.ExecuteEventArgs Class | SocketTools Namespace

FtpServer.OnIdle Event

Occurs when the there are no clients connected to the server.

[Visual Basic]

```
Public Event OnIdle As EventHandler
```

[C#]

```
public event EventHandler OnIdle;
```

Remarks

This event will only occur after at least one client has connected to the server and then closes its connection or is disconnected. This event will not occur immediately after the server has started using the **Start** method, and will not occur when the server is stopped using the **Stop** method. Your application should implement an **OnStart** event handler for when the server first starts, and an **OnStop** event handler for when the server is stopped.

If one or more new client connections are accepted after this event occurs, the event will be generated again when those clients disconnect and the active client count drops to zero. Therefore it is to be expected that this event will occur multiple times over the lifetime of the server as it continues to listen for connections

This event handler will be invoked in the context of the worker thread that is managing the server, not the thread that created an instance of the class. Because UI components should only be modified by the thread that created them, the event handler should never attempt to update the user interface directly.

See Also

FtpServer Class | SocketTools Namespace

FtpServer.OnLogin Event

Occurs when the client has successfully authenticated the session.

[Visual Basic]
```
Public Event OnLogin As OnLoginEventHandler
```

[C#]
```
public event OnLoginEventHandler OnLogin;
```

Event Data

The event handler receives an argument of type FtpServer.LoginEventArgs containing data related to this event. The following **FtpServer.LoginEventArgs** properties provide information specific to this event.

Property	Description
ClientId	Gets a value that uniquely identifies the client session.
Directory	Gets the home directory of the user that has logged into the server.
UserName	Gets the username associated with the client that logged into the server.

Remarks

The **OnLogin** event occurs after the client has successfully authenticated itself using the USER and PASS commands.

This event handler will be invoked in the context of the worker thread that is managing the client session, not the thread that created an instance of the class. Because UI components should only be modified by the thread that created them, the event handler should never attempt to update the user interface directly.

Public Instance Constructors

FtpServer.LoginEventArgs Constructor	Initializes a new instance of the FtpServer.LoginEventArgs class.

Public Instance Properties

ClientId	Gets a value that uniquely identifies the client session.
Directory	Gets the home directory of the user that has logged into the server.
UserName	Gets the username associated with the client that logged into the server.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString (inherited from Object)	Returns a String that represents the current Object.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

FtpServer.LoginEventArgs Properties

The properties of the **FtpServer.LoginEventArgs** class are listed below. For a complete list of **FtpServer.LoginEventArgs** class members, see the FtpServer.LoginEventArgs Members topic.

Public Instance Properties

ClientId	Gets a value that uniquely identifies the client session.
Directory	Gets the home directory of the user that has logged into the server.
UserName	Gets the username associated with the client that logged into the server.

See Also

FtpServer.LoginEventArgs Class | SocketTools Namespace

FtpServer.LoginEventArgs.ClientId Property

Gets a value that uniquely identifies the client session.

[Visual Basic]

```
Public ReadOnly Property ClientId As Integer
```

[C#]

```
public int ClientId {get;}
```

Property Value

An integer value which identifies the client session.

Remarks

The **ClientId** property returns a unique integer value that identifies the client session that generated the event.

See Also

FtpServer.LoginEventArgs Class | SocketTools Namespace

FtpServer.LoginEventArgs.Directory Property

Gets the home directory of the user that has logged into the server.

[Visual Basic]

```
Public ReadOnly Property Directory As String
```

[C#]

```
public string Directory {get;}
```

Property Value

A string that specifies the full path to a local directory on the server.

See Also

FtpServer.LoginEventArgs Class | SocketTools Namespace

FtpServer.LoginEventArgs.UserName Property

Gets the username associated with the client that logged into the server.

[Visual Basic]

```
Public ReadOnly Property UserName As String
```

[C#]

```
public string UserName {get;}
```

Property Value

A string that specifies the username associated with the client session.

See Also

FtpServer.LoginEventArgs Class | SocketTools Namespace

FtpServer.OnLogout Event

Occurs when the client has logged out or reinitialized the session.

[Visual Basic]

```
Public Event OnLogout As OnLogoutEventHandler
```

[C#]

```
public event OnLogoutEventHandler OnLogout;
```

Event Data

The event handler receives an argument of type FtpServer.LogoutEventArgs containing data related to this event. The following **FtpServer.LogoutEventArgs** properties provide information specific to this event.

Property	Description
ClientId	Gets a value that uniquely identifies the client session.
UserName	Gets the username associated with the client that logged out from the server.

Remarks

The **OnLogout** event occurs after the client has successfully logged out using the QUIT command or reinitialized the session using the REIN command.

The application should not depend on this event handler always being invoked when a client is disconnected from the server. This event only occurs when the client sends the QUIT or REIN commands and will not be invoked if the client connection is aborted or disconnected for some other reason, such as exceeding the idle timeout period. If the application needs to update data structures or perform some cleanup when a client disconnects, that should be done in the **OnDisconnect** event handler.

The application should not call the **Disconnect** method in the handler for this event because the client is either in the process of disconnecting or expects that it can submit new credentials to the server.

This event handler will be invoked in the context of the worker thread that is managing the client session, not the thread that created an instance of the class. Because UI components should only be modified by the thread that created them, the event handler should never attempt to update the user interface directly.

FtpServer.OnResult Event

Occurs when the command issued by the client has been processed by the server.

[Visual Basic]
```
Public Event OnResult As OnResultEventHandler
```

[C#]
```
public event OnResultEventHandler OnResult;
```

Event Data

The event handler receives an argument of type FtpServer.ResultEventArgs containing data related to this event. The following **FtpServer.ResultEventArgs** properties provide information specific to this event.

Property	Description
ClientId	Gets a value that uniquely identifies the client session.
Command	Gets a value that specifies the command issued by the client.
ResultCode	Gets the result code associated with the last command issued by the client.

Remarks

The **OnResult** event occurs after the server has processed a command issued by the client. This event will inform the application whether the command that was issued by the client was successful or not. If the command was successful, then other related events such as **OnDownload** may also fire after this event.

This event handler will be invoked in the context of the worker thread that is managing the client session, not the thread that created an instance of the class. Because UI components should only be modified by the thread that created them, the event handler should never attempt to update the user interface directly.

FtpServer.ResultEventArgs Properties

The properties of the **FtpServer.ResultEventArgs** class are listed below. For a complete list of **FtpServer.ResultEventArgs** class members, see the FtpServer.ResultEventArgs Members topic.

Public Instance Properties

ClientId	Gets a value that uniquely identifies the client session.
Command	Gets a value that specifies the command issued by the client.
ResultCode	Gets the result code associated with the last command issued by the client.

See Also

FtpServer.ResultEventArgs Class | SocketTools Namespace

FtpServer.ResultEventArgs.ClientId Property

Gets a value that uniquely identifies the client session.

[Visual Basic]

```
Public ReadOnly Property ClientId As Integer
```

[C#]

```
public int ClientId {get;}
```

Property Value

An integer value which identifies the client session.

Remarks

The **ClientId** property returns a unique integer value that identifies the client session that generated the event.

See Also

FtpServer.ResultEventArgs Class | SocketTools Namespace

FtpServer.ResultEventArgs.Command Property

Gets a value that specifies the command issued by the client.

[Visual Basic]

```
Public ReadOnly Property Command As String
```

[C#]

```
public string Command {get;}
```

Property Value

A string that specifies the command sent by the client.

See Also

FtpServer.ResultEventArgs Class | SocketTools Namespace

FtpServer.ResultEventArgs.ResultCode Property

Gets the result code associated with the last command issued by the client.

[Visual Basic]

```
Public ReadOnly Property ResultCode As Integer
```

[C#]

```
public int ResultCode {get;}
```

Property Value

An integer value that indicates if the command completed successfully.

Remarks

The **ResultCode** property is a three-digit numeric code that is used to indicate success or failure. These codes are defined as part of the File Transfer Protocol standard, with values in the range of 200-299 indicating success. Values in the range of 400-499 and 500-599 indicate failure due to various error conditions. Examples of such failures would be attempting to access a file that does not exist, issuing an unrecognized command or attempting to perform a privileged operation

See Also

FtpServer.ResultEventArgs Class | SocketTools Namespace

FtpServer.OnStart Event

Occurs when the server starts accepting connections.

[Visual Basic]

```
Public Event OnStart As EventHandler
```

[C#]

```
public event EventHandler OnStart;
```

Remarks

The **OnStart** event occurs after the **Start** method has been called and the server and begins listening for connections from clients. An application can use this event to update the user interface and perform any additional initialization functions that are required by the application

See Also

FtpServer Class | SocketTools Namespace

FtpServer.OnStop Event

Occurs when the server stops accepting connections.

[Visual Basic]
```
Public Event OnStop As EventHandler
```

[C#]
```
public event EventHandler OnStop;
```

Remarks

The **OnStop** event occurs after the **Stop** method has been called and all active client sessions have terminated. An application can use this event to update the user interface and perform any additional cleanup functions that are required by the application. If the server has a large number of active clients, this event may not occur immediately. The **OnDisconnect** event will fire for each client as the server is in the process of shutting down. During the shutdown process, the server is still considered to be active, however it will not accept any further connections. When the **OnStop** event is fired, the server thread has terminated and the listening socket has been closed.

This event will not occur if the server is forcibly stopped using the **Reset** method, or when the **Uninitialize** method is called prior to disposing an instance of the control. Applications that depend on this event should ensure that the server is shutdown gracefully using the **Stop** method prior to terminating the application

FtpServer Class | SocketTools Namespace

FtpServer.OnTimeout Event

Occurs when the client has exceeded the maximum allowed idle time.

[Visual Basic]

```
Public Event OnTimeout As OnTimeoutEventHandler
```

[C#]

```
public event OnTimeoutEventHandler OnTimeout;
```

Event Data

The event handler receives an argument of type FtpServer.TimeoutEventArgs containing data related to this event. The following **FtpServer.TimeoutEventArgs** properties provide information specific to this event.

Property	Description
ClientId	Gets a value that uniquely identifies the client session.
Elapsed	Gets the amount of time that the client was idle.

Remarks

The **OnTimeout** event occurs after the client has has exceeded the maximum allowed idle time, and immediately before the client is disconnected from the server. This event will never occur during a file transfer or directory listing.

To change the default idle timeout period for all clients, set the **IdleTime** property prior to starting the server. To set the idle timeout period for a specific client, set the **ClientIdle** property in an **OnConnect** or **OnLogin** event handler.

This event handler will be invoked in the context of the worker thread that is managing the client session, not the thread that created an instance of the class. Because UI components should only be modified by the thread that created them, the event handler should never attempt to update the user interface directly.

FtpServer.OnUpload Event

Occurs when the client has successfully uploaded a file to the server.

[Visual Basic]

```
Public Event OnUpload As OnUploadEventHandler
```

[C#]

```
public event OnUploadEventHandler OnUpload;
```

Event Data

The event handler receives an argument of type FtpServer.UploadEventArgs containing data related to this event. The following **FtpServer.UploadEventArgs** properties provide information specific to this event.

Property	Description
ClientId	Gets a value that uniquely identifies the client session.
FileName	Gets a value that specifies the file being uploaded.
FileSize	Gets a value that specifies the size of the file.

Remarks

The **OnUpload** event occurs after the client has successfully uploaded a file to the server using the APPE, STOR or STOU command. If the file transfer fails or is aborted, this event will not occur.

This event handler will be invoked in the context of the worker thread that is managing the client session, not the thread that created an instance of the class. Because UI components should only be modified by the thread that created them, the event handler should never attempt to update the user interface directly.

FtpServer.UploadEventArgs Class | SocketTools Namespace

FtpServer.OnAuthenticateEventHandler Delegate

Represents the method that will handle the OnAuthenticate event.

[Visual Basic]

```
Public Delegate Sub FtpServer.OnAuthenticateEventHandler( _
   ByVal sender As Object, _
   ByVal e As AuthenticateEventArgs _
)
```

[C#]

```
public delegate void FtpServer.OnAuthenticateEventHandler(
      object sender,
      AuthenticateEventArgs e
   );
```

Parameters

sender

The source of the event.

e

An AuthenticateEventArgs that contains the event data.

Remarks

When you create an **OnAuthenticateEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnAuthenticateEventHandler** delegate declaration.

Requirements

Namespace: SocketTools

Assembly: SocketTools.FtpServer (in SocketTools.FtpServer.dll)

See Also

SocketTools Namespace

FtpServer.OnCommandEventHandler Delegate

Represents the method that will handle the OnCommand event.

[Visual Basic]

```
Public Delegate Sub FtpServer.OnCommandEventHandler( _
   ByVal sender As Object, _
   ByVal e As CommandEventArgs _
)
```

[C#]

```
public delegate void FtpServer.OnCommandEventHandler(
      object sender,
      CommandEventArgs e
   );
```

Parameters

sender

The source of the event.

e

An CommandEventArgs that contains the event data.

Remarks

When you create an **OnCommandEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnCommandEventHandler** delegate declaration.

Requirements

Namespace: SocketTools

Assembly: SocketTools.FtpServer (in SocketTools.FtpServer.dll)

See Also

SocketTools Namespace

FtpServer.OnConnectEventHandler Delegate

Represents the method that will handle the OnConnect event.

[Visual Basic]

```
Public Delegate Sub FtpServer.OnConnectEventHandler( _
   ByVal sender As Object, _
   ByVal e As ConnectEventArgs _
)
```

[C#]

```
public delegate void FtpServer.OnConnectEventHandler(
      object sender,
      ConnectEventArgs e
   );
```

Parameters

sender

The source of the event.

e

An ConnectEventArgs that contains the event data.

Remarks

When you create an **OnConnectEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnConnectEventHandler** delegate declaration.

Requirements

Namespace: SocketTools

Assembly: SocketTools.FtpServer (in SocketTools.FtpServer.dll)

See Also

SocketTools Namespace

FtpServer.OnDisconnectEventHandler Delegate

Represents the method that will handle the OnDisconnect event.

[Visual Basic]

```
Public Delegate Sub FtpServer.OnDisconnectEventHandler( _
   ByVal sender As Object, _
   ByVal e As DisconnectEventArgs _
)
```

[C#]

```
public delegate void FtpServer.OnDisconnectEventHandler(
      object sender,
      DisconnectEventArgs e
   );
```

Parameters

sender

The source of the event.

e

An DisconnectEventArgs that contains the event data.

Remarks

When you create an **OnDisconnectEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnDisconnectEventHandler** delegate declaration.

Requirements

Namespace: SocketTools

Assembly: SocketTools.FtpServer (in SocketTools.FtpServer.dll)

See Also

SocketTools Namespace

FtpServer.OnDownloadEventHandler Delegate

Represents the method that will handle the OnDownload event.

[Visual Basic]

```
Public Delegate Sub FtpServer.OnDownloadEventHandler( _
   ByVal sender As Object, _
   ByVal e As DownloadEventArgs _
)
```

[C#]

```
public delegate void FtpServer.OnDownloadEventHandler(
      object sender,
      DownloadEventArgs e
   );
```

Parameters

sender

The source of the event.

e

An DownloadEventArgs that contains the event data.

Remarks

When you create an **OnDownloadEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnDownloadEventHandler** delegate declaration.

Requirements

Namespace: SocketTools

Assembly: SocketTools.FtpServer (in SocketTools.FtpServer.dll)

See Also

SocketTools Namespace

FtpServer.OnErrorEventHandler Delegate

Represents the method that will handle the OnError event.

[Visual Basic]

```
Public Delegate Sub FtpServer.OnErrorEventHandler( _
   ByVal sender As Object, _
   ByVal e As ErrorEventArgs _
)
```

[C#]

```
public delegate void FtpServer.OnErrorEventHandler(
      object sender,
      ErrorEventArgs e
   );
```

Parameters

sender

The source of the event.

e

An ErrorEventArgs that contains the event data.

Remarks

When you create an **OnErrorEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnErrorEventHandler** delegate declaration.

Requirements

Namespace: SocketTools

Assembly: SocketTools.FtpServer (in SocketTools.FtpServer.dll)

See Also

SocketTools Namespace

FtpServer.OnExecuteEventHandler Delegate

Represents the method that will handle the OnExecute event.

[Visual Basic]

```
Public Delegate Sub FtpServer.OnExecuteEventHandler( _
   ByVal sender As Object, _
   ByVal e As ExecuteEventArgs _
)
```

[C#]

```
public delegate void FtpServer.OnExecuteEventHandler(
      object sender,
      ExecuteEventArgs e
   );
```

Parameters

sender

The source of the event.

e

An ExecuteEventArgs that contains the event data.

Remarks

When you create an **OnExecuteEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnExecuteEventHandler** delegate declaration.

Requirements

Namespace: SocketTools

Assembly: SocketTools.FtpServer (in SocketTools.FtpServer.dll)

See Also

SocketTools Namespace

FtpServer.OnLoginEventHandler Delegate

Represents the method that will handle the OnLogin event.

[Visual Basic]
```
Public Delegate Sub FtpServer.OnLoginEventHandler( _
   ByVal sender As Object, _
   ByVal e As LoginEventArgs _
)
```

[C#]
```
public delegate void FtpServer.OnLoginEventHandler(
      object sender,
      LoginEventArgs e
   );
```

Parameters

sender

The source of the event.

e

An LoginEventArgs that contains the event data.

Remarks

When you create an **OnLoginEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnLoginEventHandler** delegate declaration.

Requirements

Namespace: SocketTools

Assembly: SocketTools.FtpServer (in SocketTools.FtpServer.dll)

See Also

SocketTools Namespace

FtpServer.OnLogoutEventHandler Delegate

Represents the method that will handle the OnLogout event.

[Visual Basic]

```
Public Delegate Sub FtpServer.OnLogoutEventHandler( _
   ByVal sender As Object, _
   ByVal e As LogoutEventArgs _
)
```

[C#]

```
public delegate void FtpServer.OnLogoutEventHandler(
      object sender,
      LogoutEventArgs e
   );
```

Parameters

sender

The source of the event.

e

An LogoutEventArgs that contains the event data.

Remarks

When you create an **OnLogoutEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnLogoutEventHandler** delegate declaration.

Requirements

Namespace: SocketTools

Assembly: SocketTools.FtpServer (in SocketTools.FtpServer.dll)

SocketTools Namespace

FtpServer.OnResultEventHandler Delegate

Represents the method that will handle the OnResult event.

[Visual Basic]

```
Public Delegate Sub FtpServer.OnResultEventHandler( _
   ByVal sender As Object, _
   ByVal e As ResultEventArgs _
)
```

[C#]

```
public delegate void FtpServer.OnResultEventHandler(
      object sender,
      ResultEventArgs e
   );
```

Parameters

sender
: The source of the event.

e
: An ResultEventArgs that contains the event data.

Remarks

When you create an **OnResultEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnResultEventHandler** delegate declaration.

Requirements

Namespace: SocketTools

Assembly: SocketTools.FtpServer (in SocketTools.FtpServer.dll)

SocketTools Namespace

FtpServer.OnTimeoutEventHandler Delegate

Represents the method that will handle the OnTimeout event.

[Visual Basic]

```
Public Delegate Sub FtpServer.OnTimeoutEventHandler( _
   ByVal sender As Object, _
   ByVal e As TimeoutEventArgs _
)
```

[C#]

```
public delegate void FtpServer.OnTimeoutEventHandler(
      object sender,
      TimeoutEventArgs e
   );
```

Parameters

sender
The source of the event.

e
An TimeoutEventArgs that contains the event data.

Remarks

When you create an **OnTimeoutEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnTimeoutEventHandler** delegate declaration.

Requirements

Namespace: SocketTools

Assembly: SocketTools.FtpServer (in SocketTools.FtpServer.dll)

SocketTools Namespace

FtpServer.OnUploadEventHandler Delegate

Represents the method that will handle the OnUpload event.

[Visual Basic]

```
Public Delegate Sub FtpServer.OnUploadEventHandler( _
   ByVal sender As Object, _
   ByVal e As UploadEventArgs _
)
```

[C#]

```
public delegate void FtpServer.OnUploadEventHandler(
      object sender,
      UploadEventArgs e
   );
```

Parameters

sender

The source of the event.

e

An UploadEventArgs that contains the event data.

Remarks

When you create an **OnUploadEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnUploadEventHandler** delegate declaration.

Requirements

Namespace: SocketTools

Assembly: SocketTools.FtpServer (in SocketTools.FtpServer.dll)

FtpServer.ErrorCode Enumeration

Specifies the error codes returned by the FtpServer class.

[Visual Basic]
```
Public Enum FtpServer.ErrorCode
```

[C#]
```
public enum FtpServer.ErrorCode
```

Remarks

The FtpServer class uses the **ErrorCode** enumeration to specify what error has occurred when a method fails. The current error code may be determined by checking the value of the **LastError** property.

Note that the last error code is only meaningful if the previous operation has failed.

Members

Member Name	Description
errorNone	No error.
errorNotHandleOwner	Handle not owned by the current thread.
errorFileNotFound	The specified file or directory does not exist.
errorFileNotCreated	The specified file could not be created.
errorOperationCanceled	The blocking operation has been canceled.
errorInvalidFileType	The specified file is a block or character device, not a regular file.
errorInvalidDevice	The specified file type is invalid or not a regular file.
errorTooManyParameters	The maximum number of function parameters has been exceeded.
errorInvalidFileName	The specified file name contains invalid characters or is too long.
errorInvalidFileHandle	Invalid file handle passed to function.
errorFileReadFailed	Unable to read data from the specified file.
errorFileWriteFailed	Unable to write data to the specified file.
errorOutOfMemory	Out of memory.
errorAccessDenied	Access denied.
errorInvalidParameter	Invalid argument passed to function.
errorClipboardUnavailable	The system clipboard is currently unavailable.
errorClipboardEmpty	The system clipboard is empty or does not contain any text data.
errorFileEmpty	The specified file does not contain any data.
errorFileExists	The specified file already exists.

errorEndOfFile	End of file.
errorDeviceNotFound	The specified device could not be found.
errorDirectoryNotFound	The specified directory could not be found.
errorInvalidbuffer	Invalid memory address passed to function.
errorBufferTooSmall	The specified buffer is not large enough to contain the data.
errorNoHandles	No more handles are available to this process.
errorOperationWouldBlock	The specified operation would block the current thread.
errorOperationInProgress	A blocking operation is currently in progress.
errorAlreadyInProgress	The specified operation is already in progress.
errorInvalidHandle	Invalid handle passed to function.
errorInvalidAddress	Invalid network address specified.
errorInvalidSize	Datagram is too large to fit in specified buffer.
errorInvalidProtocol	Invalid network protocol specified.
errorProtocolNotAvailable	The specified network protocol is not available.
errorProtocolNotSupported	The specified protocol is not supported.
errorSocketNotSupported	The specified socket type is not supported.
errorInvalidOption	The specified option is invalid.
errorProtocolFamily	Specified protocol family is not supported.
errorProtocolAddress	The specified address is invalid for this protocol family.
errorAddressInUse	The specified address is in use by another process.
errorAddressUnavailable	The specified address cannot be assigned.
errorNetworkUnavailable	The networking subsystem is unavailable.
errorNetworkUnreachable	The specified network is unreachable.
errorNetworkReset	Network dropped connection on remote reset.
errorConnectionAborted	Connection was aborted due to timeout or other failure.
errorConnectionReset	Connection was reset by remote network.
errorOutOfBuffers	No buffer space is available.
errorAlreadyConnected	Connection already established with remote host.
errorNotConnected	No connection established with remote host.
errorConnectionShutdown	Unable to send or receive data after connection shutdown.
errorOperationTimeout	The specified operation has timed out.
errorConnectionRefused	The connection has been refused by the remote host.

errorHostUnavailable	The specified host is unavailable.
errorHostUnreachable	Remote host is unreachable.
errorTooManyProcesses	Too many processes are using the networking subsystem.
errorTooManyThreads	Too many threads have been created by the current process.
errorTooManySessions	Too many client sessions have been created by the current process.
errorInternalFailure	An unexpected internal error has occurred.
errorNetworkNotReady	Network subsystem is not ready for communication.
errorInvalidVersion	This version of the operating system is not supported.
errorNetworkNotInitialized	The networking subsystem has not been initialized.
errorRemoteShutdown	The remote host has initiated a graceful shutdown sequence.
errorInvalidHostName	The specified hostname is invalid or could not be resolved.
errorHostNameNotFound	The specified hostname could not be found.
errorHostNameRefused	Unable to resolve hostname, request refused.
errorHostNameNotResolved	Unable to resolve hostname, no address for specified host.
errorInvalidLicense	The license for this product is invalid.
errorProductNotLicensed	This product is not licensed to perform this operation.
errorNotImplemented	This function has not been implemented on this platform.
errorUnknownLocalhost	Unable to determine local host name.
errorInvalidHostAddress	Invalid host address specified.
errorInvalidServicePort	Invalid service port number specified.
errorInvalidServiceName	Invalid or unknown service name specified.
errorInvalidEventId	Invalid event identifier specified.
errorOperationNotBlocking	No blocking operation in progress on this socket.
errorSecurityNotInitialized	Unable to initialize security interface for this process.
errorSecurityContext	Unable to establish security context for this session.
errorSecurityCredentials	Unable to open certificate store or establish security credentials.
errorSecurityCertificate	Unable to validate the certificate chain for this

	session.
errorSecurityDecryption	Unable to decrypt data stream.
errorSecurityEncryption	Unable to encrypt data stream.
errorOperationNotSupported	The specified operation is not supported.
errorInvalidProtocolVersion	Invalid application protocol version specified.
errorNoServerResponse	No data returned from server.
errorInvalidServerResponse	Invalid data returned from server.
errorUnexpectedServerResponse	Unexpected response code returned from server.
errorServerTransactionFailed	Server transaction failed.
errorServiceUnavailable	The service is currently unavailable.
errorServiceNotReady	The service is not ready, try again later.
errorServerResyncFailed	Unable to resynchronize with server.
errorInvalidProxyType	Invalid proxy server type specified.
errorProxyRequired	Resource must be accessed through specified proxy.
errorInvalidProxyLogin	Unable to login to proxy server using specified credentials.
errorProxyResyncFailed	Unable to resynchronize with proxy server.
errorInvalidCommand	Invalid command specified.
errorInvalidCommandParameter	Invalid command parameter specified.
errorInvalidCommandSequence	Invalid command sequence specified.
errorCommandNotImplemented	Specified command not implemented on this server.
errorCommandNotAuthorized	Specified command not authorized for the current user.
errorCommandAborted	Specified command was aborted by the remote host.
errorOptionNotSupported	The specified option is not supported on this server.
errorRequestNotCompleted	The current client request has not been completed.
errorInvalidUserName	The specified username is invalid.
errorInvalidPassword	The specified password is invalid.
errorInvalidAccount	The specified account name is invalid.
errorAccountRequired	Account name has not been specified.
errorInvalidAuthenticationType	Invalid authentication protocol specified.
errorAuthenticationRequired	User authentication is required.
errorProxyAuthenticationRequired	Proxy authentication required.

