[C#]

```
public int StoreIndex {get; set;}
```

Property Value

An integer value which specifies the current message index into the storage file.

Remarks

The **StoreIndex** property returns the current message index for the message store. Setting this property changes the current message index. When no storage file has been opened, this property will return a value of zero. After a storage file has been opened, it is changed to a value of one, the first message in the message store. The maximum value for this property is the number of messages in the store, as returned by the **StoreSize** property. Attempting to set this property to a value less than one or greater than the number of messages in the store will result in an exception being thrown.

This property value is updated whenever the **ReadStore** or **ReplaceStore** methods are used. When the **WriteStore** method is used to store the current message in the message store, this property will be updated to reflect the message index of the newly added message.

See Also

MailMessage Class | SocketTools Namespace | StoreCount Property | StoreSize Property

MailMessage.StoreSize Property

Gets the total number of messages in the current storage file, including deleted messages.

[Visual Basic]

```
Public ReadOnly Property StoreSize As Integer
```

[C#]

```
public int StoreSize {get;}
```

Property Value

An integer value which specifies the total number of messages in the storage file.

Remarks

The **StoreSize** property returns the total number of messages in the message store, including those messages that have been deleted. Because the **StoreCount** property value will decrease as messages are deleted, it is recommended that you use this property value when iterating through all of the messages in the message store.

See Also

MailMessage Class | SocketTools Namespace | StoreCount Property | StoreIndex Property

MailMessage.Subject Property

Gets and sets the subject of the current message.

[Visual Basic]

```
Public Property Subject As String
```

[C#]

```
public string Subject {get; set;}
```

Property Value

A string which specifies the subject of the message.

Remarks

The **Subject** property returns the subject of the current message. Setting this property updates the Subject header with the specified value. Note that not all messages have subjects, in which case this property will be set to an empty string.

See Also

MailMessage Class | SocketTools Namespace

MailMessage.Text Property

Gets and sets the text body of the current message part.

[Visual Basic]
```
Public Property Text As String
```

[C#]
```
public string Text {get; set;}
```

Property Value

A string which contains the body of the current message part.

Remarks

The **Text** property returns the body of the current message part. Setting this property replaces the body of the current message part with the new text.

See Also

MailMessage Class | SocketTools Namespace

MailMessage.ThrowError Property

Gets and sets a value which specifies if method calls should throw exceptions when an error occurs.

[Visual Basic]

```
Public Property ThrowError As Boolean
```

[C#]

```
public bool ThrowError {get; set;}
```

Property Value

Returns **true** if method calls will generate exceptions when an error occurs; otherwise returns **false**. The default value is **false**.

Remarks

Error handling for when calling class methods can be done in either of two different styles, according to the value of this property.

If the **ThrowError** property is set to **false**, the application should check the return value of any method that is used, and report errors based upon the documented value of the return code. It is the responsibility of the application to interpret the error code, if it is desired to explain the error in addition to reporting it. This is the default behavior.

If the **ThrowError** property is set to **true**, then exceptions will be generated whenever a method call fails. The program must be written to catch these exceptions and take the appropriate action when an error occurs. Failure to handle an exception will cause the program to terminate abnormally.

Note that if an error occurs while a property is being read or modified, an exception will be raised regardless of the value of the **ThrowError** property.

See Also

MailMessage Class | SocketTools Namespace

MailMessage.TimeZone Property

Gets and sets the current timezone offset in seconds.

[Visual Basic]

```
Public Property TimeZone As Integer
```

[C#]

```
public int TimeZone {get; set;}
```

Property Value

An integer value which specifies the current timezone offset.

Remarks

The **TimeZone** property returns the current offset from UTC in seconds. Setting the property changes the current timezone offset to the specified value. The value of this property is initially determined by the date and time settings on the local system.

The **TimeZone** property value is used in conjunction with the **Localize** property to control how message date and time localization is handled.

MailMessage Class | SocketTools Namespace

MailMessage.To Property

Gets and sets the address of the message recipient.

[Visual Basic]

```
Public Property To As String
```

[C#]

```
public string To {get; set;}
```

Property Value

A string which specifies the recipient of the message.

Remarks

The **To** property returns the address of the message recipient. Setting this property causes the To header to be updated with the specified value. Multiple addresses can be specified by separating them with commas.

MailMessage Class | SocketTools Namespace

MailMessage.Version Property

Gets a value which returns the current version of the MailMessage class library.

[Visual Basic]

```
Public ReadOnly Property Version As String
```

[C#]

```
public string Version {get;}
```

Property Value

A string which specifies the version of the class library.

Remarks

The **Version** property returns a string which identifies the current version and build of the MailMessage class library. This value can be used by an application for validation and debugging purposes.

MailMessage Class | SocketTools Namespace

MailMessage Methods

The methods of the **MailMessage** class are listed below. For a complete list of **MailMessage** class members, see the MailMessage Members topic.

Public Instance Methods

AppendMessage	Append text to the body of the current message part.
AttachData	Overloaded. Attach the contents of a byte array to the current message.
AttachFile	Overloaded. Attach the specified file to the current message.
AttachImage	Overloaded. Attach an inline image to the current message.
AttachThread	Obsolete. Attach an instance of the class to the current thread.
ClearMessage	Clear the header and body of the current message.
CloseStore	Close the current message storage file.
ComposeMessage	Overloaded. Compose a new mail message.
CreatePart	Overloaded. Create a new message part in a multipart message.
DecodeText	Overloaded. Decode a string which was previously encoded using base64 or quoted-printable encoding.
DeleteHeader	Overloaded. Delete a header field from the specified message part.
DeleteMessage	Overloaded. Remove the specified message from the current message store.
DeletePart	Delete the specified message part from the current message.
Dispose	Overloaded. Releases all resources used by MailMessage.
EncodeText	Overloaded. Encodes a string using base64 or quoted-printable encoding.
Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
ExportMessage	Overloaded. Export the current message to a file on the local system.
ExtractAllFiles	Overloaded. Extract all file attachments from the current message.
ExtractFile	Overloaded. Extract the contents of a file

	attachment and store it on the local system.
FindAttachment	Search for a specific file attachment in the current message.
FindMessage	Overloaded. Search for a message in the current message store.
GetFirstHeader	Return the first header in the current message part.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetHeader	Overloaded. Return the value of a header field in the specified message part.
GetNextHeader	Return the next header in the current message part.
GetType (inherited from Object)	Gets the Type of the current instance.
ImportMessage	Replace the current message with the contents of a file.
Initialize	Overloaded. Initialize an instance of the MailMessage class.
OpenStore	Overloaded. Open the specified message storage file.
ParseAddress	Overloaded. Parse an Internet email address.
ParseMessage	Parse the specified string, adding the contents to the current message.
PurgeStore	Purge all deleted messages from the current message store.
ReadStore	Overloaded. Retrieve a message from the message store, replacing the current message.
ReplaceMessage	Overloaded. Replace the specified message in the current message store.
Reset	Reset the internal state of the object, resetting all properties to their default values.
SetHeader	Overloaded. Set the value for a header in the specified message part.
ToString (inherited from Object)	Returns a String that represents the current Object.
Uninitialize	Uninitialize the class library and release any resources allocated for the current thread.
WriteStore	Store the current message in the message store.

Protected Instance Methods

Dispose	Overloaded. Releases the unmanaged resources allocated by the MailMessage class and optionally

	releases the managed resources.
Finalize	Destroys an instance of the class, releasing the resources allocated for the current message.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

MailMessage Class | SocketTools Namespace

MailMessage.AppendMessage Method

Append text to the body of the current message part.

[Visual Basic]

```
Public Function AppendMessage( _
   ByVal messageText As String _
) As Boolean
```

[C#]

```
public bool AppendMessage(
   string messageText
);
```

Parameters

messageText
A string which specifies the message text to be appended to the current message part.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

See Also

MailMessage Class | SocketTools Namespace

MailMessage.AttachData Method

Attach the contents of a byte array to the current message.

Overload List

Attach the contents of a byte array to the current message.

public bool AttachData(byte[],int);

Attach the contents of a byte array to the current message.

public bool AttachData(byte[],int,string);

Attach the contents of a byte array to the current message.

public bool AttachData(byte[],int,string,string);

Attach the contents of a byte array to the current message.

public bool AttachData(byte[],int,string,string,MimeAttachment);

Attach the contents of a string to the current message.

public bool AttachData(string);

Attach the contents of a string to the current message.

public bool AttachData(string,string);

Attach the contents of a string to the current message.

public bool AttachData(string,string,string);

Attach the contents of a string to the current message.

public bool AttachData(string,string,string,MimeAttachment);

See Also

MailMessage Class | SocketTools Namespace

MailMessage.AttachData Method (Byte[], Int32)

Attach the contents of a byte array to the current message.

[Visual Basic]

```
Overloads Public Function AttachData( _
   ByVal buffer As Byte(), _
   ByVal length As Integer _
) As Boolean
```

[C#]

```
public bool AttachData(
   byte[] buffer,
   int length
);
```

Parameters

buffer

A byte array that contains the data to be attached to the message.

length

An integer value which specifies the maximum number of bytes top copy from the buffer. This value cannot be larger than the size of the buffer specified by the caller.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The contents of the buffer will be attached to the message as inline content.

The buffer will be examined to determine what kind of data it contains. If there is only text characters, then the content type will be specified as text/plain. If the buffer contains binary data, then the content type will be specified as application/octet-stream, which is appropriate for any type of data.

See Also

MailMessage Class | SocketTools Namespace | MailMessage.AttachData Overload List

MailMessage.AttachData Method (Byte[], Int32, String)

Attach the contents of a byte array to the current message.

[Visual Basic]

```
Overloads Public Function AttachData( _
   ByVal buffer As Byte(), _
   ByVal length As Integer, _
   ByVal contentName As String _
) As Boolean
```

[C#]

```
public bool AttachData(
   byte[] buffer,
   int length,
   string contentName
);
```

Parameters

buffer

A byte array that contains the data to be attached to the message.

length

An integer value which specifies the maximum number of bytes top copy from the buffer. This value cannot be larger than the size of the buffer specified by the caller.

contentName

An string argument which specifies a name for the data being attached to the message. This typically is used as a file name by the mail client to store the data in. If this parameter is omitted or passed as an empty string then no name is defined and the data is attached as inline content. Note that if a file name is specified with a path, only the base file name will be used.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The buffer will be examined to determine what kind of data it contains. If there is only text characters, then the content type will be specified as text/plain. If the buffer contains binary data, then the content type will be specified as application/octet-stream, which is appropriate for any type of data.

See Also

MailMessage Class | SocketTools Namespace | MailMessage.AttachData Overload List

MailMessage.AttachData Method (Byte[], Int32, String, String)

Attach the contents of a byte array to the current message.

[Visual Basic]

```
Overloads Public Function AttachData( _
   ByVal buffer As Byte(), _
   ByVal length As Integer, _
   ByVal contentName As String, _
   ByVal contentType As String _
) As Boolean
```

[C#]

```
public bool AttachData(
   byte[] buffer,
   int length,
   string contentName,
   string contentType
);
```

Parameters

buffer

A byte array that contains the data to be attached to the message.

length

An integer value which specifies the maximum number of bytes top copy from the buffer. This value cannot be larger than the size of the buffer specified by the caller.

contentName

An string argument which specifies a name for the data being attached to the message. This typically is used as a file name by the mail client to store the data in. Note that if a file name is specified with a path, only the base file name will be used.

contentType

An string argument which specifies the type of data being attached. The value must be a valid MIME content type. If the buffer contains only text characters, then the content type will be specified as text/plain. If the buffer contains binary data, then the content type will be specified as application/octet-stream, which is appropriate for any type of data.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

See Also

MailMessage Class | SocketTools Namespace | MailMessage.AttachData Overload List

MailMessage.AttachData Method (Byte[], Int32, String, String, MimeAttachment)

Attach the contents of a byte array to the current message.

[Visual Basic]

```
Overloads Public Function AttachData( _
   ByVal buffer As Byte(), _
   ByVal length As Integer, _
   ByVal contentName As String, _
   ByVal contentType As String, _
   ByVal options As MimeAttachment _
) As Boolean
```

[C#]

```
public bool AttachData(
   byte[] buffer,
   int length,
   string contentName,
   string contentType,
   MimeAttachment options
);
```

Parameters

buffer

A byte array that contains the data to be attached to the message.

length

An integer value which specifies the maximum number of bytes top copy from the buffer. This value cannot be larger than the size of the buffer specified by the caller.

contentName

An string argument which specifies a name for the data being attached to the message. This typically is used as a file name by the mail client to store the data in. Note that if a file name is specified with a path, only the base file name will be used.

contentType

An string argument which specifies the type of data being attached. The value must be a valid MIME content type. If the buffer contains only text characters, then the content type will be specified as text/plain. If the buffer contains binary data, then the content type will be specified as application/octet-stream, which is appropriate for any type of data.

options

A MimeAttachment enumeration which specifies how the data should be attached to the message.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

See Also

MailMessage Class | SocketTools Namespace | MailMessage.AttachData Overload List

MailMessage.AttachData Method (String)

Attach the contents of a string to the current message.

[Visual Basic]

```
Overloads Public Function AttachData( _
   ByVal buffer As String _
) As Boolean
```

[C#]

```
public bool AttachData(
   string buffer
);
```

Parameters

buffer

A string that contains the data to be attached to the message.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The contents of the buffer will be attached to the message as inline content with a content type of text/plain.

This implementation of the method should never be used to attach binary data to a message. If you need to attach binary data, use the implementation of that accepts a byte array as the ***buffer*** parameter.

See Also

MailMessage Class | SocketTools Namespace | MailMessage.AttachData Overload List

MailMessage.AttachData Method (String, String)

Attach the contents of a string to the current message.

[Visual Basic]

```
Overloads Public Function AttachData( _
   ByVal buffer As String, _
   ByVal contentName As String _
) As Boolean
```

[C#]

```
public bool AttachData(
   string buffer,
   string contentName
);
```

Parameters

buffer
A string that contains the data to be attached to the message.

contentName
An string argument which specifies a name for the data being attached to the message. This typically is used as a file name by the mail client to store the data in. Note that if a file name is specified with a path, only the base file name will be used.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The content will be attached using the content type of text/plain.

This implementation of the method should never be used to attach binary data to a message. If you need to attach binary data, use the implementation of that accepts a byte array as the ***buffer*** parameter.

See Also

MailMessage Class | SocketTools Namespace | MailMessage.AttachData Overload List

MailMessage.AttachData Method (String, String, String)

Attach the contents of a string to the current message.

[Visual Basic]

```
Overloads Public Function AttachData( _
   ByVal buffer As String, _
   ByVal contentName As String, _
   ByVal contentType As String _
) As Boolean
```

[C#]

```
public bool AttachData(
   string buffer,
   string contentName,
   string contentType
);
```

Parameters

buffer
A string that contains the data to be attached to the message.

contentName
An string argument which specifies a name for the data being attached to the message. This typically is used as a file name by the mail client to store the data in.Note that if a file name is specified with a path, only the base file name will be used.

contentType
An string argument which specifies the type of data being attached. The value must be a valid MIME content type. If the buffer contains only text characters, then the content type will be specified as "text/plain". If the buffer contains binary data, then the content type will be specified as "application/octet-stream", which is appropriate for any type of data.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

This implementation of the method should never be used to attach binary data to a message. If you need to attach binary data, use the implementation of that accepts a byte array as the ***buffer*** parameter.

See Also

MailMessage Class | SocketTools Namespace | MailMessage.AttachData Overload List

MailMessage.AttachData Method (String, String, String, MimeAttachment)

Attach the contents of a string to the current message.

[Visual Basic]

```
Overloads Public Function AttachData( _
   ByVal buffer As String, _
   ByVal contentName As String, _
   ByVal contentType As String, _
   ByVal options As MimeAttachment _
) As Boolean
```

[C#]

```
public bool AttachData(
   string buffer,
   string contentName,
   string contentType,
   MimeAttachment options
);
```

Parameters

buffer
A string that contains the data to be attached to the message.

contentName
An string argument which specifies a name for the data being attached to the message. This typically is used as a file name by the mail client to store the data in.Note that if a file name is specified with a path, only the base file name will be used.

contentType
An string argument which specifies the type of data being attached. The value must be a valid MIME content type. If the buffer contains only text characters, then the content type will be specified as text/plain. If the buffer contains binary data, then the content type will be specified as application/octet-stream, which is appropriate for any type of data.

options
A MimeAttachment enumeration which specifies how the data should be attached to the message.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

This implementation of the method should never be used to attach binary data to a message. If you need to attach binary data, use the implementation of that accepts a byte array as the ***buffer*** parameter.

See Also

MailMessage Class | SocketTools Namespace | MailMessage.AttachData Overload List

MailMessage.AttachFile Method

Attach the specified file to the current message.

Overload List

Attach the specified file to the current message.

public bool AttachFile(string);

Attach the specified file to the current message.

public bool AttachFile(string,MimeAttachment);

See Also

MailMessage Class | SocketTools Namespace

MailMessage.AttachFile Method (String)

Attach the specified file to the current message.

```
[Visual Basic]
Overloads Public Function AttachFile( _
   ByVal fileName As String _
) As Boolean
```

```
[C#]
public bool AttachFile(
   string fileName
);
```

Parameters

fileName

A string which specifies the name of the file to be attached to the message.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **AttachFile** method attaches the specified file to the current message. If the message already contains one or more file attachments, then it is added to the end of the message. If the message does not contain any attached files, then it is converted to a multipart message and the file is appended to the message.

See Also

MailMessage Class | SocketTools Namespace | MailMessage.AttachFile Overload List

MailMessage.AttachFile Method (String, MimeAttachment)

Attach the specified file to the current message.

[Visual Basic]

```
Overloads Public Function AttachFile( _
   ByVal fileName As String, _
   ByVal options As MimeAttachment _
) As Boolean
```

[C#]

```
public bool AttachFile(
   string fileName,
   MimeAttachment options
);
```

Parameters

fileName

A string which specifies the name of the file to be attached to the message.

options

A MimeAttachment enumeration which specifies how the data should be attached to the message.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **AttachFile** method attaches the specified file to the current message. If the message already contains one or more file attachments, then it is added to the end of the message. If the message does not contain any attached files, then it is converted to a multipart message and the file is appended to the message.

See Also

MailMessage Class | SocketTools Namespace | MailMessage.AttachFile Overload List

MailMessage.AttachThread Method

NOTE: This method is now obsolete.

The AttachThread method has been deprecated

Attach an instance of the class to the current thread.

[Visual Basic]

```
<Obsolete(Message:="The AttachThread method has been deprecated", IsError:=False)>
Public Function AttachThread() As Boolean
```

[C#]

```
[Obsolete(Message="The AttachThread method has been deprecated", IsError=False)]
public bool AttachThread();
```

Return Value

A boolean value which specifies if the message could be attached to the current thread. If this method returns **false**, the message could not be attached to the thread and the application should check the value of the LastError property to determine the cause of the failure.

Remarks

This method has been deprecated and should no longer be used. The current version of the MailMessage class uses a free threading model which permits any thread to access methods and properties. However, applications must take care to synchronize access to the class instance across multiple threads if they are modifying the message contents.

See Also

MailMessage Class | SocketTools Namespace

MailMessage.ClearMessage Method

Clear the header and body of the current message.

[Visual Basic]

```
Public Function ClearMessage() As Boolean
```

[C#]

```
public bool ClearMessage();
```

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **ClearMessage** method clears the current message, releasing the memory allocated for the message and any attachments.

See Also

MailMessage Class | SocketTools Namespace

MailMessage.CloseStore Method

Close the current message storage file.

[Visual Basic]

```
Public Function CloseStore() As Boolean
```

[C#]

```
public bool CloseStore();
```

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **CloseStore** method closes the storage file that was previously opened, releasing all of the memory allocated for the message store and purging all deleted messages. This method must be called when the application has finished accessing the messages in the message store.

When the control instance is released by its container, the storage file will automatically be closed. To prevent deleted messages from being removed from the message store, use the **Reset** method.

See Also

MailMessage Class | SocketTools Namespace | OpenStore Method

MailMessage.ComposeMessage Method

Compose a new mail message.

Overload List

Compose a new mail message.

public bool ComposeMessage(string,string,string,string);

Compose a new mail message.

public bool ComposeMessage(string,string,string,string,string);

Compose a new mail message.

public bool ComposeMessage(string,string,string,string,string,string);

Compose a new mail message.

public bool ComposeMessage(string,string,string,string,string,string,string);

Compose a new mail message.

public bool ComposeMessage(string,string,string,string,string,string,string,MimeCharacterSet,MimeEncoding);

See Also

MailMessage Class | SocketTools Namespace

MailMessage.ComposeMessage Method (String, String, String, String)

Compose a new mail message.

[Visual Basic]

```
Overloads Public Function ComposeMessage( _
   ByVal messageFrom As String, _
   ByVal messageTo As String, _
   ByVal messageSubject As String, _
   ByVal messageText As String _
) As Boolean
```

[C#]

```
public bool ComposeMessage(
   string messageFrom,
   string messageTo,
   string messageSubject,
   string messageText
);
```

Parameters

messageFrom
A string argument which specifies the sender's email address. Only a single address should be specified. After the message has been composed, the **From** property will be updated with this value.

messageTo
A string argument which specifies one or more recipient email addresses. Multiple email addresses may be specified by separating them with commas. After the message has been composed, the **To** property will be updated with this value.

messageSubject
A string argument which specifies the subject for the message. If the argument is not specified, then no Subject header field will be created for this message. After the message has been composed, the **Subject** property will be updated with this value

messageText
An string argument which specifies the body of the message. Each line of text contained in the string should be terminated with a carriage-return/linefeed (CRLF) pair, which is recognized as the end-of-line.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **ComposeMessage** method creates a new mail message, or replaces the current message if one already exists.

See Also

MailMessage Class | SocketTools Namespace | MailMessage.ComposeMessage Overload List

MailMessage.ComposeMessage Method (String, String, String, String, String)

Compose a new mail message.

[Visual Basic]

```
Overloads Public Function ComposeMessage( _
   ByVal messageFrom As String, _
   ByVal messageTo As String, _
   ByVal messageCc As String, _
   ByVal messageSubject As String, _
   ByVal messageText As String _
) As Boolean
```

[C#]

```
public bool ComposeMessage(
   string messageFrom,
   string messageTo,
   string messageCc,
   string messageSubject,
   string messageText
);
```

Parameters

messageFrom
A string argument which specifies the sender's email address. Only a single address should be specified. After the message has been composed, the **From** property will be updated with this value.

messageTo
A string argument which specifies one or more recipient email addresses. Multiple email addresses may be specified by separating them with commas. After the message has been composed, the **To** property will be updated with this value.

messageCc
A string argument which specifies one or more additional recipient addresses that will receive a copy of the message. If this argument is not specified, then no Cc header field will be created for this message. After the message has been composed, the **Cc** property will be updated with this value.

messageSubject
A string argument which specifies the subject for the message. If the argument is not specified, then no Subject header field will be created for this message. After the message has been composed, the **Subject** property will be updated with this value

messageText
An string argument which specifies the body of the message. Each line of text contained in the string should be terminated with a carriage-return/linefeed (CRLF) pair, which is recognized as the end-of-line.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **ComposeMessage** method creates a new mail message, or replaces the current message if one already exists.

See Also

MailMessage Class | SocketTools Namespace | MailMessage.ComposeMessage Overload List

MailMessage.ComposeMessage Method (String, String, String, String, String, String)

Compose a new mail message.

[Visual Basic]

```
Overloads Public Function ComposeMessage( _
   ByVal messageFrom As String, _
   ByVal messageTo As String, _
   ByVal messageCc As String, _
   ByVal messageBcc As String, _
   ByVal messageSubject As String, _
   ByVal messageText As String _
) As Boolean
```

[C#]

```
public bool ComposeMessage(
   string messageFrom,
   string messageTo,
   string messageCc,
   string messageBcc,
   string messageSubject,
   string messageText
);
```

Parameters

messageFrom

A string argument which specifies the sender's email address. Only a single address should be specified. After the message has been composed, the **From** property will be updated with this value.

messageTo

A string argument which specifies one or more recipient email addresses. Multiple email addresses may be specified by separating them with commas. After the message has been composed, the **To** property will be updated with this value.

messageCc

A string argument which specifies one or more additional recipient addresses that will receive a copy of the message. If this argument is not specified, then no Cc header field will be created for this message. After the message has been composed, the **Cc** property will be updated with this value.

messageBcc

A string argument which specifies one or more additional recipient addresses that will receive a "blind" copy of the message. If this argument is not specified, then no Bcc header field will be created for this message. After the message has been composed, the **Bcc** property will be updated with this value. Note that the Bcc header field is not normally included in the header when the message is exported.

messageSubject

A string argument which specifies the subject for the message. If the argument is not specified, then no Subject header field will be created for this message. After the message has been composed, the **Subject** property will be updated with this value

messageText

An string argument which specifies the body of the message. Each line of text contained in the string should be terminated with a carriage-return/linefeed (CRLF) pair, which is recognized as the end-of-line.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **ComposeMessage** method creates a new mail message, or replaces the current message if one already exists.

See Also

MailMessage Class | SocketTools Namespace | MailMessage.ComposeMessage Overload List

MailMessage.ComposeMessage Method (String, String, String, String, String, String, String)

Compose a new mail message.

[Visual Basic]

```
Overloads Public Function ComposeMessage( _
   ByVal messageFrom As String, _
   ByVal messageTo As String, _
   ByVal messageCc As String, _
   ByVal messageBcc As String, _
   ByVal messageSubject As String, _
   ByVal messageText As String, _
   ByVal messageHTML As String _
) As Boolean
```

[C#]

```
public bool ComposeMessage(
   string messageFrom,
   string messageTo,
   string messageCc,
   string messageBcc,
   string messageSubject,
   string messageText,
   string messageHTML
);
```

Parameters

messageFrom

A string argument which specifies the sender's email address. Only a single address should be specified. After the message has been composed, the **From** property will be updated with this value.

messageTo

A string argument which specifies one or more recipient email addresses. Multiple email addresses may be specified by separating them with commas. After the message has been composed, the **To** property will be updated with this value.

messageCc

A string argument which specifies one or more additional recipient addresses that will receive a copy of the message. If this argument is not specified, then no Cc header field will be created for this message. After the message has been composed, the **Cc** property will be updated with this value.

messageBcc

A string argument which specifies one or more additional recipient addresses that will receive a "blind" copy of the message. If this argument is not specified, then no Bcc header field will be created for this message. After the message has been composed, the **Bcc** property will be updated with this value. Note that the Bcc header field is not normally included in the header when the message is exported.

messageSubject

A string argument which specifies the subject for the message. If the argument is not specified, then no Subject header field will be created for this message. After the message has been composed, the **Subject** property will be updated with this value

messageText

An string argument which specifies the body of the message. Each line of text contained in the string should be terminated with a carriage-return/linefeed (CRLF) pair, which is recognized as the end-of-line.

messageHTML

A string argument which specifies an alternate HTML formatted message. If the ***messageText*** argument has been specified, then a multipart message will be created with both plain text and HTML text as the alternative. This allows mail clients to select which message body they wish to display. If the ***messageText*** argument is an empty string, then the message will only contain HTML. Although this is supported, it is not recommended because older mail clients may be unable to display the message correctly.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **ComposeMessage** method creates a new mail message, or replaces the current message if one already exists.

MailMessage.ComposeMessage Method (String, String, String, String, String, String, String, MimeCharacterSet, MimeEncoding)

Compose a new mail message.

[Visual Basic]

```
Overloads Public Function ComposeMessage( _
   ByVal messageFrom As String, _
   ByVal messageTo As String, _
   ByVal messageCc As String, _
   ByVal messageBcc As String, _
   ByVal messageSubject As String, _
   ByVal messageText As String, _
   ByVal messageHTML As String, _
   ByVal characterSet As MimeCharacterSet, _
   ByVal encodingType As MimeEncoding _
) As Boolean
```

[C#]

```
public bool ComposeMessage(
   string messageFrom,
   string messageTo,
   string messageCc,
   string messageBcc,
   string messageSubject,
   string messageText,
   string messageHTML,
   MimeCharacterSet characterSet,
   MimeEncoding encodingType
);
```

Parameters

messageFrom

A string argument which specifies the sender's email address. Only a single address should be specified. After the message has been composed, the **From** property will be updated with this value.

messageTo

A string argument which specifies one or more recipient email addresses. Multiple email addresses may be specified by separating them with commas. After the message has been composed, the **To** property will be updated with this value.

messageCc

A string argument which specifies one or more additional recipient addresses that will receive a copy of the message. If this argument is not specified, then no Cc header field will be created for this message. After the message has been composed, the **Cc** property will be updated with this value.

messageBcc

A string argument which specifies one or more additional recipient addresses that will receive a "blind" copy of the message. If this argument is not specified, then no Bcc header field will be created for this message. After the message has been composed, the **Bcc** property will be updated with this value. Note that the Bcc header field is not normally included in the header when the message is exported.

messageSubject

A string argument which specifies the subject for the message. If the argument is not specified, then no Subject header field will be created for this message. After the message has been composed, the **Subject** property will be updated with this value *messageText*

An string argument which specifies the body of the message. Each line of text contained in the string should be terminated with a carriage-return/linefeed (CRLF) pair, which is recognized as the end-of-line.

messageHTML

A string argument which specifies an alternate HTML formatted message. If the ***messageText*** argument has been specified, then a multipart message will be created with both plain text and HTML text as the alternative. This allows mail clients to select which message body they wish to display. If the ***messageText*** argument is an empty string, then the message will only contain HTML. Although this is supported, it is not recommended because older mail clients may be unable to display the message correctly.

characterSet

A MimeCharacterSet enumeration value which specifies the character set to use when composing the message.

encodingType

A MimeEncoding enumeration value which specifies the encoding type to use when composing the message.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **ComposeMessage** method creates a new mail message, or replaces the current message if one already exists.

See Also

MailMessage Class | SocketTools Namespace | MailMessage.ComposeMessage Overload List

MailMessage.CreatePart Method

Create an empty message part in a multipart message.

Overload List

Create an empty message part in a multipart message.

public bool CreatePart();

Create a new message part in a multipart message.

public bool CreatePart(string);

Create a new message part in a multipart message.

public bool CreatePart(string,MimeCharacterSet,MimeEncoding);

See Also

MailMessage Class | SocketTools Namespace

MailMessage.CreatePart Method ()

Create an empty message part in a multipart message.

[Visual Basic]

```
Overloads Public Function CreatePart() As Boolean
```

[C#]

```
public bool CreatePart();
```

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **CreatePart** method creates a new empty message part. If the current message is a simple RFC822 formatted message, then this method converts it to a MIME multipart message. The current message part will be set to the new part that was just created.

See Also

MailMessage Class | SocketTools Namespace | MailMessage.CreatePart Overload List

MailMessage.CreatePart Method (String)

Create a new message part in a multipart message.

[Visual Basic]

```
Overloads Public Function CreatePart( _
   ByVal messageText As String _
) As Boolean
```

[C#]

```
public bool CreatePart(
   string messageText
);
```

Parameters

messageText

A string argument which specifies the body of the new message part. Each line of text contained in the string should be terminated with a carriage-return/linefeed (CRLF) pair, which is recognized as the end-of-line.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **CreatePart** method creates a new message part. If the current message is a simple RFC822 formatted message, then this method converts it to a MIME multipart message. The current message part will be set to the new part that was just created.

MailMessage.CreatePart Method (String, MimeCharacterSet, MimeEncoding)

Create a new message part in a multipart message.

[Visual Basic]

```
Overloads Public Function CreatePart( _
   ByVal messageText As String, _
   ByVal characterSet As MimeCharacterSet, _
   ByVal encodingType As MimeEncoding _
) As Boolean
```

[C#]

```
public bool CreatePart(
   string messageText,
   MimeCharacterSet characterSet,
   MimeEncoding encodingType
);
```

Parameters

messageText
A string argument which specifies the body of the new message part. Each line of text contained in the string should be terminated with a carriage-return/linefeed (CRLF) pair, which is recognized as the end-of-line.

characterSet
A MimeCharacterSet enumeration value which specifies the character set to use when composing the message.

encodingType
A MimeEncoding enumeration value which specifies the encoding type to use when composing the message.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **CreatePart** method creates a new message part. If the current message is a simple RFC822 formatted message, then this method converts it to a MIME multipart message. The current message part will be set to the new part that was just created.