errorAlreadyAuthenticated	User has already been authenticated.
errorAuthenticationFailed	Unable to authenticate the specified user.
errorNetworkAdapter	Unable to determine network adapter configuration.
errorInvalidRecordType	Invalid record type specified.
errorInvalidRecordName	Invalid record name specified.
errorInvalidRecordData	Invalid record data specified.
errorConnectionOpen	Data connection already established.
errorConnectionClosed	Server closed data connection.
errorConnectionPassive	Data connection is passive.
errorConnectionFailed	Unable to open data connection to server.
errorInvalidSecurityLevel	Data connection cannot be opened with this security setting.
errorCachedTLSRequired	Data connection requires cached TLS session.
errorDataReadOnly	Data connection is read-only.
errorDataWriteOnly	Data connection is write-only.
errorEndOfData	End of data.
errorRemoteFileUnavailable	Remote file is unavailable.
errorInsufficientStorage	Insufficient storage on server.
errorStorageallocation	File exceeded storage allocation on server.
errorDirectoryExists	The specified directory already exists.
errorDirectoryEmpty	No files returned by the server for the specified directory.
errorEndOfDirectory	End of directory listing.
errorUnknownDirectoryFormat	Unknown directory format.
errorInvalidResource	Invalid resource name specified.
errorResourceRedirected	The specified resource has been redirected.
errorResourceRestricted	Access to this resource has been restricted.
errorResourceNotModified	The specified resource has not been modified.
errorResourceNotFound	The specified resource cannot be found.
errorResourceConflict	Request could not be completed due to the current state of the resource.
errorResourceRemoved	The specified resource has been permanently removed from this server.
errorContentLengthRequired	Request must include the content length.
errorRequestPrecondition	Request could not be completed due to server precondition.
errorUnsupportedMediaType	Request specified an unsupported media type.

errorInvalidContentRange	Content range specified for this resource is invalid.
errorInvalidMessagePart	Message is not multipart or an invalid message part was specified.
errorInvalidMessageHeader	The specified message header is invalid or has not been defined.
errorInvalidMessageBoundary	The multipart message boundary has not been defined.
errorNoFileAttachment	The current message part does not contain a file attachment.
errorUnknownFileType	The specified file type could not be determined.
errorDataNotEncoded	The specified data block could not be encoded.
errorDataNotDecoded	The specified data block could not be decoded.
errorFileNotEncoded	The specified file could not be encoded.
errorFileNotDecoded	The specified file could not be decoded.
errorNoMessageText	No message text.
errorInvalidCharacterSet	Invalid character set specified.
errorInvalidEncodingType	Invalid encoding type specified.
errorInvalidMessageNumber	Invalid message number specified.
errorNoReturnAddress	No valid return address specified.
errorNoValidRecipients	No valid recipients specified.
errorInvalidRecipient	The specified recipient address is invalid.
errorRelayNotAuthorized	The specified domain is invalid or server will not relay messages.
errorMailboxUnavailable	Specified mailbox is currently unavailable.
errorMailboxReadOnly	The selected mailbox cannot be modified.
errorMailboxNotSelected	No mailbox has been selected.
errorInvalidMailbox	Specified mailbox is invalid.
errorInvalidDomain	The specified domain name is invalid or not recognized.
errorInvalidSender	The specified sender address is invalid or not recognized.
errorMessageNotDelivered	Message not delivered to any of the specified recipients.
errorEndOfMessageData	No more message data available to be read
errorInvalidmessageSize	The specified message size is invalid.
errorMessageNotCreated	The message could not be created in the specified mailbox.
errorNoMoreMailboxes	No more mailboxes exist on this server.

errorInvalidEmulationType	The specified terminal emulation type is invalid.
errorInvalidFontHandle	The specified font handle is invalid.
errorInvalidFontName	The specified font name is invalid or unavailable.
errorInvalidPacketSize	The specified packet size is invalid.
errorInvalidPacketData	The specified packet data is invalid.
errorInvalidPacketId	The unique packet identifier is invalid.
errorPacketTTLExpired	The specified packet time-to-live period has expired.
errorInvalidNewsGroup	Invalid newsgroup specified.
errorNoNewsgroupSelected	No newsgroup selected.
errorEmptyNewsgroup	No articles in specified newsgroup.
errorInvalidArticle	Invalid article number specified.
errorNoArticleSelected	No article selected in the current newsgroup.
errorFirstArticle	First article in current newsgroup.
errorLastArticle	Last article in current newsgroup.
errorArticleExists	Unable to transfer article, article already exists.
errorArticleRejected	Unable to transfer article, article rejected.
errorArticleTransferFailed	Article transfer failed.
errorArticlePostingDenied	Posting is not permitted on this server.
errorArticlePostingFailed	Unable to post article on this server.
errorInvalidDateFormat	The specified date format is not recognized.
errorFeatureNotSupported	The specified feature is not supported on this server.
errorInvalidFormHandle	The specified form handle is invalid or a form has not been created.
errorInvalidFormAction	The specified form action is invalid or has not been specified.
errorInvalidFormMethod	The specified form method is invalid or not supported.
errorInvalidFormType	The specified form type is invalid or not supported.
errorInvalidFormField	The specified form field name is invalid or does not exist.
errorEmptyForm	The specified form does not contain any field values.
errorMaximumConnections	The maximum number of client connections exceeded.
errorThreadCreationFailed	Unable to create a new thread for the current process.
errorInvalidThreadHandle	The specified thread handle is no longer valid.

errorThreadTerminated	The specified thread has been terminated.
errorThreadDeadlock	The operation would result in the current thread becoming deadlocked.
errorInvalidClientMoniker	The specified moniker is not associated with any client session.
errorClientMonikerExists	The specified moniker has been assigned to another client session.
errorServerInactive	The specified server is not listening for client connections.
errorServerSuspended	The specified server is suspended and not accepting client connections.
errorNoMessageStore	No message store has been specified.
errorMessageStoreChanged	The message store has changed since it was last accessed.
errorMessageNotFound	No message was found that matches the specified criteria.
errorMessageDeleted	The specified message has been deleted.
errorFileChecksumMismatch	The local and remote file checksums do not match.
errorFileSizeMismatch	The local and remote file sizes do not match.
errorInvalidFeedUrl	The news feed URL is invalid or specifies an unsupported protocol.
errorInvalidFeedFormat	The internal format of the news feed is invalid.
errorInvalidFeedVersion	This version of the news feed is not supported.
errorChannelEmpty	There are no valid items found in this news feed.
errorInvalidItemNumber	The specified channel item identifier is invalid.
errorItemNotFound	The specified channel item could not be found.
errorItemEmpty	The specified channel item does not contain any data.
errorInvalidItemProperty	The specified item property name is invalid.
errorItemPropertyNotFound	The specified item property has not been defined.
errorInvalidChannelTitle	The channel title is invalid or has not been defined.
errorInvalidChannelLink	The channel hyperlink is invalid or has not been defined.
errorInvalidChannelDescription	The channel description is invalid or has not been defined.
errorInvalidItemText	The description for an item is invalid or has not been defined.
errorInvalidItemLink	The hyperlink for an item is invalid or has not been defined.

errorInvalidServiceType	The specified service type is invalid.
errorServiceSuspended	Access to the specified service has been suspended.
errorServiceRestricted	Access to the specified service has been restricted.
errorInvalidProviderName	The specified provider name is invalid or unknown.
errorInvalidPhoneNumber	The specified phone number is invalid or not supported in this region.
errorGatewayNotFound	A message gateway cannot be found for the specified provider.
errorMessageTooLong	The message exceeds the maximum number of characters permitted.
errorInvalidProviderData	The request returned invalid or incomplete service provider data.
errorInvalidGatewayData	The request returned invalid or incomplete message gateway data.
errorMultipleProviders	The request has returned multiple service providers.
errorProviderNotFound	The specified service provider could not be found.
errorInvalidMessageService	The specified message is not supported with this service type.
errorInvalidMessageFormat	The specified message format is invalid.
errorInvalidConfiguration	The specified configuration options are invalid.
errorServerActive	The requested action is not permitted while the server is active.
errorServerPortBound	Unable to obtain exclusive use of the specified local port.
errorInvalidClientSession	The specified client identifier is invalid for this session.
errorClientNotIdentified	The specified client has not provided user credentials.
errorInvalidClientState	The requested action cannot be performed at this time.
errorInvalidResultCode	The specified result code is not valid for this protocol
errorCommandRequired	The specified command is required and cannot be disabled.
errorCommandDisabled	The specified command has been disabled.
errorCommandSequence	The command cannot be processed at this time.
errorCommandCompleted	The previous command has completed.
errorInvalidProgramName	The specified program name is invalid or unrecognized.

errorInvalidRequestHeader	The request header contains one or more invalid values.
errorInvalidVirtualHost	The specified virtual host name is invalid.
errorVirtualHostNotFound	The specified virtual host does not exist.
errorTooManyVirtualHosts	Too many virtual hosts created for this server.
errorInvalidVirtualPath	The specified virtual path name is invalid.
errorVirtualPathNotFound	The specified virtual path does not exist.
errorTooManyVirtualPaths	Too many virtual paths created for this server.
errorInvalidTask	The asynchronous task identifier is invalid.
errorTaskActive	The asynchronous task has not finished.
errorTaskQueued	The asynchronous task has been queued.
errorTaskSuspended	The asynchronous task has been suspended.
errorTaskFinished	The asynchronous task has finished.

FtpServer.FormatType Enumeration

Specifies the logfile formats that the FtpServer class supports.

[Visual Basic]

```
Public Enum FtpServer.FormatType
```

[C#]

```
public enum FtpServer.FormatType
```

Members

Member Name	Description
formatNone	This value specifies that the server should not create or update a log file. This is the default property value.
formatCommon	This value specifies that the log file should use the common log format that records a subset of information in a fixed format. This log format usually only provides information about file transfers.
formatExtended	This value specifies that the log file should use the standard W3C extended log file format. This is an extensible format that can provide additional information about the client session.

Requirements

Namespace: SocketTools

Assembly: SocketTools.FtpServer (in SocketTools.FtpServer.dll)

FtpServer.SecurityProtocols Enumeration

Specifies the security protocols that the FtpServer class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]

```
<Flags>
Public Enum FtpServer.SecurityProtocols
```

[C#]

```
[Flags]
public enum FtpServer.SecurityProtocols
```

Remarks

The FtpServer class uses the **SecurityProtocols** enumeration to specify one or more security protocols to be used when establishing a connection with a remote host. Multiple protocols may be specified if necessary and the actual protocol used will be negotiated with the remote host. It is recommended that most applications use **protocolDefault** when starting a secure server.

Members

Member Name	Description	Value
protocolNone	No security protocol will be used, a secure connection will not be established.	0
protocolSSL2	The SSL 2.0 protocol has been selected. This protocol has been deprecated and is no longer widely used. It is not recommended that this protocol be used when establishing secure connections.	1
protocolSSL3	The SSL 3.0 protocol has been selected. This protocol has been deprecated and is no longer widely used. It is not recommended that this protocol be used when establishing secure connections. In most cases, this protocol is only selected if TLS is not supported by the server.	2
protocolTLS10	The TLS 1.0 protocol has been selected. This version of the protocol is commonly used by older servers and is the only version of TLS supported on Windows platforms prior to Windows 7 SP1 and Windows Server 2008 R2.	4
protocolTLS11	The TLS 1.1 protocol has been selected. This version of TLS is supported on Windows 7 SP1 and Windows Server 2008 R2 and later versions of the	8

	operating system.	
protocolTLS12	The TLS 1.2 protocol has been selected. This is the default version of the protocol and is supported on Windows 7 SP1 and Windows Server 2008 R2 and later versions of Windows. It is recommended that you use this version of TLS.	16
protocolSSL	Any version of the Secure Sockets Layer (SSL) protocol should be used. The actual protocol version used will be negotiated with the remote host.	3
protocolTLS	Any version of the the Transport Layer Security (TLS) protocol should be used. The actual protocol version used will be negotiated with the remote host, with with preference for TLS 1.2.	28
protocolTLS1	Version 1.0, 1.1 or 1.2 of the the Transport Layer Security (TLS) protocol should be used. The actual protocol version used will be negotiated with the remote host, with preference for TLS 1.2.	28
protocolDefault	The default selection of security protocols will be used when establishing a connection. The TLS 1.2, 1.1 and 1.0 protocols will be negotiated with the host, in that order of preference. This option will always request the latest version of the preferred security protocols and is the recommended value.	16
protocolUnknown	An unknown or unsupported security protocol has been specified. This value indicates an error condition.	4096

FtpServer.ServerOptions Enumeration

Specifies the options that the FtpServer class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]

```
<Flags>
Public Enum FtpServer.ServerOptions
```

[C#]

```
[Flags]
public enum FtpServer.ServerOptions
```

Remarks

The FtpServer class uses the **ServerOptions** enumeration to specify one or more options to be used when establishing a connection with a remote host. Multiple options may be specified if necessary.

Members

Member Name	Description	Value
optionNone	No option specified.	0
optionMultiUser	This option specifies the server should be started in multi-user mode, where users are provided with their own home directories based on their username. If this option is not specified, then all users will share the server root directory by default. This option does not affect the maximum number of simultaneous client connections to the server. To isolate users to their own individual home directory, combine this option with the **optionRestricted** option	1
optionRestricted	This option specifies the server should be initialized in a restricted mode that isolates the server and limits the ability for clients to access files on the host system. All file transfers are limited to the user's home directory. This option also disables certain site-specific commands. This is a recommended option for general purpose applications designed to accept connections from clients over the Internet. This option is only meaningful if the **optionMultiUser** option has also been specified. All clients are restricted to the server root directory and its subdirectories, regardless of whether this option is specified or not	2

optionLocalUser	This option specifies the server should perform user authentication using the Windows local account database. This option is useful if the server should accept local usernames, or if the application does not wish to implement an event handler for user authentication. If this option is not specified, the application is responsible for authenticating all users.	4
optionAnonymous	This option specifies the server should accept anonymous client connections. This is typically used to provide public access to files without requiring the client to have valid credentials on the server. Anonymous clients are automatically authenticated by the server, but are restricted to a public directory and subdirectories. If this option is enabled, it is recommended that you also specify the **optionReadOnly** option to prevent anonymous clients from uploading files to the server.	8
optionReadOnly	This option specifies the server should only allow read-only access to files by default. If this option is enabled, it will change the default permissions granted to authenticated users. Anonymous clients will not be able to upload, rename or delete files and cannot create subdirectories. It is recommended that this option be enabled if the server is publicly accessible over the Internet and the **optionAnonymous** option has been specified.	16
optionLocalTime	This option specifies the server should return file and directory times adjusted for the local timezone. By default, the server will return all file times as UTC values. This option affects the time information sent to a client when a list of files is requested, as well as when status information is requested for a specific file. This option will not affect the MDTM and MFMT commands which always use file times as UTC values.	32
optionLockFiles	This option specifies that files should be exclusively locked when a client	64

	attempts to upload or download a file. If another client attempts to access the same file, the operation will fail. By default, the server will permit multiple clients to access the same file, although it will still write-lock files that are in the process of being uploaded.	
optionHiddenFiles	This option specifies that when a client requests a list of files in a directory, the server should include any hidden and system files files or subdirectories. By default, the server will not include hidden or system files, although they are still accessible to the client if it knows the name of the file. File names that begin with a period are also considered to be hidden files and will not normally be included in file listings.	128
optionUnixMode	This option specifies the server should impersonate a UNIX-based operating system. The server will identify itself as running on a UNIX system and directory listings will be in a format commonly used by UNIX. If this option is not specified, the server will identify itself as running on Windows NT and directory listings will be in the same format used by the Microsoft IIS FTP server. Note that this option does not affect the path delimiter used with file and directory names.	256
optionExternal	This option specifies the server is listening for client connections from behind a router that uses Network Address Translation (NAT). If enabled, the server will report its external IP address rather than the address assigned to it on the local network. For the server to accept connections from behind a NAT router, the router must be configured to direct inbound traffic to the specified port number on the host system.	512
optionSecure	This option specifies that secure connections using SSL and/or TLS should be enabled. If neither the **optionExplicitSSL** or **optionImplicitSSL** options are specified, the server automatically determines the appropriate type based	4096

	on the port number. If the local port number is 990, then implicit SSL will be used, otherwise explicit SSL will be used. This option requires that a valid SSL certificate be installed on the local host.	
optionExplicitSSL	This option specifies the server will accept the AUTH TLS command and negotiate a secure connection with the client after that command is issued. This option implies the **optionSecure** option and requires that a valid SSL certificate be installed on the local host.	8192
optionImplicitSSL	This option specifies the server should negotiate a secure connection with the client immediately after it connects to the server. It is recommended that you only use this option if the server is listening for connections on port 990, which is the standard port for FTP servers using implicit SSL. This option implies the **optionSecure** option and requires that a valid SSL certificate be installed on the local host.	16384
optionSecureFallback	This option specifies the server should permit the use of less secure cipher suites for compatibility with legacy clients. If this option is specified, the server will permit connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.	32768

FtpServer.ServerPriority Enumeration

Specifies the priorities that the FtpServer class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]
```
<Flags>
Public Enum FtpServer.ServerPriority
```

[C#]
```
[Flags]
public enum FtpServer.ServerPriority
```

Members

Member Name	Description	Value
priorityBackground	This priority significantly reduces the memory, processor and network resource utilization for the server. It is typically used with lightweight services running in the background that are designed for few client connections. Each client thread will be assigned a lower scheduling priority and will be frequently forced to yield execution to other threads.	0
priorityLow	This priority lowers the overall resource utilization for the client session and meters the processor utilization for the client session. Each client thread will be assigned a lower scheduling priority and will occasionally be forced to yield execution to other threads.	1
priorityNormal	The default priority which balances resource and processor utilization. It is recommended that most applications use this priority.	2
priorityHigh	This priority increases the overall resource utilization for each client session and their threads will be given higher scheduling priority. It is not recommended that this priority be used on a system with a single processor.	3
priorityCritical	This priority can significantly increase processor, memory and network utilization. Each client thread will be given higher scheduling priority and will be more responsive to network events. It is not recommended that this priority be used on a system with a single	4

	processor.	
priorityInvalid	An invalid transfer priority which indicates an error condition.	-1
priorityDefault	The default server priority. This is the same as specifying **priorityNormal**.	2
priorityLowest	The lowest valid server priority. This is the same as specifying **priorityBackground**.	0
priorityHighest	The highest valid server priority. This is the same as specifying **priorityCritical**.	4

SocketTools Namespace

FtpServer.TraceOptions Enumeration

Specifies the logging options that the FtpServer class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

```
[Visual Basic]
<Flags>
Public Enum FtpServer.TraceOptions
```

```
[C#]
[Flags]
public enum FtpServer.TraceOptions
```

Remarks

The FtpServer class uses the **TraceOptions** enumeration to specify what kind of debugging information is written to the trace logfile. These options are only meaningful when trace logging is enabled by setting the **Trace** property to **true**.

Members

Member Name	Description	Value
traceDefault	The default trace logging option. This is the same as specifying the **traceInfo** option.	0
traceInfo	All network function calls are written to the trace file. This is the default value.	0
traceError	Only those network function calls which fail are recorded in the trace file.	1
traceWarning	Only those network function calls which fail, or return values which indicate a warning, are recorded in the trace file.	2
traceHexDump	All network function calls are written to the trace file, plus all the data that is sent or received is displayed, in both ASCII and hexadecimal format.	4
traceProcess	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for multithreaded applications that are using worker threads.	4096

HttpClient Class

Implements the Hypertext Transfer Protocol.

For a list of all members of this type, see HttpClient Members.

System.Object
  SocketTools.HttpClient

[Visual Basic]
```
Public Class HttpClient
    Implements IDisposable
```

[C#]
```
public class HttpClient : IDisposable
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Example

The Hypertext Transfer Protocol (HTTP) is a lightweight, stateless application protocol that is used to access resources on web servers, as well as send data to those servers for processing. The HttpClient class provides direct, low-level access to the server and the commands that are used to retrieve resources (i.e.: documents, images, etc.). The class also provides a simple interface for downloading resources to the local host, similar to how the FtpClient class can be used to download files.

In a typical session, the class is used to establish a connection, send a request (to download a resource, post data for processing, etc.), read the data returned by the server and then disconnect. It is the responsibility of the client to process the data returned by the server, depending on the type of resource that was requested. For example, if an HTML document was requested, the client may parse the contents of the file, looking for specific information.

This class supports secure connections using the standard TLS protocols.

Requirements

Namespace: SocketTools

Assembly: SocketTools.HttpClient (in SocketTools.HttpClient.dll)

HttpClient Members

HttpClient overview

Public Static (Shared) Fields

httpPortDefault	A constant value which specifies the default port number.
httpPortSecure	A constant value which specifies the default port number for a secure connection.
httpTimeout	A constant value which specifies the default timeout period.

Public Static (Shared) Methods

ErrorText	Returns the description of an error code.

Public Instance Constructors

HttpClient Constructor	Initializes a new instance of the HttpClient class.

Public Instance Fields

CookieName	Gets a string which specifies the name of a cookie returned by the server.
CookieValue	Gets a string which specifies the value of a cookie returned by the server.

Public Instance Properties

Authentication	Gets and sets the method used to authenticate the client session.
AutoRedirect	Gets and sets a value that specifies if redirected resources are handled automatically.
AutoResolve	Gets and sets a value that determines if host names and addresses are automatically resolved.
BearerToken	Gets and sets the bearer token used with OAuth 2.0 authentication.
Blocking	Gets and sets a value which indicates if the client is in blocking mode.
CertificateExpires	Get a value that specifies the date that the security certificate expires.
CertificateIssued	Get a value that specifies the date that the security certificate was issued.
CertificateIssuer	Get a value that provides information about the organization that issued the certificate.
CertificateName	Gets and sets a value that specifies the name of the client certificate.

CertificatePassword	Gets and sets the password associated with the client certificate.
CertificateStatus	Gets a value which indicates the status of the security certificate returned by the remote host.
CertificateStore	Gets and sets a value that specifies the name of the local certificate store.
CertificateSubject	Gets a value that provides information about the organization that the server certificate was issued to.
CertificateUser	Gets and sets the user that owns the client certificate.
CipherStrength	Gets a value that indicates the length of the key used by the encryption algorithm for a secure connection.
Compression	Gets and sets a value that specifies if data compression should be enabled.
CookieCount	Gets the number of cookies set by the server in response to a request for a resource.
Encoding	Gets and sets the content encoding type.
FormAction	Gets and sets the path to the script that will accept the form data on the server.
FormMethod	Gets and sets the method used to submit the form data.
FormType	Gets and sets the type of encoding used to submit the form data.
Handle	Gets a value that specifies the client handle allocated for the current session.
HashStrength	Gets a value which specifies the length of the message digest that was selected for a secure connection.
HeaderField	Gets and sets the name of the current header field.
HeaderValue	Gets the value of a response header field or sets the value of a request header field.
HostAddress	Gets and sets a value which specifies the Internet address used to establish a connection.
HostName	Gets and sets a value which specifies the host name used to establish a connection.
IsBlocked	Gets a value which indicates if the current thread is performing a blocking client operation.
IsConnected	Gets a value which indicates if a connection to the remote host has been established.
IsInitialized	Gets a value which indicates if the current instance of the class has been initialized successfully.

IsReadable	Gets a value which indicates if there is data available to be read from the socket connection to the server.
IsWritable	Gets a value which indicates if data can be written to the client without blocking.
KeepAlive	Gets and sets a Boolean value that specifies if the connection to the server is persistent.
LastError	Gets and sets a value which specifies the last error that has occurred.
LastErrorString	Gets a value which describes the last error that has occurred.
LocalAddress	Gets the local Internet address that the client is bound to.
Localize	Gets and sets a value which specifies if date values are localized to the current timezone.
LocalName	Gets a value which specifies the host name for the local system.
LocalPort	Gets the local port number the client is bound to.
Options	Gets and sets a value which specifies one or more client options.
Password	Gets and sets the password used to authenticate the client session.
Priority	Gets and sets a value which specifies the priority of data transfers.
ProtocolVersion	Gets and sets a value which specifies the default protocol version.
ProxyHost	Gets and sets the hostname or IP address of a proxy server.
ProxyPassword	Gets and sets the password used to authenticate the connection to a proxy server.
ProxyPort	Gets and sets a value that specifies the proxy server port number.
ProxyType	Gets and sets the type of proxy server the client will use to establish a connection.
ProxyUser	Gets and sets the username used to authenticate the connection to a proxy server.
RemotePort	Gets and sets a value which specifies the remote port number.
RemoteService	Gets and sets a value which specifies the remote service.
Resource	Gets and sets a value which specifies a resource on the server.

ResultCode	Gets a value which specifies the last result code returned by the server.
ResultString	Gets a string value which describes the result of the previous command.
Secure	Gets and sets a value which specifies if a secure connection is established.
SecureCipher	Gets a value that specifies the encryption algorithm used for a secure connection.
SecureHash	Gets a value that specifies the message digest algorithm used for a secure connection.
SecureKeyExchange	Gets a value that specifies the key exchange algorithm used for a secure connection.
SecureProtocol	Gets and sets a value which specifies the protocol used for a secure connection.
Status	Gets a value which specifies the current status of the client.
TaskCount	Get the number of active background file transfers.
TaskId	Get the task identifier for the last background file transfer.
TaskList	Get an array of active background task identifiers.
ThreadModel	Gets and sets a value which specifies the threading model for the class instance.
ThrowError	Gets and sets a value which specifies if method calls should throw exceptions when an error occurs.
Timeout	Gets and sets a value which specifies a timeout period in seconds.
TimeZone	Gets and sets the current timezone offset in seconds.
Trace	Gets and sets a value which indicates if network function logging is enabled.
TraceFile	Gets and sets a value which specifies the name of the logfile.
TraceFlags	Gets and sets a value which specifies the client function tracing flags.
TransferBytes	Gets a value which specifies the number of bytes transferred to or from the server.
TransferRate	Gets a value which specifies the data transfer rate in bytes per second.
TransferTime	Gets a value which specifies the number of seconds elapsed during a data transfer.
URL	Gets and sets the current URL used to access a file

	on the server.
UserAgent	Gets and sets the current user agent value which identifies the application.
UserName	Gets and sets the username used to authenticate the client session.
Version	Gets a value which returns the current version of the HttpClient class library.

Public Instance Methods

AddField	Overloaded. Add the form field and its value to the current form.
AddFile	Append the contents of the file to the current form.
AsyncGetFile	Overloaded. Download a file from the server to the local system in the background.
AsyncPutFile	Overloaded. Upload a file from the local system to the server in the background.
AttachThread	Attach an instance of the class to the current thread
Authenticate	Overloaded. Authenticate the client session with a username and password.
Cancel	Cancel the current blocking client operation.
ClearForm	Remove all defined fields from the current form.
ClearHeaders	Clears the current request and response headers.
CloseFile	Close the file that was opened on the server.
Command	Overloaded. Send a custom command to the web server.
Connect	Overloaded. Establish a connection with a remote host.
CreateFile	Overloaded. Create a new file or overwrite an existing file on the web server.
CreateForm	Overloaded. Create a new virtual form.
DeleteField	Delete a form field and its value from the current form.
DeleteFile	Remove a file on the web server.
Disconnect	Terminate the connection with a remote host.
Dispose	Overloaded. Releases all resources used by HttpClient.
Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetCookie	Overloaded. Return information about the

	specified cookie.
GetData	Overloaded. Transfer data from the web server and store it in a local buffer.
GetFile	Overloaded. Transfer data from the web server and store it in a file on the local system.
GetFileSize	Overloaded. Return the size of the specified file on the web server.
GetFileTime	Overloaded. Return the modification date and time for specified file on the web server.
GetFirstHeader	Return the first response header field name and value.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetHeader	Return the value of the specified response header field.
GetNextHeader	Return the next response header field name and value.
GetType (inherited from Object)	Gets the Type of the current instance.
Initialize	Overloaded. Initialize an instance of the HttpClient class.
OpenFile	Open a file on the web server for reading.
PatchData	Overloaded. Submits patch data to the server and returns the result in a string.
PostData	Overloaded. Submits the contents of the specified buffer to a resource on the server.
PostFile	Overloaded. Upload the contents of a file to a resource on the server.
PostJson	Overloaded. Submits JSON formatted data to the server and returns the result in a string.
PostXml	Overloaded. Submits XML formatted data to the server and returns the result in a string.
PutData	Overloaded. Transfer data from a local buffer to the server.
PutFile	Overloaded. Transfer a file from the local system to the web server.
Read	Overloaded. Read data from the server and store it in a byte array.
Reset	Reset the internal state of the object, resetting all properties to their default values.
SetCookie	Send the specified cookie to the server when a resource is requested.

SetHeader	Set the value of a request header field.
SubmitForm	Overloaded. Submits the current form data to the server for processing.
TaskAbort	Overloaded. Abort the specified asynchronous task.
TaskDone	Overloaded. Determine if an asynchronous task has completed.
TaskResume	Overloaded. Resume execution of an asynchronous task.
TaskSuspend	Overloaded. Suspend execution of an asynchronous task.
TaskWait	Overloaded. Wait for an asynchronous task to complete.
ToString (inherited from Object)	Returns a String that represents the current Object.
Uninitialize	Uninitialize the class library and release any resources allocated for the current thread.
Write	Overloaded. Write one or more bytes of data to the server.

Public Instance Events

OnCancel	Occurs when a blocking client operation is canceled.
OnCommand	Occurs when the client sends a command to the remote host and receives a reply indicating the result of that command.
OnConnect	Occurs when a connection is established with the remote host.
OnDisconnect	Occurs when the remote host disconnects from the local system.
OnError	Occurs when an client operation fails.
OnProgress	Occurs as a data stream is being read or written to the client.
OnRead	Occurs when data is available to be read from the client.
OnRedirect	Occurs when the server indicates a resource has been moved.
OnTaskBegin	Occurs when an asynchronous task begins execution.
OnTaskEnd	Occurs when an asynchronous task completes.
OnTaskRun	Occurs while a background task is active.
OnTimeout	Occurs when a blocking operation fails to complete before the timeout period elapses.

OnWrite	Occurs when data can be written to the client.

Protected Instance Methods

Dispose	Overloaded. Releases the unmanaged resources allocated by the HttpClient class and optionally releases the managed resources.
Finalize	Destroys an instance of the class, releasing the resources allocated for the session and unloading the networking library.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

HttpClient Class | SocketTools Namespace

HttpClient Constructor

Initializes a new instance of the HttpClient class.

[Visual Basic]

```
Public Sub New()
```

[C#]

```
public HttpClient();
```

HttpClient Class | SocketTools Namespace

HttpClient Fields

The fields of the **HttpClient** class are listed below. For a complete list of **HttpClient** class members, see the HttpClient Members topic.

Public Static (Shared) Fields

httpPortDefault	A constant value which specifies the default port number.
httpPortSecure	A constant value which specifies the default port number for a secure connection.
httpTimeout	A constant value which specifies the default timeout period.

Public Instance Fields

CookieName	Gets a string which specifies the name of a cookie returned by the server.
CookieValue	Gets a string which specifies the value of a cookie returned by the server.

See Also

HttpClient Class | SocketTools Namespace

HttpClient.CookieName Field

Gets a string which specifies the name of a cookie returned by the server.

[Visual Basic]

```
Public ReadOnly CookieName As CookieNameArray
```

[C#]

```
public readonly CookieNameArray CookieName;
```

Remarks

The **CookieName** array returns a string which identifies the cookie specified by the ***index*** argument. The array is zero based, which means the name of the first available cookie is read by using an index value of zero. The **CookieCount** property indicates the total number of cookies that have been returned by the server.

See Also

HttpClient Class | SocketTools Namespace

HttpClient.CookieValue Field

Gets a string which specifies the value of a cookie returned by the server.

[Visual Basic]

```
Public ReadOnly CookieValue As CookieValueArray
```

[C#]

```
public readonly CookieValueArray CookieValue;
```

Remarks

The **CookieValue** array returns a string which contains the value for the cookie specified by the ***index*** argument. The array is zero based, which means the value of the first available cookie is read by using an index value of zero. The **CookieCount** property indicates the total number of cookies that have been returned by the server.

HttpClient Class | SocketTools Namespace

HttpClient.HttpCookie Structure

This structure is used by the GetCookie method to return information about a cookie set by the server.

For a list of all members of this type, see HttpClient.HttpCookie Members.

System.Object
  System.ValueType
    SocketTools.HttpClient.HttpCookie

[Visual Basic]
```
Public Structure HttpClient.HttpCookie
```

[C#]
```
public struct HttpClient.HttpCookie
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Requirements

Namespace: SocketTools

Assembly: SocketTools.HttpClient (in SocketTools.HttpClient.dll)

See Also

HttpClient.HttpCookie Members | SocketTools Namespace

HttpClient.HttpCookie Members

HttpClient.HttpCookie overview

Public Instance Fields

Domain	Gets a value which specifies the cookie domain.
Expires	Gets a value which specifies the date and time the cookie expires.
Flags	Gets a value which specifies one or more cookie flags.
Name	Gets a value which specifies the name of the cookie.
Path	Gets a value which specifies the cookie path.
Value	Gets a value which specifies the contents of the cookie.

Public Instance Methods

Equals (inherited from ValueType)	Indicates whether this instance and a specified object are equal.
GetHashCode (inherited from ValueType)	Returns the hash code for this instance.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString (inherited from ValueType)	Returns the fully qualified type name of this instance.

See Also

HttpClient.HttpCookie Class | SocketTools Namespace

HttpClient.HttpCookie Fields

The fields of the **HttpClient.HttpCookie** structure are listed below. For a complete list of **HttpClient.HttpCookie** structure members, see the HttpClient.HttpCookie Members topic.

Public Instance Fields

Domain	Gets a value which specifies the cookie domain.
Expires	Gets a value which specifies the date and time the cookie expires.
Flags	Gets a value which specifies one or more cookie flags.
Name	Gets a value which specifies the name of the cookie.
Path	Gets a value which specifies the cookie path.
Value	Gets a value which specifies the contents of the cookie.

See Also

HttpClient.HttpCookie Class | SocketTools Namespace

HttpClient.HttpCookie.Domain Field

Gets a value which specifies the cookie domain.

[Visual Basic]

```
Public Domain As String
```

[C#]

```
public string Domain;
```

Remarks

The cookie domain specifies the domain for which the cookie should be used. Matches are made by comparing the name of the remote host against the domain name specified in the cookie. If the domain is example.com, then any server in the example.com domain would match; for example, both shipping.example.com and orders.example.com would match the domain value. However, if the cookie domain was orders.example.com, then the cookie would only be sent if the resource was requested from orders.example.com, not if the resource was located on shipping.example.com or www.example.com.

See Also

HttpClient.HttpCookie Class | SocketTools Namespace

HttpClient.HttpCookie.Expires Field

Gets a value which specifies the date and time the cookie expires.

[Visual Basic]

```
Public Expires As Date
```

[C#]

```
public DateTime Expires;
```

Remarks

If the cookie expiration value is later than the current date and time, the cookie should not be provided to the server when a resource is requested. This is only valid for persistent cookies, since session cookies are automatically deleted when the client application terminates. The time is always expressed as Coordinated Universal Time.

See Also

HttpClient.HttpCookie Class | SocketTools Namespace

HttpClient.HttpCookie.Flags Field

Gets a value which specifies one or more cookie flags.

[Visual Basic]

```
Public Flags As CookieFlags
```

[C#]

```
public CookieFlags Flags;
```

Remarks

The cookie flags value provides additional information about the cookie. In some cases, a cookie should only be submitted to the server if the resource is requested using a secure connection. In this case, the bit flag **cookieSecure** will be set

See Also

HttpClient.HttpCookie Class | SocketTools Namespace

HttpClient.HttpCookie.Name Field

Gets a value which specifies the name of the cookie.

[Visual Basic]

```
Public Name As String
```

[C#]

```
public string Name;
```

See Also

HttpClient.HttpCookie Class | SocketTools Namespace

HttpClient.HttpCookie.Path Field

Gets a value which specifies the cookie path.

[Visual Basic]

```
Public Path As String
```

[C#]

```
public string Path;
```

Remarks

The cookie path specifies a path for the resources where the cookie should be used. For example, a path of "/" indicates that the cookie should be provided for all resources requested from the server. A path of "/data" would mean that the cookie should be included if the resource is found in the /data folder or a sub-folder, such as /data/projections.asp. However, the cookie would not be provided if the resource /info/status.asp was requested, since it is not in the /data path.

HttpClient Properties

The properties of the **HttpClient** class are listed below. For a complete list of **HttpClient** class members, see the HttpClient Members topic.

Public Instance Properties

Authentication	Gets and sets the method used to authenticate the client session.
AutoRedirect	Gets and sets a value that specifies if redirected resources are handled automatically.
AutoResolve	Gets and sets a value that determines if host names and addresses are automatically resolved.
BearerToken	Gets and sets the bearer token used with OAuth 2.0 authentication.
Blocking	Gets and sets a value which indicates if the client is in blocking mode.
CertificateExpires	Get a value that specifies the date that the security certificate expires.
CertificateIssued	Get a value that specifies the date that the security certificate was issued.
CertificateIssuer	Get a value that provides information about the organization that issued the certificate.
CertificateName	Gets and sets a value that specifies the name of the client certificate.
CertificatePassword	Gets and sets the password associated with the client certificate.
CertificateStatus	Gets a value which indicates the status of the security certificate returned by the remote host.
CertificateStore	Gets and sets a value that specifies the name of the local certificate store.
CertificateSubject	Gets a value that provides information about the organization that the server certificate was issued to.
CertificateUser	Gets and sets the user that owns the client certificate.
CipherStrength	Gets a value that indicates the length of the key used by the encryption algorithm for a secure connection.
Compression	Gets and sets a value that specifies if data compression should be enabled.
CookieCount	Gets the number of cookies set by the server in response to a request for a resource.
Encoding	Gets and sets the content encoding type.

FormAction	Gets and sets the path to the script that will accept the form data on the server.
FormMethod	Gets and sets the method used to submit the form data.
FormType	Gets and sets the type of encoding used to submit the form data.
Handle	Gets a value that specifies the client handle allocated for the current session.
HashStrength	Gets a value which specifies the length of the message digest that was selected for a secure connection.
HeaderField	Gets and sets the name of the current header field.
HeaderValue	Gets the value of a response header field or sets the value of a request header field.
HostAddress	Gets and sets a value which specifies the Internet address used to establish a connection.
HostName	Gets and sets a value which specifies the host name used to establish a connection.
IsBlocked	Gets a value which indicates if the current thread is performing a blocking client operation.
IsConnected	Gets a value which indicates if a connection to the remote host has been established.
IsInitialized	Gets a value which indicates if the current instance of the class has been initialized successfully.
IsReadable	Gets a value which indicates if there is data available to be read from the socket connection to the server.
IsWritable	Gets a value which indicates if data can be written to the client without blocking.
KeepAlive	Gets and sets a Boolean value that specifies if the connection to the server is persistent.
LastError	Gets and sets a value which specifies the last error that has occurred.
LastErrorString	Gets a value which describes the last error that has occurred.
LocalAddress	Gets the local Internet address that the client is bound to.
Localize	Gets and sets a value which specifies if date values are localized to the current timezone.
LocalName	Gets a value which specifies the host name for the local system.
LocalPort	Gets the local port number the client is bound to.

Options	Gets and sets a value which specifies one or more client options.
Password	Gets and sets the password used to authenticate the client session.
Priority	Gets and sets a value which specifies the priority of data transfers.
ProtocolVersion	Gets and sets a value which specifies the default protocol version.
ProxyHost	Gets and sets the hostname or IP address of a proxy server.
ProxyPassword	Gets and sets the password used to authenticate the connection to a proxy server.
ProxyPort	Gets and sets a value that specifies the proxy server port number.
ProxyType	Gets and sets the type of proxy server the client will use to establish a connection.
ProxyUser	Gets and sets the username used to authenticate the connection to a proxy server.
RemotePort	Gets and sets a value which specifies the remote port number.
RemoteService	Gets and sets a value which specifies the remote service.
Resource	Gets and sets a value which specifies a resource on the server.
ResultCode	Gets a value which specifies the last result code returned by the server.
ResultString	Gets a string value which describes the result of the previous command.
Secure	Gets and sets a value which specifies if a secure connection is established.
SecureCipher	Gets a value that specifies the encryption algorithm used for a secure connection.
SecureHash	Gets a value that specifies the message digest algorithm used for a secure connection.
SecureKeyExchange	Gets a value that specifies the key exchange algorithm used for a secure connection.
SecureProtocol	Gets and sets a value which specifies the protocol used for a secure connection.
Status	Gets a value which specifies the current status of the client.
TaskCount	Get the number of active background file transfers.
TaskId	Get the task identifier for the last background file

	transfer.
TaskList	Get an array of active background task identifiers.
ThreadModel	Gets and sets a value which specifies the threading model for the class instance.
ThrowError	Gets and sets a value which specifies if method calls should throw exceptions when an error occurs.
Timeout	Gets and sets a value which specifies a timeout period in seconds.
TimeZone	Gets and sets the current timezone offset in seconds.
Trace	Gets and sets a value which indicates if network function logging is enabled.
TraceFile	Gets and sets a value which specifies the name of the logfile.
TraceFlags	Gets and sets a value which specifies the client function tracing flags.
TransferBytes	Gets a value which specifies the number of bytes transferred to or from the server.
TransferRate	Gets a value which specifies the data transfer rate in bytes per second.
TransferTime	Gets a value which specifies the number of seconds elapsed during a data transfer.
URL	Gets and sets the current URL used to access a file on the server.
UserAgent	Gets and sets the current user agent value which identifies the application.
UserName	Gets and sets the username used to authenticate the client session.
Version	Gets a value which returns the current version of the HttpClient class library.

See Also

HttpClient Class | SocketTools Namespace

HttpClient.Authentication Property

Gets and sets the method used to authenticate the client session.

[Visual Basic]

```
Public Property Authentication As HttpAuthentication
```

[C#]

```
public HttpClient.HttpAuthentication Authentication {get; set;}
```

Property Value

A HttpAuthentication enumeration value which specifies the authentication method.

Remarks

By default, no authentication is used when accessing a resource on the web server. Setting the **UserName** or **Password** property will automatically set the authentication type to use **authBasic** unless a different method has already been specified.

Changing the value of the **BearerToken** property will automatically set the current authentication method to use **authBearer**.

You should only use the **authBearer** authentication method if you understand the process of how to request the access token. Obtaining an access token requires registering your application with the web service provider (e.g.: Microsoft or Google), getting a unique client ID associated with your application and then requesting the access token using the appropriate scope for the service. Obtaining the initial token will typically involve interactive confirmation on the part of the user, requiring they grant permission to your application to access the service.

See Also

HttpClient Class | SocketTools Namespace | BearerToken Poperty | Password Property | UserName Property | Connect Method

HttpClient.AutoRedirect Property

Gets and sets a value that specifies if redirected resources are handled automatically.

[Visual Basic]
```
Public Property AutoRedirect As Boolean
```

[C#]
```
public bool AutoRedirect {get; set;}
```

Property Value

A boolean value. A value of **true** specifies that requests for resources that have moved will automatically redirect the client to the new location for that resource. A value of **false** specifies that the client is responsible for requesting the resource from the new location.

Remarks

When the server indicates that a resource has been redirected, the **OnRedirect** event will fire and will provide the new location for the resource as an argument to the event handler. It is permissible for the application to change the value of the **AutoRedirect** property inside the event handler to determine whether or not the class will automatically access the resource from the new location.

See Also

HttpClient Class | SocketTools Namespace

HttpClient.AutoResolve Property

Gets and sets a value that determines if host names and addresses are automatically resolved.

[Visual Basic]
```
Public Property AutoResolve As Boolean
```

[C#]
```
public bool AutoResolve {get; set;}
```

Property Value

Returns **true** if host names are automatically resolved to Internet addresses. The default value is **false**.

Remarks

Setting the **AutoResolve** property determines if the class automatically resolves host names and addresses specified by the **HostName** and **HostAddress** properties. If set to **true**, setting the **HostName** property will cause the class to automatically determine the corresponding IP address and update the **HostAddress** property accordingly. Likewise, setting the **HostAddress** property will cause the class to determine the host name and update the **HostName** property. Setting this property to **false** prevents the class from resolving host names until a connection attempt is made.

It is important to note that setting the **HostName** or **HostAddress** property may cause the current thread to block, sometimes for several seconds, until the name or address is resolved. To prevent this behavior, set this property value to **false**.

See Also

HttpClient Class | SocketTools Namespace

HttpClient.BearerToken Property

Gets and sets the bearer token used with OAuth 2.0 authentication.

[Visual Basic]

```
Public Property BearerToken As String
```

[C#]

```
public string BearerToken {get; set;}
```

Property Value

Returns a string which contains the OAuth 2.0 bearer token. Assigning a value to this property sets the curent authentication type to use OAuth 2.0 and updates the bearer token.

Remarks

Assigning a value to the **BearerToken** property will automatically change the current authentication method to use **HttpAuthentication.authBearer** if necessary.

Obtaining a bearer token requires registering your application with the web service provider (e.g.: Microsoft or Google), getting a unique client ID associated with your application and then requesting the bearer token using the appropriate scope for the service. Obtaining the initial token will typically involve interactive confirmation on the part of the user, requiring they grant permission to your application to access the service.

Your application should not store the bearer token for later use. They have a relatively short lifespan, typically about an hour, and are designed to be used with the current client session. You should specify offline access as part of the OAuth 2.0 scope if necessary and store the refresh token provided by the service. The refresh token has a much longer validity period and can be used to obtain a new access token when needed.

If the current authentication method does not use OAuth 2.0, this property will return an empty string and you should use the **Password** property to obtain the current user password.

See Also

HttpClient Class | SocketTools Namespace | Authentication Property | Password Property | UserName Property

HttpClient.Blocking Property

Gets and sets a value which indicates if the client is in blocking mode.

[Visual Basic]

```
Public Property Blocking As Boolean
```

[C#]

```
public bool Blocking {get; set;}
```

Property Value

Returns **true** if the client is in blocking mode; otherwise it returns **false**. The default value is **true**.

Remarks

Setting the **Blocking** property determines if client operations complete synchronously or asynchronously. If set to **true**, then each client operation (such as sending or receiving data) will return when the operation has completed or timed-out. If set to **false**, client operations will return immediately. If the operation would result in the client blocking (such as attempting to read data when no data has been sent by the remote host), an error is generated.

It is important to note that certain events, such as **OnDisconnect, OnRead** and **OnWrite** are only fired if the client is in non-blocking mode.

HttpClient Class | SocketTools Namespace

HttpClient.CertificateExpires Property

Get a value that specifies the date that the security certificate expires.

[Visual Basic]

```
Public ReadOnly Property CertificateExpires As String
```

[C#]

```
public string CertificateExpires {get;}
```

Property Value

A string which specifies a date using the local date and time format.

Remarks

The **CertificateExpires** property returns a string that specifies the date and time that the security certificate expires. This property will return an empty string if a secure connection has not been established with the remote host.

See Also

HttpClient Class | SocketTools Namespace

HttpClient.CertificateIssued Property

Get a value that specifies the date that the security certificate was issued.

[Visual Basic]

```
Public ReadOnly Property CertificateIssued As String
```

[C#]

```
public string CertificateIssued {get;}
```

Property Value

A string which specifies a date using the local date and time format.

Remarks

The **CertificateIssued** property returns a string that specifies the date and time that the security certificate was issued. This property will return an empty string if a secure connection has not been established with the remote host.

See Also

HttpClient Class | SocketTools Namespace

HttpClient.CertificateIssuer Property

Get a value that provides information about the organization that issued the certificate.

[Visual Basic]

```
Public ReadOnly Property CertificateIssuer As String
```

[C#]

```
public string CertificateIssuer {get;}
```

Property Value

A string that contains a comma separated list of name value pairs.

Remarks

The **CertificateIssuer** property returns a string that contains information about the organization that issued the server certificate. The string value is a comma separated list of tagged name and value pairs. In the nomenclature of the X.500 standard, each of these pairs are called a relative distinguished name (RDN), and when concatenated together, forms the issuer's distinguished name (DN). For example:

```
C=US, O="RSA Data Security, Inc.", OU=Secure Server Certification Authority
```

To obtain a specific value, such as the name of the issuer or the issuer's country, the application must parse the string returned by this property. Some of the common tokens used in the distinguished name are:

Token	Description
C	The ISO standard two character country code.
S	The name of the state or province.
L	The name of the city or locality.
O	The name of the company or organization.
OU	The name of the department or organizational unit
CN	The common name; with X.509 certificates, this is the domain name of the site the certificate was issued for.

This property will return an empty string if a secure connection has not been established with the remote host.

See Also

HttpClient Class | SocketTools Namespace

HttpClient.CertificateName Property

Gets and sets a value that specifies the name of the client certificate.

[Visual Basic]

```
Public Property CertificateName As String
```

[C#]

```
public string CertificateName {get; set;}
```

Property Value

A string which specifies the certificate name.

Remarks

The **CertificateName** property is used to specify the name of a client certificate to use when establishing a secure connection. It is only required that you set this property value if the server requires a client certificate for authentication. If this property is not set, a client certificate will not be provided to the server. If a certificate name is specified, the certificate must have a private key associated with it, otherwise the connection attempt will fail because the control will be unable to create a security context for the session.

When the certificate store is searched for a matching certificate, it will first search for any certificate with a friendly name that matches the property value. If no valid certificate is found, it will then search for a certificate with a matching common name.

Certificates may be installed and viewed on the local system using the Certificate Manager that is included with the Windows operating system. For more information, refer to the documentation for the Microsoft Management Console.