MailMessage.DecodeText Method

Decode a string which was previously encoded using base64 or quoted-printable encoding.

Overload List

Decode a string which was previously encoded using base64 or quoted-printable encoding.

public int DecodeText(string,ref string);

Decode a string which was previously encoded using base64 or quoted-printable encoding.

public int DecodeText(string,ref string,MimeCharacterSet,MimeEncoding);

Decode a string which was previously encoded using base64 or quoted-printable encoding.

public int DecodeText(string,ref string,MimeEncoding);

See Also

MailMessage Class | SocketTools Namespace

MailMessage.DecodeText Method (String, String, MimeCharacterSet, MimeEncoding)

Decode a string which was previously encoded using base64 or quoted-printable encoding.

[Visual Basic]

```
Overloads Public Function DecodeText( _
   ByVal encodedText As String, _
   ByRef messageText As String, _
   ByVal charSet As MimeCharacterSet, _
   ByVal encoding As MimeEncoding _
) As Integer
```

[C#]

```
public int DecodeText(
   string encodedText,
   ref string messageText,
   MimeCharacterSet charSet,
   MimeEncoding encoding
);
```

Parameters

encodedText
A string which contains the encoded text which should be decoded.

messageText
A string variable passed by reference which will contain the decoded text when the method returns.

charSet
A MimeCharacterSet enumeration which specifies the character set to use when decoding the encoded text. If this value does not match the character set used when the text was originally encoded, the resulting output text may be invalid.

encoding
A MimeEncoding enumeration which specifies the content encoding type to use when decoding the text.

Return Value

The number of characters of decoded text. A return value of zero indicates no text has been decoded. If the method fails, it will return -1 and the LastError property can be used to determine the cause of the failure. In most cases where the method fails, it is because an invalid character set or encoding type has been specified.

Remarks

This method provides a means to decode text that was previously encoded using either base64 or quoted-printable encoding. In most cases, it is not necessary to use this method because the message parser will detect which character set and encoding was used, then automatically decode the message text if necessary.

The value of the ***charSet*** parameter does not affect the resulting output text, it is only used when decoding the input text. The previous contents of the ***messageText*** string will be replaced by the decoded text, and the output string will always be Unicode.

If the ***charSet*** parameter is specified as **charsetUTF16**, the encoding type must be **encodingBase64**. Other encoding methods are not supported for Unicode strings and will cause the method to fail. In most cases, it is preferable to always use **encodingBase64** as the encoding method, with quoted-printable encoding only used for legacy support. If an unsupported encoding type is specified, this method will return -1 and the output text string will be empty. This method cannot be used to decode uuencoded text.

See Also

MailMessage Class | SocketTools Namespace | MailMessage.DecodeText Overload List

MailMessage.DecodeText Method (String, String, MimeEncoding)

Decode a string which was previously encoded using base64 or quoted-printable encoding.

[Visual Basic]

```
Overloads Public Function DecodeText( _
   ByVal encodedText As String, _
   ByRef messageText As String, _
   ByVal encoding As MimeEncoding _
) As Integer
```

[C#]

```
public int DecodeText(
   string encodedText,
   ref string messageText,
   MimeEncoding encoding
);
```

Parameters

encodedText
A string which contains the encoded text which should be decoded.

messageText
A string variable passed by reference which will contain the decoded text when the method returns.

encoding
A MimeEncoding enumeration which specifies the content encoding type to use when decoding the text.

Return Value

The number of characters of decoded text. A return value of zero indicates no text has been decoded. If the method fails, it will return -1 and the LastError property can be used to determine the cause of the failure. In most cases where the method fails, it is because an invalid character set or encoding type has been specified.

Remarks

This method provides a means to decode text that was previously encoded using either base64 or quoted-printable encoding. In most cases, it is not necessary to use this method because the message parser will detect which character set and encoding was used, then automatically decode the message text if necessary.

The value of the ***charSet*** parameter does not affect the resulting output text, it is only used when decoding the input text. The previous contents of the ***messageText*** string will be replaced by the decoded text, and the output string will always be Unicode.

In most cases, it is preferable to always use **encodingBase64** as the encoding method, with quoted-printable encoding only used for legacy support. If an unsupported encoding type is specified, this method will return -1 and the output text string will be empty.

This version of the method will default to decoding the text as UTF-8. If the original text used something other than UTF-8, call the overloaded version of this method to specify the character set.

This method cannot be used to deocde uuencoded text.

See Also

MailMessage Class | SocketTools Namespace | MailMessage.DecodeText Overload List

MailMessage.DecodeText Method (String, String)

Decode a string which was previously encoded using base64 or quoted-printable encoding.

[Visual Basic]

```
Overloads Public Function DecodeText( _
   ByVal encodedText As String, _
   ByRef messageText As String _
) As Integer
```

[C#]

```
public int DecodeText(
   string encodedText,
   ref string messageText
);
```

Parameters

encodedText
A string which contains the encoded text which should be decoded.

messageText
A string variable passed by reference which will contain the decoded text when the method returns.

Return Value

The number of characters of decoded text. A return value of zero indicates no text has been decoded. If the method fails, it will return -1 and the LastError property can be used to determine the cause of the failure. In most cases where the method fails, it is because an invalid character set or encoding type has been specified.

Remarks

This method provides a means to decode text that was previously encoded using base64 encoding. In most cases, it is not necessary to use this method because the message parser will detect which character set and encoding was used, then automatically decode the message text if necessary.

This version of the method will default to using base64 encoding and will decode the text as UTF-8. If the original text used something other than UTF-8, call the overloaded version of this method to specify the character set.

This method cannot be used to deocde uuencoded text.

MailMessage Class | SocketTools Namespace | MailMessage.DecodeText Overload List

MailMessage.DeleteHeader Method

Delete a header field from the specified message part.

Overload List

Delete a header field from the specified message part.

public bool DeleteHeader(int,string);

Delete a header field from the current message part.

public bool DeleteHeader(string);

See Also

MailMessage Class | SocketTools Namespace

MailMessage.DeleteHeader Method (Int32, String)

Delete a header field from the specified message part.

[Visual Basic]

```
Overloads Public Function DeleteHeader( _
   ByVal messagePart As Integer, _
   ByVal headerName As String _
) As Boolean
```

[C#]

```
public bool DeleteHeader(
   int messagePart,
   string headerName
);
```

Parameters

messagePart
An integer which specifies the message part.

headerName
A string which specifies the header field to delete from the specified message part.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

A message part of zero specifies the main message part which contains the standard headers such as To, From and Subject. The number of message parts in the current message is returned by the **PartCount** property.

See Also

MailMessage Class | SocketTools Namespace | MailMessage.DeleteHeader Overload List

MailMessage.DeleteHeader Method (String)

Delete a header field from the current message part.

[Visual Basic]

```
Overloads Public Function DeleteHeader( _
   ByVal headerName As String _
) As Boolean
```

[C#]

```
public bool DeleteHeader(
   string headerName
);
```

Parameters

headerName

A string which specifies the header field to delete from the current message part.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The current message part is returned by the **Part** property.

See Also

MailMessage Class | SocketTools Namespace | MailMessage.DeleteHeader Overload List

MailMessage.DeleteMessage Method

Remove the current message from the current message store.

Overload List

Remove the current message from the current message store.

public bool DeleteMessage();

Remove the specified message from the current message store.

public bool DeleteMessage(int);

See Also

MailMessage Class | SocketTools Namespace

MailMessage.DeleteMessage Method (Int32)

Remove the specified message from the current message store.

[Visual Basic]

```
Overloads Public Function DeleteMessage( _
   ByVal messageIndex As Integer _
) As Boolean
```

[C#]

```
public bool DeleteMessage(
   int messageIndex
);
```

Parameters

messageIndex

An integer value which specifies the message that will be removed from the message store.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **DeleteMessage** method marks the specified message for deletion from the storage file. When the message store is closed or purged, the message is removed from the file.

Once a message has been marked for deletion, it may no longer be referenced by the application. For example, you cannot access the contents of a message that has been deleted.

The message store must be opened with write access. This method will fail if you attempt to delete a message from a storage file that has been opened for read-only access. If the application needs to delete messages in the message store, it is recommended that the file be opened for exclusive access using the **storeLock** option when calling the **OpenStore** method.

See Also

MailMessage Class | SocketTools Namespace | MailMessage.DeleteMessage Overload List

MailMessage.DeleteMessage Method ()

Remove the current message from the current message store.

[Visual Basic]

```
Overloads Public Function DeleteMessage() As Boolean
```

[C#]

```
public bool DeleteMessage();
```

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **DeleteMessage** method marks the current message for deletion from the storage file. When the message store is closed or purged, the message is removed from the file. The value of the **StoreIndex** property specifies the current message.

Once a message has been marked for deletion, it may no longer be referenced by the application. For example, you cannot access the contents of a message that has been deleted.

The message store must be opened with write access. This method will fail if you attempt to delete a message from a storage file that has been opened for read-only access. If the application needs to delete messages in the message store, it is recommended that the file be opened for exclusive access using the **storeLock** option when calling the **OpenStore** method.

See Also

MailMessage Class | SocketTools Namespace | MailMessage.DeleteMessage Overload List

MailMessage.DeletePart Method

Delete the specified message part from the current message.

[Visual Basic]

```
Public Function DeletePart( _
   ByVal messagePart As Integer _
) As Boolean
```

[C#]

```
public bool DeletePart(
   int messagePart
);
```

Parameters

messagePart

An integer which specifies the message part.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

This method cannot be used to delete part zero, which is the main body of the message. Instead use the **ClearMessage** method to clear the contents of the entire message.

The number of message parts in the current message is returned by the **PartCount** property.

MailMessage Class | SocketTools Namespace

MailMessage.Dispose Method

Releases all resources used by MailMessage.

Overload List

Releases all resources used by MailMessage.

public void Dispose();

Releases the unmanaged resources allocated by the MailMessage class and optionally releases the managed resources.

protected virtual void Dispose(bool);

See Also

MailMessage Class | SocketTools Namespace

MailMessage.Dispose Method ()

Releases all resources used by MailMessage.

[Visual Basic]
```
NotOverridable Overloads Public Sub Dispose() _
    Implements IDisposable.Dispose
```

[C#]
```
public void Dispose();
```

Implements

IDisposable.Dispose

Remarks

The **Dispose** method explicitly releases the resources allocated for this instance of the class. In some cases, better performance can be achieved if the programmer explicitly releases resources when they are no longer being used. The **Dispose** method provides explicit control over these resources.

Unlike the **Uninitialize** method, once the **Dispose** method has been called, that instance of the class cannot be re-initialized and you should not attempt to access class properties or invoke any methods. Note that this method can be called even if other references to the object are active.

See Also

MailMessage Class | SocketTools Namespace | MailMessage.Dispose Overload List

MailMessage.Dispose Method (Boolean)

Releases the unmanaged resources allocated by the MailMessage class and optionally releases the managed resources.

[Visual Basic]

```
Overridable Overloads Protected Sub Dispose( _
   ByVal disposing As Boolean _
)
```

[C#]

```
protected virtual void Dispose(
   bool disposing
);
```

Parameters

disposing

A boolean value which should be specified as **true** to release both managed and unmanaged resources; **false** to release only unmanaged resources.

Remarks

The **Dispose** method explicitly releases the resources allocated for this instance of the class. In some cases, better performance can be achieved if the programmer explicitly releases resources when they are no longer being used. The **Dispose** method provides explicit control over these resources.

Unlike the **Uninitialize** method, once the **Dispose** method has been called, that instance of the class cannot be re-initialized and you should not attempt to access class properties or invoke any methods. Note that this method can be called even if other references to the object are active.

You should call **Dispose** in your derived class when you are finished using the derived class. The **Dispose** method leaves the derived class in an unusable state. After calling **Dispose**, you must release all references to the derived class and the **MailMessage** class so the memory they were occupying can be reclaimed by garbage collection.

MailMessage.EncodeText Method

Encodes a string using base64 or quoted-printable encoding.

Overload List

Encodes a string using base64 or quoted-printable encoding.

public int EncodeText(string,ref string);

Encodes a string using base64 or quoted-printable encoding.

public int EncodeText(string,ref string,MimeCharacterSet,MimeEncoding);

Encodes a string using base64 or quoted-printable encoding.

public int EncodeText(string,ref string,MimeEncoding);

See Also

MailMessage Class | SocketTools Namespace

MailMessage.EncodeText Method (String, String, MimeCharacterSet, MimeEncoding)

Encodes a string using base64 or quoted-printable encoding.

```
[Visual Basic]
Overloads Public Function EncodeText( _
   ByVal messageText As String, _
   ByRef encodedText As String, _
   ByVal charSet As MimeCharacterSet, _
   ByVal encoding As MimeEncoding _
) As Integer
```

```
[C#]
public int EncodeText(
   string messageText,
   ref string encodedText,
   MimeCharacterSet charSet,
   MimeEncoding encoding
);
```

Parameters

messageText
A string that contains the text which should be encoded.

encodedText
A string variable passed by reference which will contain the encoded text when the method returns.

charSet
A MimeCharacterSet enumeration which specifies the character set to use when encoding the message text. It is recommended that you use UTF-8 whenever possible.

encoding
A MimeEncoding enumeration which specifies the content encoding type to use when encoding the text.

Return Value

The number of characters of encoded text. A return value of zero indicates no text has been encoded. If the method fails, it will return -1 and the LastError property can be used to determine the cause of the failure. In most cases where the method fails, it is because an invalid character set or encoding type has been specified.

Remarks

This method provides a means to encode text using either base64 or quoted-printable encoding. It is not necessary to use this method to encode text when assigning a value to Text property. The class will automatically encode message text which contains non-ASCII characters using the character set specified when the message is created.

If the ***charSet*** parameter is specified, the method will convert the message text using the ANSI code page associated with the character set, and then the text will be encoded.

If the ***charsetUTF16*** character set is specified, you must also specify ***encodingBase64*** as the encoding method. Other encoding methods are not supported and this will cause the method to fail. It is not recommended you encode text as UTF-16 unless there is a specific requirement to use that character set.

It is recommended that you use the ***charsetUTF8*** character set whenever possible. It is capable of encoding all Unicode code points, and is a standard for virtually all modern Internet applications. In most cases, it is preferable to use ***encodingBase64*** as the encoding method, with quoted-printable encoding only used for legacy support.

MailMessage.EncodeText Method (String, String, MimeEncoding)

Encodes a string using base64 or quoted-printable encoding.

[Visual Basic]

```
Overloads Public Function EncodeText( _
   ByVal messageText As String, _
   ByRef encodedText As String, _
   ByVal encoding As MimeEncoding _
) As Integer
```

[C#]

```
public int EncodeText(
   string messageText,
   ref string encodedText,
   MimeEncoding encoding
);
```

Parameters

messageText
A string that contains the text which will be encoded.

encodedText
A string variable passed by reference which will contain the encoded text when the method returns.

encoding
A MimeEncoding enumeration which specifies the content encoding type to use when decoding the text.

Return Value

The number of characters of encoded text. A return value of zero indicates no text has been encoded. If the method fails, it will return -1 and the LastError property can be used to determine the cause of the failure. In most cases where the method fails, it is because an invalid character set or encoding type has been specified.

Remarks

This method provides a means to encode text using either base64 or quoted-printable encoding. It is not necessary to use this method to encode text when assigning a value to the **Text** property. The class will automatically encode message text which contains non-ASCII characters using the character set specified when the message is created.

In most cases, it is preferable to use ***encodingBase64*** as the encoding method, with quoted-printable encoding only used for legacy support.

This version of the method will convert the message text to UTF-8 prior to encoding the text.

See Also

MailMessage Class | SocketTools Namespace | MailMessage.EncodeText Overload List

MailMessage.EncodeText Method (String, String)

Encodes a string using base64 or quoted-printable encoding.

[Visual Basic]

```
Overloads Public Function EncodeText( _
   ByVal messageText As String, _
   ByRef encodedText As String _
) As Integer
```

[C#]

```
public int EncodeText(
   string messageText,
   ref string encodedText
);
```

Parameters

messageText
A string that contains the text which will be encoded.

encodedText
A string variable passed by reference which will contain the encoded text when the method returns.

Return Value

The number of characters of encoded text. A return value of zero indicates no text has been encoded. If the method fails, it will return -1 and the LastError property can be used to determine the cause of the failure. In most cases where the method fails, it is because an invalid character set or encoding type has been specified.

Remarks

This method provides a means to encode text using base64. It is not necessary to use this method to encode text when assigning a value to the **Text** property. The class will automatically encode message text which contains non-ASCII characters using the character set specified when the message is created.

This version of the method will convert the message text to UTF-8 and then encode it using the base64 algorithm.

MailMessage.ExportMessage Method

Export the current message to a file on the local system.

Overload List

Export the current message to a file on the local system.

public bool ExportMessage(string);

Export the current message to a file on the local system.

public bool ExportMessage(string,MimeExportOptions);

See Also

MailMessage Class | SocketTools Namespace

MailMessage.ExportMessage Method (String)

Export the current message to a file on the local system.

[Visual Basic]

```
Overloads Public Function ExportMessage( _
   ByVal fileName As String _
) As Boolean
```

[C#]

```
public bool ExportMessage(
   string fileName
);
```

Parameters

fileName

A string which specifies the name of the file that will contain the message. If the file does not exist, it will be created. If it does exist, it will be overwritten with the contents of the message.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **ExportMessage** method writes the current message to a file. If the file does not exist, it will be created. If it does exist, it will be overwritten with the contents of the message.

The value of the **Options** property determines the default export options, if any have been specified.

See Also

MailMessage Class | SocketTools Namespace | MailMessage.ExportMessage Overload List

MailMessage.ExportMessage Method (String, MimeExportOptions)

Export the current message to a file on the local system.

[Visual Basic]

```
Overloads Public Function ExportMessage( _
   ByVal fileName As String, _
   ByVal options As MimeExportOptions _
) As Boolean
```

[C#]

```
public bool ExportMessage(
   string fileName,
   MimeExportOptions options
);
```

Parameters

fileName

A string which specifies the name of the file that will contain the message. If the file does not exist, it will be created. If it does exist, it will be overwritten with the contents of the message.

options

A MimeExportOptions enumeration value which specifies one or more export options.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **ExportMessage** method writes the current message to a file. If the file does not exist, it will be created. If it does exist, it will be overwritten with the contents of the message.

See Also

MailMessage Class | SocketTools Namespace | MailMessage.ExportMessage Overload List

MailMessage.ExtractAllFiles Method

Extract all file attachments from the current message.

Overload List

Extract all file attachments from the current message.

public int ExtractAllFiles();

Extract all file attachments from the current message.

public int ExtractAllFiles(string);

See Also

MailMessage Class | SocketTools Namespace

MailMessage.ExtractAllFiles Method ()

Extract all file attachments from the current message.

[Visual Basic]
```
Overloads Public Function ExtractAllFiles() As Integer
```

[C#]
```
public int ExtractAllFiles();
```

Return Value

This method returns an integer value. If the method succeeds, the return value is the number of attachments that were extracted from the message. A return value of zero indicates that the message did not contain any file attachments. If the method faile, the return value is -1. To get extended error information, check the value of the **LastError** property.

Remarks

This method will extract all of the files that are attached to the current message and store them in the current directory on the local system. If a file with the same name as the attachment already exists, it will be overwritten with the contents of the attachment. If the file attachment was encoded using base64 or uuencode, this method will automatically decode the contents of the attachment.

To store a file attachment on the local system using a name that is different than the file name of the attachment, use the **ExtractFile** method.

See Also

MailMessage Class | SocketTools Namespace | MailMessage.ExtractAllFiles Overload List

MailMessage.ExtractAllFiles Method (String)

Extract all file attachments from the current message.

[Visual Basic]

```
Overloads Public Function ExtractAllFiles( _
   ByVal pathName As String _
) As Integer
```

[C#]

```
public int ExtractAllFiles(
   string pathName
);
```

Parameters

pathName

A string that specifies the name of the directory where the file attachments should be stored. If this parameter is omitted or points to an empty string, the attached files will be stored in the current working directory on the local system.

Return Value

This method returns an integer value. If the method succeeds, the return value is the number of attachments that were extracted from the message. A return value of zero indicates that the message did not contain any file attachments. If the method faile, the return value is -1. To get extended error information, check the value of the **LastError** property.

Remarks

This method will extract all of the files that are attached to the current message and store them in the specified directory. The directory must exist and the current user must have the appropriate permissions to create files there. If a file with the same name as the attachment already exists, it will be overwritten with the contents of the attachment. If the file attachment was encoded using base64 or uuencode, this method will automatically decode the contents of the attachment.

To store a file attachment on the local system using a name that is different than the file name of the attachment, use the **ExtractFile** method.

MailMessage.ExtractFile Method

Extract the contents of a file attachment and store it on the local system.

Overload List

Extract the contents of a file attachment and store it on the local system.

public bool ExtractFile(int,string);

Extract the contents of a file attachment and store it on the local system.

public bool ExtractFile(string);

Extract the contents of a file attachment and store it on the local system.

public bool ExtractFile(string,string);

See Also

MailMessage Class | SocketTools Namespace

MailMessage.ExtractFile Method (Int32, String)

Extract the contents of a file attachment and store it on the local system.

[Visual Basic]

```
Overloads Public Function ExtractFile( _
   ByVal messagePart As Integer, _
   ByVal fileName As String _
) As Boolean
```

[C#]

```
public bool ExtractFile(
   int messagePart,
   string fileName
);
```

Parameters

messagePart

An integer which specifies the message part.

fileName

A string which specifies the name of the file that will contain the file attachment. If the file does not exist, it will be created. If it does exist, it will be overwritten with the contents of the attachment.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **ExtractFile** method writes the contents of a message part, typically a file attachment, to a file on the local system. This method will automatically decode any binary file attachments.

See Also

MailMessage Class | SocketTools Namespace | MailMessage.ExtractFile Overload List

MailMessage.ExtractFile Method (String, String)

Extract the contents of a file attachment and store it on the local system.

[Visual Basic]

```
Overloads Public Function ExtractFile( _
   ByVal attachName As String, _
   ByVal fileName As String _
) As Boolean
```

[C#]

```
public bool ExtractFile(
   string attachName,
   string fileName
);
```

Parameters

attachName

A string that specifies the name of the file attachment in the current message. This parameter should only specify a base file name; it should not include a file path and cannot be an empty string

fileName

A string which specifies the name of the file on the local system that will contain the file attachment. If the file does not exist, it will be created. If it does exist, it will be overwritten with the contents of the attachment.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

This version of the **ExtractFile** method will search the current message for a file attachment that matches the name specified by the ***attachName*** parameter. If an attachment with that name is found, its contents will be stored in the local file specified by the ***fileName*** parameter. If the message does not contain an attachment that matches the name provided, this method will fail.

To search for a file attachment by name, use the **FindAttachment** method.

See Also

MailMessage Class | SocketTools Namespace | MailMessage.ExtractFile Overload List

MailMessage.Finalize Method

Destroys an instance of the class, releasing the resources allocated for the current message.

[Visual Basic]

```
Overrides Protected Sub Finalize()
```

[C#]

```
protected override void Finalize();
```

MailMessage Class | SocketTools Namespace

MailMessage.FindAttachment Method

Search for a specific file attachment in the current message.

[Visual Basic]

```
Public Function FindAttachment( _
   ByVal fileName As String _
) As Integer
```

[C#]

```
public int FindAttachment(
   string fileName
);
```

Parameters

fileName

A string value that specifies the name of the file attachment to search for. This parameter should only specify a base file name; it should not include a file path and cannot be an empty string.

Return Value

An integer value which specifies the message part number that contains the file attachment with a matching name. If the message does not contain a file attachment with the specified name, this method will return -1.

Remarks

The **FindAttachment** method will search the current message for a attachment that matches the specified file name. The search is not case-sensitive, however it must match the attachment file name completely. This method will not match partial file names or names that include wildcard characters.

MailMessage Class | SocketTools Namespace

MailMessage.FindMessage Method

Search for a message in the current message store.

Overload List

Search for a message in the current message store.

public int FindMessage(int,string,string);

Search for a message in the current message store.

public int FindMessage(int,string,string,MimeSearch);

Search for a message in the current message store.

public int FindMessage(string,string);

Search for a message in the current message store.

public int FindMessage(string,string,MimeSearch);

See Also

MailMessage Class | SocketTools Namespace

MailMessage.FindMessage Method (Int32, String, String, MimeSearch)

Search for a message in the current message store.

[Visual Basic]

```
Overloads Public Function FindMessage( _
   ByVal messageIndex As Integer, _
   ByVal headerField As String, _
   ByVal headerValue As String, _
   ByVal searchOptions As MimeSearch _
) As Integer
```

[C#]

```
public int FindMessage(
   int messageIndex,
   string headerField,
   string headerValue,
   MimeSearch searchOptions
);
```

Parameters

messageIndex
An integer value which specifies the message number that should be used when starting the search.

headerField
A string which specifies the name of the header field that should be searched. The header field name is not case sensitive.

headerValue
A string which specifies the header value that should be searched for. The search options can be used to specify if the search is case-sensitive, and whether the search should return partial matches to the string.

searchOptions
A MimeSearch enumeration which specifies the options to be used when searching for a message.

Return Value

An integer value which specifies the message index for the message that matched the search criteria. If no matching message was found, this method will return zero.

Remarks

The **FindMessage** method is used to search the message store for a message which matches a specific header field value. For example, it can be used to find every message which is addressed to a specific recipient or has a subject which matches a particular string value.

When searching for specific email addresses, it is recommended that you use the **searchPartialMatch** option because of the different ways that addresses can be annotated.

See Also

MailMessage Class | SocketTools Namespace | MailMessage.FindMessage Overload List

MailMessage.FindMessage Method (Int32, String, String)

Search for a message in the current message store.

[Visual Basic]

```
Overloads Public Function FindMessage( _
   ByVal messageIndex As Integer, _
   ByVal headerField As String, _
   ByVal headerValue As String _
) As Integer
```

[C#]

```
public int FindMessage(
   int messageIndex,
   string headerField,
   string headerValue
);
```

Parameters

messageIndex
An integer value which specifies the message number that should be used when starting the search.

headerField
A string which specifies the name of the header field that should be searched. The header field name is not case sensitive.

headerValue
A string which specifies the header value that should be searched for. The search options can be used to specify if the search is case-sensitive, and whether the search should return partial matches to the string.

Return Value

An integer value which specifies the message index for the message that matched the search criteria. If no matching message was found, this method will return zero.

Remarks

The **FindMessage** method is used to search the message store for a message which matches a specific header field value. For example, it can be used to find every message which is addressed to a specific recipient or has a subject which matches a particular string value.

This implementation searches for a complete match to the specified header value, and the comparison is not case-sensitive.

See Also

MailMessage Class | SocketTools Namespace | MailMessage.FindMessage Overload List

MailMessage.FindMessage Method (String, String, MimeSearch)

Search for a message in the current message store.

[Visual Basic]

```
Overloads Public Function FindMessage( _
   ByVal headerField As String, _
   ByVal headerValue As String, _
   ByVal searchOptions As MimeSearch _
) As Integer
```

[C#]

```
public int FindMessage(
   string headerField,
   string headerValue,
   MimeSearch searchOptions
);
```

Parameters

headerField

A string which specifies the name of the header field that should be searched. The header field name is not case sensitive.

headerValue

A string which specifies the header value that should be searched for. The search options can be used to specify if the search is case-sensitive, and whether the search should return partial matches to the string.

searchOptions

A MimeSearch enumeration which specifies the options to be used when searching for a message.

Return Value

An integer value which specifies the message index for the message that matched the search criteria. If no matching message was found, this method will return zero.

Remarks

The **FindMessage** method is used to search the message store for a message which matches a specific header field value. For example, it can be used to find every message which is addressed to a specific recipient or has a subject which matches a particular string value.

When searching for specific email addresses, it is recommended that you use the **searchPartialMatch** option because of the different ways that addresses can be annotated.

This implementation of the method always begins the search with the first message in the message store. To iterate through multiple matches to a header value, you must specify a message index.

See Also

MailMessage Class | SocketTools Namespace | MailMessage.FindMessage Overload List

MailMessage.FindMessage Method (String, String)

Search for a message in the current message store.

[Visual Basic]

```
Overloads Public Function FindMessage( _
   ByVal headerField As String, _
   ByVal headerValue As String _
) As Integer
```

[C#]

```
public int FindMessage(
   string headerField,
   string headerValue
);
```

Parameters

headerField
: A string which specifies the name of the header field that should be searched. The header field name is not case sensitive.

headerValue
: A string which specifies the header value that should be searched for. The search options can be used to specify if the search is case-sensitive, and whether the search should return partial matches to the string.

Return Value

An integer value which specifies the message index for the message that matched the search criteria. If no matching message was found, this method will return zero.

Remarks

The **FindMessage** method is used to search the message store for a message which matches a specific header field value. For example, it can be used to find every message which is addressed to a specific recipient or has a subject which matches a particular string value.

This implementation searches for a complete match to the specified header value, and the comparison is not case-sensitive. The search always begins with the first message in the message store. To iterate through multiple matches to a header value, you must specify a message index.

See Also

MailMessage Class | SocketTools Namespace | MailMessage.FindMessage Overload List

MailMessage.GetFirstHeader Method

Return the first header in the current message part.

[Visual Basic]

```
Public Function GetFirstHeader( _
   ByRef headerName As String, _
   ByRef headerValue As String _
) As Boolean
```

[C#]

```
public bool GetFirstHeader(
   ref string headerName,
   ref string headerValue
);
```

Parameters

headerName

A string passed by reference which will contain the name of the first header field when the method returns.

headerValue

A string passed by reference which will contain the value of the first header field when the method returns.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetFirstHeader** method allows an application to enumerate all of the headers in the current message part. If the current message part does not contain any header fields, this method will return **false**.

The current message part is returned by the **Part** property.

See Also

MailMessage Class | SocketTools Namespace

MailMessage.GetHeader Method

Return the value of a header field in the specified message part.

Overload List

Return the value of a header field in the specified message part.

public bool GetHeader(int,string,ref string);

Return the value of a header field in the current message part.

public bool GetHeader(string,ref string);

See Also

MailMessage Class | SocketTools Namespace

MailMessage.GetHeader Method (Int32, String, String)

Return the value of a header field in the specified message part.

[Visual Basic]

```
Overloads Public Function GetHeader( _
   ByVal messagePart As Integer, _
   ByVal headerName As String, _
   ByRef headerValue As String _
) As Boolean
```

[C#]

```
public bool GetHeader(
   int messagePart,
   string headerName,
   ref string headerValue
);
```

Parameters

messagePart
An integer which specifies the message part.

headerName
A string which specifies the name of the header field.

headerValue
A string passed by reference which will contain the value of the header field when the method returns.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetHeader** method is used to retrieve the value for a specific header in the specified message part. If the header field exists, the method will return **true** and the ***headerValue*** argument will contain the header value. If the header does not exist, the method will return **false**.

If there are multiple headers with the same name, the first value will be returned. To enumerate all of the headers in a message, including duplicate header fields, use the **GetFirstHeader** and **GetNextHeader** methods.

See Also

MailMessage Class | SocketTools Namespace | MailMessage.GetHeader Overload List

MailMessage.GetHeader Method (String, String)

Return the value of a header field in the current message part.

[Visual Basic]

```
Overloads Public Function GetHeader( _
   ByVal headerName As String, _
   ByRef headerValue As String _
) As Boolean
```

[C#]

```
public bool GetHeader(
   string headerName,
   ref string headerValue
);
```

Parameters

headerName
A string which specifies the name of the header field.

headerValue
A string passed by reference which will contain the value of the header field when the method returns.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetHeader** method is used to retrieve the value for a specific header in the current message part. If the header field exists, the method will return **true** and the ***headerValue*** argument will contain the header value. If the header does not exist, the method will return **false**.

If there are multiple headers with the same name, the first value will be returned. To enumerate all of the headers in a message, including duplicate header fields, use the **GetFirstHeader** and **GetNextHeader** methods.

The current message part is returned by the **Part** property.