See Also

HttpClient Class | SocketTools Namespace | CertificateStore Property | Secure Property

HttpClient.CertificateStatus Property

Gets a value which indicates the status of the security certificate returned by the remote host.

[Visual Basic]

```
Public ReadOnly Property CertificateStatus As SecurityCertificate
```

[C#]

```
public HttpClient.SecurityCertificate CertificateStatus {get;}
```

Property Value

A SecurityCertificate enumeration value which specifies the status of the certificate.

Remarks

The **CertificateStatus** property is used to determine the status of the security certificate returned by the remote host when a secure connection has been established. This property value should be checked after the connection to the server has completed, but prior to beginning a transaction.

Note that if the certificate cannot be validated, the secure connection will not be automatically terminated. It is the responsibility of your application to determine the best course of action to take if the certificate is invalid. Even if the security certificate cannot be validated, the data exchanged with the remote host will still be encrypted.

See Also

HttpClient Class | SocketTools Namespace

HttpClient.CertificateStore Property

Gets and sets a value that specifies the name of the local certificate store.

[Visual Basic]

```
Public Property CertificateStore As String
```

[C#]

```
public string CertificateStore {get; set;}
```

Property Value

A string which specifies the certificate store name. The default value is the current user's personal certificate store.

Remarks

The **CertificateStore** property is used to specify the name of the certificate store which contains the security certificate to use when establishing a secure connection. The certificate may either be stored in the registry or in a file. If the certificate is stored in the registry, then this property should be set to one of the following predefined values:

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as VeriSign and Thawte act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. If a certificate store is not specified, this is the default value that is used.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as VeriSign and Thawte are installed as part of the operating system and periodically updated by Microsoft.

In most cases the client certificate will be installed in the user's personal certificate store, and therefore it is not necessary to set this property value because that is the default location that will be used to search for the certificate. This property is only used if the **CertificateName** property is also set to a valid certificate name.

If you are using a local certificate store, with the certificate and private key stored in the registry, you can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU" for the current user, or "HKLM" for the local machine. For example, a certificate store name of "HKLM:MY" would specify the personal certificate store for the local machine, rather than the current user. If neither prefix is specified, it will default to the certificate store for the current user.

This property may also be used to specify a file that contains the client certificate. In this case, the property should specify the full path to the file and must contain both the certificate and private key in PKCS12

format. If the file is protected by a password, the **CertificatePassword** property must also be set to specify the password.

See Also

HttpClient Class | SocketTools Namespace | CertificatePassword Property | Secure Property

HttpClient.CertificateSubject Property

Gets a value that provides information about the organization that the server certificate was issued to.

[Visual Basic]

```
Public ReadOnly Property CertificateSubject As String
```

[C#]

```
public string CertificateSubject {get;}
```

Property Value

A string that contains a comma separated list of name value pairs.

Remarks

The **CertificateSubject** property returns a string that contains information about the organization that the server certificate was issued to. The string value is a comma separated list of tagged name and value pairs. In the nomenclature of the X.500 standard, each of these pairs are called a relative distinguished name (RDN), and when concatenated together, forms the issuer's distinguished name (DN). For example:

```
C=US, O="RSA Data Security, Inc.", OU=Secure Server Certification Authority
```

To obtain a specific value, such as the name of the issuer or the issuer's country, the application must parse the string returned by this property. Some of the common tokens used in the distinguished name are:

Token	Description
C	The ISO standard two character country code.
S	The name of the state or province.
L	The name of the city or locality.
O	The name of the company or organization.
OU	The name of the department or organizational unit
CN	The common name; with X.509 certificates, this is the domain name of the site the certificate was issued for.

This property will return an empty string if a secure connection has not been established with the remote host.

See Also

HttpClient Class | SocketTools Namespace

HttpClient.CipherStrength Property

Gets a value that indicates the length of the key used by the encryption algorithm for a secure connection.

[Visual Basic]

```
Public ReadOnly Property CipherStrength As Integer
```

[C#]

```
public int CipherStrength {get;}
```

Property Value

An integer value which specifies the encryption key length if a secure connection has been established; otherwise a value of 0 is returned.

Remarks

The **CipherStrength** property returns the number of bits in the key used to encrypt the secure data stream. Common values returned by this property are 128 and 256. A key length of 40 or 56 bits is considered insecure and subject to brute force attacks. 128-bit and 256-bit keys are considered secure. If this property returns a value of 0, this means that a secure connection has not been established with the remote host.

See Also

HttpClient Class | SocketTools Namespace

HttpClient.Compression Property

Gets and sets a value that specifies if data compression should be enabled.

[Visual Basic]
```
Public Property Compression As Boolean
```

[C#]
```
public bool Compression {get; set;}
```

Property Value

Returns **true** if a data compression is enabled; otherwise returns **false**. The default value is **false.**

Remarks

The **Compression** property is used to indicate to the server whether or not it is acceptable to compress the data that is returned to the client. If compression is enabled, the client will advertise that it will accept compressed data by setting the **Accept-Encoding** request header. The server will decide whether a resource being requested can be compressed. If the data is compressed, the control will automatically expand the data before returning it to the caller.

Enabling compression does not guarantee that the data returned by the server will actually be compressed, it only informs the server that the client is willing to accept compressed data. Whether or not a particular resource is compressed depends on the server configuration, and the server may decide to only compress certain types of resources, such as text files. Disabling compression informs the server that the client is not willing to accept compressed data; this is the default.

If the **SetHeader** method is used to explicitly set the **Accept-Encoding** header to request compressed data and compression is not enabled, the class will not attempt to automatically expand the data returned by the server. In this case, the raw compressed data will be returned and the application is responsible for processing it. This behavior is by design to maintain backwards compatibility with previous versions of the control that did not have internal support for compression.

To determine if the server compressed the data returned to the client, use the **GetHeader** method to get the value of the **Content-Encoding** header. If the header is defined, the value specifies the compression method used, otherwise the data was not compressed.

This property value is only meaningful when downloading files from a server that supports file compression. It has no effect on file uploads.

See Also

HttpClient Class | SocketTools Namespace | GetData Method | GetFile Method

HttpClient.CookieCount Property

Gets the number of cookies set by the server in response to a request for a resource.

[Visual Basic]

```
Public ReadOnly Property CookieCount As Integer
```

[C#]

```
public int CookieCount {get;}
```

Property Value

An integer value which specifies the number of available cookies.

Remarks

This value can be used in conjunction with the **CookieName** and **CookieValue** properties to enumerate all of the available cookies and their values.

See Also

HttpClient Class | SocketTools Namespace

HttpClient.Encoding Property

Gets and sets the content encoding type.

[Visual Basic]
```
Public Property Encoding As HttpEncoding
```

[C#]
```
public HttpClient.HttpEncoding Encoding {get; set;}
```

Property Value

An HttpEncoding enumeration value which specifies the current encoding type.

Remarks

The **Encoding** property explicitly sets the type of encoding used when optional parameter data is submitted with a request for a resource. By default, data is URL encoded and the content type will be designated as application/x-www-form-urlencoded.

If an application must specify its own Content-Type header, this property must be set to **HttpEncoding.encodingNone** to prevent the control from replacing the header value when the request is sent to the server. Changes to this property and any calls to the **SetHeader** method should be made after the connection to the server has been established, immediately before the resource is requested.

See Also

HttpClient Class | SocketTools Namespace

HttpClient.FormAction Property

Gets and sets the path to the script that will accept the form data on the server.

[Visual Basic]

```
Public Property FormAction As String
```

[C#]

```
public string FormAction {get; set;}
```

Property Value

A string which specifies a script on the server.

Remarks

The **FormAction** property is used to specify the name of the script that will process the form data submitted by the control. This property is only used by the **SubmitForm** method and changing the property value does not change the current resource.

See Also

HttpClient Class | SocketTools Namespace

HttpClient.FormMethod Property

Gets and sets the method used to submit the form data.

[Visual Basic]

```
Public Property FormMethod As HttpFormMethod
```

[C#]

```
public HttpClient.HttpFormMethod FormMethod {get; set;}
```

Property Value

An HttpFormMethod enumeration which specifies the method used to submit the form data.

See Also

HttpClient Class | SocketTools Namespace

HttpClient.FormType Property

Gets and sets the type of encoding used to submit the form data.

[Visual Basic]

```
Public Property FormType As HttpFormType
```

[C#]

```
public HttpClient.HttpFormType FormType {get; set;}
```

Property Value

An HttpFormType enumeration value which specifies the form type and encoding method.

See Also

HttpClient Class | SocketTools Namespace

HttpClient.Handle Property

Gets a value that specifies the client handle allocated for the current session.

[Visual Basic]

```
Public ReadOnly Property Handle As Integer
```

[C#]

```
public int Handle {get;}
```

Property Value

An integer which represents a client handle. If there is no active connection, a value of -1 is returned.

Remarks

The **Handle** property specifies the numeric descriptor of the current client session.

See Also

HttpClient Class | SocketTools Namespace

HttpClient.HashStrength Property

Gets a value which specifies the length of the message digest that was selected for a secure connection.

[Visual Basic]

```
Public ReadOnly Property HashStrength As Integer
```

[C#]

```
public int HashStrength {get;}
```

Property Value

An integer value which specifies the length of the message digest if a secure connection has been established; otherwise a value of 0 is returned.

Remarks

The **HashStrength** property returns the number of bits used in the message digest (hash) that was selected. Common values returned by this property are 128 and 160. If this property returns a value of 0, this means that a secure connection has not been established with the remote host.

See Also

HttpClient Class | SocketTools Namespace

HttpClient.HeaderField Property

Gets and sets the name of the current header field.

[Visual Basic]
```
Public Property HeaderField As String
```

[C#]
```
public string HeaderField {get; set;}
```

Property Value

A string which specifies the current header field.

Remarks

The **HeaderField** property is used in conjunction with the **HeaderValue** property to set and/or get the values of specific fields in the HTTP request header. For example, setting this property to the value "Content-Length" and then reading the value of the **HeaderValue** property would cause the class to return length (in bytes) of the specified resource.

Note that the control automatically generates a default request header, and it is not required that the client use the **HeaderField** and **HeaderValue** properties unless it has a specific need to do so

See Also

HttpClient Class | SocketTools Namespace

HttpClient.HeaderValue Property

Gets the value of a response header field or sets the value of a request header field.

[Visual Basic]

```
Public Property HeaderValue As String
```

[C#]

```
public string HeaderValue {get; set;}
```

Property Value

A string which specifies the header field value.

Remarks

The **HeaderValue** property is used in conjunction with the **HeaderField** property to set or get the values of specific fields in the HTTP request and response headers. When the property is set to a value, then the specified request header field is set to this value. When the property is read, then the value associated with the specified response header field is returned.

Note that the control automatically generates a default request header, and it is not required that the client use the **HeaderField** and **HeaderValue** properties unless it has a specific need to do so.

See Also

HttpClient Class | SocketTools Namespace

HttpClient.HostAddress Property

Gets and sets a value which specifies the Internet address used to establish a connection.

[Visual Basic]

```
Public Property HostAddress As String
```

[C#]

```
public string HostAddress {get; set;}
```

Property Value

A string which specifies an Internet address.

Remarks

The **HostAddress** property can be used to set the Internet address for a remote system that you wish to communicate with. If the **AutoResolve** property is set to **true** and the address is assigned to a valid host name, the **HostName** property will be updated with that value.

See Also

HttpClient Class | SocketTools Namespace

HttpClient.HostName Property

Gets and sets a value which specifies the host name used to establish a connection.

[Visual Basic]

```
Public Property HostName As String
```

[C#]

```
public string HostName {get; set;}
```

Property Value

A string which specifies a host name.

Remarks

The **HostName** property can be used to set the host name for a remote system that you wish to communicate with. If the **AutoResolve** property is set to **true** and the name can be resolved to a valid Internet address, the **HostAddress** property will be updated with that value.

See Also

HttpClient Class | SocketTools Namespace

HttpClient.IsBlocked Property

Gets a value which indicates if the current thread is performing a blocking client operation.

[Visual Basic]

```
Public ReadOnly Property IsBlocked As Boolean
```

[C#]

```
public bool IsBlocked {get;}
```

Property Value

Returns **true** if the current thread is blocking, otherwise returns **false**.

Remarks

The **IsBlocked** property returns **true** if the current thread is blocked performing an operation. Because the Windows Sockets API only permits one blocking operation per thread of execution, this property should be checked before starting any blocking operation in response to an event.

If the **IsBlocked** property returns **false**, this means there are no blocking operations on the current thread at that time. However, this does not guarantee that the next client operation will not fail. An application should always check the return value from a client operation and check the value of the **LastError** property if an error occurs.

Note that this property will return **true** if there is any blocking operation being performed by the current thread, regardless of whether this specific instance of the class is responsible for the blocking operation or not.

See Also

HttpClient Class | SocketTools Namespace

HttpClient.IsConnected Property

Gets a value which indicates if a connection to the remote host has been established.

[Visual Basic]
```
Public ReadOnly Property IsConnected As Boolean
```

[C#]
```
public bool IsConnected {get;}
```

Property Value

Returns **true** if the connection has been established; otherwise returns **false**.

Remarks

The **IsConnected** property can only be used to indicate if there is still a logical connection to the remote host. It cannot be used to detect abnormal conditions such as the remote host aborting the connection, the physical network connection being lost or other critical errors.

See Also

HttpClient Class | SocketTools Namespace

HttpClient.IsInitialized Property

Gets a value which indicates if the current instance of the class has been initialized successfully.

[Visual Basic]

```
Public ReadOnly Property IsInitialized As Boolean
```

[C#]

```
public bool IsInitialized {get;}
```

Property Value

Returns **true** if the class instance has been initialized; otherwise returns **false**.

Remarks

The **IsInitialized** property is used to determine if the current instance of the class has been initialized properly. Normally this is done automatically by the class constructor, however there are circumstances where the class may not be able to initialize itself.

The most common reasons that a class instance may not initialize correctly is that no runtime license key has been defined in the assembly or the license key provided is invalid. It may also indicate a problem with the system configuration or user access rights, such as not being able to load the required networking libraries or not being able to access the system registry.

See Also

HttpClient Class | SocketTools Namespace

HttpClient.IsReadable Property

Gets a value which indicates if there is data available to be read from the socket connection to the server.

[Visual Basic]

```
Public ReadOnly Property IsReadable As Boolean
```

[C#]

```
public bool IsReadable {get;}
```

Property Value

Returns **true** if there is data available to be read; otherwise returns **false**.

Remarks

The **IsReadable** property returns **true** if data can be read from the client without blocking. For non-blocking sessions, this property can be checked before the application attempts to read the client. Note that even if this property does return **true** indicating that there is data available to be read, applications should always check the return value from the **Read** method.

See Also

HttpClient Class | SocketTools Namespace

HttpClient.IsWritable Property

Gets a value which indicates if data can be written to the client without blocking.

[Visual Basic]

```
Public ReadOnly Property IsWritable As Boolean
```

[C#]

```
public bool IsWritable {get;}
```

Property Value

Returns **true** if data can be written to the client; otherwise returns **false**.

Remarks

The **IsWritable** property returns **true** if data can be written to the client without blocking. For non-blocking sessions, this property can be checked before the application attempts to write data to the client. Note that even if this property does return **true** indicating that data can be written to the client, applications should always check the return value from the **Write** method.

See Also

HttpClient Class | SocketTools Namespace

HttpClient.KeepAlive Property

Gets and sets a Boolean value that specifies if the connection to the server is persistent.

[Visual Basic]
```
Public Property KeepAlive As Boolean
```

[C#]
```
public bool KeepAlive {get; set;}
```

Property Value

A boolean value that specifies if the connection to the server is persistent.

Remarks

Setting the **KeepAlive** property to a value of **true** indicates that the client wishes to maintain a persistent connection with the server. For those clients who wish to retrieve a number of documents, this is more efficient because the client does not need to connect, retrieve the document and disconnect each time. Instead, the client can connect, retrieve each document and then disconnect when it is finished. If the property value is **false**, a persistent connection is not maintained, and the client must establish a connection for each document that it wishes to retrieve. This property should be set to the desired value before establishing a connection with the remote server.

Note that this option is only available for those servers which support version 1.0 or later of the HTTP protocol. For version 1.0 servers, the connection header field is set to the value 'keep-alive', which instructs compliant servers to maintain a persistent connection. For version 1.1 and later, persistent connections are the default. In this case, if the property value is set to **false**, the connection header field will be set to the value 'close', telling the server that you wish to close the connection after the document has been retrieved. It is possible that the server may choose to close the connection itself, even if it supports persistent connections. If the server does not support persistent connections and the **KeepAlive** property is set to **true**, the client will attempt to simulate a persistent connection by automatically reconnecting for each request.

See Also

HttpClient Class | SocketTools Namespace

HttpClient.LastError Property

Gets and sets a value which specifies the last error that has occurred.

[Visual Basic]

```
Public Property LastError As ErrorCode
```

[C#]

```
public HttpClient.ErrorCode LastError {get; set;}
```

Property Value

Returns an ErrorCode enumeration value which specifies the last error code.

Remarks

The **LastError** property returns the error code associated with the last error that occurred for the current instance of the class. It is important to note that this value only has meaning if the previous method indicates that an error has actually occurred.

It is possible to explicitly clear the last error code by assigning the property to the value **ErrorCode.errorNone**.

The error code value can be cast to an integer value for display purposes if required. For a description of the error that can be displayed using a message box or some other similar mechanism, get the value of the **LastErrorString** property.

See Also

HttpClient Class | SocketTools Namespace

HttpClient.LastErrorString Property

Gets a value which describes the last error that has occurred.

[Visual Basic]

```
Public ReadOnly Property LastErrorString As String
```

[C#]

```
public string LastErrorString {get;}
```

Property Value

A string which describes the last error that has occurred.

Remarks

The **LastErrorString** property can be used to obtain a description of the last error that occurred for the current instance of the class. It is important to note that this value only has meaning if the previous method indicates that an error has actually occurred.

See Also

HttpClient Class | SocketTools Namespace

HttpClient.LocalAddress Property

Gets the local Internet address that the client is bound to.

[Visual Basic]

```
Public ReadOnly Property LocalAddress As String
```

[C#]

```
public string LocalAddress {get;}
```

Property Value

A string which specifies an Internet address.

Remarks

The **LocalAddress** property returns the local Internet address that the client is bound to when a connection is established with a remote host. This property may return either an IPv4 or IPv6 formatted address, depending on the type of connection that was established.

See Also

HttpClient Class | SocketTools Namespace

HttpClient.Localize Property

Gets and sets a value which specifies if date values are localized to the current timezone.

[Visual Basic]
```
Public Property Localize As Boolean
```

[C#]
```
public bool Localize {get; set;}
```

Property Value

A boolean value which specifies if date values are localized to the current timezone.

Remarks

Setting the **Localize** property controls how remote file date and time values are localized when the **GetFileTime** method is called. If the property is set to **true**, then the file date and time will be adjusted to the current timezone. If the property is set to **false**, which is the default value, then the file date and time are returned as UTC (Coordinated Universal Time) values.

See Also

HttpClient Class | SocketTools Namespace

HttpClient.LocalName Property

Gets a value which specifies the host name for the local system.

[Visual Basic]

```
Public ReadOnly Property LocalName As String
```

[C#]

```
public string LocalName {get;}
```

Property Value

A string which specifies the local host name.

Remarks

The **LocalName** property returns the fully-qualified host name assigned to the local system. If the system has not been configured with an Internet domain name, then this property will return the NetBIOS name assigned to the local system.

See Also

HttpClient Class | SocketTools Namespace

HttpClient.LocalPort Property

Gets the local port number the client is bound to.

[Visual Basic]

```
Public ReadOnly Property LocalPort As Integer
```

[C#]

```
public int LocalPort {get;}
```

Property Value

An integer value which specifies a port number. The default value is 0.

Remarks

The **LocalPort** property is used to identify the local port number that the client is bound to to when a connection is established with a remote host.

See Also

HttpClient Class | SocketTools Namespace

HttpClient.Options Property

Gets and sets a value which specifies one or more client options.

[Visual Basic]

```
Public Property Options As HttpOptions
```

[C#]

```
public HttpClient.HttpOptions Options {get; set;}
```

Property Value

Returns one or more HttpOptions enumeration flags which specify the options for the client. The default value for this property is **httpOptionNone**.

Remarks

The **Options** property specifies one or more default options options which are used when establishing a connection using the **Connect** method.

See Also

HttpClient Class | SocketTools Namespace

HttpClient.Password Property

Gets and sets the password used to authenticate the client session.

[Visual Basic]

```
Public Property Password As String
```

[C#]

```
public string Password {get; set;}
```

Property Value

A string which specifies the password.

Remarks

The **Password** property specifies the password used to authenticate the client session. This property is used as the default value for the **Connect** method if no password is specified as an argument.

Refer to the **Authentication** property for more information on the available authentication methods. If you are using the **authBearer** authentication method, this property should not be set to the user's password. Instead, you should set the **BearerToken** property to the access token issued by the mail service provider. Note that these tokens can be much larger than your typical password and are only valid for a limited period of time.

You can use the **Password** property to specify a bearer token. However, it is recommended that you use the **BearerToken** property instead of assigning it to this property. It will ensure compatibility with future versions of the class and make it clear in your code you are using an OAuth 2.0 bearer token and not a password. If the **Authentication** property specifies the **authBearer** authentication method, this property will return the bearer token.

See Also

HttpClient Class | SocketTools Namespace | Authentication Property | BearerToken Property | UserName Property | Connect Method

HttpClient.Priority Property

Gets and sets a value which specifies the priority of data transfers.

[Visual Basic]

```
Public Property Priority As HttpPriority
```

[C#]

```
public HttpClient.HttpPriority Priority {get; set;}
```

Property Value

Returns a HttpPriority enumeration value which specify the current data transfer priority. The default value for this property is **priorityNormal**.

Remarks

The **Priority** property can be used to control the processor usage, memory and network bandwidth allocated for data transfers. The default priority balances resource utilization and transfer speed while ensuring that a single-threaded application remains responsive to the user. Lower priorities reduce the overall resource utilization at the expense of transfer speed. For example, if you create a worker thread to download a file in the background and want to ensure that it has a minimal impact on the process, the **priorityBackground** value can be used.

Higher priority values increase the memory allocated for the transfers and increases processor utilization for the transfer. The **priorityCritical** priority maximizes transfer speed at the expense of system resources. It is not recommended that you increase the data transfer priority unless you understand the implications of doing so and have thoroughly tested your application. If the data transfer is being performed in the main UI thread, increasing the priority may interfere with the normal processing of Windows messages and cause the application to appear to become non-responsive. It is also important to note that when the priority is set to **priorityCritical**, normal progress events will not be generated during the transfer.

HttpClient Class | SocketTools Namespace | HttpPriority Enumeration

HttpClient.ProtocolVersion Property

Gets and sets a value which specifies the default protocol version.

[Visual Basic]

```
Public Property ProtocolVersion As HttpVersion
```

[C#]

```
public HttpClient.HttpVersion ProtocolVersion {get; set;}
```

Property Value

An HttpVersion enumeration which specifies the protocol version.

Remarks

The **ProtocolVersion** property sets or returns the current HTTP version number. It is used to determine how requests are submitted to the server, as well as what header fields are required. The default value for this property is **HttpVersion.version10**, and should be changed before any connection attempt is made by the client.

Note that setting the property value to **HttpVersion.version09** tells the client to use the preliminary protocol specification which only supported a basic version of the GET command, and did not have any provisions for features such as user authentication, virtual hosting, etc. Header fields are not supported in this version of the protocol.

See Also

HttpClient Class | SocketTools Namespace

HttpClient.ProxyHost Property

Gets and sets the hostname or IP address of a proxy server.

[Visual Basic]

```
Public Property ProxyHost As String
```

[C#]

```
public string ProxyHost {get; set;}
```

Property Value

A string which specifies the hostname or IP address of the proxy server that will be used when establishing a connection.

Remarks

The **ProxyHost** property should be set to the name of the proxy server that you want to connect to. This property may be set to either a fully qualified domain name, or an IP address. This property is only used if the **ProxyType** property specifies a proxy server type other than **proxyNone**.

See Also

HttpClient Class | SocketTools Namespace

HttpClient.ProxyPassword Property

Gets and sets the password used to authenticate the connection to a proxy server.

[Visual Basic]

```
Public Property ProxyPassword As String
```

[C#]

```
public string ProxyPassword {get; set;}
```

Property Value

A string which specifies a password.

Remarks

The **ProxyPassword** property specifies the password used to authenticate the user to the proxy server. If a password is not required by the server, this property is ignored.

See Also

HttpClient Class | SocketTools Namespace

HttpClient.ProxyPort Property

Gets and sets a value that specifies the proxy server port number.

[Visual Basic]

```
Public Property ProxyPort As Integer
```

[C#]

```
public int ProxyPort {get; set;}
```

Property Value

An integer value which specifies the proxy port number.

Remarks

The **ProxyPort** property is used to set the port number that the control will use to establish a connection with the proxy server. A value of zero specifies that the client will connect to the proxy server using the standard HTTP service port.

See Also

HttpClient Class | SocketTools Namespace

HttpClient.ProxyType Property

Gets and sets the type of proxy server the client will use to establish a connection.

[Visual Basic]

```
Public Property ProxyType As HttpProxyType
```

[C#]

```
public HttpClient.HttpProxyType ProxyType {get; set;}
```

Property Value

An HttpProxyType enumeration which specifies the type of proxy that the client will connect through.

See Also

HttpClient Class | SocketTools Namespace

HttpClient.ProxyUser Property

Gets and sets the username used to authenticate the connection to a proxy server.

[Visual Basic]

```
Public Property ProxyUser As String
```

[C#]

```
public string ProxyUser {get; set;}
```

Property Value

A string which specifies the username.

Remarks

The **ProxyUser** property specifies the user that is logging in to the proxy server. If the proxy server does not require the user to login, then this property is ignored.

See Also

HttpClient Class | SocketTools Namespace

HttpClient.RemotePort Property

Gets and sets a value which specifies the remote port number.

[Visual Basic]

```
Public Property RemotePort As Integer
```

[C#]

```
public int RemotePort {get; set;}
```

Property Value

An integer value which specifies a port number.

Remarks

The **RemotePort** property is used to set the port number that will be used to establish a connection with a remote host. If the port number specifies a well-known port, the **RemoteService** property will be updated with that name.

See Also

HttpClient Class | SocketTools Namespace

HttpClient.Resource Property

Gets and sets a value which specifies a resource on the server.

[Visual Basic]
```
Public Property Resource As String
```

[C#]
```
public string Resource {get; set;}
```

Property Value

A string which specifies a resource.

Remarks

The **Resource** property is used to specify the name of a resource on the server. The resource may be a file, such as an HTML document or an image, or it may be a script used to process data submitted by the client. Note that this property specifies the name of the resource only, not a complete URL. To specify a complete URL, set the **URL** property and the control will automatically set the **Resource** property to the correct value.

In most cases, the resource name should be specified using an absolute path that begins with a leading slash character.

See Also

HttpClient Class | SocketTools Namespace

HttpClient.ResultCode Property

Gets a value which specifies the last result code returned by the server.

[Visual Basic]
```
Public ReadOnly Property ResultCode As Integer
```

[C#]
```
public int ResultCode {get;}
```

Property Value

An integer value which specifies the last result code returned by the server.

Remarks

Result codes are three-digit numeric values returned by the remote server and may be broken down into the following ranges:

ResultCode	Description
100-199	Positive preliminary result. This indicates that the requested action is being initiated, and the client should expect another reply from the server before proceeding.
200-299	Positive completion result. This indicates that the server has successfully completed the requested action.
300-399	Positive intermediate result. This indicates that the requested action cannot complete until additional information is provided to the server.
400-499	Transient negative completion result. This indicates that the requested action did not take place, but the error condition is temporary and may be attempted again.
500-599	Permanent negative completion result. This indicates that the requested action did not take place.

It is important to note that while some result codes have become standardized, not all servers respond to commands using the same result codes. It is recommended that applications check for ranges of values to determine if a command was successful, not a specific value.

See Also

HttpClient Class | SocketTools Namespace

HttpClient.ResultString Property

Gets a string value which describes the result of the previous command.

[Visual Basic]

```
Public ReadOnly Property ResultString As String
```

[C#]

```
public string ResultString {get;}
```

Property Value

A string which describes the result of the previous command executed on the server.

Remarks

The **ResultString** property returns the result string from the last action taken by the client. This string is generated by the remote server, and typically is used to describe the result code. For example, if an error is indicated by the result code, the result string may describe the condition that caused the error.

See Also

HttpClient Class | SocketTools Namespace

HttpClient.Secure Property

Gets and sets a value which specifies if a secure connection is established.

[Visual Basic]

```
Public Property Secure As Boolean
```

[C#]

```
public bool Secure {get; set;}
```

Property Value

Returns **true** if a secure connection is established; otherwise returns **false**. The default value is **false.**

Remarks

The **Secure** property determines if a secure connection is established with the remote host. The default value for this property is **false**, which specifies that a standard connection to the server is used. To establish a secure connection, the application should set this property value to **true** prior to calling the **Connect** method. Once the connection has been established, the client may exchange data with the server as with standard connections.

It is strongly recommended that any application that sets this property **true** use error handling to trap an errors that may occur. If the control is unable to initialize the security libraries, or otherwise cannot create a secure session for the client, an exception may be generated when this property value is set.

See Also

HttpClient Class | SocketTools Namespace

HttpClient.SecureCipher Property

Gets a value that specifies the encryption algorithm used for a secure connection.

[Visual Basic]

```
Public ReadOnly Property SecureCipher As SecureCipherAlgorithm
```

[C#]

```
public HttpClient.SecureCipherAlgorithm SecureCipher {get;}
```

Property Value

A SecureCipherAlgorithm enumeration value which identifies the algorithm.

Remarks

The **SecureCipher** property returns a value which identifies the algorithm used to encrypt the data stream. If a secure connection has not been established, this property will return a value of **cipherNone**.

See Also

HttpClient Class | SocketTools Namespace

HttpClient.SecureHash Property

Gets a value that specifies the message digest algorithm used for a secure connection.

[Visual Basic]

```
Public ReadOnly Property SecureHash As SecureHashAlgorithm
```

[C#]

```
public HttpClient.SecureHashAlgorithm SecureHash {get;}
```

Property Value

A SecureHashAlgorithm enumeration value which identifies the algorithm.

Remarks

The **SecureHash** property returns a value which identifies the message digest (hash) algorithm that was selected when a secure connection was established. If a secure connection has not been established, this property will return a value of **hashNone**.

See Also

HttpClient Class | SocketTools Namespace

HttpClient.SecureKeyExchange Property

Gets a value that specifies the key exchange algorithm used for a secure connection.

[Visual Basic]
```
Public ReadOnly Property SecureKeyExchange As SecureKeyAlgorithm
```

[C#]
```
public HttpClient.SecureKeyAlgorithm SecureKeyExchange {get;}
```

Property Value

A SecureKeyAlgorithm enumeration value which identifies the algorithm.

Remarks

The **SecureKeyExchange** property returns a value which identifies the key exchange algorithm that was selected when a secure connection was established. If a secure connection has not been established, this property will return a value of **keyExchangeNone**.

See Also

HttpClient Class | SocketTools Namespace

HttpClient.SecureProtocol Property

Gets and sets a value which specifies the protocol used for a secure connection.

[Visual Basic]

```
Public Property SecureProtocol As SecurityProtocols
```

[C#]

```
public HttpClient.SecurityProtocols SecureProtocol {get; set;}
```

Property Value

A SecurityProtocols enumeration value which identifies the protocol to be used when establishing a secure connection.

Remarks

The **SecureProtocol** property can be used to specify the security protocol to be used when establishing a secure connection with a server or accepting a secure connection from a client. By default, the class will attempt to use either SSL v3 or TLS v1 to establish the connection, with the appropriate protocol automatically selected based on the capabilities of the remote host. It is recommended that you only change this property value if you fully understand the implications of doing so. Assigning a value to this property will override the default protocol and force the class to attempt to use only the protocol specified.

Multiple security protocols may be specified by combining them using a bitwise **or** operator. After a connection has been established, this property will identify the protocol that was selected. Attempting to set this property after a connection has been established will result in an exception being thrown. This property should only be set after setting the **Secure** property to **true** and before calling the **Accept** or **Connect** methods.

In some cases, a server may only accept a secure connection if the TLS v1 protocol is specified. If the security protocol is not compatible with the server, then the connection will fail with an error indicating that the control is unable to establish a security context for the session. In this case, try assigning the property to **protocolTLS1** and attempt the connection again.

See Also

HttpClient Class | SocketTools Namespace

HttpClient.Status Property

Gets a value which specifies the current status of the client.

[Visual Basic]

```
Public ReadOnly Property Status As HttpStatus
```

[C#]

```
public HttpClient.HttpStatus Status {get;}
```

Property Value

A HttpStatus enumeration value which specifies the current client status.

Remarks

The **Status** property returns the current status of the client. This property can be used to check on blocking connections to determine if the client is interacting with the remote host before taking some action.

See Also

HttpClient Class | SocketTools Namespace

HttpClient.TaskCount Property

Get the number of active background file transfers.

[Visual Basic]
```
Public ReadOnly Property TaskCount As Integer
```

[C#]
```
public int TaskCount {get;}
```

Property Value

An integer value that specifies the number of background file transfers that are currently in progress.

Remarks

The **TaskCount** property returns the number of background file transfers that are currently in progress. One common use for this property is to create a timer that periodically checks this value when a series of background transfers are started. When the property returns a value of zero, that indicates all of the background transfers have completed. This property can also be used to enumerate the active background tasks in conjunction with the **TaskList** property.

See Also

HttpClient Class | SocketTools Namespace

HttpClient.TaskId Property

Get the task identifier for the last background file transfer.

[Visual Basic]

```
Public ReadOnly Property TaskId As Integer
```

[C#]

```
public int TaskId {get;}
```

Property Value

An integer value the uniquely identifies the current background task.

Remarks

The **TaskId** property returns the task ID associated with the current background task. This identifies the last background file transfer that was initiated with a call to the **AsyncGetFile** or **AsyncPutFile** methods. This property value will change with each subsequent background transfer that is performed. If this property returns a value of zero, that indicates that no background tasks have been started for this instance of the class.

To enumerate the active background tasks, use the **TaskCount** property and the **TaskList** array.

See Also

HttpClient Class | SocketTools Namespace

HttpClient.TaskList Property

Get an array of active background task identifiers.

[Visual Basic]

```
Public ReadOnly Property TaskList As ArrayList
```

[C#]

```
public System.Collections.ArrayList TaskList {get;}
```

Property Value

An **ArrayList** object that contains a list of integer values that uniquely identify the active background tasks that have been started by this instance of the class.

Remarks

The **TaskList** property returns a read-only **ArrayList** object that is popularted with the task identifiers for all active background tasks that have been created by this instance of the class. The current number of active tasks can be determined using the **TaskCount** property.

As background tasks complete and additional tasks are started, the values stored in this array will change. The application should never make any assumptions about the numeric values stored in the array or the order they are returned. Task IDs should be considered opaque values that are unique to the process. When a background task completes, its corresponding ID is removed from the list of active tasks and this can potentially change the task ID values associated with each index into the array.

See Also

HttpClient Class | SocketTools Namespace

HttpClient.ThreadModel Property

Gets and sets a value which specifies the threading model for the class instance.

[Visual Basic]
```
Public Property ThreadModel As ThreadingModel
```

[C#]
```
public HttpClient.ThreadingModel ThreadModel {get; set;}
```

Property Value

Returns one or more ThreadingModel enumeration value which specifies the threading model for the client. The default value for this property is **modelSingleThread**.

Remarks

The **ThreadModel** property specifies the threading model that is used by the class instance when a connection is established. The default value for this property is **modelSingleThread**, which specifies that only the thread that established the connection should be permitted to invoke methods. It is important to note that this threading model does not limit the application to a single thread of execution. When a session is established using the **Connect** method, that session is attached to the thread that created it. From that point on, until the session is terminated, only the owner may invoke methods in that instance of the class. The ownership of the class instance may be transferred from one thread to another using the **AttachThread** method.

Setting this property to **modelFreeThread** disables certain internal safety checks that are performed by the class and may result in unexpected behavior unless you ensure that access to the class instance is synchronized across multiple threads. The application must ensure that no two threads will attempt to invoke a blocking method at the same time. In other words, if one thread invokes a method, the application must ensure that another thread will not attempt to invoke any other method at the same time using the same instance of the class.

Changing the value of this property will not affect an active client session. The threading model must be specified prior to invoking the **Connect** method.

See Also

HttpClient Class | SocketTools Namespace | AttachThread Method | ThreadingModel Enumeration | ThreadModel Attribute

HttpClient.ThrowError Property

Gets and sets a value which specifies if method calls should throw exceptions when an error occurs.

[Visual Basic]

```
Public Property ThrowError As Boolean
```

[C#]

```
public bool ThrowError {get; set;}
```

Property Value

Returns **true** if method calls will generate exceptions when an error occurs; otherwise returns **false**. The default value is **false**.

Remarks

Error handling for when calling class methods can be done in either of two different styles, according to the value of this property.

If the **ThrowError** property is set to **false**, the application should check the return value of any method that is used, and report errors based upon the documented value of the return code. It is the responsibility of the application to interpret the error code, if it is desired to explain the error in addition to reporting it. This is the default behavior.

If the **ThrowError** property is set to **true**, then exceptions will be generated whenever a method call fails. The program must be written to catch these exceptions and take the appropriate action when an error occurs. Failure to handle an exception will cause the program to terminate abnormally.

Note that if an error occurs while a property is being read or modified, an exception will be raised regardless of the value of the **ThrowError** property.

See Also

HttpClient Class | SocketTools Namespace

HttpClient.Timeout Property

Gets and sets a value which specifies a timeout period in seconds.

[Visual Basic]
```
Public Property Timeout As Integer
```

[C#]
```
public int Timeout {get; set;}
```

Property Value

An integer value which specifies a timeout period in seconds.

Remarks

Setting the **Timeout** property specifies the number of seconds until a blocking operation fails and returns an error.

The timeout period is only used when the client is in blocking mode. Although this property can be changed when the client is in non-blocking mode, the value will be ignored until the client is returned to blocking mode.

For most applications it is recommended the timeout period be set between 10 and 20 seconds.

See Also

HttpClient Class | SocketTools Namespace

HttpClient.TimeZone Property

Gets and sets the current timezone offset in seconds.

[Visual Basic]

```
Public Property TimeZone As Integer
```

[C#]

```
public int TimeZone {get; set;}
```

Property Value

An integer value which specifies the current timezone offset in seconds.

Remarks

The **TimeZone** property returns the current offset from UTC in seconds. Setting the property changes the current timezone offset to the specified value. The value of this property is initially determined by the date and time settings on the local system.

This property value is used in conjunction with the **Localize** property to control how date and time localization is handled.

See Also

HttpClient Class | SocketTools Namespace

HttpClient.Trace Property

Gets and sets a value which indicates if network function logging is enabled.

[Visual Basic]

```
Public Property Trace As Boolean
```

[C#]

```
public bool Trace {get; set;}
```

Property Value

Returns **true** if network function tracing is enabled; otherwise returns **false**. The default value is **false**.

Remarks

The **Trace** property is used to enable (or disable) the tracing of network function calls. When enabled, each function call is logged to a file, including the function parameters, return value and error code if applicable. This facility can be enabled and disabled at run time, and the trace log file can be specified by setting the **TraceFile** property. All function calls that are being logged are appended to the trace file, if it exists. If no trace file exists when tracing is enabled, the trace file is created.

The tracing facility is available in all of the SocketTools networking classes and is enabled or disabled for an entire process. This means that once trace logging is enabled for a given component, all of the function calls made by the process using any of the SocketTools classes will be logged. For example, if you have an application using both the File Transfer Protocol and Post Office Protocol classes, and you set the **Trace** property to **true**, function calls made by both classes will be logged. Additionally, enabling a trace is cumulative, and tracing is not stopped until it is disabled for all classes used by the process.

If trace logging is not enabled, there is no negative impact on performance or throughput. Once enabled, application performance can degrade, especially in those situations in which multiple processes are being traced or the logfile is fairly large. Since logfiles can grow very quickly, even with modest applications, it is recommended that you delete the file when it is no longer needed.

When redistributing your application, make sure that you include the **SocketTools10.TraceLog.dll** module with your installation. If this library is not present, then no trace output will be generated and the value of the **Trace** property will be ignored. Only those function calls made by the SocketTools networking classes will be logged. Calls made directly to the Windows Sockets API, or calls made by other classes, will not be logged.

See Also

HttpClient Class | SocketTools Namespace

HttpClient.TraceFile Property

Gets and sets a value which specifies the name of the logfile.

[Visual Basic]

```
Public Property TraceFile As String
```

[C#]

```
public string TraceFile {get; set;}
```

Property Value

A string which specifies the name of the file.

Remarks

The **TraceFile** property is used to specify the name of the trace file that is created when network function tracing is enabled. If this property is set to an empty string (the default value), then a file named **SocketTools.log** is created in the system's temporary directory. If no temporary directory exists, then the file is created in the current working directory.

If the file exists, the trace output is appended to the file, otherwise the file is created. Since network function tracing is enabled per-process, the trace file is shared by all instances of the class being used. If multiple class instances have tracing enabled, the **TraceFile** property should be set to the same value for each instance. Since trace files can grow very quickly, even with modest applications, it is recommended that you delete the file when it is no longer needed.

The trace file has the following format:

```
 MyApp INF: WSAAsyncSelect(46, 0xcc4, 0x7e9, 0x27) returned 0 MyApp WRN:
connect(46, 192.0.0.1:1234, 16) returned -1 [10035] MyApp ERR: accept(46,
NULL, 0x0) returned -1 [10038]
```

The first column contains the name of the process that is being traced. The second column identifies if the trace record is reporting information, a warning, or an error. What follows is the name of the function being called, the arguments passed to the function and the function's return value. If a warning or error is reported, the error code is appended to the record (the value is placed inside brackets).

If parameters are passed as integer values, they are recorded in decimal. If the parameter or return value is a pointer (a memory address), it is recorded as a hexadecimal value preceded with "0x". A special type of pointer, called a null pointer, is recorded as NULL. Those functions which expect socket addresses are displayed in the following format:

```
aa.bb.cc.dd:nnnn
```

The first four numbers separated by periods represent the IP address, and the number following the colon represents the port number in host byte order. Note that in the second line of the above example, the control is attempting to connect to a system with the IP address 192.0.0.1 on port 1234.

Note that if the specified file cannot be created, or the user does not have permission to modify an existing file, the error is silently ignored and no trace output will be generated.

See Also

HttpClient Class | SocketTools Namespace

HttpClient.TraceFlags Property

Gets and sets a value which specifies the client function tracing flags.

[Visual Basic]

```
Public Property TraceFlags As TraceOptions
```

[C#]

```
public HttpClient.TraceOptions TraceFlags {get; set;}
```

Property Value

A TraceOptions enumeration which specifies the amount of detail written to the trace logfile.

Remarks

The **TraceFlags** property is used to specify the type of information written to the trace file when network function tracing is enabled.

Because network function tracing is enabled per-process, the trace flags are shared by all instances of the class being used. If multiple class instances have tracing enabled, the **TraceFlags** property should be set to the same value for each instance. Changing the trace flags for any one instance of the class will affect the logging performed for all SocketTools classes used by the application.

Warnings are generated when a non-fatal error is returned by a network function. For example, if data is being written and the error **errorOperationWouldBlock** occurs, a warning is generated because the application simply needs to attempt to write the data at a later time.

See Also

HttpClient Class | SocketTools Namespace

HttpClient.URL Property

Gets and sets the current URL used to access a file on the server.

[Visual Basic]
```
Public Property URL As String
```

[C#]
```
public string URL {get; set;}
```

Property Value

A string which specifies the current URL.

Remarks

The **URL** property returns the current Uniform Resource Locator string which is used by the control to access a resource on the server. URLs have a specific format which provides information about the remote host, port, resource, as well as optional information such as a username and password for authentication:

```
    http://[username : [password] @] remotehost [:remoteport] / resource
[? parameters]
```

The first part of the URL is the protocol and in this case will always be "http", or "https" if a secure connection is being used. If a username and password is required for authentication, then this will be included in the URL before the name of the remote host. Next, there is the name of the remote host to connect to, optionally followed by a port number. If no port number is given, then the default port for the protocol will be used. This is followed by the resource, which is usually a path to a file or script on the server. Parameters to the resource may also be specified, which are typically used as arguments to a script that is executed on the server.

Here are some common examples of URLs used to access resources on an HTTP server:

```
http://www.example.com/products/index.html
```

In this example, the remote host is www.example.com and the resource is /products/index.html. The default port will be used to access the resource, and no username and password is provided for authentication.

```
http://www.example.com:8080/index.html
```

In this example, the remote host is www.example.com and the resource is /products/index.html. However, the client should connect to an alternative port number, in this case 8080.

```
https://www.example.com/order/confirm.asp
```

In this example, the remote host is www.example.com and the resource is the script /order/confirm.asp. Because the protocol is https, a secure connection on port 443 will be established.

```
http://jsmith:secret@www.example.com:8080/~jsmith/personal/index.html
```

In this example, the remote host is www.example.com and the resource is /~jsmith/personal/index.html. The port 8080 will be used to access the resource, and access to the resource will be authenticated with the username "jsmith" and the password "secret".

When setting the **URL** property, the control will parse the string and automatically update the **HostName**, **RemotePort**, **UserName**, **Password** and **Resource** properties according to the values specified in the URL. This enables an application to simply provide the URL and then call the **Connect** method to establish the connection.

Note that if this property is assigned a value which cannot be parsed, the control will throw an error that indicates that the property value is invalid. In a language like Visual Basic it is important that you implement an error handler, particularly if you are assigning a value to the property based on user input. If the user enters an invalid URL and there is no error handler, it could result in an exception which terminates the application.

See Also

HttpClient Class | SocketTools Namespace

HttpClient.UserName Property

Gets and sets the username used to authenticate the client session.

[Visual Basic]

```
Public Property UserName As String
```

[C#]

```
public string UserName {get; set;}
```

Property Value

A string which specifies the username.

Remarks

If a username is not specified when the **Connect** method is called, the value of this property will be used as the default username when establishing a connection with the server.

See Also

HttpClient Class | SocketTools Namespace | Authentication Property | BearerToken Property | Password Property | Connect Method

HttpClient.Version Property

Gets a value which returns the current version of the HttpClient class library.

[Visual Basic]

```
Public ReadOnly Property Version As String
```

[C#]

```
public string Version {get;}
```

Property Value

A string which specifies the version of the class library.

Remarks

The **Version** property returns a string which identifies the current version and build of the HttpClient class library. This value can be used by an application for validation and debugging purposes.

See Also

HttpClient Class | SocketTools Namespace

HttpClient Methods

The methods of the **HttpClient** class are listed below. For a complete list of **HttpClient** class members, see the HttpClient Members topic.

Public Static (Shared) Methods

ErrorText	Returns the description of an error code.

Public Instance Methods

AddField	Overloaded. Add the form field and its value to the current form.
AddFile	Append the contents of the file to the current form.
AsyncGetFile	Overloaded. Download a file from the server to the local system in the background.
AsyncPutFile	Overloaded. Upload a file from the local system to the server in the background.
AttachThread	Attach an instance of the class to the current thread
Authenticate	Overloaded. Authenticate the client session with a username and password.
Cancel	Cancel the current blocking client operation.
ClearForm	Remove all defined fields from the current form.
ClearHeaders	Clears the current request and response headers.
CloseFile	Close the file that was opened on the server.
Command	Overloaded. Send a custom command to the web server.
Connect	Overloaded. Establish a connection with a remote host.
CreateFile	Overloaded. Create a new file or overwrite an existing file on the web server.
CreateForm	Overloaded. Create a new virtual form.
DeleteField	Delete a form field and its value from the current form.
DeleteFile	Remove a file on the web server.
Disconnect	Terminate the connection with a remote host.
Dispose	Overloaded. Releases all resources used by HttpClient.
Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetCookie	Overloaded. Return information about the

	specified cookie.
GetData	Overloaded. Transfer data from the web server and store it in a local buffer.
GetFile	Overloaded. Transfer data from the web server and store it in a file on the local system.
GetFileSize	Overloaded. Return the size of the specified file on the web server.
GetFileTime	Overloaded. Return the modification date and time for specified file on the web server.
GetFirstHeader	Return the first response header field name and value.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetHeader	Return the value of the specified response header field.
GetNextHeader	Return the next response header field name and value.
GetType (inherited from Object)	Gets the Type of the current instance.
Initialize	Overloaded. Initialize an instance of the HttpClient class.
OpenFile	Open a file on the web server for reading.
PatchData	Overloaded. Submits patch data to the server and returns the result in a string.
PostData	Overloaded. Submits the contents of the specified buffer to a resource on the server.
PostFile	Overloaded. Upload the contents of a file to a resource on the server.
PostJson	Overloaded. Submits JSON formatted data to the server and returns the result in a string.
PostXml	Overloaded. Submits XML formatted data to the server and returns the result in a string.
PutData	Overloaded. Transfer data from a local buffer to the server.
PutFile	Overloaded. Transfer a file from the local system to the web server.
Read	Overloaded. Read data from the server and store it in a byte array.
Reset	Reset the internal state of the object, resetting all properties to their default values.
SetCookie	Send the specified cookie to the server when a resource is requested.

SetHeader	Set the value of a request header field.
SubmitForm	Overloaded. Submits the current form data to the server for processing.
TaskAbort	Overloaded. Abort the specified asynchronous task.
TaskDone	Overloaded. Determine if an asynchronous task has completed.
TaskResume	Overloaded. Resume execution of an asynchronous task.
TaskSuspend	Overloaded. Suspend execution of an asynchronous task.
TaskWait	Overloaded. Wait for an asynchronous task to complete.
ToString (inherited from Object)	Returns a String that represents the current Object.
Uninitialize	Uninitialize the class library and release any resources allocated for the current thread.
Write	Overloaded. Write one or more bytes of data to the server.

Protected Instance Methods

Dispose	Overloaded. Releases the unmanaged resources allocated by the HttpClient class and optionally releases the managed resources.
Finalize	Destroys an instance of the class, releasing the resources allocated for the session and unloading the networking library.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

HttpClient Class | SocketTools Namespace

HttpClient.AddField Method (String, Byte[], Int32)

Add the form field and its value to the current form.

[Visual Basic]

```
Overloads Public Function AddField( _
   ByVal fieldName As String, _
   ByVal fieldData As Byte(), _
   ByVal fieldLength As Integer _
) As Boolean
```

[C#]

```
public bool AddField(
   string fieldName,
   byte[] fieldData,
   int fieldLength
);
```

Parameters

fieldName

A string which specifies the name of the field to add to the form.

fieldData

A byte array which specifies the data for the form field.

fieldLength

An integer value which specifies the length of the field data in bytes. This value cannot be larger than the size of the byte array passed to this method.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **AddField** method is used to add a field and its associated value to a form created using the **CreateForm** method. If the field name has already been added to the form, the previous value is deleted and replaced by the new value.