See Also

MailMessage Class | SocketTools Namespace | MailMessage.GetHeader Overload List

MailMessage.GetNextHeader Method

Return the next header in the current message part.

[Visual Basic]

```
Public Function GetNextHeader( _
   ByRef headerName As String, _
   ByRef headerValue As String _
) As Boolean
```

[C#]

```
public bool GetNextHeader(
   ref string headerName,
   ref string headerValue
);
```

Parameters

headerName
A string passed by reference which will contain the name of the first header field when the method returns.

headerValue
A string passed by reference which will contain the value of the first header field when the method returns.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetNextHeader** method allows an application to enumerate all of the headers in the current message part. If the current message part does not contain any header fields, this method will return **false**.

The current message part is returned by the **Part** property.

See Also

MailMessage Class | SocketTools Namespace

MailMessage.ImportMessage Method

Replace the current message with the contents of a file.

[Visual Basic]

```
Public Function ImportMessage( _
   ByVal fileName As String _
) As Boolean
```

[C#]

```
public bool ImportMessage(
   string fileName
);
```

Parameters

fileName

A string which specifies the name of the text file to import.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

MailMessage Class | SocketTools Namespace

MailMessage.Initialize Method

Initialize an instance of the MailMessage class.

Overload List

Initialize an instance of the MailMessage class.

public bool Initialize();

Initialize an instance of the MailMessage class.

public bool Initialize(string);

See Also

MailMessage Class | SocketTools Namespace | Uninitialize Method

MailMessage.Initialize Method ()

Initialize an instance of the MailMessage class.

[Visual Basic]
```
Overloads Public Function Initialize() As Boolean
```

[C#]
```
public bool Initialize();
```

Return Value

A boolean value which specifies if the class was initialized successfully.

Remarks

The Initialize method can be used to explicitly initialize an instance of the MailMessage class, allocating resources for the current thread. Typically it is not necessary to explicitly call this method because the instance of the class is initialized by the class constructor. However, if the **Uninitialize** method is called, the class must be re-initialized before any other methods are called.

See Also

MailMessage Class | SocketTools Namespace | MailMessage.Initialize Overload List | Uninitialize Method

MailMessage.Initialize Method (String)

Initialize an instance of the MailMessage class.

[Visual Basic]

```
Overloads Public Function Initialize( _
   ByVal licenseKey As String _
) As Boolean
```

[C#]

```
public bool Initialize(
   string licenseKey
);
```

Return Value

A boolean value which specifies if the class was initialized successfully.

Remarks

The Initialize method can be used to explicitly initialize an instance of the MailMessage class, loading the networking library and allocating resources for the current thread. Typically an application would define the license key as a custom attribute, however this method can be used to initialize the class directly.

The runtime license key for your copy of SocketTools can be generated using the License Manager utility that is included with the product. Note that if you have installed an evaluation license, you will not have a runtime license key and cannot redistribute any applications which use the MailMessage class.

Example

The following example shows how to use the Initialize method to initialize an instance of the class. This example assumes that the license key string has been defined in code.

```
SocketTools.MailMessage mimeClient = new SocketTools.MailMessage();

if (mimeClient.Initialize(strLicenseKey) == false)
{
    MessageBox.Show(mimeClient.LastErrorString, "Error",
                    MessageBoxButtons.OK, MessageBoxIcon.Exclamation);
    return;
}
```

```
Dim mimeClient As New SocketTools.MailMessage

If mimeClient.Initialize(strLicenseKey) = False Then
    MsgBox(mimeClient.LastErrorString, vbIconExclamation)
    Exit Sub
End If
```

MailMessage.OpenStore Method

Open the specified message storage file for read-only access.

Overload List

Open the specified message storage file for read-only access.

public bool OpenStore(string);

Open the specified message storage file.

public bool OpenStore(string,MimeStorage);

See Also

MailMessage Class | SocketTools Namespace

MailMessage.OpenStore Method (String, MimeStorage)

Open the specified message storage file.

[Visual Basic]

```
Overloads Public Function OpenStore( _
   ByVal fileName As String, _
   ByVal openMode As MimeStorage _
) As Boolean
```

[C#]

```
public bool OpenStore(
   string fileName,
   MimeStorage openMode
);
```

Parameters

fileName
A string which specifies the name of the storage file.

openMode
A MimeStorage enumeration which specifies how the storage file should be opened.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **OpenStore** method opens a message storage file which contains one or more messages. If the storage file is opened for read access, the application can search the message store and extract messages but it cannot add or delete messages. To add new messages or delete existing messages from the store, it must be opened with write access.

The message store is designed to be a simple, effective way to store multiple messages together in a single file. When the message store is opened, the contents are indexed in memory. Although there is no specific limit to the number of messages that can be stored, there must be sufficient memory available to build an index of each message and its headers. If the application must store and manage a very large number of messages, it is recommended that you use a database rather than a flat-file message store.

Message Store Format

Each message is prefixed by a control sequence of five ASCII 01 characters followed by an ASCII 10 and ASCII 13 character. The messages themselves are stored unmodified in their original text format. The length of each message is calculated based on the location of the control sequence that delimits each message, and explicit message lengths are not stored in the file. This means that it is safe to manually change the message contents, as long as the message delimiters are preserved.

If the message store is compressed, the contents of the storage file are expanded when the file is opened and then re-compressed when the storage file is closed. Using the **MimeStorage.storeCompress** option reduces the size of the storage file and prevents the contents of the message store from being read using a text file editor. However, enabling compression will increase the amount of memory allocated by the class and can increase the amount of time that it takes to open and close the storage file.

The class also has a backwards compatibility mode where it will recognize storage files that use the UNIX mbox format. While this format is supported for accessing existing files, it is not recommended that you use it when creating new message stores or adding messages to an existing store. There are a number of different variants on the mbox format that have been used by different Mail Transfer Agents (MTAs) on the UNIX platform. For example, the mboxrd variant looks identical to the mboxcl2 variant, and they are programmatically indistinguishable from one another, but they are not compatible. For this reason, the use of the mbox format is strongly discouraged.

MailMessage Class | SocketTools Namespace | MailMessage.OpenStore Overload List

MailMessage.OpenStore Method (String)

Open the specified message storage file for read-only access.

[Visual Basic]

```
Overloads Public Function OpenStore( _
   ByVal fileName As String _
) As Boolean
```

[C#]

```
public bool OpenStore(
   string fileName
);
```

Parameters

fileName

A string which specifies the name of the storage file.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **OpenStore** method opens a message storage file for read-only access. The application can search the message store and extract messages but it cannot add or delete messages. To add new messages or delete existing messages from the store, it must be opened with write access.

MailMessage Class | SocketTools Namespace | MailMessage.OpenStore Overload List

MailMessage.ParseAddress Method

Parse an Internet email address.

Overload List

Parse an Internet email address.

public bool ParseAddress(string,string,ref string);

Parse an Internet email address.

public bool ParseAddress(string,ref string);

See Also

MailMessage Class | SocketTools Namespace

MailMessage.ParseAddress Method (String, String, String)

Parse an Internet email address.

[Visual Basic]

```
Overloads Public Function ParseAddress( _
   ByVal mailAddress As String, _
   ByVal mailDomain As String, _
   ByRef parsedAddress As String _
) As Boolean
```

[C#]

```
public bool ParseAddress(
   string mailAddress,
   string mailDomain,
   ref string parsedAddress
);
```

Parameters

mailAddress
A string which specifies the email address to be parsed.

mailDomain
A string which specifies a default domain for the address if no domain name is specified in the *mailAddress* parameter.

parsedAddress
A string passed by reference which will contain the parsed email address.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **ParseAddress** method is useful for parsing the email addresses that may be specified in various header fields in the message. In many cases, the addresses have additional comment characters which are not part of the address itself. For example, one common format is "User Name" <user@domain.com>. In this case, the email address is enclosed in angle brackets and the name outside of the brackets is considered to be a comment which is not part of the address itself.

Another common format is user@domain.com (User Name). In this case, there is the address followed by a comment which is enclosed in parenthesis. The **ParseAddress** method recognizes both formats, and when passed either string, would return the address user@domain.com.

If there was no domain specified in the address, that is just a user name was specified, then the value the *mailDomain* parameter is added to the address.

MailMessage Class | SocketTools Namespace | MailMessage.ParseAddress Overload List

MailMessage.ParseAddress Method (String, String)

Parse an Internet email address.

```
[Visual Basic]
Overloads Public Function ParseAddress( _
   ByVal mailAddress As String, _
   ByRef parsedAddress As String _
) As Boolean
```

```
[C#]
public bool ParseAddress(
   string mailAddress,
   ref string parsedAddress
);
```

Parameters

mailAddress
A string which specifies the email address to be parsed.

parsedAddress
A string passed by reference which will contain the parsed email address.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **ParseAddress** method is useful for parsing the email addresses that may be specified in various header fields in the message. In many cases, the addresses have additional comment characters which are not part of the address itself. For example, one common format is "User Name" <user@domain.com>. In this case, the email address is enclosed in angle brackets and the name outside of the brackets is considered to be a comment which is not part of the address itself.

Another common format is user@domain.com (User Name). In this case, there is the address followed by a comment which is enclosed in parenthesis. The **ParseAddress** method recognizes both formats, and when passed either string, would return the address user@domain.com.

MailMessage Class | SocketTools Namespace | MailMessage.ParseAddress Overload List

MailMessage.ParseMessage Method

Parse the specified string, adding the contents to the current message.

[Visual Basic]

```
Public Function ParseMessage( _
   ByVal messageText As String _
) As Boolean
```

[C#]

```
public bool ParseMessage(
   string messageText
);
```

Parameters

messageText
A string which contains the message text to be parsed.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **ParseMessage** method parses a string which contains message data, adding it to the current message. This method is useful when the application needs to parse an arbitrary block of text and add it to the current message. If the string contains header fields, the values will be added to the message header. Once the end of the header block is detected, all subsequent text is added to the body of the message.

Note that unlike the **ImportMessage** method, the **ParseMessage** method does not clear the contents of the current message and may be called multiple times. Use the **ClearMessage** method to clear the current message before calling **ParseMessage** if necessary.

See Also

MailMessage Class | SocketTools Namespace

MailMessage.PurgeStore Method

Purge all deleted messages from the current message store.

[Visual Basic]

```
Public Function PurgeStore() As Boolean
```

[C#]

```
public bool PurgeStore();
```

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **PurgeStore** method purges all deleted messages from the message store. If the storage file has been opened in read-only mode or there are no messages marked for deletion, this method will take no action.

When the **CloseStore** method is called, the storage file will automatically be purged. To prevent deleted messages from being removed from the message store, use the **Reset** method.

See Also

MailMessage Class | SocketTools Namespace

MailMessage.Reset Method

Reset the internal state of the object, resetting all properties to their default values.

[Visual Basic]

```
Public Sub Reset()
```

[C#]

```
public void Reset();
```

Remarks

The **Reset** method returns the object to its default state. All properties will be reset to their default values.

MailMessage Class | SocketTools Namespace

MailMessage.ReadStore Method

Retrieve a message from the message store, replacing the current message.

Overload List

Retrieve a message from the message store, replacing the current message.

public bool ReadStore();

Retrieve a message from the message store, replacing the current message.

public bool ReadStore(int);

See Also

MailMessage Class | SocketTools Namespace

MailMessage.ReadStore Method (Int32)

Retrieve a message from the message store, replacing the current message.

[Visual Basic]

```
Overloads Public Function ReadStore( _
   ByVal messageIndex As Integer _
) As Boolean
```

[C#]

```
public bool ReadStore(
   int messageIndex
);
```

Parameters

messageIndex

An integer value which specifies the message that will be removed from the message store.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **ReadStore** method reads the specified message from the message store, and the contents of that message will replace the current message.

See Also

MailMessage Class | SocketTools Namespace | MailMessage.ReadStore Overload List

MailMessage.ReadStore Method ()

Retrieve a message from the message store, replacing the current message.

[Visual Basic]

```
Overloads Public Function ReadStore() As Boolean
```

[C#]

```
public bool ReadStore();
```

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **ReadStore** method reads a message from the message store, and the contents of that message will replace the current message. The **StoreIndex** property specifies the current message index into the storage file.

See Also

MailMessage Class | SocketTools Namespace | MailMessage.ReadStore Overload List

MailMessage.ReplaceMessage Method

Replace the current message in the message store.

Overload List

Replace the current message in the message store.

public bool ReplaceMessage();

Replace the specified message in the current message store.

public bool ReplaceMessage(int);

See Also

MailMessage Class | SocketTools Namespace

MailMessage.ReplaceMessage Method (Int32)

Replace the specified message in the current message store.

[Visual Basic]

```
Overloads Public Function ReplaceMessage( _
   ByVal messageIndex As Integer _
) As Boolean
```

[C#]

```
public bool ReplaceMessage(
   int messageIndex
);
```

Parameters

messageIndex
An integer value which specifies the message that will be replaced in the message store.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **ReplaceMessage** method replaces the specified message with a new message. The message number may be a message that has been previously marked for deletion. It is important to note that the change will not be reflected in the physical storage file until it has been closed. This method will update the current message index in the storage file.

The message store must be opened with write access. This method will fail if you attempt to replace a message from a storage file that has been opened for read-only access. If the application needs to replace messages in the message store, it is recommended that the file be opened for exclusive access using the **storeLock** option when calling the **OpenStore** method.

See Also

MailMessage Class | SocketTools Namespace | MailMessage.ReplaceMessage Overload List

MailMessage.ReplaceMessage Method ()

Replace the current message in the message store.

[Visual Basic]
```
Overloads Public Function ReplaceMessage() As Boolean
```

[C#]
```
public bool ReplaceMessage();
```

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **ReplaceMessage** method replaces the current message in the message store. The current message index into the storage file is specified by the **StoreIndex** property and this may be a message that has been previously marked for deletion. It is important to note that the change will not be reflected in the physical storage file until it has been closed. This method will update the current message index in the storage file.

The message store must be opened with write access. This method will fail if you attempt to replace a message from a storage file that has been opened for read-only access. If the application needs to replace messages in the message store, it is recommended that the file be opened for exclusive access using the **storeLock** option when calling the **OpenStore** method.

MailMessage Class | SocketTools Namespace | MailMessage.ReplaceMessage Overload List

MailMessage.SetHeader Method

Set the value for a header in the specified message part.

Overload List

Set the value for a header in the specified message part.

public bool SetHeader(int,string,string);

Set the value for a header in the current message part.

public bool SetHeader(string,string);

See Also

MailMessage Class | SocketTools Namespace

MailMessage.SetHeader Method (Int32, String, String)

Set the value for a header in the specified message part.

[Visual Basic]

```
Overloads Public Function SetHeader( _
   ByVal messagePart As Integer, _
   ByVal headerName As String, _
   ByVal headerValue As String _
) As Boolean
```

[C#]

```
public bool SetHeader(
   int messagePart,
   string headerName,
   string headerValue
);
```

Parameters

messagePart
: An integer which specifies the message part.

headerName
: A string which specifies the name of the header field.

headerValue
: A string which specifies the value of the header field. If an empty string is specified, the header field is removed from the header block in the specified message part.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

See Also

MailMessage Class | SocketTools Namespace | MailMessage.SetHeader Overload List

MailMessage.SetHeader Method (String, String)

Set the value for a header in the current message part.

[Visual Basic]

```
Overloads Public Function SetHeader( _
   ByVal headerName As String, _
   ByVal headerValue As String _
) As Boolean
```

[C#]

```
public bool SetHeader(
   string headerName,
   string headerValue
);
```

Parameters

headerName

A string which specifies the name of the header field.

headerValue

A string which specifies the value of the header field. If an empty string is specified, the header field is removed from the header block in the current message part.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The current message part is returned by the **Part** property.

See Also

MailMessage Class | SocketTools Namespace | MailMessage.SetHeader Overload List

MailMessage.Uninitialize Method

Uninitialize the class library and release any resources allocated for the current thread.

[Visual Basic]

```
Public Sub Uninitialize()
```

[C#]

```
public void Uninitialize();
```

Remarks

The **Uninitialize** method releases resources allocated for the current process. After this method has been called, no further operations may be performed until the class instance has been re-initialized.

If the **Initialize** method is explicitly called by the application, it should be matched by a call to the **Uninitialize** method when that instance of the class is no longer needed.

See Also

MailMessage Class | SocketTools Namespace | Initialize Method

MailMessage.WriteStore Method

Store the current message in the message store.

[Visual Basic]

```
Public Function WriteStore() As Boolean
```

[C#]

```
public bool WriteStore();
```

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **WriteStore** method will always append the current message to the storage file. If you want to replace a message in the message store, you should use the **ReplaceMessage** method.

This method will update the value of the **StoreIndex** property to specify the message number for the new message that has been added to the storage file.

MailMessage Class | SocketTools Namespace | ReplaceMessage Method

MailMessage Events

The events of the **MailMessage** class are listed below. For a complete list of **MailMessage** class members, see the MailMessage Members topic.

Public Instance Events

⚡ OnError	Occurs when an client operation fails.

See Also

MailMessage Class | SocketTools Namespace

MailMessage.OnError Event

Occurs when an client operation fails.

[Visual Basic]

```
Public Event OnError As OnErrorEventHandler
```

[C#]

```
public event OnErrorEventHandler OnError;
```

Event Data

The event handler receives an argument of type MailMessage.ErrorEventArgs containing data related to this event. The following **MailMessage.ErrorEventArgs** properties provide information specific to this event.

Property	Description
Description	Gets a value which describes the last error that has occurred.
Error	Gets a value which specifies the last error that has occurred.

Remarks

The **OnError** event occurs when a client operation fails.

See Also

MailMessage Class | SocketTools Namespace

MailMessage.ErrorEventArgs Class

Provides data for the OnError event.

For a list of all members of this type, see MailMessage.ErrorEventArgs Members.

System.Object
  System.EventArgs
    SocketTools.MailMessage.ErrorEventArgs

[Visual Basic]

```
Public Class MailMessage.ErrorEventArgs
    Inherits EventArgs
```

[C#]

```
public class MailMessage.ErrorEventArgs : EventArgs
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

ErrorEventArgs specifies the numeric error code and a description of the error that has occurred.

An OnError event occurs when a method fails.

Requirements

Namespace: SocketTools

Assembly: SocketTools.MailMessage (in SocketTools.MailMessage.dll)

See Also

MailMessage.ErrorEventArgs Members | SocketTools Namespace

MailMessage.ErrorEventArgs Members

MailMessage.ErrorEventArgs overview

Public Instance Constructors

MailMessage.ErrorEventArgs Constructor	Initializes a new instance of the MailMessage.ErrorEventArgs class.

Public Instance Properties

Description	Gets a value which describes the last error that has occurred.
Error	Gets a value which specifies the last error that has occurred.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString (inherited from Object)	Returns a String that represents the current Object.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

MailMessage.ErrorEventArgs Class | SocketTools Namespace

MailMessage.ErrorEventArgs Constructor

Initializes a new instance of the MailMessage.ErrorEventArgs class.

[Visual Basic]

```
Public Sub New()
```

[C#]

```
public MailMessage.ErrorEventArgs();
```

See Also

MailMessage.ErrorEventArgs Class | SocketTools Namespace

MailMessage.ErrorEventArgs Properties

The properties of the **MailMessage.ErrorEventArgs** class are listed below. For a complete list of **MailMessage.ErrorEventArgs** class members, see the MailMessage.ErrorEventArgs Members topic.

Public Instance Properties

Description	Gets a value which describes the last error that has occurred.
Error	Gets a value which specifies the last error that has occurred.

See Also

MailMessage.ErrorEventArgs Class | SocketTools Namespace

MailMessage.ErrorEventArgs.Description Property

Gets a value which describes the last error that has occurred.

[Visual Basic]

```
Public ReadOnly Property Description As String
```

[C#]

```
public string Description {get;}
```

Property Value

A string which describes the last error that has occurred.

See Also

MailMessage.ErrorEventArgs Class | SocketTools Namespace | Error Property

MailMessage.ErrorEventArgs.Error Property

Gets a value which specifies the last error that has occurred.

[Visual Basic]

```
Public ReadOnly Property Error As ErrorCode
```

[C#]

```
public MailMessage.ErrorCode Error {get;}
```

Property Value

ErrorCode enumeration which specifies the error.

See Also

MailMessage.ErrorEventArgs Class | SocketTools Namespace | Description Property

MailMessage.ErrorCode Enumeration

Specifies the error codes returned by the MailMessage class.

[Visual Basic]

```
Public Enum MailMessage.ErrorCode
```

[C#]

```
public enum MailMessage.ErrorCode
```

Remarks

The MailMessage class uses the **ErrorCode** enumeration to specify what error has occurred when a method fails. The current error code may be determined by checking the value of the **LastError** property.

Note that the last error code is only meaningful if the previous operation has failed.

Members

Member Name	Description
errorNone	No error.
errorNotHandleOwner	Handle not owned by the current thread.
errorFileNotFound	The specified file or directory does not exist.
errorFileNotCreated	The specified file could not be created.
errorOperationCanceled	The blocking operation has been canceled.
errorInvalidFileType	The specified file is a block or character device, not a regular file.
errorInvalidDevice	The specified file type is invalid or not a regular file.
errorTooManyParameters	The maximum number of function parameters has been exceeded.
errorInvalidFileName	The specified file name contains invalid characters or is too long.
errorInvalidFileHandle	Invalid file handle passed to function.
errorFileReadFailed	Unable to read data from the specified file.
errorFileWriteFailed	Unable to write data to the specified file.
errorOutOfMemory	Out of memory.
errorAccessDenied	Access denied.
errorInvalidParameter	Invalid argument passed to function.
errorClipboardUnavailable	The system clipboard is currently unavailable.
errorClipboardEmpty	The system clipboard is empty or does not contain any text data.
errorFileEmpty	The specified file does not contain any data.
errorFileExists	The specified file already exists.

errorEndOfFile	End of file.
errorDeviceNotFound	The specified device could not be found.
errorDirectoryNotFound	The specified directory could not be found.
errorInvalidbuffer	Invalid memory address passed to function.
errorBufferTooSmall	The specified buffer is not large enough to contain the data.
errorNoHandles	No more handles are available to this process.
errorOperationWouldBlock	The specified operation would block the current thread.
errorOperationInProgress	A blocking operation is currently in progress.
errorAlreadyInProgress	The specified operation is already in progress.
errorInvalidHandle	Invalid handle passed to function.
errorInvalidAddress	Invalid network address specified.
errorInvalidSize	Datagram is too large to fit in specified buffer.
errorInvalidProtocol	Invalid network protocol specified.
errorProtocolNotAvailable	The specified network protocol is not available.
errorProtocolNotSupported	The specified protocol is not supported.
errorSocketNotSupported	The specified socket type is not supported.
errorInvalidOption	The specified option is invalid.
errorProtocolFamily	Specified protocol family is not supported.
errorProtocolAddress	The specified address is invalid for this protocol family.
errorAddressInUse	The specified address is in use by another process.
errorAddressUnavailable	The specified address cannot be assigned.
errorNetworkUnavailable	The networking subsystem is unavailable.
errorNetworkUnreachable	The specified network is unreachable.
errorNetworkReset	Network dropped connection on remote reset.
errorConnectionAborted	Connection was aborted due to timeout or other failure.
errorConnectionReset	Connection was reset by remote network.
errorOutOfBuffers	No buffer space is available.
errorAlreadyConnected	Connection already established with remote host.
errorNotConnected	No connection established with remote host.
errorConnectionShutdown	Unable to send or receive data after connection shutdown.
errorOperationTimeout	The specified operation has timed out.
errorConnectionRefused	The connection has been refused by the remote host.

errorHostUnavailable	The specified host is unavailable.
errorHostUnreachable	Remote host is unreachable.
errorTooManyProcesses	Too many processes are using the networking subsystem.
errorTooManyThreads	Too many threads have been created by the current process.
errorTooManySessions	Too many client sessions have been created by the current process.
errorInternalFailure	An unexpected internal error has occurred.
errorNetworkNotReady	Network subsystem is not ready for communication.
errorInvalidVersion	This version of the operating system is not supported.
errorNetworkNotInitialized	The networking subsystem has not been initialized.
errorRemoteShutdown	The remote host has initiated a graceful shutdown sequence.
errorInvalidHostName	The specified hostname is invalid or could not be resolved.
errorHostNameNotFound	The specified hostname could not be found.
errorHostNameRefused	Unable to resolve hostname, request refused.
errorHostNameNotResolved	Unable to resolve hostname, no address for specified host.
errorInvalidLicense	The license for this product is invalid.
errorProductNotLicensed	This product is not licensed to perform this operation.
errorNotImplemented	This function has not been implemented on this platform.
errorUnknownLocalhost	Unable to determine local host name.
errorInvalidHostAddress	Invalid host address specified.
errorInvalidServicePort	Invalid service port number specified.
errorInvalidServiceName	Invalid or unknown service name specified.
errorInvalidEventId	Invalid event identifier specified.
errorOperationNotBlocking	No blocking operation in progress on this socket.
errorSecurityNotInitialized	Unable to initialize security interface for this process.
errorSecurityContext	Unable to establish security context for this session.
errorSecurityCredentials	Unable to open certificate store or establish security credentials.
errorSecurityCertificate	Unable to validate the certificate chain for this

	session.
errorSecurityDecryption	Unable to decrypt data stream.
errorSecurityEncryption	Unable to encrypt data stream.
errorOperationNotSupported	The specified operation is not supported.
errorInvalidProtocolVersion	Invalid application protocol version specified.
errorNoServerResponse	No data returned from server.
errorInvalidServerResponse	Invalid data returned from server.
errorUnexpectedServerResponse	Unexpected response code returned from server.
errorServerTransactionFailed	Server transaction failed.
errorServiceUnavailable	The service is currently unavailable.
errorServiceNotReady	The service is not ready, try again later.
errorServerResyncFailed	Unable to resynchronize with server.
errorInvalidProxyType	Invalid proxy server type specified.
errorProxyRequired	Resource must be accessed through specified proxy.
errorInvalidProxyLogin	Unable to login to proxy server using specified credentials.
errorProxyResyncFailed	Unable to resynchronize with proxy server.
errorInvalidCommand	Invalid command specified.
errorInvalidCommandParameter	Invalid command parameter specified.
errorInvalidCommandSequence	Invalid command sequence specified.
errorCommandNotImplemented	Specified command not implemented on this server.
errorCommandNotAuthorized	Specified command not authorized for the current user.
errorCommandAborted	Specified command was aborted by the remote host.
errorOptionNotSupported	The specified option is not supported on this server.
errorRequestNotCompleted	The current client request has not been completed.
errorInvalidUserName	The specified username is invalid.
errorInvalidPassword	The specified password is invalid.
errorInvalidAccount	The specified account name is invalid.
errorAccountRequired	Account name has not been specified.
errorInvalidAuthenticationType	Invalid authentication protocol specified.
errorAuthenticationRequired	User authentication is required.
errorProxyAuthenticationRequired	Proxy authentication required.

errorAlreadyAuthenticated	User has already been authenticated.
errorAuthenticationFailed	Unable to authenticate the specified user.
errorNetworkAdapter	Unable to determine network adapter configuration.
errorInvalidRecordType	Invalid record type specified.
errorInvalidRecordName	Invalid record name specified.
errorInvalidRecordData	Invalid record data specified.
errorConnectionOpen	Data connection already established.
errorConnectionClosed	Server closed data connection.
errorConnectionPassive	Data connection is passive.
errorConnectionFailed	Unable to open data connection to server.
errorInvalidSecurityLevel	Data connection cannot be opened with this security setting.
errorCachedTLSRequired	Data connection requires cached TLS session.
errorDataReadOnly	Data connection is read-only.
errorDataWriteOnly	Data connection is write-only.
errorEndOfData	End of data.
errorRemoteFileUnavailable	Remote file is unavailable.
errorInsufficientStorage	Insufficient storage on server.
errorStorageallocation	File exceeded storage allocation on server.
errorDirectoryExists	The specified directory already exists.
errorDirectoryEmpty	No files returned by the server for the specified directory.
errorEndOfDirectory	End of directory listing.
errorUnknownDirectoryFormat	Unknown directory format.
errorInvalidResource	Invalid resource name specified.
errorResourceRedirected	The specified resource has been redirected.
errorResourceRestricted	Access to this resource has been restricted.
errorResourceNotModified	The specified resource has not been modified.
errorResourceNotFound	The specified resource cannot be found.
errorResourceConflict	Request could not be completed due to the current state of the resource.
errorResourceRemoved	The specified resource has been permanently removed from this server.
errorContentLengthRequired	Request must include the content length.
errorRequestPrecondition	Request could not be completed due to server precondition.
errorUnsupportedMediaType	Request specified an unsupported media type.

errorInvalidContentRange	Content range specified for this resource is invalid.
errorInvalidMessagePart	Message is not multipart or an invalid message part was specified.
errorInvalidMessageHeader	The specified message header is invalid or has not been defined.
errorInvalidMessageBoundary	The multipart message boundary has not been defined.
errorNoFileAttachment	The current message part does not contain a file attachment.
errorUnknownFileType	The specified file type could not be determined.
errorDataNotEncoded	The specified data block could not be encoded.
errorDataNotDecoded	The specified data block could not be decoded.
errorFileNotEncoded	The specified file could not be encoded.
errorFileNotDecoded	The specified file could not be decoded.
errorNoMessageText	No message text.
errorInvalidCharacterSet	Invalid character set specified.
errorInvalidEncodingType	Invalid encoding type specified.
errorInvalidMessageNumber	Invalid message number specified.
errorNoReturnAddress	No valid return address specified.
errorNoValidRecipients	No valid recipients specified.
errorInvalidRecipient	The specified recipient address is invalid.
errorRelayNotAuthorized	The specified domain is invalid or server will not relay messages.
errorMailboxUnavailable	Specified mailbox is currently unavailable.
errorMailboxReadOnly	The selected mailbox cannot be modified.
errorMailboxNotSelected	No mailbox has been selected.
errorInvalidMailbox	Specified mailbox is invalid.
errorInvalidDomain	The specified domain name is invalid or not recognized.
errorInvalidSender	The specified sender address is invalid or not recognized.
errorMessageNotDelivered	Message not delivered to any of the specified recipients.
errorEndOfMessageData	No more message data available to be read
errorInvalidmessageSize	The specified message size is invalid.
errorMessageNotCreated	The message could not be created in the specified mailbox.
errorNoMoreMailboxes	No more mailboxes exist on this server.

errorInvalidEmulationType	The specified terminal emulation type is invalid.
errorInvalidFontHandle	The specified font handle is invalid.
errorInvalidFontName	The specified font name is invalid or unavailable.
errorInvalidPacketSize	The specified packet size is invalid.
errorInvalidPacketData	The specified packet data is invalid.
errorInvalidPacketId	The unique packet identifier is invalid.
errorPacketTTLExpired	The specified packet time-to-live period has expired.
errorInvalidNewsGroup	Invalid newsgroup specified.
errorNoNewsgroupSelected	No newsgroup selected.
errorEmptyNewsgroup	No articles in specified newsgroup.
errorInvalidArticle	Invalid article number specified.
errorNoArticleSelected	No article selected in the current newsgroup.
errorFirstArticle	First article in current newsgroup.
errorLastArticle	Last article in current newsgroup.
errorArticleExists	Unable to transfer article, article already exists.
errorArticleRejected	Unable to transfer article, article rejected.
errorArticleTransferFailed	Article transfer failed.
errorArticlePostingDenied	Posting is not permitted on this server.
errorArticlePostingFailed	Unable to post article on this server.
errorInvalidDateFormat	The specified date format is not recognized.
errorFeatureNotSupported	The specified feature is not supported on this server.
errorInvalidFormHandle	The specified form handle is invalid or a form has not been created.
errorInvalidFormAction	The specified form action is invalid or has not been specified.
errorInvalidFormMethod	The specified form method is invalid or not supported.
errorInvalidFormType	The specified form type is invalid or not supported.
errorInvalidFormField	The specified form field name is invalid or does not exist.
errorEmptyForm	The specified form does not contain any field values.
errorMaximumConnections	The maximum number of client connections exceeded.
errorThreadCreationFailed	Unable to create a new thread for the current process.
errorInvalidThreadHandle	The specified thread handle is no longer valid.

errorThreadTerminated	The specified thread has been terminated.
errorThreadDeadlock	The operation would result in the current thread becoming deadlocked.
errorInvalidClientMoniker	The specified moniker is not associated with any client session.
errorClientMonikerExists	The specified moniker has been assigned to another client session.
errorServerInactive	The specified server is not listening for client connections.
errorServerSuspended	The specified server is suspended and not accepting client connections.
errorNoMessageStore	No message store has been specified.
errorMessageStoreChanged	The message store has changed since it was last accessed.
errorMessageNotFound	No message was found that matches the specified criteria.
errorMessageDeleted	The specified message has been deleted.
errorFileChecksumMismatch	The local and remote file checksums do not match.
errorFileSizeMismatch	The local and remote file sizes do not match.
errorInvalidFeedUrl	The news feed URL is invalid or specifies an unsupported protocol.
errorInvalidFeedFormat	The internal format of the news feed is invalid.
errorInvalidFeedVersion	This version of the news feed is not supported.
errorChannelEmpty	There are no valid items found in this news feed.
errorInvalidItemNumber	The specified channel item identifier is invalid.
errorItemNotFound	The specified channel item could not be found.
errorItemEmpty	The specified channel item does not contain any data.
errorInvalidItemProperty	The specified item property name is invalid.
errorItemPropertyNotFound	The specified item property has not been defined.
errorInvalidChannelTitle	The channel title is invalid or has not been defined.
errorInvalidChannelLink	The channel hyperlink is invalid or has not been defined.
errorInvalidChannelDescription	The channel description is invalid or has not been defined.
errorInvalidItemText	The description for an item is invalid or has not been defined.
errorInvalidItemLink	The hyperlink for an item is invalid or has not been defined.

errorInvalidServiceType	The specified service type is invalid.
errorServiceSuspended	Access to the specified service has been suspended.
errorServiceRestricted	Access to the specified service has been restricted.
errorInvalidProviderName	The specified provider name is invalid or unknown.
errorInvalidPhoneNumber	The specified phone number is invalid or not supported in this region.
errorGatewayNotFound	A message gateway cannot be found for the specified provider.
errorMessageTooLong	The message exceeds the maximum number of characters permitted.
errorInvalidProviderData	The request returned invalid or incomplete service provider data.
errorInvalidGatewayData	The request returned invalid or incomplete message gateway data.
errorMultipleProviders	The request has returned multiple service providers.
errorProviderNotFound	The specified service provider could not be found.
errorInvalidMessageService	The specified message is not supported with this service type.
errorInvalidMessageFormat	The specified message format is invalid.
errorInvalidConfiguration	The specified configuration options are invalid.
errorServerActive	The requested action is not permitted while the server is active.
errorServerPortBound	Unable to obtain exclusive use of the specified local port.
errorInvalidClientSession	The specified client identifier is invalid for this session.
errorClientNotIdentified	The specified client has not provided user credentials.
errorInvalidClientState	The requested action cannot be performed at this time.
errorInvalidResultCode	The specified result code is not valid for this protocol
errorCommandRequired	The specified command is required and cannot be disabled.
errorCommandDisabled	The specified command has been disabled.
errorCommandSequence	The command cannot be processed at this time.
errorCommandCompleted	The previous command has completed.
errorInvalidProgramName	The specified program name is invalid or unrecognized.

errorInvalidRequestHeader	The request header contains one or more invalid values.
errorInvalidVirtualHost	The specified virtual host name is invalid.
errorVirtualHostNotFound	The specified virtual host does not exist.
errorTooManyVirtualHosts	Too many virtual hosts created for this server.
errorInvalidVirtualPath	The specified virtual path name is invalid.
errorVirtualPathNotFound	The specified virtual path does not exist.
errorTooManyVirtualPaths	Too many virtual paths created for this server.
errorInvalidTask	The asynchronous task identifier is invalid.
errorTaskActive	The asynchronous task has not finished.
errorTaskQueued	The asynchronous task has been queued.
errorTaskSuspended	The asynchronous task has been suspended.
errorTaskFinished	The asynchronous task has finished.

Requirements

MailMessage.MimeAttachment Enumeration

Specifies the file attachment options supported by the MailMessage class.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]