HttpClient.AddField Method (String, String)

Add the form field and its value to the current form.

[Visual Basic]

```
Overloads Public Function AddField( _
   ByVal fieldName As String, _
   ByVal fieldData As String _
) As Boolean
```

[C#]

```
public bool AddField(
   string fieldName,
   string fieldData
);
```

Parameters

fieldName
A string which specifies the name of the field to add to the form.

fieldData
A string which specifies the data for the form field.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **AddField** method is used to add a field and its associated value to a form created using the **CreateForm** method. If the field name has already been added to the form, the previous value is deleted and replaced by the new value.

HttpClient.AddFile Method

Append the contents of the file to the current form.

[Visual Basic]

```
Public Function AddFile( _
   ByVal fieldName As String, _
   ByVal fileName As String _
) As Boolean
```

[C#]

```
public bool AddFile(
   string fieldName,
   string fileName
);
```

Parameters

fieldName
A string which specifies the name of the field to add to the form.

fileName
A string which specifies the name of the file.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **AddFile** method is used to add the contents of a file to a form created using the **CreateForm** method. If the field name has already been added to the form, the previous value is deleted and replaced by the new value.

HttpClient.AsyncGetFile Method

Download a file from the server to the local system in the background.

Overload List

Download a file from the server to the local system in the background.

public bool AsyncGetFile(string);

Download a file from the server to the local system in the background.

public bool AsyncGetFile(string,string);

Download a file from the server to the local system in the background.

public bool AsyncGetFile(string,string,HttpTransferOptions);

Download a file from the server to the local system in the background.

public bool AsyncGetFile(string,string,HttpTransferOptions,long);

See Also

HttpClient Class | SocketTools Namespace | AsyncPutFile Method

HttpClient.AsyncGetFile Method (String)

Download a file from the server to the local system in the background.

[Visual Basic]

```
Overloads Public Function AsyncGetFile( _
   ByVal localFile As String _
) As Boolean
```

[C#]

```
public bool AsyncGetFile(
   string localFile
);
```

Parameters

localFile

A string that specifies the file on the local system that will be created, overwritten or appended to. The file pathing and name conventions must be that of the local host.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **AsyncGetFile** method will download the contents of a remote file to a file on the local system. It is similar to the **GetFile** method, however it retrieves the file using a background worker thread and does not block the current working thread. This enables the application to continue to perform other operations while the file is being downloaded from the server. This method requires that you explicitly establish a connection using the **Connect** method. All background tasks will duplicate the active connection and use it establish a secondary connection with the server to perform the file transfer. If you wish to perform multiple asynchronous file transfers from different servers, you must create a new instance of this class for each server.

After this method is called, the **OnTaskBegin** event will be fired, indicating that the background task has begun the process of connecting to the server and performing the file transfer. As the file is downloaded, the class will periodically invoke the **OnTaskRun** event handler. When the transfer has completed, the **OnTaskEnd** event will be fired. It is not required that you implement handlers for these events.

To determine when a transfer has completed without implementing any event handlers, periodically call the **TaskDone** method. If you wish to block the current thread and wait for the transfer to complete, call the **TaskWait** method. To stop a background file transfer that is in progress, call the **TaskAbort** method. This will signal the background worker thread to cancel the transfer and terminate the session.

This method can be called multiple times to download more than one file in the background; however, most servers limit the number of simultaneous connections that can originate from a single IP address. The application should not make any assumptions about the sequence in which background transfers are performed or the order in which they may complete.

   ByVal localFile As String, _
   ByVal remoteFile As String _
) As Boolean
```

[C#]

```
public bool AsyncGetFile(
   string localFile,
   string remoteFile
);
```

Parameters

localFile

A string that specifies the file on the local system that will be created, overwritten or appended to. The file pathing and name conventions must be that of the local host.

remoteFile

A string that specifies the file on the server that will be transferred to the local system. The file pathing and name conventions must be that of the server.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **AsyncGetFile** method will download the contents of a remote file to a file on the local system. It is similar to the **GetFile** method, however it retrieves the file using a background worker thread and does not block the current working thread. This enables the application to continue to perform other operations while the file is being downloaded from the server. This method requires that you explicitly establish a connection using the **Connect** method. HttpClient Class | SocketTools Namespace | HttpClient.AsyncGetFile Overload List | AsyncPutFile Method

HttpClient.AsyncGetFile Method (String, String, HttpTransferOptions, Int64)

Download a file from the server to the local system in the background.

[Visual Basic]

```
Overloads Public Function AsyncGetFile( _
   ByVal localFile As String, _
   ByVal remoteFile As String, _
   ByVal options As HttpTransferOptions, _
   ByVal offset As Long _
) As Boolean
```

[C#]

```
public bool AsyncGetFile(
   string localFile,
   string remoteFile,
   HttpTransferOptions options,
   long offset
);
```

Parameters

localFile
A string that specifies the file on the local system that will be created, overwritten or appended to. The file pathing and name conventions must be that of the local host.

remoteFile
A string that specifies the file on the server that will be transferred to the local system. The file pathing and name conventions must be that of the server.

options
An HttpTransferOptions enumeration value which specifies one or more file transfer options.

offset
A byte offset which specifies where the file transfer should begin. The default value of zero specifies that the file transfer should start at the beginning of the file. A value greater than zero is typically used to restart a transfer that has not completed successfully. Note that specifying a non-zero offset requires that the server support the REST command to restart transfers.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **AsyncGetFile** method will download the contents of a remote file to a file on the local system. It is similar to the **GetFile** method, however it retrieves the file using a background worker thread and does not block the current working thread. This enables the application to continue to perform other operations while the file is being downloaded from the server. This method requires that you explicitly establish a connection using the **Connect** method. All background tasks will duplicate the active connection and use it establish a secondary connection with the server to perform the file transfer. If you wish to perform multiple asynchronous file transfers from different servers, you must create a new instance of this class for each server.

After this method is called, the **OnTaskBegin** event will be fired, indicating that the background task has begun the process of connecting to the server and performing the file transfer. As the file is downloaded, the class will periodically invoke the **OnTaskRun** event handler. When the transfer has completed, the **OnTaskEnd** event will be fired. It is not required that you implement handlers for these events.

To determine when a transfer has completed without implementing any event handlers, periodically call the **TaskDone** method. If you wish to block the current thread and wait for the transfer to complete, call the **TaskWait** method. To stop a background file transfer that is in progress, call the **TaskAbort** method. This will signal the background worker thread to cancel the transfer and terminate the session.

This method can be called multiple times to download more than one file in the background; however, most servers limit the number of simultaneous connections that can originate from a single IP address. The application should not make any assumptions about the sequence in which background transfers are performed or the order in which they may complete.

HttpClient Class | SocketTools Namespace | HttpClient.AsyncPutFile Overload List | AsyncGetFile Method

HttpClient.AttachThread Method

Attach an instance of the class to the current thread

[Visual Basic]
```
Public Function AttachThread() As Boolean
```

[C#]
```
public bool AttachThread();
```

Return Value

A boolean value which specifies if the client could be attached to the current thread. If this method returns **false**, the client could not be attached to the thread and the application should check the value of the LastError property to determine the cause of the failure.

Remarks

When an instance of the class is created it is associated with the current thread that created it. Normally, if another thread attempts to perform an operation using that instance, an error is returned. This is used to ensure that other threads cannot interfere with an operation being performed by the owner thread. In some cases, it may be desirable for one thread in an application to create an instance of the class, establish a connection and then pass that instance to another worker thread. The **AttachThread** method can be used to change the ownership of the class instance to the new worker thread.

This method should be called by the new thread immediately after it has been created, and if the new thread does not release the handle itself, the ownership of the handle should be restored by the original thread. Under no circumstances should **AttachThread** be used to forcibly destroy an instance of a class allocated by another thread while a blocking operation is in progress. To cancel a blocking operation, use the **Cancel** method and then delete the class instance after the blocking function exits and control is returned to the current thread.

```

Parameters

userName

A string which specifies the username used to authenticate the client session.

userPassword

A string which specifies the password which will be used to authenticate the client session with the remote host. Not all server resources require the client to authenticate the session. If you are using OAuth 2.0 authentication, this parameter specifies the bearer token.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

This method will set the Authorization request header for the client session using the credentials provided by the caller. It will always override any custom Authorization header value which may have been previously set using the **SetHeader** method.

If both the **userName** and **userPassword** parameters specify empty strings, the current authentication type will always be set to **HttpAuthentication.authNone**, effectively clearing the current user credentials for the client session.

If you provide a username and password, and the **Authentication** property has not been explicitly set, it will automatically default to using the **HttpAuthentication.authBasic** authentication type.

If you provide a user name and password to the **Connect** method, or you set the **UserName** property and either the **Password** or **BearerToken** property prior to calling the **Connect** method, authentication will be automatically attempted at the time the connection is made. This method is only required if you do not provide user credentials when the connection is established and wish to authenticate the client session at a later time.

See Also

HttpClient Class | SocketTools Namespace | HttpClient.Authenticate Overload List | Authentication Property | BearerToken Property | Password Property | UserName Property | SetHeader Method

HttpClient.Authenticate Method (String, String, HttpAuthentication)

Authenticate the client session with a username and password.

[Visual Basic]

```
Overloads Public Function Authenticate( _
   ByVal userName As String, _
   ByVal userPassword As String, _
   ByVal authType As HttpAuthentication _
) As Boolean
```

[C#]

```
public bool Authenticate(
   string userName,
   string userPassword,
   HttpAuthentication authType
);
```

Parameters

userName
A string which specifies the username used to authenticate the client session.

userPassword
A string which specifies the password which will be used to authenticate the client session with the remote host. Not all server resources require the client to authenticate the session. If you are using OAuth 2.0 authentication, this parameter specifies the bearer token.

authType
A HttpAuthentication enumeration value which specifies the authentication method.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

This method will set the Authorization request header for the client session using the credentials provided by the caller. This method will always override any custom Authorization header value which may have been previously set using the **SetHeader** method.

If both the **userName** and **userPassword** parameters specify empty strings, the current authentication type will always be set to **HttpAuthentication.authNone** regardless of the value of the **authType** parameter. This effectively clears the current user credentials for the client session.

If you provide a user name and password to the **Connect** method, or you set the **UserName** property and either the **Password** or **BearerToken** property prior to calling the **Connect** method, authentication will be automatically attempted at the time the connection is made. This method is only required if you do not provde user credentials when the connection is established and wish to authenticate the client session at a later time.

HttpClient.Cancel Method

Cancel the current blocking client operation.

[Visual Basic]

```
Public Sub Cancel()
```

[C#]

```
public void Cancel();
```

Remarks

When the **Cancel** method is called, the blocking client operation will not immediately fail. An internal flag is set which causes the blocking operation to exit with an error. This means that the application cannot cancel an operation and immediately perform some other blocking function. Instead it must allow the calling stack to unwind, returning back to the blocking operation before making any further function calls.

HttpClient Class | SocketTools Namespace

HttpClient.ClearForm Method

Remove all defined fields from the current form.

[Visual Basic]
```
Public Sub ClearForm()
```

[C#]
```
public void ClearForm();
```

Remarks

The **ClearForm** deletes all form fields, releasing the memory allocated for the field data and resetting the internal state of the current form.

See Also

HttpClient Class | SocketTools Namespace

HttpClient.ClearHeaders Method

Clears the current request and response headers.

[Visual Basic]

```
Public Sub ClearHeaders()
```

[C#]

```
public void ClearHeaders();
```

Remarks

The **ClearHeaders** method clears the request and response headers for the current session, including any cookies which may have been set. This method can be useful in persistent connections, where the client wishes to clear any previously set header values without disconnecting from the server.

HttpClient Class | SocketTools Namespace

HttpClient.CloseFile Method

Close the file that was opened on the server.

[Visual Basic]

```
Public Function CloseFile() As Boolean
```

[C#]

```
public bool CloseFile();
```

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **CloseFile** method is used to close a file that was opened using the **OpenFile** method, or created using the **CreateFile** method. It should be called before the client disconnects from the server.

HttpClient Class | SocketTools Namespace

HttpClient.Command Method (String, String)

Send a custom command to the web server.

[Visual Basic]

```
Overloads Public Function Command( _
   ByVal command As String, _
   ByVal resource As String _
) As Boolean
```

[C#]

```
public bool Command(
   string command,
   string resource
);
```

Parameters

command

A string which specifies the command to send.

resource

A string which specifies the resource that the command will be performed upon. The resource may be a file, such as an HTML document or an image, or it may be a script used to process data submitted by the client. Note that this argument specifies the name of the resource only, not a complete URL. In most cases, the resource name should be specified using an absolute path (a path that begins with a leading slash character).

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

There are a number of standard commands which may be used, and there are extended commands which depend on the type of server that the client is connected to. Consult the protocol standard and/or the technical reference documentation for the server to determine what commands may be issued by a client application. An example of some common HTTP commands are:

Command	Description
GET	Return the contents of the specified resource. This command is recognized by all servers.
HEAD	Return only header information for the specified resource. This command is recognized by servers that support at least version 1.0 of the protocol.
POST	Post data to the specified resource. This command is recognized by servers that support at least version 1.0 of the protocol.
PUT	Create or replace the specified resource on the server. This command is recognized by servers that support at least version 1.0 of the protocol. Not all servers support this command.

DELETE	Delete the specified resource from the server. This command is recognized by servers that support at least version 1.1 of the protocol. Not all servers support this command.

Not all servers support all of the listed commands, and some commands may require specific changes to the server configuration. In particular, the PUT and DELETE commands typically require that configuration changes be made by the site administrator. All servers will support the use of the GET command, and all servers that support at least version 1.0 of the protocol will support the POST command.

Only one request may be in progress at one time for each client session. Use the **CloseFile** method to terminate the request after all of the data has been read from the server.

See Also

HttpClient Class | SocketTools Namespace | HttpClient.Command Overload List

HttpClient.Command Method (String, String, Byte[], Int32)

Send a custom command to the web server.

```
[Visual Basic]
Overloads Public Function Command( _
   ByVal command As String, _
   ByVal resource As String, _
   ByVal parameter As Byte(), _
   ByVal length As Integer _
) As Boolean
```

```
[C#]
public bool Command(
   string command,
   string resource,
   byte[] parameter,
   int length
);
```

Parameters

command

A string which specifies the command to send.

resource

A string which specifies the resource that the command will be performed upon. The resource may be a file, such as an HTML document or an image, or it may be a script used to process data submitted by the client. Note that this argument specifies the name of the resource only, not a complete URL. In most cases, the resource name should be specified using an absolute path (a path that begins with a leading slash character).

parameter

A byte array which specifies one or more parameters to be sent along with the command. The parameter data is encoded according to the encoding type specified by the **Encoding** property. If the resource does not require any parameters, this argument should be omitted.

length

An integer value which specifies the length of the parameter data in bytes. This value cannot be larger than the size of the byte array passed to this method.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

There are a number of standard commands which may be used, and there are extended commands which depend on the type of server that the client is connected to. Consult the protocol standard and/or the technical reference documentation for the server to determine what commands may be issued by a client application. An example of some common HTTP commands are:

Command	Description
GET	Return the contents of the specified resource. This command is recognized by all servers.

HEAD	Return only header information for the specified resource. This command is recognized by servers that support at least version 1.0 of the protocol.
POST	Post data to the specified resource. This command is recognized by servers that support at least version 1.0 of the protocol.
PUT	Create or replace the specified resource on the server. This command is recognized by servers that support at least version 1.0 of the protocol. Not all servers support this command.
DELETE	Delete the specified resource from the server. This command is recognized by servers that support at least version 1.1 of the protocol. Not all servers support this command.

Not all servers support all of the listed commands, and some commands may require specific changes to the server configuration. In particular, the PUT and DELETE commands typically require that configuration changes be made by the site administrator. All servers will support the use of the GET command, and all servers that support at least version 1.0 of the protocol will support the POST command.

The ***parameter*** argument is used to pass additional information to the server when a resource is requested. This is most commonly used to provide information to scripts, similar to how arguments are used when executing a program from the command line. Unless the POST command is being executed, the data in the buffer will automatically be encoded using the current encoding mechanism specified for the client.

By default, the parameter data is URL encoded, which means that any spaces and non-printable characters are converted to printable characters before submitted to the server. The type of encoding that is performed can be changed by setting the **Encoding** property. Although the default encoding is appropriate for most applications, those that submit XML formatted data may need to change the encoding type.

Only one request may be in progress at one time for each client session. Use the **CloseFile** method to terminate the request after all of the data has been read from the server.

HttpClient Class | SocketTools Namespace

HttpClient.Connect Method (String, Int32)

Establish a connection with a remote host.

[Visual Basic]
```
Overloads Public Function Connect( _
   ByVal hostName As String, _
   ByVal hostPort As Integer _
) As Boolean
```

[C#]
```
public bool Connect(
   string hostName,
   int hostPort
);
```

Parameters

hostName
A string which specifies the remote host to establish a connection with. This may specify a host name or an Internet address in dot-notation.

hostPort
An integer which specifies the port number for the connection. This value must be greater than zero and the maximum valid port number is 65535.

Return Value

A boolean value which specifies if the connection has been established. If the client is in blocking mode, a return value of **true** indicates that the connection has completed and the application may send and receive data from the remote host. If the client is in non-blocking mode, a return value of **true** indicates that the client has successfully created a socket and the connection is in progress.

When a non-blocking connection has completed, the OnConnect event will be fired. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

Remarks

This method establishes a connection using assigned property values.

The value of the **UserName** property will be used to determine the username if authentication is required.

The value of the **Password** property will be used to determine the username if authentication is required.

The value of the **Timeout** property will be used to specify the timeout period.

The value of the **Options** property will be used to specify the default options for the connection.

The value of the **ProtocolVersion** property will be used to specify the protocol version.

HttpClient.Connect Method (String, Int32, Int32)

Establish a connection with a remote host.

[Visual Basic]

```
Overloads Public Function Connect( _
   ByVal hostName As String, _
   ByVal hostPort As Integer, _
   ByVal timeout As Integer _
) As Boolean
```

[C#]

```
public bool Connect(
   string hostName,
   int hostPort,
   int timeout
);
```

Parameters

hostName

A string which specifies the remote host to establish a connection with. This may specify a host name or an Internet address in dot-notation.

hostPort

An integer which specifies the port number for the connection. This value must be greater than zero and the maximum valid port number is 65535.

timeout

An integer value that specifies the number of seconds that the method will wait for the connection to complete before failing the operation and returning to the caller. This value is only meaningful for blocking connections.

Return Value

A boolean value which specifies if the connection has been established. If the client is in blocking mode, a return value of **true** indicates that the connection has completed and the application may send and receive data from the remote host. If the client is in non-blocking mode, a return value of **true** indicates that the client has successfully created a socket and the connection is in progress.

When a non-blocking connection has completed, the OnConnect event will be fired. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

Remarks

This method establishes a connection using assigned property values.

The value of the **UserName** property will be used to determine the username if authentication is required.

The value of the **Password** property will be used to determine the username if authentication is required.

The value of the **Options** property will be used to specify the default options for the connection.

The value of the **ProtocolVersion** property will be used to specify the protocol version.

HttpClient Class | SocketTools Namespace | HttpClient.Connect Overload List

HttpClient.Connect Method (String, Int32, Int32, HttpOptions)

Establish a connection with a remote host.

[Visual Basic]

```
Overloads Public Function Connect( _
   ByVal hostName As String, _
   ByVal hostPort As Integer, _
   ByVal timeout As Integer, _
   ByVal options As HttpOptions _
) As Boolean
```

[C#]

```
public bool Connect(
   string hostName,
   int hostPort,
   int timeout,
   HttpOptions options
);
```

Parameters

hostName
: A string which specifies the remote host to establish a connection with. This may specify a host name or an Internet address in dot-notation.

hostPort
: An integer which specifies the port number for the connection. This value must be greater than zero and the maximum valid port number is 65535.

timeout
: An integer value that specifies the number of seconds that the method will wait for the connection to complete before failing the operation and returning to the caller. This value is only meaningful for blocking connections.

options
: One or more of the HttpOptions enumeration flags.

Return Value

A boolean value which specifies if the connection has been established. If the client is in blocking mode, a return value of **true** indicates that the connection has completed and the application may send and receive data from the remote host. If the client is in non-blocking mode, a return value of **true** indicates that the client has successfully created a socket and the connection is in progress.

When a non-blocking connection has completed, the OnConnect event will be fired. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

Remarks

This method establishes a connection using assigned property values.

The value of the **UserName** property will be used to determine the username if authentication is required.

The value of the **Password** property will be used to determine the username if authentication is required.

The value of the **Timeout** property will be used to specify the timeout period.

Parameters

resourceName

A string which specifies the name of the file being created on the server. The client must have the appropriate access rights to create the file or an error will be returned.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

This method uses the PUT command to create the file. The server must support this command and the user must have the appropriate permission to create the specified file. If this method is successful, the client should then use the **Write** method to send the contents of the file to the server. Once all of the data has been written, the **CloseFile** method should be called to close the file and complete the operation. Note that this method is typically only accepted by servers that support version 1.1 of the protocol or later.

When using **Write** to send the contents of the file to the server, it is recommended that the data be written in logical blocks that are no larger than 8,192 bytes in size. Attempting to write very large amounts of data in a single call can either cause the current thread to block or, in the case of an asynchronous connection, return an error if the internal buffers cannot accommodate all of the data. To send the entire contents of a file at once, use the **PutData** method instead of calling **CreateFile**.

HttpClient Class | SocketTools Namespace | HttpClient.CreateFile Overload List

HttpClient.CreateFile Method (String, Int32)

Create a new file or overwrite an existing file on the web server.

[Visual Basic]

```
Overloads Public Function CreateFile( _
   ByVal resourceName As String, _
   ByVal fileSize As Integer _
) As Boolean
```

[C#]

```
public bool CreateFile(
   string resourceName,
   int fileSize
);
```

Parameters

resourceName
: A string which specifies the name of the file being created on the server. The client must have the appropriate access rights to create the file or an error will be returned.

fileSize
: A number which specifies the size of the file in bytes. This value must be greater than zero.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

This method uses the PUT command to create the file. The server must support this command and the user must have the appropriate permission to create the specified file. If this method is successful, the client should then use the **Write** method to send the contents of the file to the server. Once all of the data has been written, the **CloseFile** method should be called to close the file and complete the operation. Note that this method is typically only accepted by servers that support version 1.1 of the protocol or later.

When using **Write** to send the contents of the file to the server, it is recommended that the data be written in logical blocks that are no larger than 8,192 bytes in size. Attempting to write very large amounts of data in a single call can either cause the current thread to block or, in the case of an asynchronous connection, return an error if the internal buffers cannot accommodate all of the data. To send the entire contents of a file at once, use the **PutData** method instead of calling **CreateFile**.

HttpClient Class | SocketTools Namespace

HttpClient.CreateForm Method ()

Create a new virtual form.

[Visual Basic]

```
Overloads Public Function CreateForm() As Boolean
```

[C#]

```
public bool CreateForm();
```

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **CreateForm** method is used to create a new form that will be populated with values and then submitted to the server for processing. Any previously defined form data will be deleted when this method is called.

This method creates the form using assigned property values.

The value of the **FormAction** property will be used to determine the script that will accept the form data on the server.

The value of the **FormMethod** property will be used to determine the method used to submit the form data.

The value of the **FormType** property will be used to specify the form type and encoding method.

HttpClient Class | SocketTools Namespace | HttpClient.CreateForm Overload List

HttpClient.CreateForm Method (String)

Create a new virtual form.

[Visual Basic]

```
Overloads Public Function CreateForm( _
   ByVal formAction As String _
) As Boolean
```

[C#]

```
public bool CreateForm(
   string formAction
);
```

Parameters

formAction

A string which specifies the name of the resource that the form data will be submitted to. Typically this is the name of a script that is executed on the server. If this argument is omitted, the value of the **FormAction** property is used as the default value. If the **FormAction** property is undefined, the value of the **Resource** property will be used as the default value.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **CreateForm** method is used to create a new form that will be populated with values and then submitted to the server for processing. Any previously defined form data will be deleted when this method is called.

This method creates the form using assigned property values.

The value of the **FormMethod** property will be used to determine the method used to submit the form data.

The value of the **FormType** property will be used to specify the form type and encoding method.

HttpClient.CreateForm Method (String, HttpFormMethod)

Create a new virtual form.

[Visual Basic]

```
Overloads Public Function CreateForm( _
   ByVal formAction As String, _
   ByVal formMethod As HttpFormMethod _
) As Boolean
```

[C#]

```
public bool CreateForm(
   string formAction,
   HttpFormMethod formMethod
);
```

Parameters

formAction

A string which specifies the name of the resource that the form data will be submitted to. Typically this is the name of a script that is executed on the server. If this argument is omitted, the value of the **FormAction** property is used as the default value. If the **FormAction** property is undefined, the value of the **Resource** property will be used as the default value.

formMethod

An HttpFormMethod enumeration value which specifies how the form data will be submitted to the server.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **CreateForm** method is used to create a new form that will be populated with values and then submitted to the server for processing. Any previously defined form data will be deleted when this method is called.

This method creates the form using assigned property values.

The value of the **FormType** property will be used to specify the form type and encoding method.

Create a new virtual form.

[Visual Basic]

```
Overloads Public Function CreateForm( _
   ByVal formAction As String, _
   ByVal formMethod As HttpFormMethod, _
   ByVal formType As HttpFormType _
) As Boolean
```

[C#]

```
public bool CreateForm(
   string formAction,
   HttpFormMethod formMethod,
   HttpFormType formType
);
```

Parameters

formAction
A string which specifies the name of the resource that the form data will be submitted to. Typically this is the name of a script that is executed on the server. If this argument is omitted, the value of the **FormAction** property is used as the default value. If the **FormAction** property is undefined, the value of the **Resource** property will be used as the default value.

formMethod
An HttpFormMethod enumeration value which specifies how the form data will be submitted to the server.

formType
An HttpFormType enumeration value which specifies the type of form and how the form data will be encoded.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **CreateForm** method is used to create a new form that will be populated with values and then submitted to the server for processing. Any previously defined form data will be deleted when this method is called.

See Also

HttpClient Class | SocketTools Namespace | HttpClient.CreateForm Overload List

HttpClient.DeleteField Method

Delete a form field and its value from the current form.

[Visual Basic]

```
Public Function DeleteField( _
   ByVal fieldName As String _
) As Boolean
```

[C#]

```
public bool DeleteField(
   string fieldName
);
```

Parameters

fieldName

A string which specifies the name of the field to remove from the form.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **DeleteField** method is used to remove a field and its associated value from the current form. The memory allocated for the field data will be released.

See Also

HttpClient Class | SocketTools Namespace

HttpClient.DeleteFile Method

Remove a file on the web server.

[Visual Basic]

```
Public Function DeleteFile( _
   ByVal fileName As String _
) As Boolean
```

[C#]

```
public bool DeleteFile(
   string fileName
);
```

Parameters

fileName

A string which specifies the name of the file to delete.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **DeleteFile** method deletes an existing file or resource from the web server using the DELETE command. This command is typically only accepted by servers that support version 1.1 of the protocol or later. This method requires the user have the appropriate permissions to remove the file or resource.

See Also

HttpClient Class | SocketTools Namespace

HttpClient.Disconnect Method

Terminate the connection with a remote host.

[Visual Basic]

```
Public Sub Disconnect()
```

[C#]

```
public void Disconnect();
```

Remarks

The **Disconnect** method terminates the connection with the remote host and releases the client handle allocated by the class. Note that the socket is not immediately released when the connection is terminated and will enter a wait state for two minutes. After the time wait period has elapsed, the client will be released by the operating system. This is a normal safety mechanism to handle any packets that may arrive after the connection has been closed.

HttpClient Class | SocketTools Namespace

HttpClient.Dispose Method

Releases all resources used by HttpClient.

Overload List

Releases all resources used by HttpClient.

public void Dispose();

Releases the unmanaged resources allocated by the HttpClient class and optionally releases the managed resources.

protected virtual void Dispose(bool);

See Also

HttpClient Class | SocketTools Namespace

HttpClient.Dispose Method ()

Releases all resources used by HttpClient.

[Visual Basic]

```
NotOverridable Overloads Public Sub Dispose() _
    Implements IDisposable.Dispose
```

[C#]

```
public void Dispose();
```

Implements

IDisposable.Dispose

Remarks

The **Dispose** method terminates any active connection and explicitly releases the resources allocated for this instance of the class. In some cases, better performance can be achieved if the programmer explicitly releases resources when they are no longer being used. The **Dispose** method provides explicit control over these resources.

Unlike the **Uninitialize** method, once the **Dispose** method has been called, that instance of the class cannot be re-initialized and you should not attempt to access class properties or invoke any methods. Note that this method can be called even if other references to the object are active.

See Also

HttpClient Class | SocketTools Namespace | HttpClient.Dispose Overload List

HttpClient.Dispose Method (Boolean)

Releases the unmanaged resources allocated by the HttpClient class and optionally releases the managed resources.

```
[Visual Basic]
Overridable Overloads Protected Sub Dispose( _
   ByVal disposing As Boolean _
)
```

```
[C#]
protected virtual void Dispose(
   bool disposing
);
```

Parameters

disposing

A boolean value which should be specified as **true** to release both managed and unmanaged resources; **false** to release only unmanaged resources.

Remarks

The **Dispose** method terminates any active connection and explicitly releases the resources allocated for this instance of the class. In some cases, better performance can be achieved if the programmer explicitly releases resources when they are no longer being used. The **Dispose** method provides explicit control over these resources.

Unlike the **Uninitialize** method, once the **Dispose** method has been called, that instance of the class cannot be re-initialized and you should not attempt to access class properties or invoke any methods. Note that this method can be called even if other references to the object are active.

You should call **Dispose** in your derived class when you are finished using the derived class. The **Dispose** method leaves the derived class in an unusable state. After calling **Dispose**, you must release all references to the derived class and the **HttpClient** class so the memory they were occupying can be reclaimed by garbage collection.

HttpClient.GetCookie Method

Return information about the specified cookie.

Overload List

Return information about the specified cookie.

public bool GetCookie(string,ref HttpCookie);

Return information about the specified cookie.

public bool GetCookie(string,ref string);

See Also

HttpClient Class | SocketTools Namespace

HttpClient.GetCookie Method (String, HttpCookie)

Return information about the specified cookie.

```
[Visual Basic]
Overloads Public Function GetCookie( _
   ByVal cookieName As String, _
   ByRef cookieInfo As HttpCookie _
) As Boolean
```

```
[C#]
public bool GetCookie(
   string cookieName,
   ref HttpCookie cookieInfo
);
```

Parameters

cookieName
A string which specifies the name of the cookie to return information about. To obtain a list of cookies which have been set by the server, use the **CookieCount** and **CookieName** properties.

cookieInfo
An HttpCookie structure which will contain information about the cookie when the method returns.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The Hypertext Transfer Protocol uses special tokens called "cookies" to maintain persistent state information between requests for a resource. These cookies are exchanged between the client and server by setting specific header fields. When a server wants the client to use a cookie, it will include a header field named Set-Cookie in the response header when the client requests a resource. The client can then take this cookie and store it, either temporarily in memory or permanently in a file on the local system. The next time that the client requests a resource from that server, it can send the cookie back to the server by setting the Cookie header field. The **GetCookie** method searches for a cookie set by the server in the Set-Cookie header field. The **SetCookie** method creates or modifies the Cookie header field for the next resource requested by the client.

There are two general types of cookies that are used by servers. Session cookies exist only for the duration of the client session; they are stored in memory and not saved in any kind of permanent storage. When the client application terminates, session cookies are deleted and no longer used. Persistent cookies are stored on the local system and are used by the client until their expiration time. It is the responsibility of the client application to store persistent cookies; applications may use a flat text file, a database or any other storage method available.

HttpClient.GetCookie Method (String, String)

Return information about the specified cookie.

[Visual Basic]

```
Overloads Public Function GetCookie( _
   ByVal cookieName As String, _
   ByRef cookieValue As String _
) As Boolean
```

[C#]

```
public bool GetCookie(
   string cookieName,
   ref string cookieValue
);
```

Parameters

cookieName

A string which specifies the name of the cookie to return information about. To obtain a list of cookies which have been set by the server, use the **CookieCount** and **CookieName** properties.

cookieValue

A string passed by reference which will contain the value of the specified cookie when the method returns.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The Hypertext Transfer Protocol uses special tokens called "cookies" to maintain persistent state information between requests for a resource. These cookies are exchanged between the client and server by setting specific header fields. When a server wants the client to use a cookie, it will include a header field named Set-Cookie in the response header when the client requests a resource. The client can then take this cookie and store it, either temporarily in memory or permanently in a file on the local system. The next time that the client requests a resource from that server, it can send the cookie back to the server by setting the Cookie header field. The **GetCookie** method searches for a cookie set by the server in the Set-Cookie header field. The **SetCookie** method creates or modifies the Cookie header field for the next resource requested by the client.

There are two general types of cookies that are used by servers. HttpClient.GetData Method

Transfer data from the web server and store it in a local buffer.

Overload List

Transfer data from the web server and store it in a local buffer.

public bool GetData(byte[],ref int);

Transfer data from the web server and store it in a local buffer.

public bool GetData(string,byte[],ref int);

Transfer data from the web server and store it in a local buffer.

public bool GetData(string,byte[],ref int,HttpTransferOptions);

Transfers the contents of a file from the server and stores it in a MemoryStream.

public bool GetData(string,MemoryStream);

Transfers the contents of a file from the server and stores it in a MemoryStream.

public bool GetData(string,MemoryStream,HttpTransferOptions);

Transfer data from the web server and store it in a local buffer.

public bool GetData(string,ref string);

Transfer data from the web server and store it in a local buffer.

public bool GetData(string,ref string,HttpTransferOptions);

Transfer data from the web server and store it in a local buffer.

public bool GetData(ref string);

HttpClient Class | SocketTools Namespace

HttpClient.GetData Method (String)

Transfer data from the web server and store it in a local buffer.

[Visual Basic]

```
Overloads Public Function GetData( _
   ByRef buffer As String _
) As Boolean
```

[C#]

```
public bool GetData(
   ref string buffer
);
```

Parameters

buffer
: A string passed by reference that the data will be stored in.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetData** method transfers data from the server to the local system, storing it in the specified buffer. This method will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

HttpClient.GetData Method (String, String)

Transfer data from the web server and store it in a local buffer.

[Visual Basic]

```
Overloads Public Function GetData( _
   ByVal resourceName As String, _
   ByRef buffer As String _
) As Boolean
```

[C#]

```
public bool GetData(
   string resourceName,
   ref string buffer
);
```

Parameters

resourceName

A string that specifies the resource on the server that will be accessed. If the resource specifies a file, then the contents of the file will be returned by the server. If the resource specifies a script or other executable content, it will be executed and the output will be transferred to the local system. The resource name should be specified using an absolute path that begins with a leading slash character.

buffer

A string passed by reference that the data will be stored in.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetData** method transfers data from the server to the local system, storing it in the specified buffer. This method will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

   ByVal resourceName As String, _
   ByRef buffer As String, _
   ByVal options As HttpTransferOptions _
) As Boolean
```

[C#]

```
public bool GetData(
   string resourceName,
   ref string buffer,
   HttpTransferOptions options
);
```

Parameters

resourceName

A string that specifies the resource on the server that will be accessed. If the resource specifies a file, then the contents of the file will be returned by the server. If the resource specifies a script or other executable content, it will be executed and the output will be transferred to the local system. The resource name should be specified using an absolute path that begins with a leading slash character.

buffer

A string passed by reference that the data will be stored in.

options

An HttpTransferOptions enumeration value which specifies one or more options when transferring the data from the server to the local system.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetData** method transfers data from the server to the local system, storing it in the specified buffer. This method will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

HttpClient Class | SocketTools Namespace | HttpClient.GetData Overload List

HttpClient.GetData Method (Byte[], Int32)

Transfer data from the web server and store it in a local buffer.

[Visual Basic]
```
Overloads Public Function GetData( _
   ByVal buffer As Byte(), _
   ByRef length As Integer _
) As Boolean
```

[C#]
```
public bool GetData(
   byte[] buffer,
   ref int length
);
```

Parameters

buffer
A byte array that the data will be stored in.

length
An integer value which specifies the maximum number of bytes of data to read. This value cannot be larger than the size of the buffer specified by the caller.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetData** method transfers data from the server to the local system, storing it in the specified buffer. This method will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

HttpClient Class | SocketTools Namespace | HttpClient.GetData Overload List

HttpClient.GetData Method (String, MemoryStream, HttpTransferOptions)

Transfers the contents of a file from the server and stores it in a MemoryStream.

[Visual Basic]

```
Overloads Public Function GetData( _
   ByVal resourceName As String, _
   ByVal memStream As MemoryStream, _
   ByVal options As HttpTransferOptions _
) As Boolean
```

[C#]

```
public bool GetData(
   string resourceName,
   MemoryStream memStream,
   HttpTransferOptions options
);
```

Parameters

resourceName

A string that specifies the resource on the server that will be accessed. If the resource specifies a file, then the contents of the file will be returned by the server. If the resource specifies a script or other executable content, it will be executed and the output will be transferred to the local system. The resource name should be specified using an absolute path that begins with a leading slash character.

memStream

A System.IO.MemoryStream object that will contain the file data when the method returns. This stream must be open and writable.

options

An HttpTransferOptions enumeration value which specifies one or more options when transferring the data from the server to the local system.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetData** method transfers data from a file on the server to the local system, storing it in the specified MemoryStream. This method will cause the calling current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

The contents of the MemoryStream will be replaced by the contents of the file and the current position will be reset to the beginning of the stream. The stream must be open and writable, otherwise this method will throw **System.NotSupportedException**.

```

Parameters

resourceName

A string that specifies the resource on the server that will be accessed. If the resource specifies a file, then the contents of the file will be returned by the server. If the resource specifies a script or other executable content, it will be executed and the output will be transferred to the local system. The resource name should be specified using an absolute path that begins with a leading slash character.

memStream

A System.IO.MemoryStream object that will contain the file data when the method returns. This stream must be open and writable.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetData** method transfers data from a file on the server to the local system, storing it in the specified MemoryStream. This method will cause the calling current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

The contents of the MemoryStream will be replaced by the contents of the file and the current position will be reset to the beginning of the stream. The stream must be open and writable, otherwise this method will throw **System.NotSupportedException**.

HttpClient Class | SocketTools Namespace

HttpClient.GetFile Method (String)

Transfer data from the web server and store it in a file on the local system.

[Visual Basic]

```
Overloads Public Function GetFile( _
   ByVal localFile As String _
) As Boolean
```

[C#]

```
public bool GetFile(
   string localFile
);
```

Parameters

localFile

A string that specifies the file on the local system that will be created. If the file already exists, it will be overwritten. The file pathing and name conventions must be that of the local host.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetFile** method downloads a file from the server to the local system. This method will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

HttpClient.GetFile Method (String, String)

Transfer data from the web server and store it in a file on the local system.

[Visual Basic]

```
Overloads Public Function GetFile( _
   ByVal localFile As String, _
   ByVal remoteFile As String _
) As Boolean
```

[C#]

```
public bool GetFile(
   string localFile,
   string remoteFile
);
```

Parameters

localFile

A string that specifies the file on the local system that will be created. If the file already exists, it will be overwritten. The file pathing and name conventions must be that of the local host.

remoteFile

A string that specifies the resource on the server that will be accessed. If the resource specifies a file, then the contents of the file will be returned by the server. If the resource specifies a script or other executable content, it will be executed and the output will be transferred to the local system. The resource name should be specified using an absolute path that begins with a leading slash character.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetFile** method downloads a file from the server to the local system. This method will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

HttpClient.GetFile Method (String, HttpTransferOptions)

Transfer data from the web server and store it in a file on the local system.

[Visual Basic]

```
Overloads Public Function GetFile( _
   ByVal localFile As String, _
   ByVal options As HttpTransferOptions _
) As Boolean
```

[C#]

```
public bool GetFile(
   string localFile,
   HttpTransferOptions options
);
```

Parameters

localFile

A string that specifies the file on the local system that will be created. If the file already exists, it will be overwritten. The file pathing and name conventions must be that of the local host.

options

An HttpTransferOptions enumeration value which specifies one or more options when transferring the data from the server to the local system.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetFile** method downloads a file from the server to the local system. This method will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

HttpClient.GetFile Method (String, String, HttpTransferOptions)

Transfer data from the web server and store it in a file on the local system.

[Visual Basic]

```
Overloads Public Function GetFile( _
   ByVal localFile As String, _
   ByVal remoteFile As String, _
   ByVal options As HttpTransferOptions _
) As Boolean
```

[C#]

```
public bool GetFile(
   string localFile,
   string remoteFile,
   HttpTransferOptions options
);
```

Parameters

localFile

A string that specifies the file on the local system that will be created. If the file already exists, it will be overwritten. The file pathing and name conventions must be that of the local host.

remoteFile

A string that specifies the resource on the server that will be accessed. If the resource specifies a file, then the contents of the file will be returned by the server. If the resource specifies a script or other executable content, it will be executed and the output will be transferred to the local system. The resource name should be specified using an absolute path that begins with a leading slash character.

options

An HttpTransferOptions enumeration value which specifies one or more options when transferring the data from the server to the local system.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetFile** method downloads a file from the server to the local system. This method will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

HttpClient Class | SocketTools Namespace | HttpClient.GetFile Overload List

HttpClient.GetFile Method (String, String, HttpTransferOptions, Int64)

Transfer data from the web server and store it in a file on the local system.

[Visual Basic]

```
Overloads Public Function GetFile( _
   ByVal localFile As String, _
   ByVal remoteFile As String, _
   ByVal options As HttpTransferOptions, _
   ByVal offset As Long _
) As Boolean
```

[C#]

```
public bool GetFile(
   string localFile,
   string remoteFile,
   HttpTransferOptions options,
   long offset
);
```

Parameters

localFile
: A string that specifies the file on the local system that will be created. If the file already exists, it will be overwritten. The file pathing and name conventions must be that of the local host.

remoteFile
: A string that specifies the resource on the server that will be accessed. If the resource specifies a file, then the contents of the file will be returned by the server. If the resource specifies a script or other executable content, it will be executed and the output will be transferred to the local system. The resource name should be specified using an absolute path that begins with a leading slash character.

options
: An HttpTransferOptions enumeration value which specifies one or more options when transferring the data from the server to the local system.

offset
: A integer value which specifies the offset where the file transfer should begin. A value of zero specifies that the file transfer should start at the beginning of the file. A value greater than zero is typically used to restart a transfer that has not completed successfully. Note that specifying a non-zero offset requires that the server support the option to restart file transfers.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetFile** method downloads a file from the server to the local system. This method will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

public bool GetFileSize(string,ref int);

Return the size of the specified file on the web server.

public bool GetFileSize(string,ref long);

See Also

HttpClient Class | SocketTools Namespace

HttpClient.GetFileSize Method (String, Int32)

Return the size of the specified file on the web server.

[Visual Basic]

```
Overloads Public Function GetFileSize( _
   ByVal fileName As String, _
   ByRef fileSize As Integer _
) As Boolean
```

[C#]

```
public bool GetFileSize(
   string fileName,
   ref int fileSize
);
```

Parameters

fileName

A string that specifies a file on the server. The file name should be specified using an absolute path that begins with a leading slash character.

fileSize

An integer passed by reference which will contain the size of the file in bytes when the method returns.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

This method uses the HEAD command to retrieve header information about the file without downloading the contents of the file itself. This requires that the server support at least version 1.0 of the protocol standard, or an error will be returned.

The server may not return a file size for some resources. This is typically the case with scripts that generate dynamic content because the server has no way of determining the size of the output generated by the script without actually executing it. The server may also not provide a file size for HTML documents which use server side includes (SSI) because that content is also dynamically created by the server. If the request to the server was successful and the file exists, but the server does not return a file size, the method will succeed but the file size returned to the caller will be zero.

When a request is made to the server for information about the file, the class library will attempt to keep the connection alive, even if the **KeepAlive** property has not been set to **true**. This allows an application to request the file size and then download the file without having to write additional code to re-establish the connection. However, it is possible that the attempt to keep the connection open will fail. In that case, an error will be returned and the session will no longer be valid. If this happens, the method may still return a valid file size. To determine if an error occurred, check the value of the **LastError** property.

Note that if the file on the server is a text file, it is possible that the value returned by this method will not match the size of the file when it is downloaded to the local system. This is because different operating systems use different sequences of characters to mark the end of a line of text, and when a file is transferred in text mode, the end of line character sequence is automatically converted to a carriage return-linefeed, which is the convention used by the Windows platform.

HttpClient Class | SocketTools Namespace | HttpClient.GetFileSize Overload List

HttpClient.GetFileSize Method (String, Int64)

Return the size of the specified file on the web server.

[Visual Basic]

```
Overloads Public Function GetFileSize( _
   ByVal fileName As String, _
   ByRef fileSize As Long _
) As Boolean
```

[C#]

```
public bool GetFileSize(
   string fileName,
   ref long fileSize
);
```

Parameters

fileName

A string that specifies a file on the server. The file name should be specified using an absolute path that begins with a leading slash character.

fileSize

A long integer passed by reference which will contain the size of the file in bytes when the method returns.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

This method uses the HEAD command to retrieve header information about the file without downloading the contents of the file itself. This requires that the server support at least version 1.0 of the protocol standard, or an error will be returned.

The server may not return a file size for some resources. This is typically the case with scripts that generate dynamic content because the server has no way of determining the size of the output generated by the script without actually executing it. The server may also not provide a file size for HTML documents which use server side includes (SSI) because that content is also dynamically created by the server. HttpClient.GetFileTime Method

Return the modification date and time for specified file on the web server.

Overload List

Return the modification date and time for specified file on the web server.

public bool GetFileTime(string,ref DateTime);

Return the modification date and time for specified file on the web server.

public bool GetFileTime(string,ref DateTime,bool);

See Also

HttpClient Class | SocketTools Namespace

HttpClient.GetFileTime Method (String, DateTime)

Return the modification date and time for specified file on the web server.

[Visual Basic]

```
Overloads Public Function GetFileTime( _
   ByVal fileName As String, _
   ByRef fileDate As Date _
) As Boolean
```

[C#]

```
public bool GetFileTime(
   string fileName,
   ref DateTime fileDate
);
```

Parameters

fileName
: A string that specifies a file on the server. The file name should be specified using an absolute path that begins with a leading slash character.

fileDate
: A **System.DateTime** structure passed by reference which will contain the file modification date and time when the method returns.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

This method uses the HEAD command to retrieve header information about the file without downloading the contents of the file itself. This requires that the server support at least version 1.0 of the protocol standard, or an error will be returned.

When a request is made to the server for information about the file, the class library will attempt to keep the connection alive, even if the **KeepAlive** property has not been set to **true**. This allows an application to request the modification time and then download the file without having to write additional code to re-establish the connection. However, it is possible that the attempt to keep the connection open will fail. In that case, an error will be returned and the session will no longer be valid. If this happens, the method may still return a valid date and time. To determine if an error occurred, check the value of the **LastError** property.

The **Localize** property will determine if the returned file time is adjusted for the local timezone.

See Also

HttpClient Class | SocketTools Namespace | HttpClient.GetFileTime Overload List

HttpClient.GetFileTime Method (String, DateTime, Boolean)

Return the modification date and time for specified file on the web server.

[Visual Basic]

```
Overloads Public Function GetFileTime( _
   ByVal fileName As String, _
   ByRef fileDate As Date, _
   ByVal localDate As Boolean _
) As Boolean
```

[C#]

```
public bool GetFileTime(
   string fileName,
   ref DateTime fileDate,
   bool localDate
);
```

Parameters

fileName

A string that specifies a file on the server. The file name should be specified using an absolute path that begins with a leading slash character.

fileDate

A **System.DateTime** structure passed by reference which will contain the file modification date and time when the method returns.

localDate

A boolean value which specifies if the date and time value should be localized for the current timezone.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

This method uses the HEAD command to retrieve header information about the file without downloading the contents of the file itself. This requires that the server support at least version 1.0 of the protocol standard, or an error will be returned.

When a request is made to the server for information about the file, the class library will attempt to keep the connection alive, even if the **KeepAlive** property has not been set to **true**. This allows an application to request the modification time and then download the file without having to write additional code to re-establish the connection. However, it is possible that the attempt to keep the connection open will fail. In that case, an error will be returned and the session will no longer be valid. If this happens, the method may still return a valid date and time. To determine if an error occurred, check the value of the **LastError** property.

HttpClient Class | SocketTools Namespace | HttpClient.GetFileTime Overload List

HttpClient.GetFirstHeader Method

Return the first response header field name and value.

[Visual Basic]

```
Public Function GetFirstHeader( _
   ByRef headerField As String, _
   ByRef headerValue As String _
) As Boolean
```

[C#]

```
public bool GetFirstHeader(
   ref string headerField,
   ref string headerValue
);
```

Parameters

headerField

A string passed by reference that will contain the name of the first header field returned by the server.

headerValue

A string passed by reference that will contain the value of the specified header field.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetFirstHeader** method is used get the first header field name and value from the response header returned by the server. This method should only be called after the client has requested the resource. This method is typically used in conjunction with the **GetNextHeader** method to enumerate all of the response header fields returned by the server.

See Also

HttpClient Class | SocketTools Namespace

HttpClient.GetHeader Method

Return the value of the specified response header field.

[Visual Basic]

```
Public Function GetHeader( _
   ByVal headerName As String, _
   ByRef headerValue As String _
) As Boolean
```

[C#]

```
public bool GetHeader(
   string headerName,
   ref string headerValue
);
```

Parameters

headerName
A string that specifies the name of the header field.

headerValue
A string passed by reference that will contain the value of the specified header field.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetHeader** method is used get the value of a specific header field from the response headers returned by the server. This method should only be called after the client has requested the resource. To enumerate all of the header fields returned by the server, use the **GetFirstHeader** and **GetNextHeader** methods.

See Also

HttpClient Class | SocketTools Namespace

HttpClient.GetNextHeader Method

Return the next response header field name and value.

[Visual Basic]

```
Public Function GetNextHeader( _
   ByRef headerField As String, _
   ByRef headerValue As String _
) As Boolean
```

[C#]

```
public bool GetNextHeader(
   ref string headerField,
   ref string headerValue
);
```

Parameters

headerField

A string passed by reference that will contain the name of the first header field returned by the server.

headerValue

A string passed by reference that will contain the value of the specified header field.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetNextHeader** method is used get the next header field name and value from the response header returned by the server. This method should only be called after the client has requested the resource. This method is used in conjunction with the **GetFirstHeader** method to enumerate all of the response header fields returned by the server.

See Also

HttpClient Class | SocketTools Namespace

HttpClient.Initialize Method

Initialize an instance of the HttpClient class.