```
<Flags>
Public Enum MailMessage.MimeAttachment
```

[C#]

```
[Flags]
public enum MailMessage.MimeAttachment
```

Remarks

The **attachAlternative** and **attachInline** values can be combined with one of the attachment options using a bitwise OR operator.

Members

Member Name	Description	Value
attachDefault	The file attachment encoding is based on the file content type. Text files are not encoded, and binary files are encoded using the standard base64 encoding algorithm. This is the default option for file attachments.	0
attachBase64	The file attachment is always encoded using the standard base64 algorithm, even if the attached file is a plain text file.	1
attachUucode	The file attachment is always encoded using the uuencode algorithm, even if the attached file is a plain text file.	2
attachQuoted	The file attachment is always encoded using the quoted-printable algorithm, even if the attached file is a plain text file.	3
attachAlternative	The attached data is an alternative format for the contents of the message. This can only be used with textual data.	65536
attachInline	The attached data will be displayed inline with the contents of the message. This is typically used with images that are to be displayed along with the message text.	131072

MailMessage.MimeCharacterSet Enumeration

Specifies the character sets recognized by the MailMessage class.

[Visual Basic]

```
Public Enum MailMessage.MimeCharacterSet
```

[C#]

```
public enum MailMessage.MimeCharacterSet
```

Members

Member Name	Description
charsetUnknown	The character set is unknown.
charsetDefault	The default character set. This is the same as specifying the character set **charsetUTF8**.
charsetUSASCII	A character set using US-ASCII which defines 7-bit printable characters with values ranging from 20h to 7Eh. An application that uses this character set has the broadest compatibility with most mail servers (MTAs) because it does not require the server to handle 8-bit characters correctly when the message is delivered. This is the most commonly used character set for plain text email messages in the English language and is the default character set used by the class.
charsetISO8859_1	An 8-bit character set for most western European languages such as English, French, Spanish and German. This character set is also commonly referred to as Latin1. The Windows code page for this character set is 28591, however Windows code page 1252 (Windows-1252) is typically used to represent this character set in most applications.
charsetISO8859_2	An 8-bit character set for most central and eastern European languages such as Czech, Hungarian, Polish and Romanian. This character set is also commonly referred to as Latin2. This character set is similar to Windows code page 1250, however the characters are arranged differently.
charsetISO8859_3	A character set for southern European languages such as Maltese and Esperanto. This character set was also used with the Turkish language, but it was superseded by ISO 8859-9 which is the preferred character set for Turkish. This character set is not widely used in mail messages and it is recommended that you use UTF-8 instead.
charsetISO8859_4	A character set for northern European languages such as Latvian, Lithuanian and Greenlandic. This character set is not widely used in mail messages

	and it is recommended that you use UTF-8 instead.
charsetISO8859_5	An 8-bit character set for Cyrillic languages such as Russian, Bulgarian and Serbian. The Windows code page for this character set is 28595. This character set is not widely used and it is recommended that you use UTF-8 instead.
charsetISO8859_6	An 8-bit character set for Arabic languages. Note that the application is responsible for displaying text that uses this character set. In particular, any display engine needs to be able to handle the reverse writing direction and analyze the context of the message to correctly combine the glyphs. This character set is not widely used and it is recommended that you use UTF-8 instead.
charsetISO8859_7	An 8-bit character set for the Greek language. This character set is also commonly referred to as Latin/Greek. The Windows code page for this character set is 28597.
charsetISO8859_8	An 8-bit character set for the Hebrew language. Note that similar to Arabic, Hebrew uses a reverse writing direction. An application which displays this character should be capable of processing bi-directional text where a single message may include both right-to-left and left-to-right languages, such as Hebrew and English. The Windows code page for this character set is 28598.
charsetISO8859_9	An 8-bit character set for the Turkish language. This character set is also commonly referred to as Latin5. The Windows code page for this character set is 28599.
charsetISO8859_10	A character set for the Danish, Icelandic, Norwegian and Swedish languages. This character set is also commonly referred to as Latin-6 and is similar to ISO 8859-4.
charsetISO8859_13	A character set for Baltic languages. This character set is also commonly referred to as Latin-7. This character set is similar to ISO 8859-4, except it adds certain Polish characters and does not support Nordic languages.
charsetISO8859_14	A character set for Gaelic languages such as Irish, Manx and Scottish Gaelic. This character set is also commonly referred to as Latin-8. This character set replaced ISO 8859-12 which was never fully implemented.
charsetISO8859_15	A character set for western European languages. This character set is also commonly referred to as Latin-9 and is nearly identical to ISO8859-1 except

	that it replaces lesser-used symbols with the Euro sign and some letters.
charsetISO2022_JP	A multi-byte character encoding for Japanese that is widely used with mail messages. This is a 7-bit encoding where all characters start with ASCII and uses escape sequences to switch to the double-byte character sets.
charsetISO2022_KR	A multi-byte character encoding for Korean which encodes both ASCII and Korean double-byte characters. This is a 7-bit encoding which uses the shift in and shift out control characters to switch to the double-byte character set.
charsetISO2022_CN	A multi-byte character encoding for Simplified Chinese which encodes both ASCII and Chinese double-byte characters. This is a 7-bit encoding which uses the shift in and shift out control characters to switch to the double-byte character set.
charsetKOI8R	A character set for Russian using the Cyrillic alphabet. This character set also covers the Bulgarian language. Most mail messages in the Russian language use this character set or UTF-8 instead of ISO 8859-5, which was never widely adopted.
charsetKOI8U	A character set for Ukrainian using the Cyrillic alphabet. This character set is similar to the KOI8-R character set, but replaces certain symbols with Ukrainian letters. Most mail messages in the Ukrainian language use this character set or UTF-8 instead of ISO 8859-5, which was never widely adopted.
charsetGB2312	A multi-byte character encoding which can represent ASCII and simplified Chinese characters. It has been superseded by GB18030, however it remains widely used in China.
charsetGB18030	A Unicode transformation format which can represent all Unicode code points and supports both simplified and traditional Chinese characters. It is backwards compatible with GB2312 and supersedes that character set.
charsetBIG5	A multi-byte character set that supports both ASCII characters and traditional Chinese characters. It is widely used in Taiwan, Hong Kong and Macau. It is no longer commonly used in China, which has developed GB18030 as a standard encoding. Note that Microsoft's implementation of Big5 on Windows does not support all of the extensions and is missing certain

	code points.
charsetUTF7	A 7-bit Unicode Transformation Format that uses variable-length character encoding to represent Unicode text as a stream of ASCII characters that are safe to transport between mail servers that only support 7-bit printable characters. It is primarily used as an alternative to UTF-8 which requires that the mail server support 8-bit text or use quoted-printable encoding.
charsetUTF8	An 8-bit Unicode Transformation Format that uses multibyte character sequences to represent Unicode text. It is backwards compatible with the ASCII character set, however because it uses 8-bit text, it should be encoded using either quoted-printable or base64 encoding to ensure that mail servers that do not support 8-bit characters.
charsetUTF16	A 16-bit Unicode Transformation Format that uses two bytes to represent each Unicode character. Messages that use UTF-16 are commonly encoded using the base64 algorithm. It is recommended that most applications use the UTF-8 character set, which is capable of representing all Unicode characters.

Requirements

Namespace: SocketTools

Assembly: SocketTools.MailMessage (in SocketTools.MailMessage.dll)

SocketTools Namespace

MailMessage.MimeContent Enumeration

Specifies the content types supported by the MailMessage class.

[Visual Basic]
```
Public Enum MailMessage.MimeContent
```

[C#]
```
public enum MailMessage.MimeContent
```

Members

Member Name	Description
contentUnknown	The content type is unknown. This value may be returned if the message handle is invalid, or if the file extension is unknown and the file could not be opened for read access.
contentDefault	The default content type. This is the same as specifying the content type **contentText**.
contentApplication	The content is application specific. Examples of this type of file would be a Microsoft Word document or an executable program. This is also the default type for files which have an unrecognized file name extension and contain binary data.
contentAudio	The content is audio data in one of several standard formats. Examples of this type of file would be a Windows (.wav) file or MPEG3 (.mp3) file.
contentImage	The content is an image data in one of several standard formats. Examples of this type of file would be a GIF or JPEG image file.
contentMessage	The content is an email message encapsulated within the current message.
contentMultipart	The content is a multipart MIME email message which contains additional message parts. For example, an email message which contains both a text message and file attachment would be identified as a multipart message.
contentText	The content is textual data. This is also the default type for files which have an unrecognized file name extension and contain only printable text.
contentVideo	The content is video data in one of several standard formats. Examples of this type of file would be a Windows (.avi) or Quicktime (.mov) video file.
contentWideText	The content is Unicode text. This is also the default type for files which have an unrecognized file

	name extension. The content must be prefixed with a byte order mark (BOM) to be recognized as Unicode text.

MailMessage.MimeEncoding Enumeration

Specifies the encoding types supported by the MailMessage class.

[Visual Basic]
```
Public Enum MailMessage.MimeEncoding
```

[C#]
```
public enum MailMessage.MimeEncoding
```

Members

Member Name	Description
encodingUnknown	The encoding type is unknown.
encodingDefault	The encoding type is based on the content type. Textual data is not encoded, and binary data is encoded using the standard base64 encoding algorithm. This is the default option for file attachments.
encoding7Bit	The data contains printable UTF-8 and ANSI text characters. This is the default encoding type for most email messages.
encoding8Bit	The data contains printable ASCII characters as well as printable characters using UTF-8 encoding and the ISO8859 (Latin1) character set. In some cases, it may be necessary to use basse64 encoding if the mail server cannot accept 8-bit characters.
encodingBinary	The data contains unmodified 8-bit binary data. Messages which contain binary data should be encoded using the base64 algorithm.
encodingQuoted	The data is encoded using quoted-printable encoding. Printable ASCII characters are left as-is, with non-printable characters encoded as their hexadecimal value. Quoted-printable encoding is commonly used with HTML formatted email messages.
encodingBase64	The data is encoded using the standard base64 algorithm. This is the most common encoding method for binary data in an email message.
encodingUucode	The data is encoded using the uuencode algorithm. This encoding method is common for binary attachments to news articles, but is rarely used with email messages.

MailMessage.MimeExportOptions Enumeration

Specifies the export options that the MailMessage class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]

```
<Flags>
Public Enum MailMessage.MimeExportOptions
```

[C#]

```
[Flags]
public enum MailMessage.MimeExportOptions
```

Members

Member Name	Description	Value
exportDefault	The default export options. The headers for the message are written out in a specific consistent order, with custom headers written to the end of the header block regardless of the order in which they were set or imported from another message. If the message contains Bcc, Received, Return-Path, Status or X400-Received header fields, they will not be exported.	0
exportAllHeaders	All headers, including the Bcc, Received, Return-Path, Status and X400-Received header fields will be exported. Normally these headers are not exported because they are only used by the mail transport system. This option can be useful when exporting a message to be stored on the local system, but should not be used when exporting a message to be delivered to another user.	1
exportKeepOrder	The original order in which the message header fields were set or imported are preserved when the message is exported.	2
exportNoHeaders	When exporting a message, the main header block will not be included. This can be useful when creating a multipart message for services which expect MIME formatted data, such as HTTP POST requests. This option should never be used for email messages being submitted using SMTP.	4

Requirements

Namespace: SocketTools

Assembly: SocketTools.MailMessage (in SocketTools.MailMessage.dll)

See Also

SocketTools Namespace

MailMessage.MimeSearch Enumeration

Specifies the search options supported by the MailMessage class.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]
```
<Flags>
Public Enum MailMessage.MimeSearch
```

[C#]
```
[Flags]
public enum MailMessage.MimeSearch
```

Members

Member Name	Description	Value
searchDefault	Perform a complete match against the specified header value. The comparison is not case-sensitive. It is the default search option used if a search option is not specified.	0
searchCaseSensitive	The header value comparison will be case-sensitive. Note that this does not affect header field names. Matches for header names are always case-insensitive.	1
searchPartialMatch	Perform a partial match against the specified header value. It recommended that this option be used when searching for matches to email addresses.	2
searchDecodeHeaders	Decode any encoded message headers before comparing them to the specified value. This option can increase the amount of time required to search the message store and should only be used when necessary.	4

Requirements

Namespace: SocketTools

Assembly: SocketTools.MailMessage (in SocketTools.MailMessage.dll)

See Also

SocketTools Namespace | FindMessage Method (SocketTools.MailMessage)

MailMessage.MimeStorage Enumeration

Specifies the message store access options supported by the MailMessage class.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]

```
<Flags>
Public Enum MailMessage.MimeStorage
```

[C#]

```
[Flags]
public enum MailMessage.MimeStorage
```

Members

Member Name	Description	Value
storeRead	The message store will be opened for read access. The contents of the message store can be accessed, but cannot be modified by the process unless it has also been opened for writing.	0
storeWrite	The message store will be opened for writing. This mode also implies read access and must be specified if the application needs to modify the contents of the message store.	1
storeCreate	The message store will be created if the storage file does not exist. If the file exists, it will be truncated. This mode implies read and write access.	2
storeLock	The message store will be opened so that it may only be accessed and modified by the current process.	4
storeCompress	The contents of the message store are compressed. This option is automatically enabled if a compressed message store is opened for reading or writing.	4096
storeMailbox	The message store should use the UNIX mbox format when reading and storing messages. This option is provided for backwards compatibility and is not recommended for general use.	8192

Requirements

Namespace: SocketTools

Assembly: SocketTools.MailMessage (in SocketTools.MailMessage.dll)

See Also

SocketTools Namespace | OpenStore Method (SocketTools.MailMessage)

MailMessage.OnErrorEventHandler Delegate

Represents the method that will handle the OnError event.

[Visual Basic]

```
Public Delegate Sub MailMessage.OnErrorEventHandler( _
   ByVal sender As Object, _
   ByVal e As ErrorEventArgs _
)
```

[C#]

```
public delegate void MailMessage.OnErrorEventHandler(
      object sender,
      ErrorEventArgs e
   );
```

Parameters

sender

The source of the event.

e

An ErrorEventArgs that contains the event data.

Remarks

When you create an **OnErrorEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnErrorEventHandler** delegate declaration.

Requirements

Namespace: SocketTools

Assembly: SocketTools.MailMessage (in SocketTools.MailMessage.dll)

See Also

SocketTools Namespace

MailMessage.RuntimeLicenseAttribute Class

Attribute that defines the runtime license key for the class.

For a list of all members of this type, see MailMessage.RuntimeLicenseAttribute Members.

System.Object
  System.Attribute
    SocketTools.MailMessage.RuntimeLicenseAttribute

[Visual Basic]

```
<AttributeUsage(ValidOn:=AttributeTargets.Assembly, AllowMultiple:=False,
   Inherited:=True)>
Public Class MailMessage.RuntimeLicenseAttribute
    Inherits Attribute
```

[C#]

```
[AttributeUsage(ValidOn=AttributeTargets.Assembly, AllowMultiple=False,
   Inherited=True)]
public class MailMessage.RuntimeLicenseAttribute : Attribute
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

The RuntimeLicense attribute is used to define the runtime license key that will be used when an instance of the class is created. This attribute is defined in the assembly information module for the language, such as AssemblyInfo.cs when programming C#. The runtime license key must be defined if you wish to redistribute your application.

The runtime license key for your copy of SocketTools can be generated using the License Manager utility that is included with the product. Note that if you have installed an evaluation license, you will not have a runtime license key and cannot redistribute any applications which use the MailMessage class.

Example

```
<Assembly: SocketTools.MailMessage.RuntimeLicense("abcdefghijklmnop")>
```

```
[assembly: SocketTools.MailMessage.RuntimeLicense("abcdefghijklmnop")]
```

Requirements

Namespace: SocketTools

Assembly: SocketTools.MailMessage (in SocketTools.MailMessage.dll)

See Also

MailMessage.RuntimeLicenseAttribute Members | SocketTools Namespace

MailMessage.RuntimeLicenseAttribute Members

MailMessage.RuntimeLicenseAttribute overview

Public Instance Constructors

MailMessage.RuntimeLicenseAttribute Constructor	Constructor for the RuntimeLicense attribute which defines the runtime license key.

Public Instance Properties

LicenseKey	Returns the value of the runtime license key.
TypeId (inherited from Attribute)	When implemented in a derived class, gets a unique identifier for this Attribute.

Public Instance Methods

Equals (inherited from Attribute)	
GetHashCode (inherited from Attribute)	Returns the hash code for this instance.
GetType (inherited from Object)	Gets the Type of the current instance.
IsDefaultAttribute (inherited from Attribute)	When overridden in a derived class, returns an indication whether the value of this instance is the default value for the derived class.
Match (inherited from Attribute)	When overridden in a derived class, returns a value indicating whether this instance equals a specified object.
ToString (inherited from Object)	Returns a String that represents the current Object.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

MailMessage.RuntimeLicenseAttribute Class | SocketTools Namespace

MailMessage.RuntimeLicenseAttribute Constructor

Constructor for the RuntimeLicense attribute which defines the runtime license key.

[Visual Basic]

```
Public Sub New( _
   ByVal licenseKey As String _
)
```

[C#]

```
public MailMessage.RuntimeLicenseAttribute(
   string licenseKey
);
```

Parameters

licenseKey

A string argument which specifies the runtime license key which will be used to initialize the class library.

Remarks

The runtime license key for your copy of SocketTools can be generated using the License Manager utility that is included with the product. Note that if you have installed an evaluation license, you will not have a runtime license key and cannot redistribute any applications which use the MailMessage class.

See Also

MailMessage.RuntimeLicenseAttribute Class | SocketTools Namespace

MailMessage.RuntimeLicenseAttribute Properties

The properties of the **MailMessage.RuntimeLicenseAttribute** class are listed below. For a complete list of **MailMessage.RuntimeLicenseAttribute** class members, see the MailMessage.RuntimeLicenseAttribute Members topic.

Public Instance Properties

LicenseKey	Returns the value of the runtime license key.
TypeId (inherited from Attribute)	When implemented in a derived class, gets a unique identifier for this Attribute.

See Also

MailMessage.RuntimeLicenseAttribute Class | SocketTools Namespace

MailMessage.RuntimeLicenseAttribute.LicenseKey Property

Returns the value of the runtime license key.

[Visual Basic]

```
Public Property LicenseKey As String
```

[C#]

```
public string LicenseKey {get; set;}
```

Property Value

A string which contains the runtime license key.

See Also

MailMessage.RuntimeLicenseAttribute Class | SocketTools Namespace

MailMessageException Class

The exception that is thrown when a client error occurs.

For a list of all members of this type, see MailMessageException Members.

System.Object
  System.Exception
    System.ApplicationException
      SocketTools.MailMessageException

[Visual Basic]

```
Public Class MailMessageException
    Inherits ApplicationException
```

[C#]

```
public class MailMessageException : ApplicationException
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

A MailMessageException is thrown by the MailMessage class when an error occurs.

The default constructor for the MailMessageException class sets the **ErrorCode** property to the last client error that occurred.

Requirements

Namespace: SocketTools

Assembly: SocketTools.MailMessage (in SocketTools.MailMessage.dll)

See Also

MailMessageException Members | SocketTools Namespace

MailMessageException Members

MailMessageException overview

Public Instance Constructors

MailMessageException	Overloaded. Initializes a new instance of the MailMessageException class.

Public Instance Properties

ErrorCode	Gets a value which specifies the error that caused the exception.
HelpLink (inherited from Exception)	Gets or sets a link to the help file associated with this exception.
InnerException (inherited from Exception)	Gets the Exception instance that caused the current exception.
Message	Gets a value which describes the error that caused the exception.
Number	Gets a value which specifies the numeric value of the error that caused the exception.
Source (inherited from Exception)	Gets or sets the name of the application or the object that causes the error.
StackTrace (inherited from Exception)	Gets a string representation of the frames on the call stack at the time the current exception was thrown.
TargetSite (inherited from Exception)	Gets the method that throws the current exception.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetBaseException (inherited from Exception)	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetObjectData (inherited from Exception)	When overridden in a derived class, sets the SerializationInfo with information about the exception.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString	Creates and returns a string representation of the current exception.

Protected Instance Properties

HResult (inherited from Exception)	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

MailMessageException Class | SocketTools Namespace

MailMessageException Constructor

Initializes a new instance of the MailMessageException class with the last network error code.

Overload List

Initializes a new instance of the MailMessageException class with the last network error code.

public MailMessageException();

Initializes a new instance of the MailMessageException class with a specified error number.

public MailMessageException(int);

Initializes a new instance of the MailMessageException class with a specified error message.

public MailMessageException(string);

Initializes a new instance of the MailMessageException class with a specified error message and a reference to the inner exception that is the cause of this exception.

public MailMessageException(string,Exception);

See Also

MailMessageException Class | SocketTools Namespace

MailMessageException Constructor ()

Initializes a new instance of the MailMessageException class with the last network error code.

[Visual Basic]

```
Overloads Public Sub New()
```

[C#]

```
public MailMessageException();
```

Remarks

The ctor constructor sets the **ErrorCode** property to the last client error that occurred. For more information about the errors that may occur, refer to the MailMessage.ErrorCode enumeration.

See Also

MailMessageException Class | SocketTools Namespace | MailMessageException Constructor Overload List

MailMessageException Constructor (String)

Initializes a new instance of the MailMessageException class with a specified error message.

[Visual Basic]

```
Overloads Public Sub New( _
   ByVal message As String _
)
```

[C#]

```
public MailMessageException(
   string message
);
```

Parameters

message
The error message that explains the reason for the exception.

Remarks

The content of the ***message*** parameter is intended to be understood by humans. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

See Also

MailMessageException Class | SocketTools Namespace | MailMessageException Constructor Overload List

MailMessageException Constructor (String, Exception)

Initializes a new instance of the MailMessageException class with a specified error message and a reference to the inner exception that is the cause of this exception.

```
[Visual Basic]
Overloads Public Sub New( _
   ByVal message As String, _
   ByVal innerException As Exception _
)
```

```
[C#]
public MailMessageException(
   string message,
   Exception innerException
);
```

Parameters

message
The error message that explains the reason for the exception.

innerException
The exception that is the cause of the current exception. If the ***innerException*** parameter is not a null reference, the current exception is raised in a **catch** block that handles the inner exception.

Remarks

The content of the message parameter is intended to be understood by humans. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

An exception that is thrown as a direct result of a previous exception should include a reference to the previous exception in the **InnerException** property. The **InnerException** property returns the same value that is passed into the constructor, or a null reference if the **InnerException** property does not supply the inner exception value to the constructor.

MailMessageException Class | SocketTools Namespace | MailMessageException Constructor Overload List

MailMessageException Constructor (Int32)

Initializes a new instance of the MailMessageException class with a specified error number.

```
[Visual Basic]
Overloads Public Sub New( _
   ByVal code As Integer _
)
```

```
[C#]
public MailMessageException(
   int code
);
```

Parameters

code

An integer value which specifies an error code.

Remarks

This constructor sets the **ErrorCode** property to the specified error code. For more information about the errors that may occur, refer to the MailMessage.ErrorCode enumeration.

See Also

MailMessageException Class | SocketTools Namespace | MailMessageException Constructor Overload List

MailMessageException Properties

The properties of the **MailMessageException** class are listed below. For a complete list of **MailMessageException** class members, see the MailMessageException Members topic.

Public Instance Properties

ErrorCode	Gets a value which specifies the error that caused the exception.
HelpLink (inherited from Exception)	Gets or sets a link to the help file associated with this exception.
InnerException (inherited from Exception)	Gets the Exception instance that caused the current exception.
Message	Gets a value which describes the error that caused the exception.
Number	Gets a value which specifies the numeric value of the error that caused the exception.
Source (inherited from Exception)	Gets or sets the name of the application or the object that causes the error.
StackTrace (inherited from Exception)	Gets a string representation of the frames on the call stack at the time the current exception was thrown.
TargetSite (inherited from Exception)	Gets the method that throws the current exception.

Protected Instance Properties

HResult (inherited from Exception)	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception.

See Also

MailMessageException Class | SocketTools Namespace

MailMessageException.ErrorCode Property

Gets a value which specifies the error that caused the exception.

[Visual Basic]
```
Public ReadOnly Property ErrorCode As ErrorCode
```

[C#]
```
public MailMessage.ErrorCode ErrorCode {get;}
```

Property Value

Returns a MailMessage.ErrorCode enumeration value which specifies the error code.

Remarks

The **ErrorCode** property returns the error code that specifies the cause of the exception.

The default constructor for the MailMessageException class sets the error code to the last network error that occurred. For more information about the errors that may occur, refer to the MailMessage.ErrorCode enumeration.

See Also

MailMessageException Class | SocketTools Namespace

MailMessageException.Message Property

Gets a value which describes the error that caused the exception.

[Visual Basic]

```
Overrides Public ReadOnly Property Message As String
```

[C#]

```
public override string Message {get;}
```

Property Value

A string which describes the error that caused the exception.

Remarks

The **Message** property returns a string which describes the error that caused the exception.

See Also

MailMessageException Class | SocketTools Namespace

MailMessageException.Number Property

Gets a value which specifies the numeric value of the error that caused the exception.

[Visual Basic]

```
Public ReadOnly Property Number As Integer
```

[C#]

```
public int Number {get;}
```

Property Value

An integer value that specifies the error that caused the exception.

Remarks

The **Number** property returns an integer value which specifies the numeric value of the error that caused the exception. This value is the same as the values returned by the Windows Sockets API. For more information about socket error codes, see the Windows Socket Version 2 API error code documentation in MSDN.

MailMessageException Class | SocketTools Namespace

MailMessageException Methods

The methods of the **MailMessageException** class are listed below. For a complete list of **MailMessageException** class members, see the MailMessageException Members topic.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetBaseException (inherited from Exception)	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetObjectData (inherited from Exception)	When overridden in a derived class, sets the SerializationInfo with information about the exception.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString	Creates and returns a string representation of the current exception.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

MailMessageException Class | SocketTools Namespace

MailMessageException.ToString Method

Creates and returns a string representation of the current exception.

[Visual Basic]

```
Overrides Public Function ToString() As String
```

[C#]

```
public override string ToString();
```

Return Value

A string representation of the current exception.

Remarks

The **ToString** method returns a representation of the current exception that is intended to be understood by humans. Where the exception contains culture-sensitive data, the string representation returned by **ToString** is required to take into account the current system culture. Although there are no exact requirements for the format of the returned string, it should attempt to reflect the value of the object as perceived by the user.

This implementation of **ToString** obtains the numeric error code value and a description of the error that caused the current exception. If there is no error message or it is an empty string, then no error message is returned.

This method overrides **ApplicationException.ToString**.

MailMessageException Class | SocketTools Namespace

NntpClient Class

Implements the Network News Transfer Protocol.

For a list of all members of this type, see NntpClient Members.

System.Object
  SocketTools.NntpClient

```
[Visual Basic]
Public Class NntpClient
    Implements IDisposable
```

```
[C#]
public class NntpClient : IDisposable
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

The Network News Transfer Protocol (NNTP) is used with servers that provide news services. This is similar in functionality to bulletin boards or message boards, where topics are organized hierarchically into groups, called newsgroups. Users can browse and search for messages, called news articles, which have been posted by other users. On many servers, they can also post their own articles which can be read by others. The largest collection of public newsgroups available is called USENET, a world-wide distributed discussion system. In addition, there are a large number of smaller news servers. For example, Microsoft operates a news server which functions as a forum for technical questions and announcements.

The NntpClient class provides a comprehensive interface for accessing newsgroups, retrieving articles and posting new articles. In combination with the MailMessage class to process the news articles, this class can be used to integrate newsgroup access with an existing email application, or you can implement your own full-featured newsgroup client.

This class supports secure connections using the standard SSL and TLS protocols.

Requirements

Namespace: SocketTools

Assembly: SocketTools.NntpClient (in SocketTools.NntpClient.dll)

See Also

NntpClient Members | SocketTools Namespace

NntpClient Members

NntpClient overview

Public Static (Shared) Fields

nntpPortDefault	A constant value which specifies the default port number.
nntpPortSecure	A constant value which specifies the default port number for a secure connection.
nntpTimeout	A constant value which specifies the default timeout period.

Public Instance Constructors

NntpClient Constructor	Initializes a new instance of the NntpClient class.