Overload List

Initialize an instance of the HttpClient class.

public bool Initialize();

Initialize an instance of the HttpClient class.

public bool Initialize(string);

See Also

HttpClient Class | SocketTools Namespace | Uninitialize Method

HttpClient.Initialize Method ()

Initialize an instance of the HttpClient class.

[Visual Basic]
```
Overloads Public Function Initialize() As Boolean
```

[C#]
```
public bool Initialize();
```

Return Value

A boolean value which specifies if the class was initialized successfully.

Remarks

The **Initialize** method can be used to explicitly initialize an instance of the HttpClient class, loading the networking library and allocating resources for the current thread. Typically it is not necessary to explicitly call this method because the instance of the class is initialized by the class constructor. However, if the **Uninitialize** method is called, the class must be re-initialized before any other methods are called.

See Also

HttpClient Class | SocketTools Namespace | HttpClient.Initialize Overload List | Uninitialize Method

HttpClient.Initialize Method (String)

Initialize an instance of the HttpClient class.

[Visual Basic]

```
Overloads Public Function Initialize( _
   ByVal licenseKey As String _
) As Boolean
```

[C#]

```
public bool Initialize(
   string licenseKey
);
```

Return Value

A boolean value which specifies if the class was initialized successfully.

Remarks

The **Initialize** method can be used to explicitly initialize an instance of the HttpClient class, loading the networking library and allocating resources for the current thread. Typically an application would define the license key as a custom attribute, however this method can be used to initialize the class directly.

The runtime license key for your copy of SocketTools can be generated using the License Manager utility that is included with the product. Note that if you have installed an evaluation license, you will not have a runtime license key and cannot redistribute any applications which use the HttpClient class.

Example

The following example shows how to use the Initialize method to initialize an instance of the class. This example assumes that the license key string has been defined in code.

```
SocketTools.HttpClient httpClient = new SocketTools.HttpClient();

if (httpClient.Initialize(strLicenseKey) == false)
{
    MessageBox.Show(httpClient.LastErrorString, "Error",
                    MessageBoxButtons.OK, MessageBoxIcon.Exclamation);
    return;
}
```

```
Dim httpClient As New SocketTools.HttpClient

If httpClient.Initialize(strLicenseKey) = False Then
    MsgBox(httpClient.LastErrorString, vbIconExclamation)
    Exit Sub
End If
```

See Also

HttpClient Class | SocketTools Namespace | HttpClient.Initialize Overload List | RuntimeLicenseAttribute Class | Uninitialize Method

HttpClient.OpenFile Method

Open a file on the web server for reading.

[Visual Basic]

```
Public Function OpenFile( _
   ByVal fileName As String _
) As Boolean
```

[C#]

```
public bool OpenFile(
   string fileName
);
```

Parameters

fileName

A string which specifies the name of the file being opened on the server. The file name should be specified using an absolute path that begins with a leading slash character.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

This method uses the GET command to retrieve the file. If this method is successful, the client should then use the **Read** method to read the contents of the file from the server. Once all of the data has been read, the **CloseFile** method should be called to close the file and complete the operation. If the file being opened is not an HTML or text document, then it's recommended that you read the data into a byte array.

This method should not be used to post data to a script or other executable resource on the server. If you wish to post data to a script, then the **PostData** method should be used instead.

The client must have the appropriate access rights to open the file for reading or an error will be returned. It may be required that the **UserName** and **Password** properties be set to authenticate the client session so that access to the resource is permitted.

HttpClient.PatchData Method

Submits patch data to the server and returns the result in a string.

Overload List

Submits patch data to the server and returns the result in a string.

public bool PatchData(string,string,ref string);

Submits patch data to the server and returns the result in a string.

public bool PatchData(string,string,ref string,HttpPatchOptions);

Submits patch data to the server and returns the result in a string.

public bool PatchData(string,ref string);

See Also

HttpClient Class | SocketTools Namespace

HttpClient.PatchData Method (String, String, String, HttpPatchOptions)

Submits patch data to the server and returns the result in a string.

[Visual Basic]

```
Overloads Public Function PatchData( _
   ByVal resourceName As String, _
   ByVal patchData As String, _
   ByRef outputBuffer As String, _
   ByVal options As HttpPatchOptions _
) As Boolean
```

[C#]

```
public bool PatchData(
   string resourceName,
   string patchData,
   ref string outputBuffer,
   HttpPatchOptions options
);
```

Parameters

resourceName
A string that specifies the resource on the server that the data will be posted to. Typically this is the name of an executable script on the server. The resource name should be specified using an absolute path that begins with a leading slash character.

patchData
A string that contains the patch data which will be provided to the server.

outputBuffer
A string passed by reference which will contain the reponse from the server when the method returns.

options
An HttpPatchOptions enumeration that specifies one or more options when posting data to the server.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **PatchData** method is used to submit XML or JSON formatted patch data to a service, and then returns a copy of the response from the server into a string buffer. This method will not perform any encoding and will not automatically define the type of patch data being submitted. Your application is responsible for specifying the content type for the patch data and ensuring that the XML or JSON data being submitted to the server is formatted correctly.

This method sends a PATCH command to the server, which is similar to a POST or PUT request. It is used to make partial updates to a resource, rather than creating or replacing it entirely. The format of the patch data is specific to the service being used. If the resource being patched does not exist, the behavior is defined by the server. If enough information is provided, it may choose to create the resource just as if a PUT command was used, or it may return an error.

Your application should use the **SetHeader** method to define the Content-Type header prior to calling the **PatchData** method. One of the most common formats used is the JSON Merge Patch which is defined in RFC 7396. The value for the Content-Type header for this patch format is "application/merge-patch+json". Refer to your service API documentation to determine what patch formats are acceptable, along with any additional header values which must be defined.

This method will cause the current thread to block until the operation completes, a timeout occurs or the post is canceled. During the operation, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

See Also

HttpClient Class | SocketTools Namespace | HttpClient.PatchData Overload List

HttpClient.PatchData Method (String, String, String)

Submits patch data to the server and returns the result in a string.

[Visual Basic]

```
Overloads Public Function PatchData( _
   ByVal resourceName As String, _
   ByVal patchData As String, _
   ByRef outputBuffer As String _
) As Boolean
```

[C#]

```
public bool PatchData(
   string resourceName,
   string patchData,
   ref string outputBuffer
);
```

Parameters

resourceName
A string that specifies the resource on the server that the data will be posted to. Typically this is the name of an executable script on the server. The resource name should be specified using an absolute path that begins with a leading slash character.

patchData
A string that contains the patch data which will be provided to the server.

outputBuffer
A string passed by reference which will contain the reponse from the server when the method returns.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **PatchData** method is used to submit XML or JSON formatted patch data to a service, and then returns a copy of the response from the server into a string buffer. This method will not perform any encoding and will not automatically define the type of patch data being submitted. Your application is responsible for specifying the content type for the patch data and ensuring that the XML or JSON data being submitted to the server is formatted correctly.

This method sends a PATCH command to the server, which is similar to a POST or PUT request. It is used to make partial updates to a resource, rather than creating or replacing it entirely. The format of the patch data is specific to the service being used. If the resource being patched does not exist, the behavior is defined by the server. If enough information is provided, it may choose to create the resource just as if a PUT command was used, or it may return an error.

Your application should use the **SetHeader** method to define the Content-Type header prior to calling the **PatchData** method. One of the most common formats used is the JSON Merge Patch which is defined in RFC 7396. The value for the Content-Type header for this patch format is "application/merge-patch+json". Refer to your service API documentation to determine what patch formats are acceptable, along with any additional header values which must be defined.

This method will cause the current thread to block until the operation completes, a timeout occurs or the post is canceled. During the operation, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

HttpClient.PatchData Method (String, String)

Submits patch data to the server and returns the result in a string.

[Visual Basic]

```
Overloads Public Function PatchData( _
   ByVal patchData As String, _
   ByRef outputBuffer As String _
) As Boolean
```

[C#]

```
public bool PatchData(
   string patchData,
   ref string outputBuffer
);
```

Parameters

patchData
A string that contains the patch data which will be provided to the server.

outputBuffer
A string passed by reference which will contain the reponse from the server when the method returns.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **PatchData** method is used to submit XML or JSON formatted patch data to a service, and then returns a copy of the response from the server into a string buffer. This method will not perform any encoding and will not automatically define the type of patch data being submitted. Your application is responsible for specifying the content type for the patch data and ensuring that the XML or JSON data being submitted to the server is formatted correctly.

This method sends a PATCH command to the server, which is similar to a POST or PUT request. It is used to make partial updates to a resource, rather than creating or replacing it entirely. The format of the patch data is specific to the service being used. If the resource being patched does not exist, the behavior is defined by the server. If enough information is provided, it may choose to create the resource just as if a PUT command was used, or it may return an error.

Your application should use the **SetHeader** method to define the Content-Type header prior to calling the **PatchData** method. One of the most common formats used is the JSON Merge Patch which is defined in RFC 7396. The value for the Content-Type header for this patch format is "application/merge-patch+json". Refer to your service API documentation to determine what patch formats are acceptable, along with any additional header values which must be defined.

This version of the method submits the patch data to the resourse specified by the **Resource** property.

This method will cause the current thread to block until the operation completes, a timeout occurs or the post is canceled. During the operation, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

HttpClient Class | SocketTools Namespace

HttpClient.PostData Method (String, String)

Submits the contents of the specified buffer to a script on the server.

[Visual Basic]

```
Overloads Public Function PostData( _
   ByVal inputBuffer As String, _
   ByRef outputBuffer As String _
) As Boolean
```

[C#]

```
public bool PostData(
   string inputBuffer,
   ref string outputBuffer
);
```

Parameters

inputBuffer

A string which contains the data that will be sent to the server. Unicode strings are automatically UTF-8 encoded prior to being submitted.

outputBuffer

A string passed by reference that will contain the output generated by the script. Typically this is HTML content which is generated by the script as a result of processing the data that was posted to it.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **PostData** method submits the contents of the specified buffer to a script on the remote server and returns the result in a string provided by the caller. This method will cause the current thread to block until the operation completes, a timeout occurs or the post is canceled. During the operation, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

```
Overloads Public Function PostData( _
   ByVal resourceName As String, _
   ByVal inputBuffer As String, _
   ByRef outputBuffer As String _
) As Boolean
```

[C#]

```
public bool PostData(
   string resourceName,
   string inputBuffer,
   ref string outputBuffer
);
```

Parameters

resourceName

A string that specifies the resource on the server that the data will be posted to. Typically this is the name of an executable script on the server. The resource name should be specified using an absolute path that begins with a leading slash character.

inputBuffer

A string which contains the data which will be sent to the server. Unicode strings are automatically UTF-8 encoded prior to being submitted.

outputBuffer

A string passed by reference that will contain the output generated by the script. Typically this is HTML content which is generated by the script as a result of processing the data that was posted to it.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **PostData** method submits the contents of the specified buffer to a script on the remote server and returns the result in a string provided by the caller. This method will cause the current thread to block until the operation completes, a timeout occurs or the post is canceled. HttpClient.PostData Method (Byte[], Int32, Byte[], Int32)

Submits the contents of the specified buffer to a resource on the server.

[Visual Basic]

```
Overloads Public Function PostData( _
   ByVal inputBuffer As Byte(), _
   ByVal inputLength As Integer, _
   ByVal outputBuffer As Byte(), _
   ByRef outputLength As Integer _
) As Boolean
```

[C#]

```
public bool PostData(
   byte[] inputBuffer,
   int inputLength,
   byte[] outputBuffer,
   ref int outputLength
);
```

Parameters

inputBuffer
A byte array which contains the data to be submitted to the server.

inputLength
An integer value which specifies the size of the input buffer byte array. This value cannot be larger than the size of the buffer specified by the caller.

outputBuffer
A byte array that will contain the output generated by the script. Typically this is HTML content which is generated by the script as a result of processing the data that was posted to it.

outputLength
An integer value which specifies the maximum number of bytes of data to store in the output buffer. This value cannot be larger than the size of the buffer specified by the caller

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **PostData** method submits the contents of the specified buffer to a script on the remote server and returns the result in a byte array provided by the caller. This method will cause the current thread to block until the operation completes, a timeout occurs or the post is canceled. HttpClient Class | SocketTools Namespace

HttpClient.PostFile Method (String)

Post the contents of the specified file to a script executed on the remote server.

[Visual Basic]

```
Overloads Public Function PostFile( _
   ByVal fileName As String _
) As Boolean
```

[C#]

```
public bool PostFile(
   string fileName
);
```

Parameters

fileName

A string that specifies the file on the local system that will be transferred to the server. The file pathing and name conventions must be that of the local host.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **PostFile** method posts the contents of a file to a script that is executed on the server. This method will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

The **PostFile** method is similar to the **PutFile** method in that it can be used to upload the contents of a local file to a remote server. However, instead of using the PUT command, the POST command is used to send the file data to a script that is executed on the server. This method has the advantage of not requiring any special configuration settings on the server, however it does require that the script be able to process multipart/form-data as defined in RFC 2388.

To support uploading files from a form on a webpage, the FILE input type is used along with the action that specifies the script that will accept the file data and process it. For example, the HTML code could look like this:

```
 <form action="/upload.php" method="post" enctype="multipart/form-data">
<input type="file" name="datafile" size="20"> <input type="submit">
</form>
```

In this example, the script /upload.php is responsible for processing the file data that is posted by the client, and the form field name "datafile" is used. The user can select a file, and when the Submit button is clicked, the file data is posted to the script. To simulate this using the **PostFile** method, the *LocalFile* argument should be set to the name of the local file that is to be posted to the server. The *Resource* argument should be the name of the script, in this case "/upload.php". The *FieldName* argument should be specified as the string "datafile" to match the name of the field used by the form.

Note that the **PostFile** function always submits the file contents as multipart/form-data with the content type set to application/octet-stream. The script that accepts the posted data must be able to parse the multipart header block and correctly process 8-bit data. If the script assumes that the data will be posted using a specific encoding type such as base64, then the file data may not be accepted or may be corrupted by the script.

Overloads Public Function PostFile( _
   ByVal fileName As String, _
   ByVal resourceName As String, _
   ByVal fieldName As String _
) As Boolean
```

[C#]

```
public bool PostFile(
   string fileName,
   string resourceName,
   string fieldName
);
```

Parameters

fileName

A string that specifies the file on the local system that will be transferred to the server. The file pathing and name conventions must be that of the local host.

resourceName

A string that specifies the resource on the server that the data will be posted to. Typically this is the name of an executable script on the server. The resource name should be specified using an absolute path that begins with a leading slash character.

fieldName

A string argument that specifies the form field name that the script expects. If this argument is omitted or is an empty string, a default field name of "File1" is used.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **PostFile** method posts the contents of a file to a script that is executed on the server. This method will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. HttpClient Class | SocketTools Namespace

HttpClient.PutData Method (String)

Transfer data from a local buffer to the server.

[Visual Basic]

```
Overloads Public Function PutData( _
   ByVal buffer As String _
) As Boolean
```

[C#]

```
public bool PutData(
   string buffer
);
```

Parameters

buffer

A string which contains the data to be uploaded. Unicode strings are automatically UTF-8 encoded prior to being submitted.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **PutData** method transfers data from a local buffer and submits it to the server using the PUT command. This may be used to create a new file, replace the contents of an file which alread exists, or a request to submit data to a service API.

If you are using this method to upload the contents of a file, check to make sure the service allows the use of the PUT command. Not all servers permit files to be created using this method, and some may require specific configuration changes be made to the server to support this functionality.

The value of the **Resource** property will specify the resource path which will be used to submit the data.

It may be required for the client authenticate itself by setting the **UserName** and **Password** properties prior to submitting the data.

This method will cause the current thread to block until the data transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

   ByVal buffer As String _
) As Boolean
```

[C#]

```
public bool PutData(
   string resourceName,
   string buffer
);
```

Parameters

resourceName

A string that specifies the resource on the server that will receive the data being submitted. Depending on usage, this may be the name of a file or a URL which is used with an API.

buffer

A string which contains the data to be uploaded. Unicode strings are automatically UTF-8 encoded prior to being submitted.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **PutData** method transfers data from a local buffer and submits it to the server using the PUT command. This may be used to create a new file, replace the contents of an file which alread exists, or a request to submit data to a service API.

If you are using this method to upload the contents of a file, check to make sure the service allows the use of the PUT command. Not all servers permit files to be created using this method, and some may require specific configuration changes be made to the server to support this functionality.

It may be required for the client authenticate itself by setting the **UserName** and **Password** properties prior to submitting the data.

This method will cause the current thread to block until the data transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

HttpClient Class | SocketTools Namespace | HttpClient.PutData Overload List

HttpClient.PutData Method (String, String, Int32)

Transfer data from a local buffer to the server.

[Visual Basic]

```
Overloads Public Function PutData( _
   ByVal resourceName As String, _
   ByVal buffer As String, _
   ByVal length As Integer _
) As Boolean
```

[C#]

```
public bool PutData(
   string resourceName,
   string buffer,
   int length
);
```

Parameters

resourceName

A string that specifies the resource on the server that will receive the data being submitted. Depending on usage, this may be the name of a file or a URL which is used with an API.

buffer

A string which contains the data to be uploaded. Unicode strings are automatically UTF-8 encoded prior to being submitted.

length

An integer value which specifies the maximum number of bytes of data to sent. This value cannot be larger than the size of the buffer specified by the caller.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **PutData** method transfers data from a local buffer and submits it to the server using the PUT command. This may be used to create a new file, replace the contents of an file which alread exists, or a request to submit data to a service API.

If you are using this method to upload the contents of a file, check to make sure the service allows the use of the PUT command. Not all servers permit files to be created using this method, and some may require specific configuration changes be made to the server to support this functionality.

It may be required for the client authenticate itself by setting the **UserName** and **Password** properties prior to submitting the data.

This method will cause the current thread to block until the data transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

HttpClient Class | SocketTools Namespace | HttpClient.PutData Overload List

HttpClient.PutData Method (Byte[], Int32)

Transfer data from a local buffer to the server.

[Visual Basic]

```
Overloads Public Function PutData( _
   ByVal buffer As Byte(), _
   ByVal length As Integer _
) As Boolean
```

[C#]

```
public bool PutData(
   byte[] buffer,
   int length
);
```

Parameters

buffer

A byte array which contains the data to be submitted.

length

An integer value which specifies the maximum number of bytes of data to sent. This value cannot be larger than the size of the buffer specified by the caller.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **PutData** method transfers data from a local buffer and submits it to the server using the PUT command. This may be used to create a new file, replace the contents of an file which alread exists, or a request to submit data to a service API.

If you are using this method to upload the contents of a file, check to make sure the service allows the use of the PUT command. Not all servers permit files to be created using this method, and some may require specific configuration changes be made to the server to support this functionality.

The value of the **Resource** property will specify the resource path which will be used to submit the data.

It may be required for the client authenticate itself by setting the **UserName** and **Password** properties prior to submitting the data.

This method will cause the current thread to block until the data transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

HttpClient Class | SocketTools Namespace | HttpClient.PutData Overload List

HttpClient.PutData Method (String, Byte[], Int32)

Transfer data from a local buffer to the server.

[Visual Basic]

```
Overloads Public Function PutData( _
   ByVal resourceName As String, _
   ByVal buffer As Byte(), _
   ByVal length As Integer _
) As Boolean
```

[C#]

```
public bool PutData(
   string resourceName,
   byte[] buffer,
   int length
);
```

Parameters

resourceName
A string that specifies the resource on the server that will receive the data being submitted. Depending on usage, this may be the name of a file or a URL which is used with an API.

buffer
A byte array which contains the data to be submitted.

length
An integer value which specifies the maximum number of bytes of data to sent. This value cannot be larger than the size of the buffer specified by the caller.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **PutData** method transfers data from a local buffer and submits it to the server using the PUT command. This may be used to create a new file, replace the contents of an file which alread exists, or a request to submit data to a service API.

If you are using this method to upload the contents of a file, check to make sure the service allows the use of the PUT command. Not all servers permit files to be created using this method, and some may require specific configuration changes be made to the server to support this functionality.

It may be required for the client authenticate itself by setting the **UserName** and **Password** properties prior to submitting the data.

This method will cause the current thread to block until the data transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

HttpClient.PutData Method (String, MemoryStream)

Transfer data from a local buffer to the server.

[Visual Basic]

```
Overloads Public Function PutData( _
   ByVal resourceName As String, _
   ByVal memStream As MemoryStream _
) As Boolean
```

[C#]

```
public bool PutData(
   string resourceName,
   MemoryStream memStream
);
```

Parameters

resourceName

A string that specifies the resource on the server that will receive the data being submitted. Depending on usage, this may be the name of a file or a URL which is used with an API.

memStream

A MemoryStream object which contains the data to be uploaded to the server. This stream must be open and readable.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **PutData** method transfers data from a local buffer and submits it to the server using the PUT command. This may be used to create a new file, replace the contents of an file which alread exists, or a request to submit data to a service API.

If you are using this method to upload the contents of a file, check to make sure the service allows the use of the PUT command. Not all servers permit files to be created using this method, and some may require specific configuration changes be made to the server to support this functionality.

It may be required for the client authenticate itself by setting the **UserName** and **Password** properties prior to submitting the data.

This method will cause the current thread to block until the data transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

HttpClient Class | SocketTools Namespace

HttpClient.PostXml Method (String, String)

Submits XML formatted data to the server and returns the result in a string.

[Visual Basic]

```
Overloads Public Function PostXml( _
   ByVal xmlData As String, _
   ByRef outputBuffer As String _
) As Boolean
```

[C#]

```
public bool PostXml(
   string xmlData,
   ref string outputBuffer
);
```

Parameters

xmlData

A string that contains the XML formatted data which will be provided to the script.

outputBuffer

A string passed by reference that will contain the output generated by the script. Typically this is HTML content which is generated by the script as a result of processing the data that was posted to it.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **PostXml** method is used to submit XML formatted data to a script that executes on the server and then copy the output from that script into a local buffer. This function automatically sets the correct content type and encoding required for submitting XML data to a server, however it does not parse the XML data itself to ensure that it is well-formed. Your application is responsible for ensuring that the XML data that is being submitted to the server is formatted correctly.

This method will cause the current thread to block until the operation completes, a timeout occurs or the post is canceled. During the operation, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

The XML data will be submitted to the server using the value of the **Resource** property to specify the script that will process the data.

HttpClient.PostXml Method (String, String, String)

Submits XML formatted data to the server and returns the result in a string.

[Visual Basic]

```
Overloads Public Function PostXml( _
   ByVal resourceName As String, _
   ByVal xmlData As String, _
   ByRef outputBuffer As String _
) As Boolean
```

[C#]

```
public bool PostXml(
   string resourceName,
   string xmlData,
   ref string outputBuffer
);
```

Parameters

resourceName
A string that specifies the resource on the server that the data will be posted to. Typically this is the name of an executable script on the server. The resource name should be specified using an absolute path that begins with a leading slash character.

xmlData
A string that contains the XML formatted data which will be provided to the script.

outputBuffer
A string passed by reference that will contain the output generated by the script. Typically this is HTML content which is generated by the script as a result of processing the data that was posted to it.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **PostXml** method is used to submit XML formatted data to a script that executes on the server and then copy the output from that script into a local buffer. This function automatically sets the correct content type and encoding required for submitting XML data to a server, however it does not parse the XML data itself to ensure that it is well-formed. Your application is responsible for ensuring that the XML data that is being submitted to the server is formatted correctly.

This method will cause the current thread to block until the operation completes, a timeout occurs or the post is canceled. During the operation, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

Submits XML formatted data to the server and returns the result in a string.

[Visual Basic]

```
Overloads Public Function PostXml( _
   ByVal resourceName As String, _
   ByVal xmlData As String, _
   ByRef outputBuffer As String, _
   ByVal options As HttpPostOptions _
) As Boolean
```

[C#]

```
public bool PostXml(
   string resourceName,
   string xmlData,
   ref string outputBuffer,
   HttpPostOptions options
);
```

Parameters

resourceName

A string that specifies the resource on the server that the data will be posted to. Typically this is the name of an executable script on the server. The resource name should be specified using an absolute path that begins with a leading slash character.

xmlData

A string that contains the XML formatted data which will be provided to the script.

outputBuffer

A string passed by reference that will contain the output generated by the script. Typically this is HTML content which is generated by the script as a result of processing the data that was posted to it.

options

An HttpPostOptions enumeration that specifies one or more options when posting data to the server.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **PostXml** method is used to submit XML formatted data to a script that executes on the server and then copy the output from that script into a local buffer. This function automatically sets the correct content type and encoding required for submitting XML data to a server, however it does not parse the XML data itself to ensure that it is well-formed. HttpClient Class | SocketTools Namespace

HttpClient.PutFile Method (String, String)

Transfer a file from the local system to the web server.

[Visual Basic]

```
Overloads Public Function PutFile( _
   ByVal localFile As String, _
   ByVal remoteFile As String _
) As Boolean
```

[C#]

```
public bool PutFile(
   string localFile,
   string remoteFile
);
```

Parameters

localFile

A string that specifies the file on the local system that will be transferred from the local system. The file pathing and name conventions must be that of the local host.

remoteFile

A string that specifies the file on the server that will contain the data being transferred. If the file already exists, it will be overwritten. The file name should be specified using an absolute path that begins with a leading slash character.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **PutFile** method is used to transfer a file from the local system to a remote server. Not all servers permit files to be uploaded using this method, and some may require that specific configuration changes be made to the server in order to support this functionality. Consult your server's technical reference documentation to see if it supports the PUT command, and if so, what must be done to enable it. It may be required that the client authenticate itself by setting the **UserName** and **Password** properties prior to uploading the file.