Public Instance Properties

Article	Gets and sets the current article number in the selected newsgroup.
ArticleCount	Gets the number of available articles in the current newsgroup.
AutoResolve	Gets and sets a value that determines if host names and addresses are automatically resolved.
Blocking	Gets and sets a value which indicates if the client is in blocking mode.
CertificateExpires	Get a value that specifies the date that the security certificate expires.
CertificateIssued	Get a value that specifies the date that the security certificate was issued.
CertificateIssuer	Get a value that provides information about the organization that issued the certificate.
CertificateName	Gets and sets a value that specifies the name of the client certificate.
CertificatePassword	Gets and sets the password associated with the client certificate.
CertificateStatus	Gets a value which indicates the status of the security certificate returned by the remote host.
CertificateStore	Gets and sets a value that specifies the name of the local certificate store.
CertificateSubject	Gets a value that provides information about the organization that the server certificate was issued to.
CertificateUser	Gets and sets the user that owns the client certificate.

CipherStrength	Gets a value that indicates the length of the key used by the encryption algorithm for a secure connection.
FirstArticle	Gets the first available article in the selected newsgroup.
GroupName	Gets and sets the name of the currently selected newsgroup.
GroupTitle	Gets the title associated with the currently selected newsgroup.
Handle	Gets a value that specifies the client handle allocated for the current session.
HashStrength	Gets a value which specifies the length of the message digest that was selected for a secure connection.
HostAddress	Gets and sets a value which specifies the Internet address used to establish a connection.
HostName	Gets and sets a value which specifies the host name used to establish a connection.
IsBlocked	Gets a value which indicates if the current thread is performing a blocking client operation.
IsConnected	Gets a value which indicates if a connection to the remote host has been established.
IsInitialized	Gets a value which indicates if the current instance of the class has been initialized successfully.
IsReadable	Gets a value which indicates if there is data available to be read from the socket connection to the server.
IsWritable	Gets a value which indicates if data can be written to the client without blocking.
LastArticle	Gets the last available article in the selected newsgroup.
LastError	Gets and sets a value which specifies the last error that has occurred.
LastErrorString	Gets a value which describes the last error that has occurred.
LocalAddress	Gets the local Internet address that the client is bound to.
Localize	Gets a value that specifies if the date and time are localized.
LocalName	Gets a value which specifies the host name for the local system.
LocalPort	Gets the local port number the client is bound to.
MessageId	Gets the unique message identifier for the current

	news article.
Options	Gets and sets a value which specifies one or more client options.
Password	Gets and sets the password used to authenticate the client session.
RemotePort	Gets and sets a value which specifies the remote port number.
RemoteService	Gets and sets a value which specifies the remote service.
ResultCode	Gets a value which specifies the last result code returned by the server.
ResultString	Gets a string value which describes the result of the previous command.
Secure	Gets and sets a value which specifies if a secure connection is established.
SecureCipher	Gets a value that specifies the encryption algorithm used for a secure connection.
SecureHash	Gets a value that specifies the message digest algorithm used for a secure connection.
SecureKeyExchange	Gets a value that specifies the key exchange algorithm used for a secure connection.
SecureProtocol	Gets and sets a value which specifies the protocol used for a secure connection.
Status	Gets a value which specifies the current status of the client.
ThreadModel	Gets and sets a value which specifies the threading model for the class instance.
ThrowError	Gets and sets a value which specifies if method calls should throw exceptions when an error occurs.
Timeout	Gets and sets a value which specifies a timeout period in seconds.
TimeZone	Gets and sets the current timezone offset in seconds.
Trace	Gets and sets a value which indicates if network function logging is enabled.
TraceFile	Gets and sets a value which specifies the name of the logfile.
TraceFlags	Gets and sets a value which specifies the client function tracing flags.
UserName	Gets and sets the username used to authenticate the client session.

Version	Gets a value which returns the current version of the NntpClient class library.

Public Instance Methods

AttachThread	Attach an instance of the class to the current thread
Authenticate	Overloaded. Authenticate the client session with a username and password.
Cancel	Cancel the current blocking client operation.
CloseArticle	Closes the current article that has been opened or created.
Command	Overloaded. Send a custom command to the server.
Connect	Overloaded. Establish a connection with a remote host.
CreateArticle	Creates a new article in the current newsgroup.
Disconnect	Terminate the connection with a remote host.
Dispose	Overloaded. Releases all resources used by NntpClient.
Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetArticle	Overloaded. Retrieve an article from the server.
GetFirstArticle	Overloaded. Return information about a selected range of articles in the current newsgroup.
GetFirstGroup	Overloaded. Return information about newsgroups created after the specified date.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetHeaders	Overloaded. Retrieves the headers for the specified article from the server.
GetNextArticle	Return information about the next article available in the current newsgroup.
GetNextGroup	Return information about the next available newsgroup.
GetType (inherited from Object)	Gets the Type of the current instance.
Initialize	Overloaded. Initialize an instance of the NntpClient class.
OpenArticle	Overloaded. Opens the specified article in the currently selected newsgroup.
PostArticle	Overloaded. Post a new article to the currently selected newsgroup.

Read	Overloaded. Read data from the server and store it in a byte array.
Reset	Reset the internal state of the object, resetting all properties to their default values.
SelectGroup	Selects the specified newsgroup as the current newsgroup.
StoreArticle	Overloaded. Retrieve an article from the selected newsgroup and store it in a file.
ToString (inherited from Object)	Returns a String that represents the current Object.
Uninitialize	Uninitialize the class library and release any resources allocated for the current thread.
Write	Overloaded. Write one or more bytes of data to the server.

Public Instance Events

OnCancel	Occurs when a blocking client operation is canceled.
OnCommand	Occurs when the client sends a command to the remote host and receives a reply indicating the result of that command.
OnConnect	Occurs when a connection is established with the remote host.
OnDisconnect	Occurs when the remote host disconnects from the local system.
OnError	Occurs when an client operation fails.
OnProgress	Occurs as a data stream is being read or written to the client.
OnRead	Occurs when data is available to be read from the client.
OnTimeout	Occurs when a blocking operation fails to complete before the timeout period elapses.
OnWrite	Occurs when data can be written to the client.

Protected Instance Methods

Dispose	Overloaded. Releases the unmanaged resources allocated by the NntpClient class and optionally releases the managed resources.
Finalize	Destroys an instance of the class, releasing the resources allocated for the session and unloading the networking library.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

NntpClient Properties

The properties of the **NntpClient** class are listed below. For a complete list of **NntpClient** class members, see the NntpClient Members topic.

Public Instance Properties

Article	Gets and sets the current article number in the selected newsgroup.
ArticleCount	Gets the number of available articles in the current newsgroup.
AutoResolve	Gets and sets a value that determines if host names and addresses are automatically resolved.
Blocking	Gets and sets a value which indicates if the client is in blocking mode.
CertificateExpires	Get a value that specifies the date that the security certificate expires.
CertificateIssued	Get a value that specifies the date that the security certificate was issued.
CertificateIssuer	Get a value that provides information about the organization that issued the certificate.
CertificateName	Gets and sets a value that specifies the name of the client certificate.
CertificatePassword	Gets and sets the password associated with the client certificate.
CertificateStatus	Gets a value which indicates the status of the security certificate returned by the remote host.
CertificateStore	Gets and sets a value that specifies the name of the local certificate store.
CertificateSubject	Gets a value that provides information about the organization that the server certificate was issued to.
CertificateUser	Gets and sets the user that owns the client certificate.
CipherStrength	Gets a value that indicates the length of the key used by the encryption algorithm for a secure connection.
FirstArticle	Gets the first available article in the selected newsgroup.
GroupName	Gets and sets the name of the currently selected newsgroup.
GroupTitle	Gets the title associated with the currently selected newsgroup.
Handle	Gets a value that specifies the client handle

	allocated for the current session.
HashStrength	Gets a value which specifies the length of the message digest that was selected for a secure connection.
HostAddress	Gets and sets a value which specifies the Internet address used to establish a connection.
HostName	Gets and sets a value which specifies the host name used to establish a connection.
IsBlocked	Gets a value which indicates if the current thread is performing a blocking client operation.
IsConnected	Gets a value which indicates if a connection to the remote host has been established.
IsInitialized	Gets a value which indicates if the current instance of the class has been initialized successfully.
IsReadable	Gets a value which indicates if there is data available to be read from the socket connection to the server.
IsWritable	Gets a value which indicates if data can be written to the client without blocking.
LastArticle	Gets the last available article in the selected newsgroup.
LastError	Gets and sets a value which specifies the last error that has occurred.
LastErrorString	Gets a value which describes the last error that has occurred.
LocalAddress	Gets the local Internet address that the client is bound to.
Localize	Gets a value that specifies if the date and time are localized.
LocalName	Gets a value which specifies the host name for the local system.
LocalPort	Gets the local port number the client is bound to.
MessageId	Gets the unique message identifier for the current news article.
Options	Gets and sets a value which specifies one or more client options.
Password	Gets and sets the password used to authenticate the client session.
RemotePort	Gets and sets a value which specifies the remote port number.
RemoteService	Gets and sets a value which specifies the remote service.

ResultCode	Gets a value which specifies the last result code returned by the server.
ResultString	Gets a string value which describes the result of the previous command.
Secure	Gets and sets a value which specifies if a secure connection is established.
SecureCipher	Gets a value that specifies the encryption algorithm used for a secure connection.
SecureHash	Gets a value that specifies the message digest algorithm used for a secure connection.
SecureKeyExchange	Gets a value that specifies the key exchange algorithm used for a secure connection.
SecureProtocol	Gets and sets a value which specifies the protocol used for a secure connection.
Status	Gets a value which specifies the current status of the client.
ThreadModel	Gets and sets a value which specifies the threading model for the class instance.
ThrowError	Gets and sets a value which specifies if method calls should throw exceptions when an error occurs.
Timeout	Gets and sets a value which specifies a timeout period in seconds.
TimeZone	Gets and sets the current timezone offset in seconds.
Trace	Gets and sets a value which indicates if network function logging is enabled.
TraceFile	Gets and sets a value which specifies the name of the logfile.
TraceFlags	Gets and sets a value which specifies the client function tracing flags.
UserName	Gets and sets the username used to authenticate the client session.
Version	Gets a value which returns the current version of the NntpClient class library.

See Also

NntpClient Class | SocketTools Namespace

NntpClient.Article Property

Gets and sets the current article number in the selected newsgroup.

[Visual Basic]

```
Public Property Article As Integer
```

[C#]

```
public int Article {get; set;}
```

Property Value

An integer value which specifies the article number.

Remarks

When a newsgroup is selected using the **SelectGroup** method, the value of this property is initialized to the first available news article in the group.

Setting the **Article** property updates the **MessageId** property to reflect the specified article's message ID.

See Also

NntpClient Class | SocketTools Namespace

NntpClient.ArticleCount Property

Gets the number of available articles in the current newsgroup.

[Visual Basic]
```
Public ReadOnly Property ArticleCount As Integer
```

[C#]
```
public int ArticleCount {get;}
```

Property Value

An integer value which specifies the number of available news articles.

Remarks

This property value is only meaningful after the **SelectGroup** method has been called.

See Also

NntpClient Class | SocketTools Namespace

NntpClient.AutoResolve Property

Gets and sets a value that determines if host names and addresses are automatically resolved.

[Visual Basic]

```
Public Property AutoResolve As Boolean
```

[C#]

```
public bool AutoResolve {get; set;}
```

Property Value

Returns **true** if host names are automatically resolved to Internet addresses. The default value is **false**.

Remarks

Setting the **AutoResolve** property determines if the class automatically resolves host names and addresses specified by the **HostName** and **HostAddress** properties. If set to **true**, setting the **HostName** property will cause the class to automatically determine the corresponding IP address and update the **HostAddress** property accordingly. Likewise, setting the **HostAddress** property will cause the class to determine the host name and update the **HostName** property. Setting this property to **false** prevents the class from resolving host names until a connection attempt is made.

It is important to note that setting the **HostName** or **HostAddress** property may cause the current thread to block, sometimes for several seconds, until the name or address is resolved. To prevent this behavior, set this property value to **false**.

See Also

NntpClient Class | SocketTools Namespace

NntpClient.Blocking Property

Gets and sets a value which indicates if the client is in blocking mode.

[Visual Basic]

```
Public Property Blocking As Boolean
```

[C#]

```
public bool Blocking {get; set;}
```

Property Value

Returns **true** if the client is in blocking mode; otherwise it returns **false**. The default value is **true**.

Remarks

Setting the **Blocking** property determines if client operations complete synchronously or asynchronously. If set to **true**, then each client operation (such as sending or receiving data) will return when the operation has completed or timed-out. If set to **false**, client operations will return immediately. If the operation would result in the client blocking (such as attempting to read data when no data has been sent by the remote host), an error is generated.

It is important to note that certain events, such as **OnDisconnect, OnRead** and **OnWrite** are only fired if the client is in non-blocking mode.

See Also

NntpClient Class | SocketTools Namespace

NntpClient.CertificateExpires Property

Get a value that specifies the date that the security certificate expires.

[Visual Basic]

```
Public ReadOnly Property CertificateExpires As String
```

[C#]

```
public string CertificateExpires {get;}
```

Property Value

A string which specifies a date using the local date and time format.

Remarks

The **CertificateExpires** property returns a string that specifies the date and time that the security certificate expires. This property will return an empty string if a secure connection has not been established with the remote host.

See Also

NntpClient Class | SocketTools Namespace

NntpClient.CertificateIssued Property

Get a value that specifies the date that the security certificate was issued.

[Visual Basic]

```
Public ReadOnly Property CertificateIssued As String
```

[C#]

```
public string CertificateIssued {get;}
```

Property Value

A string which specifies a date using the local date and time format.

Remarks

The **CertificateIssued** property returns a string that specifies the date and time that the security certificate was issued. This property will return an empty string if a secure connection has not been established with the remote host.

See Also

NntpClient Class | SocketTools Namespace

NntpClient.CertificateIssuer Property

Get a value that provides information about the organization that issued the certificate.

[Visual Basic]

```
Public ReadOnly Property CertificateIssuer As String
```

[C#]

```
public string CertificateIssuer {get;}
```

Property Value

A string that contains a comma separated list of name value pairs.

Remarks

The **CertificateIssuer** property returns a string that contains information about the organization that issued the server certificate. The string value is a comma separated list of tagged name and value pairs. In the nomenclature of the X.500 standard, each of these pairs are called a relative distinguished name (RDN), and when concatenated together, forms the issuer's distinguished name (DN). For example:

```
C=US, O="RSA Data Security, Inc.", OU=Secure Server Certification Authority
```

To obtain a specific value, such as the name of the issuer or the issuer's country, the application must parse the string returned by this property. Some of the common tokens used in the distinguished name are:

Token	Description
C	The ISO standard two character country code.
S	The name of the state or province.
L	The name of the city or locality.
O	The name of the company or organization.
OU	The name of the department or organizational unit
CN	The common name; with X.509 certificates, this is the domain name of the site the certificate was issued for.

This property will return an empty string if a secure connection has not been established with the remote host.

See Also

NntpClient Class | SocketTools Namespace

NntpClient.CertificateName Property

Gets and sets a value that specifies the name of the client certificate.

[Visual Basic]

```
Public Property CertificateName As String
```

[C#]

```
public string CertificateName {get; set;}
```

Property Value

A string which specifies the certificate name.

Remarks

The **CertificateName** property is used to specify the name of a client certificate to use when establishing a secure connection. It is only required that you set this property value if the server requires a client certificate for authentication. If this property is not set, a client certificate will not be provided to the server. If a certificate name is specified, the certificate must have a private key associated with it, otherwise the connection attempt will fail because the control will be unable to create a security context for the session.

When the certificate store is searched for a matching certificate, it will first search for any certificate with a friendly name that matches the property value. If no valid certificate is found, it will then search for a certificate with a matching common name.

Certificates may be installed and viewed on the local system using the Certificate Manager that is included with the Windows operating system. For more information, refer to the documentation for the Microsoft Management Console.

See Also

NntpClient Class | SocketTools Namespace | CertificateStore Property | Secure Property

NntpClient.CertificateStatus Property

Gets a value which indicates the status of the security certificate returned by the remote host.

[Visual Basic]

```
Public ReadOnly Property CertificateStatus As SecurityCertificate
```

[C#]

```
public NntpClient.SecurityCertificate CertificateStatus {get;}
```

Property Value

A SecurityCertificate enumeration value which specifies the status of the certificate.

Remarks

The **CertificateStatus** property is used to determine the status of the security certificate returned by the remote host when a secure connection has been established. This property value should be checked after the connection to the server has completed, but prior to beginning a transaction.

Note that if the certificate cannot be validated, the secure connection will not be automatically terminated. It is the responsibility of your application to determine the best course of action to take if the certificate is invalid. Even if the security certificate cannot be validated, the data exchanged with the remote host will still be encrypted.

See Also

NntpClient Class | SocketTools Namespace

NntpClient.CertificateStore Property

Gets and sets a value that specifies the name of the local certificate store.

[Visual Basic]
```
Public Property CertificateStore As String
```

[C#]
```
public string CertificateStore {get; set;}
```

Property Value

A string which specifies the certificate store name. The default value is the current user's personal certificate store.

Remarks

The **CertificateStore** property is used to specify the name of the certificate store which contains the security certificate to use when establishing a secure connection. The certificate may either be stored in the registry or in a file. If the certificate is stored in the registry, then this property should be set to one of the following predefined values:

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as VeriSign and Thawte act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. If a certificate store is not specified, this is the default value that is used.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as VeriSign and Thawte are installed as part of the operating system and periodically updated by Microsoft.

In most cases the client certificate will be installed in the user's personal certificate store, and therefore it is not necessary to set this property value because that is the default location that will be used to search for the certificate. This property is only used if the **CertificateName** property is also set to a valid certificate name.

If you are using a local certificate store, with the certificate and private key stored in the registry, you can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU" for the current user, or "HKLM" for the local machine. For example, a certificate store name of "HKLM:MY" would specify the personal certificate store for the local machine, rather than the current user. If neither prefix is specified, it will default to the certificate store for the current user.

This property may also be used to specify a file that contains the client certificate. In this case, the property should specify the full path to the file and must contain both the certificate and private key in PKCS12

format. If the file is protected by a password, the **CertificatePassword** property must also be set to specify the password.

See Also

NntpClient Class | SocketTools Namespace | CertificatePassword Property | Secure Property

NntpClient.CertificateSubject Property

Gets a value that provides information about the organization that the server certificate was issued to.

[Visual Basic]

```
Public ReadOnly Property CertificateSubject As String
```

[C#]

```
public string CertificateSubject {get;}
```

Property Value

A string that contains a comma separated list of name value pairs.

Remarks

The **CertificateSubject** property returns a string that contains information about the organization that the server certificate was issued to. The string value is a comma separated list of tagged name and value pairs. In the nomenclature of the X.500 standard, each of these pairs are called a relative distinguished name (RDN), and when concatenated together, forms the issuer's distinguished name (DN). For example:

```
C=US, O="RSA Data Security, Inc.", OU=Secure Server Certification Authority
```

To obtain a specific value, such as the name of the issuer or the issuer's country, the application must parse the string returned by this property. Some of the common tokens used in the distinguished name are:

Token	Description
C	The ISO standard two character country code.
S	The name of the state or province.
L	The name of the city or locality.
O	The name of the company or organization.
OU	The name of the department or organizational unit
CN	The common name; with X.509 certificates, this is the domain name of the site the certificate was issued for.

This property will return an empty string if a secure connection has not been established with the remote host.

See Also

NntpClient Class | SocketTools Namespace

NntpClient.CipherStrength Property

Gets a value that indicates the length of the key used by the encryption algorithm for a secure connection.

[Visual Basic]

```
Public ReadOnly Property CipherStrength As Integer
```

[C#]

```
public int CipherStrength {get;}
```

Property Value

An integer value which specifies the encryption key length if a secure connection has been established; otherwise a value of 0 is returned.

Remarks

The **CipherStrength** property returns the number of bits in the key used to encrypt the secure data stream. Common values returned by this property are 128 and 256. A key length of 40 or 56 bits is considered insecure and subject to brute force attacks. 128-bit and 256-bit keys are considered secure. If this property returns a value of 0, this means that a secure connection has not been established with the remote host.

See Also

NntpClient Class | SocketTools Namespace

NntpClient.FirstArticle Property

Gets the first available article in the selected newsgroup.

[Visual Basic]
```
Public Property FirstArticle As Integer
```

[C#]
```
public int FirstArticle {get; set;}
```

Property Value

An integer value which specifies the first article number.

See Also

NntpClient Class | SocketTools Namespace

NntpClient.GroupName Property

Gets and sets the name of the currently selected newsgroup.

[Visual Basic]

```
Public Property GroupName As String
```

[C#]

```
public string GroupName {get; set;}
```

Property Value

A string which specifies the current newsgroup name.

Remarks

Setting this property value is similar to calling the **SelectGroup** method. The current newsgroup will change to the specified newsgroup and the current article will be changed to the first available article in the group.

See Also

NntpClient Class | SocketTools Namespace

NntpClient.GroupTitle Property

Gets the title associated with the currently selected newsgroup.

[Visual Basic]

```
Public ReadOnly Property GroupTitle As String
```

[C#]

```
public string GroupTitle {get;}
```

Property Value

A string describing the currently selected newsgroup.

Remarks

The news server must support the XGTITLE command so that the group description can be obtained when the newsgroup is selected. If this command is not recognized, then no description will be returned.

See Also

NntpClient Class | SocketTools Namespace

NntpClient.Handle Property

Gets a value that specifies the client handle allocated for the current session.

[Visual Basic]

```
Public ReadOnly Property Handle As Integer
```

[C#]

```
public int Handle {get;}
```

Property Value

An integer which represents a client handle. If there is no active connection, a value of -1 is returned.

Remarks

The **Handle** property specifies the numeric descriptor of the current client session.

See Also

NntpClient Class | SocketTools Namespace

NntpClient.HashStrength Property

Gets a value which specifies the length of the message digest that was selected for a secure connection.

[Visual Basic]

```
Public ReadOnly Property HashStrength As Integer
```

[C#]

```
public int HashStrength {get;}
```

Property Value

An integer value which specifies the length of the message digest if a secure connection has been established; otherwise a value of 0 is returned.

Remarks

The **HashStrength** property returns the number of bits used in the message digest (hash) that was selected. Common values returned by this property are 128 and 160. If this property returns a value of 0, this means that a secure connection has not been established with the remote host.

See Also

NntpClient Class | SocketTools Namespace

NntpClient.HostAddress Property

Gets and sets a value which specifies the Internet address used to establish a connection.

[Visual Basic]

```
Public Property HostAddress As String
```

[C#]

```
public string HostAddress {get; set;}
```

Property Value

A string which specifies an Internet address.

Remarks

The **HostAddress** property can be used to set the Internet address for a remote system that you wish to communicate with. If the **AutoResolve** property is set to **true** and the address is assigned to a valid host name, the **HostName** property will be updated with that value.

See Also

NntpClient Class | SocketTools Namespace

NntpClient.HostName Property

Gets and sets a value which specifies the host name used to establish a connection.

[Visual Basic]

```
Public Property HostName As String
```

[C#]

```
public string HostName {get; set;}
```

Property Value

A string which specifies a host name.

Remarks

The **HostName** property can be used to set the host name for a remote system that you wish to communicate with. If the **AutoResolve** property is set to **true** and the name can be resolved to a valid Internet address, the **HostAddress** property will be updated with that value.

See Also

NntpClient Class | SocketTools Namespace

NntpClient.IsBlocked Property

Gets a value which indicates if the current thread is performing a blocking client operation.

[Visual Basic]
```
Public ReadOnly Property IsBlocked As Boolean
```

[C#]
```
public bool IsBlocked {get;}
```

Property Value

Returns **true** if the current thread is blocking, otherwise returns **false**.

Remarks

The **IsBlocked** property returns **true** if the current thread is blocked performing an operation. Because the Windows Sockets API only permits one blocking operation per thread of execution, this property should be checked before starting any blocking operation in response to an event.

If the **IsBlocked** property returns **false**, this means there are no blocking operations on the current thread at that time. However, this does not guarantee that the next client operation will not fail. An application should always check the return value from a client operation and check the value of the **LastError** property if an error occurs.

Note that this property will return **true** if there is any blocking operation being performed by the current thread, regardless of whether this specific instance of the class is responsible for the blocking operation or not.

See Also

NntpClient Class | SocketTools Namespace

NntpClient.IsConnected Property

Gets a value which indicates if a connection to the remote host has been established.

[Visual Basic]
```
Public ReadOnly Property IsConnected As Boolean
```

[C#]
```
public bool IsConnected {get;}
```

Property Value

Returns **true** if the connection has been established; otherwise returns **false**.

Remarks

The **IsConnected** property can only be used to indicate if there is still a logical connection to the remote host. It cannot be used to detect abnormal conditions such as the remote host aborting the connection, the physical network connection being lost or other critical errors.

See Also

NntpClient Class | SocketTools Namespace

NntpClient.IsInitialized Property

Gets a value which indicates if the current instance of the class has been initialized successfully.

[Visual Basic]

```
Public ReadOnly Property IsInitialized As Boolean
```

[C#]

```
public bool IsInitialized {get;}
```

Property Value

Returns **true** if the class instance has been initialized; otherwise returns **false**.

Remarks

The **IsInitialized** property is used to determine if the current instance of the class has been initialized properly. Normally this is done automatically by the class constructor, however there are circumstances where the class may not be able to initialize itself.

The most common reasons that a class instance may not initialize correctly is that no runtime license key has been defined in the assembly or the license key provided is invalid. It may also indicate a problem with the system configuration or user access rights, such as not being able to load the required networking libraries or not being able to access the system registry.

See Also

NntpClient Class | SocketTools Namespace

NntpClient.IsReadable Property

Gets a value which indicates if there is data available to be read from the socket connection to the server.

[Visual Basic]

```
Public ReadOnly Property IsReadable As Boolean
```

[C#]

```
public bool IsReadable {get;}
```

Property Value

Returns **true** if there is data available to be read; otherwise returns **false**.

Remarks

The **IsReadable** property returns **true** if data can be read from the client without blocking. For non-blocking sessions, this property can be checked before the application attempts to read the client. Note that even if this property does return **true** indicating that there is data available to be read, applications should always check the return value from the **Read** method.

See Also

NntpClient Class | SocketTools Namespace

NntpClient.IsWritable Property

Gets a value which indicates if data can be written to the client without blocking.

[Visual Basic]
```
Public ReadOnly Property IsWritable As Boolean
```

[C#]
```
public bool IsWritable {get;}
```

Property Value

Returns **true** if data can be written to the client; otherwise returns **false**.

Remarks

The **IsWritable** property returns **true** if data can be written to the client without blocking. For non-blocking sessions, this property can be checked before the application attempts to write data to the client. Note that even if this property does return **true** indicating that data can be written to the client, applications should always check the return value from the **Write** method.

See Also

NntpClient Class | SocketTools Namespace

NntpClient.LastArticle Property

Gets the last available article in the selected newsgroup.

[Visual Basic]

```
Public Property LastArticle As Integer
```

[C#]

```
public int LastArticle {get; set;}
```

Property Value

An integer value which specifies the last article number.

See Also

NntpClient Class | SocketTools Namespace

NntpClient.LastError Property

Gets and sets a value which specifies the last error that has occurred.

[Visual Basic]

```
Public Property LastError As ErrorCode
```

[C#]

```
public NntpClient.ErrorCode LastError {get; set;}
```

Property Value

Returns an ErrorCode enumeration value which specifies the last error code.

Remarks

The **LastError** property returns the error code associated with the last error that occurred for the current instance of the class. It is important to note that this value only has meaning if the previous method indicates that an error has actually occurred.

It is possible to explicitly clear the last error code by assigning the property to the value **ErrorCode.errorNone**.

The error code value can be cast to an integer value for display purposes if required. For a description of the error that can be displayed using a message box or some other similar mechanism, get the value of the **LastErrorString** property.

See Also

NntpClient Class | SocketTools Namespace

NntpClient.LastErrorString Property

Gets a value which describes the last error that has occurred.

[Visual Basic]

```
Public ReadOnly Property LastErrorString As String
```

[C#]

```
public string LastErrorString {get;}
```

Property Value

A string which describes the last error that has occurred.

Remarks

The **LastErrorString** property can be used to obtain a description of the last error that occurred for the current instance of the class. It is important to note that this value only has meaning if the previous method indicates that an error has actually occurred.

See Also

NntpClient Class | SocketTools Namespace

NntpClient.LocalAddress Property

Gets the local Internet address that the client is bound to.

[Visual Basic]
```
Public ReadOnly Property LocalAddress As String
```

[C#]
```
public string LocalAddress {get;}
```

Property Value

A string which specifies an Internet address.

Remarks

The **LocalAddress** property returns the local Internet address that the client is bound to when a connection is established with a remote host. This property may return either an IPv4 or IPv6 formatted address, depending on the type of connection that was established.

See Also

NntpClient Class | SocketTools Namespace

NntpClient.Localize Property

Gets a value that specifies if the date and time are localized.

[Visual Basic]

```
Public Property Localize As Boolean
```

[C#]

```
public bool Localize {get; set;}
```

Property Value

A boolean value which specifies if the date and time is localized.

Remarks

Setting the **Localize** property controls how date and time values are localized. If the property is set to **true**, then the date and time will be adjusted to the current timezone. If the property is set to **false**, the date and time are returned as UTC (Coordinated Universal Time) values.

See Also

NntpClient Class | SocketTools Namespace

NntpClient.LocalName Property

Gets a value which specifies the host name for the local system.

[Visual Basic]

```
Public ReadOnly Property LocalName As String
```

[C#]

```
public string LocalName {get;}
```

Property Value

A string which specifies the local host name.

Remarks

The **LocalName** property returns the fully-qualified host name assigned to the local system. If the system has not been configured with an Internet domain name, then this property will return the NetBIOS name assigned to the local system.

See Also

NntpClient Class | SocketTools Namespace

NntpClient.LocalPort Property

Gets the local port number the client is bound to.

[Visual Basic]
```
Public ReadOnly Property LocalPort As Integer
```

[C#]
```
public int LocalPort {get;}
```

Property Value

An integer value which specifies a port number. The default value is 0.

Remarks

The **LocalPort** property is used to identify the local port number that the client is bound to to when a connection is established with a remote host.

See Also

NntpClient Class | SocketTools Namespace

NntpClient.MessageId Property

Gets the unique message identifier for the current news article.

[Visual Basic]

```
Public Property MessageId As String
```

[C#]

```
public string MessageId {get; set;}
```

Property Value

A string that specifies the unique message identifier for the current article.

Remarks

Setting this property will cause the current article number to change to match the article that the message identifier specifies. If no such article exists, an exception will be generated.

See Also

NntpClient Class | SocketTools Namespace

NntpClient.Options Property

Gets and sets a value which specifies one or more client options.

[Visual Basic]

```
Public Property Options As NewsOptions
```

[C#]

```
public NntpClient.NewsOptions Options {get; set;}
```

Property Value

Returns one or more NewsOptions enumeration flags which specify the options for the client. The default value for this property is **NewsOptions.optionNone**.

Remarks

The **Options** property specifies one or more default options options which are used when establishing a connection using the **Connect** method.

See Also

NntpClient Class | SocketTools Namespace

NntpClient.Password Property

Gets and sets the password used to authenticate the client session.

[Visual Basic]

```
Public Property Password As String
```

[C#]

```
public string Password {get; set;}
```

Property Value

A string which specifies the password.

Remarks

If a password is not specified when the **Connect** method is called, the value of this property will be used as the default password when establishing a connection with the server.

See Also

NntpClient Class | SocketTools Namespace

NntpClient.RemotePort Property

Gets and sets a value which specifies the remote port number.

[Visual Basic]

```
Public Property RemotePort As Integer
```

[C#]

```
public int RemotePort {get; set;}
```

Property Value

An integer value which specifies a port number.

Remarks

The **RemotePort** property is used to set the port number that will be used to establish a connection with a remote host. If the port number specifies a well-known port, the **RemoteService** property will be updated with that name.

See Also

NntpClient Class | SocketTools Namespace

NntpClient.ResultCode Property

Gets a value which specifies the last result code returned by the server.

[Visual Basic]

```
Public ReadOnly Property ResultCode As Integer
```

[C#]

```
public int ResultCode {get;}
```

Property Value

An integer value which specifies the last result code returned by the server.

Remarks

Result codes are three-digit numeric values returned by the remote server and may be broken down into the following ranges:

ResultCode	Description
100-199	Positive preliminary result. This indicates that the requested action is being initiated, and the client should expect another reply from the server before proceeding.
200-299	Positive completion result. This indicates that the server has successfully completed the requested action.
300-399	Positive intermediate result. This indicates that the requested action cannot complete until additional information is provided to the server.
400-499	Transient negative completion result. This indicates that the requested action did not take place, but the error condition is temporary and may be attempted again.
500-599	Permanent negative completion result. This indicates that the requested action did not take place.

It is important to note that while some result codes have become standardized, not all servers respond to commands using the same result codes. For example, one server may respond with a result code of 221 to indicate success, while another may respond with a value of 235. It is recommended that applications check for ranges of values to determine if a command was successful, not a specific value.

See Also

NntpClient Class | SocketTools Namespace

NntpClient.ResultString Property

Gets a string value which describes the result of the previous command.

[Visual Basic]

```
Public ReadOnly Property ResultString As String
```

[C#]

```
public string ResultString {get;}
```

Property Value

A string which describes the result of the previous command executed on the server.

Remarks

The **ResultString** property returns the result string from the last action taken by the client. This string is generated by the remote server, and typically is used to describe the result code. For example, if an error is indicated by the result code, the result string may describe the condition that caused the error.

See Also

NntpClient Class | SocketTools Namespace

NntpClient.Secure Property

Gets and sets a value which specifies if a secure connection is established.

[Visual Basic]

```
Public Property Secure As Boolean
```

[C#]

```
public bool Secure {get; set;}
```

Property Value

Returns **true** if a secure connection is established; otherwise returns **false**. The default value is **false**.

Remarks

The **Secure** property determines if a secure connection is established with the remote host. The default value for this property is **false**, which specifies that a standard connection to the server is used. To establish a secure connection, the application should set this property value to **true** prior to calling the **Connect** method. Once the connection has been established, the client may exchange data with the server as with standard connections.

It is strongly recommended that any application that sets this property **true** use error handling to trap an errors that may occur. If the control is unable to initialize the security libraries, or otherwise cannot create a secure session for the client, an exception may be generated when this property value is set.

See Also

NntpClient Class | SocketTools Namespace

NntpClient.SecureCipher Property

Gets a value that specifies the encryption algorithm used for a secure connection.

[Visual Basic]

```
Public ReadOnly Property SecureCipher As SecureCipherAlgorithm
```

[C#]

```
public NntpClient.SecureCipherAlgorithm SecureCipher {get;}
```

Property Value

A SecureCipherAlgorithm enumeration value which identifies the algorithm.

Remarks

The **SecureCipher** property returns a value which identifies the algorithm used to encrypt the data stream. If a secure connection has not been established, this property will return a value of **cipherNone**.

See Also

NntpClient Class | SocketTools Namespace

NntpClient.SecureHash Property

Gets a value that specifies the message digest algorithm used for a secure connection.

[Visual Basic]
```
Public ReadOnly Property SecureHash As SecureHashAlgorithm
```

[C#]
```
public NntpClient.SecureHashAlgorithm SecureHash {get;}
```

Property Value

A SecureHashAlgorithm enumeration value which identifies the algorithm.

Remarks

The **SecureHash** property returns a value which identifies the message digest (hash) algorithm that was selected when a secure connection was established. If a secure connection has not been established, this property will return a value of **hashNone**.

See Also

NntpClient Class | SocketTools Namespace

NntpClient.SecureKeyExchange Property

Gets a value that specifies the key exchange algorithm used for a secure connection.

[Visual Basic]
```
Public ReadOnly Property SecureKeyExchange As SecureKeyAlgorithm
```

[C#]
```
public NntpClient.SecureKeyAlgorithm SecureKeyExchange {get;}
```

Property Value

A SecureKeyAlgorithm enumeration value which identifies the algorithm.

Remarks

The **SecureKeyExchange** property returns a value which identifies the key exchange algorithm that was selected when a secure connection was established. If a secure connection has not been established, this property will return a value of **keyExchangeNone**.

See Also

NntpClient Class | SocketTools Namespace

NntpClient.SecureProtocol Property

Gets and sets a value which specifies the protocol used for a secure connection.

[Visual Basic]
```
Public Property SecureProtocol As SecurityProtocols
```

[C#]
```
public NntpClient.SecurityProtocols SecureProtocol {get; set;}
```

Property Value

A SecurityProtocols enumeration value which identifies the protocol to be used when establishing a secure connection.

Remarks

The **SecureProtocol** property can be used to specify the security protocol to be used when establishing a secure connection with a server or accepting a secure connection from a client. By default, the class will attempt to use either SSL v3 or TLS v1 to establish the connection, with the appropriate protocol automatically selected based on the capabilities of the remote host. It is recommended that you only change this property value if you fully understand the implications of doing so. Assigning a value to this property will override the default protocol and force the class to attempt to use only the protocol specified.

Multiple security protocols may be specified by combining them using a bitwise **or** operator. After a connection has been established, this property will identify the protocol that was selected. Attempting to set this property after a connection has been established will result in an exception being thrown. This property should only be set after setting the **Secure** property to **true** and before calling the **Accept** or **Connect** methods.

In some cases, a server may only accept a secure connection if the TLS v1 protocol is specified. If the security protocol is not compatible with the server, then the connection will fail with an error indicating that the control is unable to establish a security context for the session. In this case, try assigning the property to **protocolTLS1** and attempt the connection again.

See Also

NntpClient Class | SocketTools Namespace

NntpClient.Status Property

Gets a value which specifies the current status of the client.

[Visual Basic]

```
Public ReadOnly Property Status As NewsStatus
```

[C#]

```
public NntpClient.NewsStatus Status {get;}
```

Property Value

A NewsStatus enumeration value which specifies the current client status.

Remarks

The **Status** property returns the current status of the client. This property can be used to check on blocking connections to determine if the client is interacting with the remote host before taking some action.

See Also

NntpClient Class | SocketTools Namespace

NntpClient.ThreadModel Property

Gets and sets a value which specifies the threading model for the class instance.

[Visual Basic]
```
Public Property ThreadModel As ThreadingModel
```

[C#]
```
public NntpClient.ThreadingModel ThreadModel {get; set;}
```

Property Value

Returns one or more ThreadingModel enumeration value which specifies the threading model for the client. The default value for this property is **modelSingleThread**.

Remarks

The **ThreadModel** property specifies the threading model that is used by the class instance when a connection is established. The default value for this property is **modelSingleThread**, which specifies that only the thread that established the connection should be permitted to invoke methods. It is important to note that this threading model does not limit the application to a single thread of execution. When a session is established using the **Connect** method, that session is attached to the thread that created it. From that point on, until the session is terminated, only the owner may invoke methods in that instance of the class. The ownership of the class instance may be transferred from one thread to another using the **AttachThread** method.

Setting this property to **modelFreeThread** disables certain internal safety checks that are performed by the class and may result in unexpected behavior unless you ensure that access to the class instance is synchronized across multiple threads. The application must ensure that no two threads will attempt to invoke a blocking method at the same time. In other words, if one thread invokes a method, the application must ensure that another thread will not attempt to invoke any other method at the same time using the same instance of the class.

Changing the value of this property will not affect an active client session. The threading model must be specified prior to invoking the **Connect** method.

NntpClient Class | SocketTools Namespace | AttachThread Method | ThreadingModel Enumeration | ThreadModel Attribute

NntpClient.ThrowError Property

Gets and sets a value which specifies if method calls should throw exceptions when an error occurs.

[Visual Basic]

```
Public Property ThrowError As Boolean
```

[C#]

```
public bool ThrowError {get; set;}
```

Property Value

Returns **true** if method calls will generate exceptions when an error occurs; otherwise returns **false**. The default value is **false**.

Remarks

Error handling for when calling class methods can be done in either of two different styles, according to the value of this property.

If the **ThrowError** property is set to **false**, the application should check the return value of any method that is used, and report errors based upon the documented value of the return code. It is the responsibility of the application to interpret the error code, if it is desired to explain the error in addition to reporting it. This is the default behavior.

If the **ThrowError** property is set to **true**, then exceptions will be generated whenever a method call fails. The program must be written to catch these exceptions and take the appropriate action when an error occurs. Failure to handle an exception will cause the program to terminate abnormally.

Note that if an error occurs while a property is being read or modified, an exception will be raised regardless of the value of the **ThrowError** property.

See Also

NntpClient Class | SocketTools Namespace

NntpClient.Timeout Property

Gets and sets a value which specifies a timeout period in seconds.

[Visual Basic]

```
Public Property Timeout As Integer
```

[C#]

```
public int Timeout {get; set;}
```

Property Value

An integer value which specifies a timeout period in seconds.

Remarks

Setting the **Timeout** property specifies the number of seconds until a blocking operation fails and returns an error.

The timeout period is only used when the client is in blocking mode. Although this property can be changed when the client is in non-blocking mode, the value will be ignored until the client is returned to blocking mode.

For most applications it is recommended the timeout period be set between 10 and 20 seconds.

See Also

NntpClient Class | SocketTools Namespace

NntpClient.TimeZone Property

Gets and sets the current timezone offset in seconds.

[Visual Basic]

```
Public Property TimeZone As Integer
```

[C#]

```
public int TimeZone {get; set;}
```

Property Value

An integer value which specifies the current timezone offset in seconds.

Remarks

The **TimeZone** property returns the current offset from UTC in seconds. Setting the property changes the current timezone offset to the specified value. The value of this property is initially determined by the date and time settings on the local system.

This property value is used in conjunction with the **Localize** property to control how date and time localization is handled.

See Also

NntpClient Class | SocketTools Namespace

NntpClient.Trace Property

Gets and sets a value which indicates if network function logging is enabled.

[Visual Basic]
```
Public Property Trace As Boolean
```

[C#]
```
public bool Trace {get; set;}
```

Property Value

Returns **true** if network function tracing is enabled; otherwise returns **false**. The default value is **false**.

Remarks

The **Trace** property is used to enable (or disable) the tracing of network function calls. When enabled, each function call is logged to a file, including the function parameters, return value and error code if applicable. This facility can be enabled and disabled at run time, and the trace log file can be specified by setting the **TraceFile** property. All function calls that are being logged are appended to the trace file, if it exists. If no trace file exists when tracing is enabled, the trace file is created.

The tracing facility is available in all of the SocketTools networking classes and is enabled or disabled for an entire process. This means that once trace logging is enabled for a given component, all of the function calls made by the process using any of the SocketTools classes will be logged. For example, if you have an application using both the File Transfer Protocol and Post Office Protocol classes, and you set the **Trace** property to **true**, function calls made by both classes will be logged. Additionally, enabling a trace is cumulative, and tracing is not stopped until it is disabled for all classes used by the process.

If trace logging is not enabled, there is no negative impact on performance or throughput. Once enabled, application performance can degrade, especially in those situations in which multiple processes are being traced or the logfile is fairly large. Since logfiles can grow very quickly, even with modest applications, it is recommended that you delete the file when it is no longer needed.

When redistributing your application, make sure that you include the **SocketTools10.TraceLog.dll** module with your installation. If this library is not present, then no trace output will be generated and the value of the **Trace** property will be ignored. Only those function calls made by the SocketTools networking classes will be logged. Calls made directly to the Windows Sockets API, or calls made by other classes, will not be logged.

See Also

NntpClient Class | SocketTools Namespace

NntpClient.TraceFile Property

Gets and sets a value which specifies the name of the logfile.

[Visual Basic]
```
Public Property TraceFile As String
```

[C#]
```
public string TraceFile {get; set;}
```

Property Value

A string which specifies the name of the file.

Remarks

The **TraceFile** property is used to specify the name of the trace file that is created when network function tracing is enabled. If this property is set to an empty string (the default value), then a file named **SocketTools.log** is created in the system's temporary directory. If no temporary directory exists, then the file is created in the current working directory.

If the file exists, the trace output is appended to the file, otherwise the file is created. Since network function tracing is enabled per-process, the trace file is shared by all instances of the class being used. If multiple class instances have tracing enabled, the **TraceFile** property should be set to the same value for each instance. Since trace files can grow very quickly, even with modest applications, it is recommended that you delete the file when it is no longer needed.

The trace file has the following format:

```
 MyApp INF: WSAAsyncSelect(46, 0xcc4, 0x7e9, 0x27) returned 0 MyApp WRN:
connect(46, 192.0.0.1:1234, 16) returned -1 [10035] MyApp ERR: accept(46,
NULL, 0x0) returned -1 [10038]
```

The first column contains the name of the process that is being traced. The second column identifies if the trace record is reporting information, a warning, or an error. What follows is the name of the function being called, the arguments passed to the function and the function's return value. If a warning or error is reported, the error code is appended to the record (the value is placed inside brackets).

If parameters are passed as integer values, they are recorded in decimal. If the parameter or return value is a pointer (a memory address), it is recorded as a hexadecimal value preceded with "0x". A special type of pointer, called a null pointer, is recorded as NULL. Those functions which expect socket addresses are displayed in the following format:

```
aa.bb.cc.dd:nnnn
```

The first four numbers separated by periods represent the IP address, and the number following the colon represents the port number in host byte order. Note that in the second line of the above example, the control is attempting to connect to a system with the IP address 192.0.0.1 on port 1234.

Note that if the specified file cannot be created, or the user does not have permission to modify an existing file, the error is silently ignored and no trace output will be generated.

See Also

NntpClient Class | SocketTools Namespace

NntpClient.TraceFlags Property

Gets and sets a value which specifies the client function tracing flags.

[Visual Basic]

```
Public Property TraceFlags As TraceOptions
```

[C#]

```
public NntpClient.TraceOptions TraceFlags {get; set;}
```

Property Value

A TraceOptions enumeration which specifies the amount of detail written to the trace logfile.

Remarks

The **TraceFlags** property is used to specify the type of information written to the trace file when network function tracing is enabled.

Because network function tracing is enabled per-process, the trace flags are shared by all instances of the class being used. If multiple class instances have tracing enabled, the **TraceFlags** property should be set to the same value for each instance. Changing the trace flags for any one instance of the class will affect the logging performed for all SocketTools classes used by the application.

Warnings are generated when a non-fatal error is returned by a network function. For example, if data is being written and the error **errorOperationWouldBlock** occurs, a warning is generated because the application simply needs to attempt to write the data at a later time.

See Also

NntpClient Class | SocketTools Namespace

NntpClient.UserName Property

Gets and sets the username used to authenticate the client session.

[Visual Basic]

```
Public Property UserName As String
```

[C#]

```
public string UserName {get; set;}
```

Property Value

A string which specifies the username.

Remarks

If a username is not specified when the **Connect** method is called, the value of this property will be used as the default username when establishing a connection with the server.

See Also

NntpClient Class | SocketTools Namespace

NntpClient.Version Property

Gets a value which returns the current version of the NntpClient class library.

[Visual Basic]

```
Public ReadOnly Property Version As String
```

[C#]

```
public string Version {get;}
```

Property Value

A string which specifies the version of the class library.

Remarks

The **Version** property returns a string which identifies the current version and build of the NntpClient class library. This value can be used by an application for validation and debugging purposes.

NntpClient Class | SocketTools Namespace

NntpClient Methods

The methods of the **NntpClient** class are listed below. For a complete list of **NntpClient** class members, see the NntpClient Members topic.

Public Instance Methods

AttachThread	Attach an instance of the class to the current thread
Authenticate	Overloaded. Authenticate the client session with a username and password.
Cancel	Cancel the current blocking client operation.
CloseArticle	Closes the current article that has been opened or created.
Command	Overloaded. Send a custom command to the server.
Connect	Overloaded. Establish a connection with a remote host.
CreateArticle	Creates a new article in the current newsgroup.
Disconnect	Terminate the connection with a remote host.
Dispose	Overloaded. Releases all resources used by NntpClient.
Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetArticle	Overloaded. Retrieve an article from the server.
GetFirstArticle	Overloaded. Return information about a selected range of articles in the current newsgroup.
GetFirstGroup	Overloaded. Return information about newsgroups created after the specified date.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetHeaders	Overloaded. Retrieves the headers for the specified article from the server.
GetNextArticle	Return information about the next article available in the current newsgroup.
GetNextGroup	Return information about the next available newsgroup.
GetType (inherited from Object)	Gets the Type of the current instance.
Initialize	Overloaded. Initialize an instance of the NntpClient class.
OpenArticle	Overloaded. Opens the specified article in the currently selected newsgroup.

PostArticle	Overloaded. Post a new article to the currently selected newsgroup.
Read	Overloaded. Read data from the server and store it in a byte array.
Reset	Reset the internal state of the object, resetting all properties to their default values.
SelectGroup	Selects the specified newsgroup as the current newsgroup.
StoreArticle	Overloaded. Retrieve an article from the selected newsgroup and store it in a file.
ToString (inherited from Object)	Returns a String that represents the current Object.
Uninitialize	Uninitialize the class library and release any resources allocated for the current thread.
Write	Overloaded. Write one or more bytes of data to the server.

Protected Instance Methods

Dispose	Overloaded. Releases the unmanaged resources allocated by the NntpClient class and optionally releases the managed resources.
Finalize	Destroys an instance of the class, releasing the resources allocated for the session and unloading the networking library.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

NntpClient Class | SocketTools Namespace

NntpClient.AttachThread Method

Attach an instance of the class to the current thread

[Visual Basic]

```
Public Function AttachThread() As Boolean
```

[C#]

```
public bool AttachThread();
```

Return Value

A boolean value which specifies if the client could be attached to the current thread. If this method returns **false**, the client could not be attached to the thread and the application should check the value of the LastError property to determine the cause of the failure.

Remarks

When an instance of the class is created it is associated with the current thread that created it. Normally, if another thread attempts to perform an operation using that instance, an error is returned. This is used to ensure that other threads cannot interfere with an operation being performed by the owner thread. In some cases, it may be desirable for one thread in an application to create an instance of the class, establish a connection and then pass that instance to another worker thread. The **AttachThread** method can be used to change the ownership of the class instance to the new worker thread.

This method should be called by the new thread immediately after it has been created, and if the new thread does not release the handle itself, the ownership of the handle should be restored by the original thread. Under no circumstances should **AttachThread** be used to forcibly destroy an instance of a class allocated by another thread while a blocking operation is in progress. To cancel a blocking operation, use the **Cancel** method and then delete the class instance after the blocking function exits and control is returned to the current thread.

NntpClient Class | SocketTools Namespace

NntpClient.Authenticate Method

Authenticate the client session.

Overload List

Authenticate the client session.

public bool Authenticate();

Authenticate the client session with a username and password.

public bool Authenticate(string,string);

See Also

NntpClient Class | SocketTools Namespace

NntpClient.Authenticate Method ()

Authenticate the client session.

[Visual Basic]

```
Overloads Public Function Authenticate() As Boolean
```

[C#]

```
public bool Authenticate();
```

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **Authenticate** method identifies the client to the news server, which may be required to access certain newsgroups or to post articles. If the user name or password is invalid, an error will occur. This method should only be used if the server indicates that authentication is required by returning an error.

The value of the **UserName** property is used to specify the username and the value of the **Password** property is used to specify the password.

See Also

NntpClient Class | SocketTools Namespace | NntpClient.Authenticate Overload List

NntpClient.Authenticate Method (String, String)

Authenticate the client session with a username and password.

[Visual Basic]

```
Overloads Public Function Authenticate( _
   ByVal userName As String, _
   ByVal userPassword As String _
) As Boolean
```

[C#]

```
public bool Authenticate(
   string userName,
   string userPassword
);
```

Parameters

userName
A string which specifies the username used to authenticate the client session.

userPassword
A string which specifies the password used to authenticate the client session.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **Authenticate** method identifies the client to the news server, which may be required to access certain newsgroups or to post articles. If the user name or password is invalid, an error will occur. This method should only be used if the server indicates that authentication is required by returning an error.

See Also

NntpClient Class | SocketTools Namespace | NntpClient.Authenticate Overload List

NntpClient.Cancel Method

Cancel the current blocking client operation.

[Visual Basic]

```
Public Sub Cancel()
```

[C#]

```
public void Cancel();
```

Remarks

When the **Cancel** method is called, the blocking client operation will not immediately fail. An internal flag is set which causes the blocking operation to exit with an error. This means that the application cannot cancel an operation and immediately perform some other blocking function. Instead it must allow the calling stack to unwind, returning back to the blocking operation before making any further function calls.

See Also

NntpClient Class | SocketTools Namespace

NntpClient.CloseArticle Method

Closes the current article that has been opened or created.

[Visual Basic]

```
Public Function CloseArticle() As Boolean
```

[C#]

```
public bool CloseArticle();
```

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **CloseArticle** method closes the current article that has been opened or created. If an article is being created, this method actually submits the article to the server. Note that the client application is responsible for generating the message headers as well as the body of the message. News articles conform to the same general characteristics of an email message.

NntpClient.Command Method

Send a custom command to the server.

Overload List

Send a custom command to the server.

public bool Command(string);

Send a custom command to the server.

public bool Command(string,bool);

Send a custom command to the server.

public bool Command(string,string);

Send a custom command to the server.

public bool Command(string,string,bool);

See Also

NntpClient Class | SocketTools Namespace

NntpClient.Command Method (String)

Send a custom command to the server.

[Visual Basic]

```
Overloads Public Function Command( _
   ByVal command As String _
) As Boolean
```

[C#]

```
public bool Command(
   string command
);
```

Parameters

command

A string which specifies the command to send. Valid commands vary based on the Internet protocol and the type of server that the client is connected to. Consult the protocol standard and/or the technical reference documentation for the server to determine what commands may be issued by a client application.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **Command** method sends a command to the remote host and processes the result code sent back in response to that command. This method can be used to send custom commands to a server to take advantage of features or capabilities that may not be supported internally by the class library.

To determine the specific status code returned by the server, check the value of the **ResultCode** property after the method returns.

See Also

NntpClient Class | SocketTools Namespace | NntpClient.Command Overload List

NntpClient.Command Method (String, Boolean)

Send a custom command to the server.

[Visual Basic]

```
Overloads Public Function Command( _
   ByVal command As String, _
   ByVal isMultiLine As Boolean _
) As Boolean
```

[C#]

```
public bool Command(
   string command,
   bool isMultiLine
);
```

Parameters

command

A string which specifies the command to send. Valid commands vary based on the Internet protocol and the type of server that the client is connected to. Consult the protocol standard and/or the technical reference documentation for the server to determine what commands may be issued by a client application.

isMultiLine

A boolean value which specifies if the command will result in multiple lines of output from the server. For more information about a specific command, consult the standards documentation for the protocol.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **Command** method sends a command to the remote host and processes the result code sent back in response to that command. This method can be used to send custom commands to a server to take advantage of features or capabilities that may not be supported internally by the class library.

The *isMultiLine* parameter is used by the method to determine if multiple lines of data will be returned by the server as the result of a command. Unlike a single line response, which consists of a result code and result string, a multi-line response consists of one or more lines of text, terminated by a special end-of-data marker.

To determine the specific status code returned by the server, check the value of the **ResultCode** property after the method returns.

See Also

NntpClient Class | SocketTools Namespace | NntpClient.Command Overload List

NntpClient.Command Method (String, String)

Send a custom command to the server.

[Visual Basic]

```
Overloads Public Function Command( _
   ByVal command As String, _
   ByVal parameters As String _
) As Boolean
```

[C#]

```
public bool Command(
   string command,
   string parameters
);
```

Parameters

command

A string which specifies the command to send. Valid commands vary based on the Internet protocol and the type of server that the client is connected to. Consult the protocol standard and/or the technical reference documentation for the server to determine what commands may be issued by a client application.

parameters

An string which specifies one or more parameters to be sent along with the command. If more than one parameter is required, they must be separated by a single space character. Consult the protocol standard and/or technical reference documentation for the server to determine what parameters should be provided when issuing a specific command.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **Command** method sends a command to the remote host and processes the result code sent back in response to that command. This method can be used to send custom commands to a server to take advantage of features or capabilities that may not be supported internally by the class library.

To determine the specific status code returned by the server, check the value of the **ResultCode** property after the method returns.

   ByVal parameters As String, _
   ByVal isMultiLine As Boolean _
) As Boolean
```

[C#]

```
public bool Command(
   string command,
   string parameters,
   bool isMultiLine
);
```

Parameters

command

A string which specifies the command to send. Valid commands vary based on the Internet protocol and the type of server that the client is connected to. Consult the protocol standard and/or the technical reference documentation for the server to determine what commands may be issued by a client application.

parameters

An string which specifies one or more parameters to be sent along with the command. If more than one parameter is required, they must be separated by a single space character. Consult the protocol standard and/or technical reference documentation for the server to determine what parameters should be provided when issuing a specific command.

isMultiLine

A boolean value which specifies if the command will result in multiple lines of output from the server. For more information about a specific command, consult the standards documentation for the protocol.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **Command** method sends a command to the remote host and processes the result code sent back in response to that command. This method can be used to send custom commands to a server to take advantage of features or capabilities that may not be supported internally by the class library.

The ***isMultiLine*** parameter is used by the method to determine if multiple lines of data will be returned by the server as the result of a command. Unlike a single line response, which consists of a result code and result string, a multi-line response consists of one or more lines of text, terminated by a special end-of-data marker.

To determine the specific status code returned by the server, check the value of the **ResultCode** property after the method returns.

NntpClient Class | SocketTools Namespace

NntpClient.Connect Method ()

Establish a connection with a remote host.

[Visual Basic]

```
Overloads Public Function Connect() As Boolean
```

[C#]

```
public bool Connect();
```

Return Value

A boolean value which specifies if the connection has been established. If the client is in blocking mode, a return value of **true** indicates that the connection has completed and the application may send and receive data from the remote host. If the client is in non-blocking mode, a return value of **true** indicates that the client has successfully created a socket and the connection is in progress.

When a non-blocking connection has completed, the OnConnect event will be fired. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

Remarks

This method establishes a connection using assigned property values.

The value of the **HostName** or **HostAddress** property will be used to determine the host name or address to connect to.

The value of the **RemotePort** property will be used to determine the port number to connect to.

The value of the **Timeout** property will be used to specify the timeout period.

The value of the **Options** property will be used to specify the default options for the connection.

NntpClient.Connect Method (String)

Establish a connection with a remote host.

[Visual Basic]

```
Overloads Public Function Connect( _
   ByVal hostName As String _
) As Boolean
```

[C#]

```
public bool Connect(
   string hostName
);
```

Parameters

hostName

A string which specifies the remote host to establish a connection with. This may specify a host name or an Internet address in dot-notation.

Return Value

A boolean value which specifies if the connection has been established. If the client is in blocking mode, a return value of **true** indicates that the connection has completed and the application may send and receive data from the remote host. If the client is in non-blocking mode, a return value of **true** indicates that the client has successfully created a socket and the connection is in progress.

When a non-blocking connection has completed, the OnConnect event will be fired. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

NntpClient.Connect Method (String, Int32)

Establish a connection with a remote host.

[Visual Basic]

```
Overloads Public Function Connect( _
   ByVal hostName As String, _
   ByVal hostPort As Integer _
) As Boolean
```

[C#]

```
public bool Connect(
   string hostName,
   int hostPort
);
```

Parameters

hostName

A string which specifies the remote host to establish a connection with. This may specify a host name or an Internet address in dot-notation.

hostPort

An integer which specifies the port number for the connection. This value must be greater than zero and the maximum valid port number is 65535.

Return Value

A boolean value which specifies if the connection has been established. If the client is in blocking mode, a return value of **true** indicates that the connection has completed and the application may send and receive data from the remote host. If the client is in non-blocking mode, a return value of **true** indicates that the client has successfully created a socket and the connection is in progress.

When a non-blocking connection has completed, the OnConnect event will be fired. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

Establish a connection with a remote host.

[Visual Basic]

```
Overloads Public Function Connect( _
   ByVal hostName As String, _
   ByVal hostPort As Integer, _
   ByVal timeout As Integer _
) As Boolean
```

[C#]

```
public bool Connect(
   string hostName,
   int hostPort,
   int timeout
);
```

Parameters

hostName

A string which specifies the remote host to establish a connection with. This may specify a host name or an Internet address in dot-notation.

hostPort

An integer which specifies the port number for the connection. This value must be greater than zero and the maximum valid port number is 65535.

timeout

An integer value that specifies the number of seconds that the method will wait for the connection to complete before failing the operation and returning to the caller. This value is only meaningful for blocking connections.

Return Value

A boolean value which specifies if the connection has been established. If the client is in blocking mode, a return value of **true** indicates that the connection has completed and the application may send and receive data from the remote host. If the client is in non-blocking mode, a return value of **true** indicates that the client has successfully created a socket and the connection is in progress.

When a non-blocking connection has completed, the OnConnect event will be fired. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

   ByVal hostName As String, _
   ByVal hostPort As Integer, _
   ByVal timeout As Integer, _
   ByVal options As NewsOptions _
) As Boolean
```

[C#]

```
public bool Connect(
   string hostName,
   int hostPort,
   int timeout,
   NewsOptions options
);
```

Parameters

hostName

A string which specifies the remote host to establish a connection with. This may specify a host name or an Internet address in dot-notation.

hostPort

An integer which specifies the port number for the connection. This value must be greater than zero and the maximum valid port number is 65535.

timeout

An integer value that specifies the number of seconds that the method will wait for the connection to complete before failing the operation and returning to the caller. This value is only meaningful for blocking connections.

options

One or more of the NewsOptions enumeration flags.

Return Value

A boolean value which specifies if the connection has been established. If the client is in blocking mode, a return value of **true** indicates that the connection has completed and the application may send and receive data from the remote host. If the client is in non-blocking mode, a return value of **true** indicates that the client has successfully created a socket and the connection is in progress.

When a non-blocking connection has completed, the OnConnect event will be fired. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

See Also

NntpClient Class | SocketTools Namespace | NntpClient.Connect Overload List

NntpClient.Connect Method (String, Int32, String, String, Int32, NewsOptions)

Establish a connection with a remote host.

[Visual Basic]

```
Overloads Public Function Connect( _
   ByVal hostName As String, _
   ByVal hostPort As Integer, _
   ByVal userName As String, _
   ByVal userPassword As String, _
   ByVal timeout As Integer, _
   ByVal options As NewsOptions _
) As Boolean
```

[C#]

```
public bool Connect(
   string hostName,
   int hostPort,
   string userName,
   string userPassword,
   int timeout,
   NewsOptions options
);
```

Parameters

hostName

A string which specifies the remote host to establish a connection with. This may specify a host name or an Internet address in dot-notation.

hostPort

An integer which specifies the port number for the connection. This value must be greater than zero and the maximum valid port number is 65535.

userName

A string which specifies the username which will be used to authenticate the client session with the remote host. Not all news servers require the client to authenticate the session.

userPassword

A string which specifies the password which will be used to authenticate the client session with the remote host. Not all news servers require the client to authenticate the session.

timeout

An integer value that specifies the number of seconds that the method will wait for the connection to complete before failing the operation and returning to the caller. This value is only meaningful for blocking connections.

options

One or more of the NewsOptions enumeration flags.

Return Value

A boolean value which specifies if the connection has been established. If the client is in blocking mode, a return value of **true** indicates that the connection has completed and the application may send and receive data from the remote host. If the client is in non-blocking mode, a return value of **true** indicates that the client has successfully created a socket and the connection is in progress.

When a non-blocking connection has completed, the OnConnect event will be fired. If this method returns

false, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

See Also

NntpClient Class | SocketTools Namespace | NntpClient.Connect Overload List

NntpClient.CreateArticle Method

Creates a new article in the current newsgroup.

[Visual Basic]

```
Public Function CreateArticle() As Boolean
```

[C#]

```
public bool CreateArticle();
```

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **CreateArticle** method sends the POST command to the news server. Not all servers permit clients to post articles. The client application is responsible for generating the message headers as well as the body of the message. News articles conform to the same general characteristics of an email message.

The **CloseArticle** method must be called once the contents of the article has been written to the server.

See Also

NntpClient Class | SocketTools Namespace

NntpClient.Disconnect Method

Terminate the connection with a remote host.

[Visual Basic]

```
Public Sub Disconnect()
```

[C#]

```
public void Disconnect();
```

Remarks

The **Disconnect** method terminates the connection with the remote host and releases the client handle allocated by the class. Note that the socket is not immediately released when the connection is terminated and will enter a wait state for two minutes. After the time wait period has elapsed, the client will be released by the operating system. This is a normal safety mechanism to handle any packets that may arrive after the connection has been closed.

NntpClient Class | SocketTools Namespace

NntpClient.Dispose Method

Releases all resources used by NntpClient.

Overload List

Releases all resources used by NntpClient.

public void Dispose();

Releases the unmanaged resources allocated by the NntpClient class and optionally releases the managed resources.

protected virtual void Dispose(bool);

See Also

NntpClient Class | SocketTools Namespace

NntpClient.Dispose Method ()

Releases all resources used by NntpClient.

[Visual Basic]

```
NotOverridable Overloads Public Sub Dispose() _
    Implements IDisposable.Dispose
```

[C#]

```
public void Dispose();
```

Implements

IDisposable.Dispose

Remarks

The **Dispose** method terminates any active connection and explicitly releases the resources allocated for this instance of the class. In some cases, better performance can be achieved if the programmer explicitly releases resources when they are no longer being used. The **Dispose** method provides explicit control over these resources.

Unlike the **Uninitialize** method, once the **Dispose** method has been called, that instance of the class cannot be re-initialized and you should not attempt to access class properties or invoke any methods. Note that this method can be called even if other references to the object are active.

See Also

NntpClient Class | SocketTools Namespace | NntpClient.Dispose Overload List

NntpClient.Dispose Method (Boolean)

Releases the unmanaged resources allocated by the NntpClient class and optionally releases the managed resources.

[Visual Basic]

```
Overridable Overloads Protected Sub Dispose( _
   ByVal disposing As Boolean _
)
```

[C#]

```
protected virtual void Dispose(
   bool disposing
);
```

Parameters

disposing

A boolean value which should be specified as **true** to release both managed and unmanaged resources; **false** to release only unmanaged resources.

Remarks

The **Dispose** method terminates any active connection and explicitly releases the resources allocated for this instance of the class. In some cases, better performance can be achieved if the programmer explicitly releases resources when they are no longer being used. The **Dispose** method provides explicit control over these resources.

Unlike the **Uninitialize** method, once the **Dispose** method has been called, that instance of the class cannot be re-initialized and you should not attempt to access class properties or invoke any methods. Note that this method can be called even if other references to the object are active.

You should call **Dispose** in your derived class when you are finished using the derived class. The **Dispose** method leaves the derived class in an unusable state. After calling **Dispose**, you must release all references to the derived class and the **NntpClient** class so the memory they were occupying can be reclaimed by garbage collection.

NntpClient.GetArticle Method

Retrieve an article from the server.

Overload List

Retrieve an article from the server.

public bool GetArticle(int,byte[],ref int);

Retrieve an article from the server.

public bool GetArticle(int,ref string);

Retrieve an article from the server.

public bool GetArticle(string,byte[],ref int);

Retrieve an article from the server.

public bool GetArticle(string,ref string);

See Also

NntpClient Class | SocketTools Namespace

NntpClient.GetArticle Method (Int32, Byte[], Int32)

Retrieve an article from the server.

[Visual Basic]

```
Overloads Public Function GetArticle( _
   ByVal articleId As Integer, _
   ByVal buffer As Byte(), _
   ByRef length As Integer _
) As Boolean
```

[C#]

```
public bool GetArticle(
   int articleId,
   byte[] buffer,
   ref int length
);
```

Parameters

articleId

An integer value which specifies the number of the article to retrieve from the server. This value must be greater than zero.

buffer

A byte array that the news article will be stored in.

length

An integer value which specifies the maximum number of bytes of data to read. This value cannot be larger than the size of the buffer specified by the caller.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetArticle** method is used to retrieve an article from the server and copy it into a local buffer. This method will cause the current thread to block until the article transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

The first available article in the newsgroup can be determined by checking the value of the **FirstArticle** property. The last available article in the newsgroup is returned by the **LastArticle** property.

See Also

NntpClient Class | SocketTools Namespace | NntpClient.GetArticle Overload List

NntpClient.GetArticle Method (String, Byte[], Int32)

Retrieve an article from the server.

```
[Visual Basic]
Overloads Public Function GetArticle( _
   ByVal messageId As String, _
   ByVal buffer As Byte(), _
   ByRef length As Integer _
) As Boolean
```

```
[C#]
public bool GetArticle(
   string messageId,
   byte[] buffer,
   ref int length
);
```

Parameters

messageId
A string value which specifies the message ID of the article to retrieve from the server.

buffer
A byte array that the news article will be stored in.

length
An integer value which specifies the maximum number of bytes of data to read. This value cannot be larger than the size of the buffer specified by the caller.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetArticle** method is used to retrieve an article from the server and copy it into a local buffer. This method will cause the current thread to block until the article transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

NntpClient Class | SocketTools Namespace | NntpClient.GetArticle Overload List

NntpClient.GetFirstArticle Method

Return information about all articles available in the current newsgroup.

Overload List

Return information about all articles available in the current newsgroup.

public bool GetFirstArticle(ref NewsArticle);

Return information about a selected range of articles in the current newsgroup.

public bool GetFirstArticle(int,int,ref NewsArticle);

See Also

NntpClient Class | SocketTools Namespace

NntpClient.GetFirstArticle Method (NewsArticle)

Return information about all articles available in the current newsgroup.

[Visual Basic]

```
Overloads Public Function GetFirstArticle( _
   ByRef article As NewsArticle _
) As Boolean
```

[C#]

```
public bool GetFirstArticle(
   ref NewsArticle article
);
```

Parameters

article

A NewsArticle structure which will contain information about the article when the method returns.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetFirstArticle** method returns information about the first article in the currently selected newsgroup. This method is used in conjunction with the **GetNextArticle** method to enumerate all of the articles in the newsgroup. Typically this is used to provide the user with a list of articles to access.

While the articles in the newsgroup are being listed, the client cannot retrieve the contents of a specific article. For example, the **GetArticle** method cannot be called while inside a loop calling **GetNextArticle**. The client should store those articles which it wants to retrieve in an array, and then once all of the articles have been listed, it can begin calling **GetArticle** for each article number to retrieve the article text.

The values of the **FirstArticle** and **LastArticle** properties determines the ranges of articles returned by this method.

See Also

NntpClient Class | SocketTools Namespace | NntpClient.GetFirstArticle Overload List

NntpClient.GetFirstArticle Method (Int32, Int32, NewsArticle)

Return information about a selected range of articles in the current newsgroup.

[Visual Basic]

```
Overloads Public Function GetFirstArticle( _
   ByVal firstArticle As Integer, _
   ByVal lastArticle As Integer, _
   ByRef article As NewsArticle _
) As Boolean
```

[C#]

```
public bool GetFirstArticle(
   int firstArticle,
   int lastArticle,
   ref NewsArticle article
);
```

Parameters

firstArticle

An integer which specifies the first article to return. A value of -1 specifies that the first available article in the newsgroup should be returned.

lastArticle

An integer which specifies the last article to return. A value of -1 specifies that the last available article in the newsgroup should be returned.

article

A NewsArticle structure which will contain information about the article when the method returns.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetFirstArticle** method returns information about the first article in the currently selected newsgroup. This method is used in conjunction with the **GetNextArticle** method to enumerate all of the articles in the newsgroup. Typically this is used to provide the user with a list of articles to access.

While the articles in the newsgroup are being listed, the client cannot retrieve the contents of a specific article. For example, the **GetArticle** method cannot be called while inside a loop calling **GetNextArticle**. The client should store those articles which it wants to retrieve in an array, and then once all of the articles have been listed, it can begin calling **GetArticle** for each article number to retrieve the article text.

NntpClient.GetFirstGroup Method

Return information about all available newsgroups.

Overload List

Return information about all available newsgroups.

public bool GetFirstGroup(ref NewsGroup);

Return information about newsgroups created after the specified date.

public bool GetFirstGroup(DateTime,ref NewsGroup);

See Also

NntpClient Class | SocketTools Namespace

NntpClient.GetFirstGroup Method (NewsGroup)

Return information about all available newsgroups.

[Visual Basic]

```
Overloads Public Function GetFirstGroup( _
   ByRef group As NewsGroup _
) As Boolean
```

[C#]

```
public bool GetFirstGroup(
   ref NewsGroup group
);
```

Parameters

group

A NewsGroup structure which will contain information about the newsgroup when the method returns.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetFirstGroup** method returns information about the first newsgroup on the server. This method is used in conjunction with the **GetNextGroup** method to enumerate all of the available newsgroups. Typically this is used to provide the user with a list of newsgroups to select. If the **LastUpdate** property is set, then only newsgroups that have been created since that date will be returned.

While the the newsgroups are being listed, the client cannot select a newsgroup or retrieve the contents of a specific article. The client should store those newsgroups which it wants to retrieve articles from, and then once all of the newsgroups have been listed, it can then select each newsgroup and retrieve the available articles from that group.

See Also

NntpClient Class | SocketTools Namespace | NntpClient.GetFirstGroup Overload List

NntpClient.GetFirstGroup Method (DateTime, NewsGroup)

Return information about newsgroups created after the specified date.

```
[Visual Basic]
Overloads Public Function GetFirstGroup( _
   ByVal lastUpdate As Date, _
   ByRef group As NewsGroup _
) As Boolean
```

```
[C#]
public bool GetFirstGroup(
   DateTime lastUpdate,
   ref NewsGroup group
);
```

Parameters

lastUpdate

A **System.DateTime** structure. Only those newsgroups which were created after this date and time will be returned. This is useful for checking for newsgroups that have been recently added to the server without incurring the overhead of listing every available newsgroup.

group

A NewsGroup structure which will contain information about the newsgroup when the method returns.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetFirstGroup** method returns information about the first newsgroup on the server. This method is used in conjunction with the **GetNextGroup** method to enumerate all of the available newsgroups. Typically this is used to provide the user with a list of newsgroups to select.

While the the newsgroups are being listed, the client cannot select a newsgroup or retrieve the contents of a specific article. The client should store those newsgroups which it wants to retrieve articles from, and then once all of the newsgroups have been listed, it can then select each newsgroup and retrieve the available articles from that group.

NntpClient.GetHeaders Method

Retrieves the headers for the specified article from the server.

Overload List

Retrieves the headers for the specified article from the server.

public bool GetHeaders(int,byte[],ref int);

Retrieves the headers for the specified article from the server.

public bool GetHeaders(int,ref string);

Retrieves the headers for the specified article from the server.

public bool GetHeaders(string,byte[],ref int);

Retrieves the headers for the specified article from the server.

public bool GetHeaders(string,ref string);

See Also

NntpClient Class | SocketTools Namespace

NntpClient.GetHeaders Method (Int32, Byte[], Int32)

Retrieves the headers for the specified article from the server.

[Visual Basic]

```
Overloads Public Function GetHeaders( _
   ByVal articleId As Integer, _
   ByVal buffer As Byte(), _
   ByRef length As Integer _
) As Boolean
```

[C#]

```
public bool GetHeaders(
   int articleId,
   byte[] buffer,
   ref int length
);
```

Parameters

articleId
An integer value which specifies the article to retrieve from the server. This value must be greater than zero.

buffer
A byte array that will contain the article headers when the method returns.

length
An integer value which specifies the maximum number of bytes of data to read. This value cannot be larger than the size of the buffer specified by the caller.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetHeaders** method is used to retrieve an article header block from the server and copy it into a local buffer. This method will cause the current thread to block until the article transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

The first available article in the newsgroup can be determined by checking the value of the **FirstArticle** property. The last available article in the newsgroup is returned by the **LastArticle** property.

Retrieves the headers for the specified article from the server.

[Visual Basic]

```
Overloads Public Function GetHeaders( _
   ByVal messageId As String, _
   ByVal buffer As Byte(), _
   ByRef length As Integer _
) As Boolean
```

[C#]

```
public bool GetHeaders(
   string messageId,
   byte[] buffer,
   ref int length
);
```

Parameters

messageId
A string value which specifies the message number of the article to retrieve from the server.

buffer
A byte array that will contain the article headers when the method returns.

length
An integer value which specifies the maximum number of bytes of data to read. This value cannot be larger than the size of the buffer specified by the caller.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetHeaders** method is used to retrieve an article header block from the server and copy it into a local buffer. This method will cause the current thread to block until the article transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

NntpClient Class | SocketTools Namespace | NntpClient.GetHeaders Overload List

NntpClient.GetNextArticle Method

Return information about the next article available in the current newsgroup.

[Visual Basic]

```
Public Function GetNextArticle( _
   ByRef article As NewsArticle _
) As Boolean
```

[C#]

```
public bool GetNextArticle(
   ref NewsArticle article
);
```

Parameters

article

A NewsArticle structure which will contain information about the article when the method returns.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetNextArticle** method returns information about the next available article in the currently selected newsgroup. This method is used in conjunction with the **GetFirstArticle** method to enumerate all of the articles in the newsgroup. Typically this is used to provide the user with a list of articles to access.

While the articles in the newsgroup are being listed, the client cannot retrieve the contents of a specific article. For example, the **GetArticle** method cannot be called while inside a loop calling **GetNextArticle**. The client should store those articles which it wants to retrieve in an array, and then once all of the articles have been listed, it can begin calling **GetArticle** for each article number to retrieve the article text.

See Also

NntpClient Class | SocketTools Namespace

NntpClient.GetNextGroup Method

Return information about the next available newsgroup.

[Visual Basic]

```
Public Function GetNextGroup( _
   ByRef group As NewsGroup _
) As Boolean
```

[C#]

```
public bool GetNextGroup(
   ref NewsGroup group
);
```

Parameters

group
A NewsGroup structure which will contain information about the newsgroup when the method returns.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetNextGroup** method returns information about the next available newsgroup on the server. This method is used in conjunction with the **GetFirstGroup** method to enumerate all of the available newsgroups. Typically this is used to provide the user with a list of newsgroups to select. If the **LastUpdate** property is set, then only newsgroups that have been created since that date will be returned.

While the the newsgroups are being listed, the client cannot select a newsgroup or retrieve the contents of a specific article. The client should store those newsgroups which it wants to retrieve articles from, and then once all of the newsgroups have been listed, it can then select each newsgroup and retrieve the available articles from that group.

A program should use either the **ListGroups** method or the **GetFirstGroup** and **GetNextGroup** methods, but never in combination with one another.

NntpClient Class | SocketTools Namespace

NntpClient.Initialize Method

Initialize an instance of the NntpClient class.

Overload List

Initialize an instance of the NntpClient class.

```
public bool Initialize();
```

Initialize an instance of the NntpClient class.

```
public bool Initialize(string);
```

See Also

NntpClient Class | SocketTools Namespace | Uninitialize Method

NntpClient.Initialize Method ()

Initialize an instance of the NntpClient class.

[Visual Basic]

```
Overloads Public Function Initialize() As Boolean
```

[C#]

```
public bool Initialize();
```

Return Value

A boolean value which specifies if the class was initialized successfully.

Remarks

The Initialize method can be used to explicitly initialize an instance of the NntpClient class, loading the networking library and allocating resources for the current thread. Typically it is not necessary to explicitly call this method because the instance of the class is initialized by the class constructor. However, if the **Uninitialize** method is called, the class must be re-initialized before any other methods are called.

See Also

NntpClient Class | SocketTools Namespace | NntpClient.Initialize Overload List | Uninitialize Method

NntpClient.Initialize Method (String)

Initialize an instance of the NntpClient class.

[Visual Basic]

```
Overloads Public Function Initialize( _
   ByVal licenseKey As String _
) As Boolean
```

[C#]

```
public bool Initialize(
   string licenseKey
);
```

Return Value

A boolean value which specifies if the class was initialized successfully.

Remarks

The Initialize method can be used to explicitly initialize an instance of the NntpClient class, loading the networking library and allocating resources for the current thread. Typically an application would define the license key as a custom attribute, however this method can be used to initialize the class directly.

The runtime license key for your copy of SocketTools can be generated using the License Manager utility that is included with the product. Note that if you have installed an evaluation license, you will not have a runtime license key and cannot redistribute any applications which use the NntpClient class.

Example

The following example shows how to use the Initialize method to initialize an instance of the class. This example assumes that the license key string has been defined in code.

```
SocketTools.NntpClient nntpClient = new SocketTools.NntpClient();

if (nntpClient.Initialize(strLicenseKey) == false)
{
    MessageBox.Show(nntpClient.LastErrorString, "Error",
                    MessageBoxButtons.OK, MessageBoxIcon.Exclamation);
    return;
}
```

```
Dim nntpClient As New SocketTools.NntpClient

If nntpClient.Initialize(strLicenseKey) = False Then
    MsgBox(nntpClient.LastErrorString, vbIconExclamation)
    Exit Sub
End If
```

NntpClient.OpenArticle Method

Opens the current article in the currently selected newsgroup.

Overload List

Opens the current article in the currently selected newsgroup.

public bool OpenArticle();

Opens the specified article in the currently selected newsgroup.

public bool OpenArticle(int);

See Also

NntpClient Class | SocketTools Namespace

NntpClient.OpenArticle Method ()

Opens the current article in the currently selected newsgroup.

[Visual Basic]

```
Overloads Public Function OpenArticle() As Boolean
```

[C#]

```
public bool OpenArticle();
```

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **OpenArticle** method opens the specified article in the currently selected newsgroup. The article data can be read using the **Read** method, and once all of the data has been returned, the **CloseArticle** method should be used to close the article on the server.

The **Article** property returns the current article number.

See Also

NntpClient Class | SocketTools Namespace | NntpClient.OpenArticle Overload List

NntpClient.OpenArticle Method (Int32)

Opens the specified article in the currently selected newsgroup.

[Visual Basic]

```
Overloads Public Function OpenArticle( _
   ByVal articleId As Integer _
) As Boolean
```

[C#]

```
public bool OpenArticle(
   int articleId
);
```

Parameters

articleId

An integer value which specifies the number of the article to retrieve from the server. This value must be greater than zero and it becomes the current article number for the selected newsgroup.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **OpenArticle** method opens the specified article in the currently selected newsgroup. The article data can be read using the **Read** method, and once all of the data has been returned, the **CloseArticle** method should be used to close the article on the server.

The first available article in the current newsgroup can be determined by checking the value of the **FirstArticle** property. The last available article in the current newsgroup is returned by the **LastArticle** property.

NntpClient Class | SocketTools Namespace | NntpClient.OpenArticle Overload List

NntpClient.PostArticle Method

Post a new article to the currently selected newsgroup.

Overload List

Post a new article to the currently selected newsgroup.

public bool PostArticle(byte[],int);

Post a new article to the currently selected newsgroup.

public bool PostArticle(string);

See Also

NntpClient Class | SocketTools Namespace

NntpClient.PostArticle Method (Byte[], Int32)

Post a new article to the currently selected newsgroup.

[Visual Basic]

```
Overloads Public Function PostArticle( _
   ByVal buffer As Byte(), _
   ByVal length As Integer _
) As Boolean
```

[C#]

```
public bool PostArticle(
   byte[] buffer,
   int length
);
```

Parameters

buffer
A byte array which contains the data to be posted to the server.

length
An integer value which specifies the number of bytes to write to the server. This value cannot be larger than the size of the buffer specified by the caller.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **PostArticle** method is used to submit the contents of the specified buffer to the server as a new article in the current newsgroup. This method will cause the current thread to block until the article transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

Not all newsgroups permit new articles to be posted, and some newsgroups may require that you email the article to a moderator for approval instead of posting directly to the group. It may be required that the client authenticate itself using the **Authenticate** method prior to posting the article.

A news article is similar to an email message in that it contains one or more header fields, followed by an empty line, followed by the body of the article. Each line of text should be terminated by a carriage return/linefeed sequence of characters. The **SocketTools.MailMessage** class can be used to compose the news article if needed. Note that the article header must contain a header field named "Newsgroups" with a value that specifies the newsgroup or newsgroups the article is being posted to. If this header field is missing, the news server will reject the article.

See Also

NntpClient Class | SocketTools Namespace | NntpClient.PostArticle Overload List

NntpClient.PostArticle Method (String)

Post a new article to the currently selected newsgroup.

[Visual Basic]

```
Overloads Public Function PostArticle( _
   ByVal buffer As String _
) As Boolean
```

[C#]

```
public bool PostArticle(
   string buffer
);
```

Parameters

buffer
A string which contains the data to be posted to the server.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **PostArticle** method is used to submit the contents of the specified buffer to the server as a new article in the current newsgroup. This method will cause the current thread to block until the article transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

Not all newsgroups permit new articles to be posted, and some newsgroups may require that you email the article to a moderator for approval instead of posting directly to the group. It may be required that the client authenticate itself using the **Authenticate** method prior to posting the article.

A news article is similar to an email message in that it contains one or more header fields, followed by an empty line, followed by the body of the article. Each line of text should be terminated by a carriage return/linefeed sequence of characters. The **SocketTools.MailMessage** class can be used to compose the news article if needed. Note that the article header must contain a header field named "Newsgroups" with a value that specifies the newsgroup or newsgroups the article is being posted to. If this header field is missing, the news server will reject the article.

NntpClient.Read Method

Read data from the server and store it in a byte array.

Overload List

Read data from the server and store it in a byte array.

public int Read(byte[]);

Read data from the server and store it in a byte array.

public int Read(byte[],int);

Read data from the server and store it in a string.

public int Read(ref string);

Read data from the server and store it in a string.

public int Read(ref string,int);

See Also

NntpClient Class | SocketTools Namespace

NntpClient.Read Method (Byte[])

Read data from the server and store it in a byte array.

[Visual Basic]

```
Overloads Public Function Read( _
   ByVal buffer As Byte() _
) As Integer
```

[C#]

```
public int Read(
   byte[] buffer
);
```

Parameters

buffer

A byte array that the data will be stored in.

Return Value

An integer value which specifies the number of bytes actually read from the server. A return value of zero specifies that the remote host has closed the connection and there is no more data available to be read. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Read** method returns data that has been read from the server, up to the size of the byte array passed to the method. If no data is available to be read, an error will be generated if the client is in non-blocking mode. If the client is in blocking mode, the program will stop until data is received from the server or the connection is closed.

See Also

NntpClient Class | SocketTools Namespace | NntpClient.Read Overload List

NntpClient.Read Method (Byte[], Int32)

Read data from the server and store it in a byte array.

[Visual Basic]

```
Overloads Public Function Read( _
   ByVal buffer As Byte(), _
   ByVal length As Integer _
) As Integer
```

[C#]

```
public int Read(
   byte[] buffer,
   int length
);
```

Parameters

buffer

A byte array that the data will be stored in.

length

An integer value which specifies the maximum number of bytes of data to read. This value cannot be larger than the size of the buffer specified by the caller.

Return Value

An integer value which specifies the number of bytes actually read from the server. A return value of zero specifies that the remote host has closed the connection and there is no more data available to be read. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Read** method returns data that has been read from the server, up to the number of bytes specified. If no data is available to be read, an error will be generated if the client is in non-blocking mode. If the client is in blocking mode, the program will stop until data is received from the server or the connection is closed.

See Also

NntpClient Class | SocketTools Namespace | NntpClient.Read Overload List

NntpClient.Read Method (String)

Read data from the server and store it in a string.

[Visual Basic]

```
Overloads Public Function Read( _
   ByRef buffer As String _
) As Integer
```

[C#]

```
public int Read(
   ref string buffer
);
```

Parameters

buffer

A string that will contain the data read from the client.

Return Value

An integer value which specifies the number of bytes actually read from the server. A return value of zero specifies that the remote host has closed the connection and there is no more data available to be read. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Read** method returns data that has been read from the server, up to a maximum of 4096 bytes. If no data is available to be read, an error will be generated if the client is in non-blocking mode. If the client is in blocking mode, the program will stop until data is received from the server or the connection is closed.

This method should only be used if the remote host is sending data that consists of printable characters. Binary data should be read using the method that accepts a byte array as the buffer parameter.

See Also

NntpClient Class | SocketTools Namespace | NntpClient.Read Overload List

NntpClient.Read Method (String, Int32)

Read data from the server and store it in a string.

[Visual Basic]

```
Overloads Public Function Read( _
   ByRef buffer As String, _
   ByVal length As Integer _
) As Integer
```

[C#]

```
public int Read(
   ref string buffer,
   int length
);
```

Parameters

buffer

A string that will contain the data read from the client.

length

An integer value which specifies the maximum number of bytes of data to read.

Return Value

An integer value which specifies the number of bytes actually read from the server. A return value of zero specifies that the remote host has closed the connection and there is no more data available to be read. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Read** method returns data that has been read from the server, up to the number of bytes specified. If no data is available to be read, an error will be generated if the client is in non-blocking mode. If the client is in blocking mode, the program will stop until data is received from the server or the connection is closed.

This method should only be used if the remote host is sending data that consists of printable characters. Binary data should be read using the method that accepts a byte array as the buffer parameter.

NntpClient.Reset Method

Reset the internal state of the object, resetting all properties to their default values.

[Visual Basic]
```
Public Sub Reset()
```

[C#]
```
public void Reset();
```

Remarks

The **Reset** method returns the object to its default state. If a socket has been allocated, it will be released and any active connections will be terminated. All properties will be reset to their default values.

See Also

NntpClient Class | SocketTools Namespace

NntpClient.SelectGroup Method

Selects the specified newsgroup as the current newsgroup.

[Visual Basic]

```
Public Function SelectGroup( _
   ByVal groupName As String _
) As Boolean
```

[C#]

```
public bool SelectGroup(
   string groupName
);
```

Parameters

groupName

A string which specifies the name of the newsgroup to select.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **SelectGroup** method selects a newsgroup and updates the control with information about the group.

The values of the **FirstArticle** and **LastArticle** properties will be updated to reflect the range of available articles in the newsgroup. The value of the **Article** property will be set to the first available article in the newsgroup.

NntpClient Class | SocketTools Namespace

NntpClient.StoreArticle Method

Retrieve an article from the selected newsgroup and store it in a file.

Overload List

Retrieve an article from the selected newsgroup and store it in a file.

public bool StoreArticle(int,string);

Retrieve the current article from the selected newsgroup and store it in a file.

public bool StoreArticle(string);

See Also

NntpClient Class | SocketTools Namespace

NntpClient.StoreArticle Method (Int32, String)

Retrieve an article from the selected newsgroup and store it in a file.

[Visual Basic]

```
Overloads Public Function StoreArticle( _
   ByVal articleId As Integer, _
   ByVal fileName As String _
) As Boolean
```

[C#]

```
public bool StoreArticle(
   int articleId,
   string fileName
);
```

Parameters

articleId

An integer value which specifies the number of the article to retrieve from the server. This value must be greater than zero.

fileName

A string which specifies the name of the file that will contain the article. If the file does not exist, it will be created. If the file already exists, it will be overwritten.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **StoreArticle** method retrieves an article from the server and stores it in a file on the local system. The contents of the article is stored as a text file, using the specified file name. This method will cause the current thread to block until the message transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

The first available article in the current newsgroup can be determined by checking the value of the **FirstArticle** property. The last available article in the current newsgroup is returned by the **LastArticle** property.

See Also

NntpClient Class | SocketTools Namespace | NntpClient.StoreArticle Overload List

NntpClient.StoreArticle Method (String)

Retrieve the current article from the selected newsgroup and store it in a file.

[Visual Basic]
```
Overloads Public Function StoreArticle( _
   ByVal fileName As String _
) As Boolean
```

[C#]
```
public bool StoreArticle(
   string fileName
);
```

Parameters

fileName
A string which specifies the name of the file that will contain the article. If the file does not exist, it will be created. If the file already exists, it will be overwritten.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **StoreArticle** method retrieves an article from the server and stores it in a file on the local system. The contents of the article is stored as a text file, using the specified file name. This method will cause the current thread to block until the message transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

The **Article** property returns the current article number.

See Also

NntpClient Class | SocketTools Namespace | NntpClient.StoreArticle Overload List

NntpClient.Uninitialize Method

Uninitialize the class library and release any resources allocated for the current thread.

[Visual Basic]

```
Public Sub Uninitialize()
```

[C#]

```
public void Uninitialize();
```

Remarks

The **Uninitialize** method terminates any active connection, releases resources allocated for the current thread and unloads the networking library. After this method has been called, no further client operations may be performed until the class instance has been re-initialized.

If the **Initialize** method is explicitly called by the application, it should be matched by a call to the **Uninitialize** method when that instance of the class is no longer needed.

NntpClient Class | SocketTools Namespace | Initialize Method

NntpClient.Write Method

Write one or more bytes of data to the server.

Overload List

Write one or more bytes of data to the server.

public int Write(byte[]);

Write one or more bytes of data to the server.

public int Write(byte[],int);

Write a string of characters to the server.

public int Write(string);

Write a string of characters to the server.

public int Write(string,int);

See Also

NntpClient Class | SocketTools Namespace

NntpClient.Write Method (Byte[])

Write one or more bytes of data to the server.

```
[Visual Basic]
Overloads Public Function Write( _
   ByVal buffer As Byte() _
) As Integer
```

```
[C#]
public int Write(
   byte[] buffer
);
```

Parameters

buffer
A byte array that contains the data to be written to the server.

Return Value

An integer value which specifies the number of bytes actually written to the server. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Write** method sends one or more bytes of data to the server. If there is enough room in the client's internal send buffer to accommodate all of the data, it is copied to the send buffer and control immediately returns to the caller. If amount of data exceeds the available buffer space and the client is in blocking mode, then the method will block until the data can be sent. If the client is in non-blocking mode and the send buffer is full, an error will occur.

See Also

NntpClient Class | SocketTools Namespace | NntpClient.Write Overload List

NntpClient.Write Method (Byte[], Int32)

Write one or more bytes of data to the server.

[Visual Basic]

```
Overloads Public Function Write( _
   ByVal buffer As Byte(), _
   ByVal length As Integer _
) As Integer
```

[C#]

```
public int Write(
   byte[] buffer,
   int length
);
```

Parameters

buffer
A byte array that contains the data to be written to the server.

length
An integer value which specifies the maximum number of bytes of data to write. This value cannot be larger than the size of the buffer specified by the caller.

Return Value

An integer value which specifies the number of bytes actually written to the server. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Write** method sends one or more bytes of data to the server. If there is enough room in the client's internal send buffer to accommodate all of the data, it is copied to the send buffer and control immediately returns to the caller. If amount of data exceeds the available buffer space and the client is in blocking mode, then the method will block until the data can be sent. If the client is in non-blocking mode and the send buffer is full, an error will occur.

See Also

NntpClient Class | SocketTools Namespace | NntpClient.Write Overload List

NntpClient.Write Method (String)

Write a string of characters to the server.

[Visual Basic]

```
Overloads Public Function Write( _
   ByVal buffer As String _
) As Integer
```

[C#]

```
public int Write(
   string buffer
);
```

Parameters

buffer

A string which contains the data to be written to the server.

Return Value

An integer value which specifies the number of characters actually written to the server. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Write** method sends a string of characters to the server. If there is enough room in the client's internal send buffer to accommodate all of the data, it is copied to the send buffer and control immediately returns to the caller. If amount of data exceeds the available buffer space and the client is in blocking mode, then the method will block until the data can be sent. If the client is in non-blocking mode and the send buffer is full, an error will occur.

NntpClient.Write Method (String, Int32)

Write a string of characters to the server.

[Visual Basic]
```
Overloads Public Function Write( _
   ByVal buffer As String, _
   ByVal length As Integer _
) As Integer
```

[C#]
```
public int Write(
   string buffer,
   int length
);
```

Parameters

buffer
A string which contains the data to be written to the server.

length
An integer value which specifies the maximum number of characters to write. This value cannot be larger than the length of the string specified by the caller.

Return Value

An integer value which specifies the number of characters actually written to the server. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Write** method sends a string of characters to the server. If there is enough room in the client's internal send buffer to accommodate all of the data, it is copied to the send buffer and control immediately returns to the caller. If amount of data exceeds the available buffer space and the client is in blocking mode, then the method will block until the data can be sent. If the client is in non-blocking mode and the send buffer is full, an error will occur.

NntpClient Events

The events of the **NntpClient** class are listed below. For a complete list of **NntpClient** class members, see the NntpClient Members topic.

Public Instance Events

⚡ OnCancel	Occurs when a blocking client operation is canceled.
⚡ OnCommand	Occurs when the client sends a command to the remote host and receives a reply indicating the result of that command.
⚡ OnConnect	Occurs when a connection is established with the remote host.
⚡ OnDisconnect	Occurs when the remote host disconnects from the local system.
⚡ OnError	Occurs when an client operation fails.
⚡ OnProgress	Occurs as a data stream is being read or written to the client.
⚡ OnRead	Occurs when data is available to be read from the client.
⚡ OnTimeout	Occurs when a blocking operation fails to complete before the timeout period elapses.
⚡ OnWrite	Occurs when data can be written to the client.

See Also

NntpClient Class | SocketTools Namespace

NntpClient.OnCancel Event

Occurs when a blocking client operation is canceled.

[Visual Basic]

```
Public Event OnCancel As EventHandler
```

[C#]

```
public event EventHandler OnCancel;
```

Remarks

The **OnCancel** event is generated when a blocking client operation, such as sending or receiving data, is canceled with the **Cancel** method. To assist in determining which operation was canceled, check the value of the **Status** property.

See Also

NntpClient Class | SocketTools Namespace

NntpClient.OnCommand Event

Occurs when the client sends a command to the remote host and receives a reply indicating the result of that command.

[Visual Basic]
```
Public Event OnCommand As OnCommandEventHandler
```

[C#]
```
public event OnCommandEventHandler OnCommand;
```

Event Data

The event handler receives an argument of type NntpClient.CommandEventArgs containing data related to this event. The following **NntpClient.CommandEventArgs** properties provide information specific to this event.

Property	Description
ResultCode	Gets a value which specifies the last result code returned by the server.
ResultString	Gets a string value which describes the result of the previous command.

Remarks

The **OnCommand** event is generated when the client receives a reply from the server after some action has been taken.

See Also

NntpClient Class | SocketTools Namespace

NntpClient.CommandEventArgs Class

Provides data for the OnCommand event.

For a list of all members of this type, see NntpClient.CommandEventArgs Members.

System.Object
  System.EventArgs
    SocketTools.NntpClient.CommandEventArgs

[Visual Basic]

```
Public Class NntpClient.CommandEventArgs
    Inherits EventArgs
```

[C#]

```
public class NntpClient.CommandEventArgs : EventArgs
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

CommandEventArgs specifies the result code and result string for the last command executed by the server.

The OnCommand event occurs whenever a command is executed on the server.

Requirements

Namespace: SocketTools

Assembly: SocketTools.NntpClient (in SocketTools.NntpClient.dll)

See Also

NntpClient.CommandEventArgs Members | SocketTools Namespace

NntpClient.CommandEventArgs Members

NntpClient.CommandEventArgs overview

Public Instance Constructors

NntpClient.CommandEventArgs Constructor	Initializes a new instance of the NntpClient.CommandEventArgs class.

Public Instance Properties

ResultCode	Gets a value which specifies the last result code returned by the server.
ResultString	Gets a string value which describes the result of the previous command.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString (inherited from Object)	Returns a String that represents the current Object.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

NntpClient.CommandEventArgs Class | SocketTools Namespace

NntpClient.CommandEventArgs Constructor

Initializes a new instance of the NntpClient.CommandEventArgs class.

[Visual Basic]

```
Public Sub New()
```

[C#]

```
public NntpClient.CommandEventArgs();
```

See Also

NntpClient.CommandEventArgs Class | SocketTools Namespace

NntpClient.CommandEventArgs Properties

The properties of the **NntpClient.CommandEventArgs** class are listed below. For a complete list of **NntpClient.CommandEventArgs** class members, see the NntpClient.CommandEventArgs Members topic.

Public Instance Properties

ResultCode	Gets a value which specifies the last result code returned by the server.
ResultString	Gets a string value which describes the result of the previous command.

See Also

NntpClient.CommandEventArgs Class | SocketTools Namespace

NntpClient.CommandEventArgs.ResultCode Property

Gets a value which specifies the last result code returned by the server.

[Visual Basic]
```
Public ReadOnly Property ResultCode As Integer
```

[C#]
```
public int ResultCode {get;}
```

Property Value

An integer value which specifies the last result code returned by the server.

Remarks

This property should be checked after the **Command** method is used to execute a command on the server to determine if the operation was successful. Result codes are three-digit numeric values returned by the remote server and may be broken down into the following ranges:

ResultCode	Description
100-199	Positive preliminary result. This indicates that the requested action is being initiated, and the client should expect another reply from the server before proceeding.
200-299	Positive completion result. This indicates that the server has successfully completed the requested action.
300-399	Positive intermediate result. This indicates that the requested action cannot complete until additional information is provided to the server.
400-499	Transient negative completion result. This indicates that the requested action did not take place, but the error condition is temporary and may be attempted again.
500-599	Permanent negative completion result. This indicates that the requested action did not take place.

It is important to note that while some result codes have become standardized, not all servers respond to commands using the same result codes. For example, one server may respond with a result code of 221 to indicate success, while another may respond with a value of 235. It is recommended that applications check for ranges of values to determine if a command was successful, not a specific value.

See Also

NntpClient.CommandEventArgs Class | SocketTools Namespace

NntpClient.CommandEventArgs.ResultString Property

Gets a string value which describes the result of the previous command.

[Visual Basic]
```
Public ReadOnly Property ResultString As String
```

[C#]
```
public string ResultString {get;}
```

Property Value

A string which describes the result of the previous command executed on the server.

Remarks

This string is generated by the remote server, and typically is used to describe the result code. For example, if an error is indicated by the result code, the result string may describe the condition that caused the error.

See Also

NntpClient.CommandEventArgs Class | SocketTools Namespace

NntpClient.OnConnect Event

Occurs when a connection is established with the remote host.

[Visual Basic]

```
Public Event OnConnect As EventHandler
```

[C#]

```
public event EventHandler OnConnect;
```

Remarks

The **OnConnect** event occurs when a connection is made with a remote host as a result of a **Connect** method call. When the **Connect** method is called and the **Blocking** property is set to **false**, a socket is created but the connection is not actually established until after this event occurs. Between the time connection process is started and this event fires, no operation may be performed on the client other than calling the **Disconnect** method.

This event is only generated if the client is in non-blocking mode.

See Also

NntpClient Class | SocketTools Namespace

NntpClient.OnDisconnect Event

Occurs when the remote host disconnects from the local system.

[Visual Basic]

```
Public Event OnDisconnect As EventHandler
```

[C#]

```
public event EventHandler OnDisconnect;
```

Remarks

The **OnDisconnect** event occurs when the remote host closes its connection, terminating the client session with the application. Because there may still be data in the client receive buffers, you should continue to read data from the client until the **Read** method returns a value of 0. Once all of the data has been read, you should call the **Disconnect** method to close the local socket and release the resources allocated for the client.

This event is only generated if the client is in non-blocking mode.

See Also

NntpClient Class | SocketTools Namespace

NntpClient.OnError Event

Occurs when an client operation fails.

[Visual Basic]

```
Public Event OnError As OnErrorEventHandler
```

[C#]

```
public event OnErrorEventHandler OnError;
```

Event Data

The event handler receives an argument of type NntpClient.ErrorEventArgs containing data related to this event. The following **NntpClient.ErrorEventArgs** properties provide information specific to this event.

Property	Description
Description	Gets a value which describes the last error that has occurred.
Error	Gets a value which specifies the last error that has occurred.

Remarks

The **OnError** event occurs when a client operation fails.

See Also

NntpClient Class | SocketTools Namespace

NntpClient.ErrorEventArgs Class

Provides data for the OnError event.

For a list of all members of this type, see NntpClient.ErrorEventArgs Members.

System.Object
  System.EventArgs
    SocketTools.NntpClient.ErrorEventArgs

```
[Visual Basic]
Public Class NntpClient.ErrorEventArgs
    Inherits EventArgs
```

```
[C#]
public class NntpClient.ErrorEventArgs : EventArgs
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

ErrorEventArgs specifies the numeric error code and a description of the error that has occurred.

An OnError event occurs when a method fails.

Requirements

Namespace: SocketTools

Assembly: SocketTools.NntpClient (in SocketTools.NntpClient.dll)

```

[C#]

```
public string Description {get;}
```

Property Value

A string which describes the last error that has occurred.

See Also

NntpClient.ErrorEventArgs Class | SocketTools Namespace | Error Property

NntpClient.ErrorEventArgs.Error Property

Gets a value which specifies the last error that has occurred.

[Visual Basic]

```
Public ReadOnly Property Error As ErrorCode
```

[C#]

```
public NntpClient.ErrorCode Error {get;}
```

Property Value

ErrorCode enumeration which specifies the error.

See Also

NntpClient.ErrorEventArgs Class | SocketTools Namespace | Description Property

NntpClient.OnProgress Event

Occurs as a data stream is being read or written to the client.

[Visual Basic]

```
Public Event OnProgress As OnProgressEventHandler
```

[C#]

```
public event OnProgressEventHandler OnProgress;
```

Event Data

The event handler receives an argument of type NntpClient.ProgressEventArgs containing data related to this event. The following **NntpClient.ProgressEventArgs** properties provide information specific to this event.

Property	Description
Article	Gets the current article number.
BytesCopied	Gets a value which specifies the number of bytes of data that has been read or written.
BytesTotal	Gets a value which specifies the total number of bytes in the data stream.
Percent	Gets a value which specifies the percentage of data that has been read or written.

Remarks

The **OnProgress** event occurs as a data stream is being read or written to the client. If large amounts of data are being read or written, this event can be used to update a progress bar or other user-interface component to provide the user with some visual feedback on the progress of the operation.

See Also

NntpClient Class | SocketTools Namespace

NntpClient.ProgressEventArgs Class

Provides data for the OnProgress event.

For a list of all members of this type, see NntpClient.ProgressEventArgs Members.

System.Object
  System.EventArgs
    SocketTools.NntpClient.ProgressEventArgs

[Visual Basic]

```
Public Class NntpClient.ProgressEventArgs
    Inherits EventArgs
```

[C#]

```
public class NntpClient.ProgressEventArgs : EventArgs
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

ProgressEventArgs specifies the number of bytes copied from the data stream, the total number of bytes in the data stream and a completion percentage.

The OnProgress event occurs as a data stream is being read or written to the client.

Requirements

Namespace: SocketTools

Assembly: SocketTools.NntpClient (in SocketTools.NntpClient.dll)

NntpClient.ProgressEventArgs Members | SocketTools Namespace

NntpClient.ProgressEventArgs Members

NntpClient.ProgressEventArgs overview

Public Instance Constructors

NntpClient.ProgressEventArgs Constructor	Initializes a new instance of the NntpClient.ProgressEventArgs class.

Public Instance Properties

Article	Gets the current article number.
BytesCopied	Gets a value which specifies the number of bytes of data that has been read or written.
BytesTotal	Gets a value which specifies the total number of bytes in the data stream.
Percent	Gets a value which specifies the percentage of data that has been read or written.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString (inherited from Object)	Returns a String that represents the current Object.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

NntpClient.ProgressEventArgs Class | SocketTools Namespace

NntpClient.ProgressEventArgs Constructor

Initializes a new instance of the NntpClient.ProgressEventArgs class.

[Visual Basic]

```
Public Sub New()
```

[C#]

```
public NntpClient.ProgressEventArgs();
```

See Also

NntpClient.ProgressEventArgs Class | SocketTools Namespace

NntpClient.ProgressEventArgs Properties

The properties of the **NntpClient.ProgressEventArgs** class are listed below. For a complete list of **NntpClient.ProgressEventArgs** class members, see the NntpClient.ProgressEventArgs Members topic.

Public Instance Properties

Article	Gets the current article number.
BytesCopied	Gets a value which specifies the number of bytes of data that has been read or written.
BytesTotal	Gets a value which specifies the total number of bytes in the data stream.
Percent	Gets a value which specifies the percentage of data that has been read or written.

See Also

NntpClient.ProgressEventArgs Class | SocketTools Namespace

NntpClient.ProgressEventArgs.Article Property

Gets the current article number.

[Visual Basic]

```
Public ReadOnly Property Article As Integer
```

[C#]

```
public int Article {get;}
```

Property Value

An integer value which specifies the article number.

Remarks

The **Article** property specifies the article number that is currently being retrieved from the news server. If the **OnProgress** event occurs while a new article is being posted to the server, this property will return a value of zero.

See Also

NntpClient.ProgressEventArgs Class | SocketTools Namespace

NntpClient.ProgressEventArgs.BytesCopied Property

Gets a value which specifies the number of bytes of data that has been read or written.

[Visual Basic]

```
Public ReadOnly Property BytesCopied As Integer
```

[C#]

```
public int BytesCopied {get;}
```

Property Value

An integer value which specifies the number of bytes of data.

Remarks

The **BytesCopied** property specifies the number of bytes that have been read from the client and stored in the local stream buffer, or written from the stream buffer to the client.

See Also

NntpClient.ProgressEventArgs Class | SocketTools Namespace | BytesTotal Property | Percent Property

NntpClient.ProgressEventArgs.BytesTotal Property

Gets a value which specifies the total number of bytes in the data stream.

[Visual Basic]

```
Public ReadOnly Property BytesTotal As Integer
```

[C#]

```
public int BytesTotal {get;}
```

Property Value

An integer value which specifies the number of bytes of data.

Remarks

The **BytesTotal** property specifies the total amount of data being read from the client and stored in the data stream, or written from the data stream to the client. If the amount of data was unknown or unspecified at the time the method call was made, then this value will always be the same as the **BytesCopied** property.

See Also

NntpClient.ProgressEventArgs Class | SocketTools Namespace | BytesCopied Property | Percent Property

NntpClient.ProgressEventArgs.Percent Property

Gets a value which specifies the percentage of data that has been read or written.

[Visual Basic]

```
Public ReadOnly Property Percent As Integer
```

[C#]

```
public int Percent {get;}
```

Property Value

An integer value which specifies a percentage.

Remarks

The **Percent** property specifies the percentage of data that has been transmitted, expressed as an integer value between 0 and 100, inclusive. If the maximum size of the data stream was not specified by the caller, this value will always be 100.

See Also

NntpClient.ProgressEventArgs Class | SocketTools Namespace | BytesCopied Property | BytesTotal Property

NntpClient.OnRead Event

Occurs when data is available to be read from the client.

[Visual Basic]

```
Public Event OnRead As EventHandler
```

[C#]

```
public event EventHandler OnRead;
```

Remarks

The **OnRead** event occurs when data is available to be read from the client. This event is level-triggered, which means that once this event fires, it will not occur again until some data has been read from the client. This design prevents an application from being flooded with event notifications. It is recommended that your application read all of the available data from the server and store it in a local buffer for processing. See the example below.

This event is only generated if the client is in non-blocking mode.

Example

```
Private Sub Socket_OnRead(ByVal sender As Object, ByVal e As System.EventArgs)
Handles Socket.OnRead
    Dim strBuffer As String
    Dim nRead As Integer

    Do
        ' Read up to m_nBufferSize bytes of data from the server
        nRead = Socket.Read(strBuffer, m_nBufferSize)

        If nRead > 0 Then
            ' Append the data to an internal buffer for processing
            m_dataBuffer = m_dataBuffer + strBuffer
        End If
    Loop Until nRead < 1

    ProcessData()
End Sub
```

See Also

NntpClient Class | SocketTools Namespace

NntpClient.OnTimeout Event

Occurs when a blocking operation fails to complete before the timeout period elapses.

[Visual Basic]

```
Public Event OnTimeout As EventHandler
```

[C#]

```
public event EventHandler OnTimeout;
```

Remarks

The **OnTimeout** event occurs when a blocking operation, such as sending or receiving data on the client, fails to complete before the specified timeout period elapses. The timeout period for a blocking operation can be adjusted by setting the **Timeout** property.

This event is only generated if the client is in blocking mode.

See Also

NntpClient Class | SocketTools Namespace

NntpClient.OnWrite Event

Occurs when data can be written to the client.

[Visual Basic]

```
Public Event OnWrite As EventHandler
```

[C#]

```
public event EventHandler OnWrite;
```

Remarks

The **OnWrite** event occurs when the application can write data to the client. This event will typically occur when a connection is first established with the remote host, and after the **Write** method has failed because there was insufficient memory available in the client send buffers. In the second case, when some of the buffered data has been successfully sent to the remote host and there is space available in the send buffers, this event is used to signal the application that it may attempt to send more data.

This event is only generated if the client is in non-blocking mode.

NntpClient Class | SocketTools Namespace

NntpClient.ErrorCode Enumeration

Specifies the error codes returned by the NntpClient class.

[Visual Basic]

```
Public Enum NntpClient.ErrorCode
```

[C#]

```
public enum NntpClient.ErrorCode
```

Remarks

The NntpClient class uses the **ErrorCode** enumeration to specify what error has occurred when a method fails. The current error code may be determined by checking the value of the **LastError** property.

Note that the last error code is only meaningful if the previous operation has failed.

Members

Member Name	Description
errorNone	No error.
errorNotHandleOwner	Handle not owned by the current thread.
errorFileNotFound	The specified file or directory does not exist.
errorFileNotCreated	The specified file could not be created.
errorOperationCanceled	The blocking operation has been canceled.
errorInvalidFileType	The specified file is a block or character device, not a regular file.
errorInvalidDevice	The specified file type is invalid or not a regular file.
errorTooManyParameters	The maximum number of function parameters has been exceeded.
errorInvalidFileName	The specified file name contains invalid characters or is too long.
errorInvalidFileHandle	Invalid file handle passed to function.
errorFileReadFailed	Unable to read data from the specified file.
errorFileWriteFailed	Unable to write data to the specified file.
errorOutOfMemory	Out of memory.
errorAccessDenied	Access denied.
errorInvalidParameter	Invalid argument passed to function.
errorClipboardUnavailable	The system clipboard is currently unavailable.
errorClipboardEmpty	The system clipboard is empty or does not contain any text data.
errorFileEmpty	The specified file does not contain any data.
errorFileExists	The specified file already exists.

errorEndOfFile	End of file.
errorDeviceNotFound	The specified device could not be found.
errorDirectoryNotFound	The specified directory could not be found.
errorInvalidbuffer	Invalid memory address passed to function.
errorBufferTooSmall	The specified buffer is not large enough to contain the data.
errorNoHandles	No more handles are available to this process.
errorOperationWouldBlock	The specified operation would block the current thread.
errorOperationInProgress	A blocking operation is currently in progress.
errorAlreadyInProgress	The specified operation is already in progress.
errorInvalidHandle	Invalid handle passed to function.
errorInvalidAddress	Invalid network address specified.
errorInvalidSize	Datagram is too large to fit in specified buffer.
errorInvalidProtocol	Invalid network protocol specified.
errorProtocolNotAvailable	The specified network protocol is not available.
errorProtocolNotSupported	The specified protocol is not supported.
errorSocketNotSupported	The specified socket type is not supported.
errorInvalidOption	The specified option is invalid.
errorProtocolFamily	Specified protocol family is not supported.
errorProtocolAddress	The specified address is invalid for this protocol family.
errorAddressInUse	The specified address is in use by another process.
errorAddressUnavailable	The specified address cannot be assigned.
errorNetworkUnavailable	The networking subsystem is unavailable.
errorNetworkUnreachable	The specified network is unreachable.
errorNetworkReset	Network dropped connection on remote reset.
errorConnectionAborted	Connection was aborted due to timeout or other failure.
errorConnectionReset	Connection was reset by remote network.
errorOutOfBuffers	No buffer space is available.
errorAlreadyConnected	Connection already established with remote host.
errorNotConnected	No connection established with remote host.
errorConnectionShutdown	Unable to send or receive data after connection shutdown.
errorOperationTimeout	The specified operation has timed out.
errorConnectionRefused	The connection has been refused by the remote host.

errorHostUnavailable	The specified host is unavailable.
errorHostUnreachable	Remote host is unreachable.
errorTooManyProcesses	Too many processes are using the networking subsystem.
errorTooManyThreads	Too many threads have been created by the current process.
errorTooManySessions	Too many client sessions have been created by the current process.
errorInternalFailure	An unexpected internal error has occurred.
errorNetworkNotReady	Network subsystem is not ready for communication.
errorInvalidVersion	This version of the operating system is not supported.
errorNetworkNotInitialized	The networking subsystem has not been initialized.
errorRemoteShutdown	The remote host has initiated a graceful shutdown sequence.
errorInvalidHostName	The specified hostname is invalid or could not be resolved.
errorHostNameNotFound	The specified hostname could not be found.
errorHostNameRefused	Unable to resolve hostname, request refused.
errorHostNameNotResolved	Unable to resolve hostname, no address for specified host.
errorInvalidLicense	The license for this product is invalid.
errorProductNotLicensed	This product is not licensed to perform this operation.
errorNotImplemented	This function has not been implemented on this platform.
errorUnknownLocalhost	Unable to determine local host name.
errorInvalidHostAddress	Invalid host address specified.
errorInvalidServicePort	Invalid service port number specified.
errorInvalidServiceName	Invalid or unknown service name specified.
errorInvalidEventId	Invalid event identifier specified.
errorOperationNotBlocking	No blocking operation in progress on this socket.
errorSecurityNotInitialized	Unable to initialize security interface for this process.
errorSecurityContext	Unable to establish security context for this session.
errorSecurityCredentials	Unable to open certificate store or establish security credentials.
errorSecurityCertificate	Unable to validate the certificate chain for this

	session.
errorSecurityDecryption	Unable to decrypt data stream.
errorSecurityEncryption	Unable to encrypt data stream.
errorOperationNotSupported	The specified operation is not supported.
errorInvalidProtocolVersion	Invalid application protocol version specified.
errorNoServerResponse	No data returned from server.
errorInvalidServerResponse	Invalid data returned from server.
errorUnexpectedServerResponse	Unexpected response code returned from server.
errorServerTransactionFailed	Server transaction failed.
errorServiceUnavailable	The service is currently unavailable.
errorServiceNotReady	The service is not ready, try again later.
errorServerResyncFailed	Unable to resynchronize with server.
errorInvalidProxyType	Invalid proxy server type specified.
errorProxyRequired	Resource must be accessed through specified proxy.
errorInvalidProxyLogin	Unable to login to proxy server using specified credentials.
errorProxyResyncFailed	Unable to resynchronize with proxy server.
errorInvalidCommand	Invalid command specified.
errorInvalidCommandParameter	Invalid command parameter specified.
errorInvalidCommandSequence	Invalid command sequence specified.
errorCommandNotImplemented	Specified command not implemented on this server.
errorCommandNotAuthorized	Specified command not authorized for the current user.
errorCommandAborted	Specified command was aborted by the remote host.
errorOptionNotSupported	The specified option is not supported on this server.
errorRequestNotCompleted	The current client request has not been completed.
errorInvalidUserName	The specified username is invalid.
errorInvalidPassword	The specified password is invalid.
errorInvalidAccount	The specified account name is invalid.
errorAccountRequired	Account name has not been specified.
errorInvalidAuthenticationType	Invalid authentication protocol specified.
errorAuthenticationRequired	User authentication is required.
errorProxyAuthenticationRequired	Proxy authentication required.

errorAlreadyAuthenticated	User has already been authenticated.
errorAuthenticationFailed	Unable to authenticate the specified user.
errorNetworkAdapter	Unable to determine network adapter configuration.
errorInvalidRecordType	Invalid record type specified.
errorInvalidRecordName	Invalid record name specified.
errorInvalidRecordData	Invalid record data specified.
errorConnectionOpen	Data connection already established.
errorConnectionClosed	Server closed data connection.
errorConnectionPassive	Data connection is passive.
errorConnectionFailed	Unable to open data connection to server.
errorInvalidSecurityLevel	Data connection cannot be opened with this security setting.
errorCachedTLSRequired	Data connection requires cached TLS session.
errorDataReadOnly	Data connection is read-only.
errorDataWriteOnly	Data connection is write-only.
errorEndOfData	End of data.
errorRemoteFileUnavailable	Remote file is unavailable.
errorInsufficientStorage	Insufficient storage on server.
errorStorageallocation	File exceeded storage allocation on server.
errorDirectoryExists	The specified directory already exists.
errorDirectoryEmpty	No files returned by the server for the specified directory.
errorEndOfDirectory	End of directory listing.
errorUnknownDirectoryFormat	Unknown directory format.
errorInvalidResource	Invalid resource name specified.
errorResourceRedirected	The specified resource has been redirected.
errorResourceRestricted	Access to this resource has been restricted.
errorResourceNotModified	The specified resource has not been modified.
errorResourceNotFound	The specified resource cannot be found.
errorResourceConflict	Request could not be completed due to the current state of the resource.
errorResourceRemoved	The specified resource has been permanently removed from this server.
errorContentLengthRequired	Request must include the content length.
errorRequestPrecondition	Request could not be completed due to server precondition.
errorUnsupportedMediaType	Request specified an unsupported media type.

errorInvalidContentRange	Content range specified for this resource is invalid.
errorInvalidMessagePart	Message is not multipart or an invalid message part was specified.
errorInvalidMessageHeader	The specified message header is invalid or has not been defined.
errorInvalidMessageBoundary	The multipart message boundary has not been defined.
errorNoFileAttachment	The current message part does not contain a file attachment.
errorUnknownFileType	The specified file type could not be determined.
errorDataNotEncoded	The specified data block could not be encoded.
errorDataNotDecoded	The specified data block could not be decoded.
errorFileNotEncoded	The specified file could not be encoded.
errorFileNotDecoded	The specified file could not be decoded.
errorNoMessageText	No message text.
errorInvalidCharacterSet	Invalid character set specified.
errorInvalidEncodingType	Invalid encoding type specified.
errorInvalidMessageNumber	Invalid message number specified.
errorNoReturnAddress	No valid return address specified.
errorNoValidRecipients	No valid recipients specified.
errorInvalidRecipient	The specified recipient address is invalid.
errorRelayNotAuthorized	The specified domain is invalid or server will not relay messages.
errorMailboxUnavailable	Specified mailbox is currently unavailable.
errorMailboxReadOnly	The selected mailbox cannot be modified.
errorMailboxNotSelected	No mailbox has been selected.
errorInvalidMailbox	Specified mailbox is invalid.
errorInvalidDomain	The specified domain name is invalid or not recognized.
errorInvalidSender	The specified sender address is invalid or not recognized.
errorMessageNotDelivered	Message not delivered to any of the specified recipients.
errorEndOfMessageData	No more message data available to be read
errorInvalidmessageSize	The specified message size is invalid.
errorMessageNotCreated	The message could not be created in the specified mailbox.
errorNoMoreMailboxes	No more mailboxes exist on this server.

errorInvalidEmulationType	The specified terminal emulation type is invalid.
errorInvalidFontHandle	The specified font handle is invalid.
errorInvalidFontName	The specified font name is invalid or unavailable.
errorInvalidPacketSize	The specified packet size is invalid.
errorInvalidPacketData	The specified packet data is invalid.
errorInvalidPacketId	The unique packet identifier is invalid.
errorPacketTTLExpired	The specified packet time-to-live period has expired.
errorInvalidNewsGroup	Invalid newsgroup specified.
errorNoNewsgroupSelected	No newsgroup selected.
errorEmptyNewsgroup	No articles in specified newsgroup.
errorInvalidArticle	Invalid article number specified.
errorNoArticleSelected	No article selected in the current newsgroup.
errorFirstArticle	First article in current newsgroup.
errorLastArticle	Last article in current newsgroup.
errorArticleExists	Unable to transfer article, article already exists.
errorArticleRejected	Unable to transfer article, article rejected.
errorArticleTransferFailed	Article transfer failed.
errorArticlePostingDenied	Posting is not permitted on this server.
errorArticlePostingFailed	Unable to post article on this server.
errorInvalidDateFormat	The specified date format is not recognized.
errorFeatureNotSupported	The specified feature is not supported on this server.
errorInvalidFormHandle	The specified form handle is invalid or a form has not been created.
errorInvalidFormAction	The specified form action is invalid or has not been specified.
errorInvalidFormMethod	The specified form method is invalid or not supported.
errorInvalidFormType	The specified form type is invalid or not supported.
errorInvalidFormField	The specified form field name is invalid or does not exist.
errorEmptyForm	The specified form does not contain any field values.
errorMaximumConnections	The maximum number of client connections exceeded.
errorThreadCreationFailed	Unable to create a new thread for the current process.
errorInvalidThreadHandle	The specified thread handle is no longer valid.

errorThreadTerminated	The specified thread has been terminated.
errorThreadDeadlock	The operation would result in the current thread becoming deadlocked.
errorInvalidClientMoniker	The specified moniker is not associated with any client session.
errorClientMonikerExists	The specified moniker has been assigned to another client session.
errorServerInactive	The specified server is not listening for client connections.
errorServerSuspended	The specified server is suspended and not accepting client connections.
errorNoMessageStore	No message store has been specified.
errorMessageStoreChanged	The message store has changed since it was last accessed.
errorMessageNotFound	No message was found that matches the specified criteria.
errorMessageDeleted	The specified message has been deleted.
errorFileChecksumMismatch	The local and remote file checksums do not match.
errorFileSizeMismatch	The local and remote file sizes do not match.
errorInvalidFeedUrl	The news feed URL is invalid or specifies an unsupported protocol.
errorInvalidFeedFormat	The internal format of the news feed is invalid.
errorInvalidFeedVersion	This version of the news feed is not supported.
errorChannelEmpty	There are no valid items found in this news feed.
errorInvalidItemNumber	The specified channel item identifier is invalid.
errorItemNotFound	The specified channel item could not be found.
errorItemEmpty	The specified channel item does not contain any data.
errorInvalidItemProperty	The specified item property name is invalid.
errorItemPropertyNotFound	The specified item property has not been defined.
errorInvalidChannelTitle	The channel title is invalid or has not been defined.
errorInvalidChannelLink	The channel hyperlink is invalid or has not been defined.
errorInvalidChannelDescription	The channel description is invalid or has not been defined.
errorInvalidItemText	The description for an item is invalid or has not been defined.
errorInvalidItemLink	The hyperlink for an item is invalid or has not been defined.

errorInvalidServiceType	The specified service type is invalid.
errorServiceSuspended	Access to the specified service has been suspended.
errorServiceRestricted	Access to the specified service has been restricted.
errorInvalidProviderName	The specified provider name is invalid or unknown.
errorInvalidPhoneNumber	The specified phone number is invalid or not supported in this region.
errorGatewayNotFound	A message gateway cannot be found for the specified provider.
errorMessageTooLong	The message exceeds the maximum number of characters permitted.
errorInvalidProviderData	The request returned invalid or incomplete service provider data.
errorInvalidGatewayData	The request returned invalid or incomplete message gateway data.
errorMultipleProviders	The request has returned multiple service providers.
errorProviderNotFound	The specified service provider could not be found.
errorInvalidMessageService	The specified message is not supported with this service type.
errorInvalidMessageFormat	The specified message format is invalid.
errorInvalidConfiguration	The specified configuration options are invalid.
errorServerActive	The requested action is not permitted while the server is active.
errorServerPortBound	Unable to obtain exclusive use of the specified local port.
errorInvalidClientSession	The specified client identifier is invalid for this session.
errorClientNotIdentified	The specified client has not provided user credentials.
errorInvalidClientState	The requested action cannot be performed at this time.
errorInvalidResultCode	The specified result code is not valid for this protocol
errorCommandRequired	The specified command is required and cannot be disabled.
errorCommandDisabled	The specified command has been disabled.
errorCommandSequence	The command cannot be processed at this time.
errorCommandCompleted	The previous command has completed.
errorInvalidProgramName	The specified program name is invalid or unrecognized.

errorInvalidRequestHeader	The request header contains one or more invalid values.
errorInvalidVirtualHost	The specified virtual host name is invalid.
errorVirtualHostNotFound	The specified virtual host does not exist.
errorTooManyVirtualHosts	Too many virtual hosts created for this server.
errorInvalidVirtualPath	The specified virtual path name is invalid.
errorVirtualPathNotFound	The specified virtual path does not exist.
errorTooManyVirtualPaths	Too many virtual paths created for this server.
errorInvalidTask	The asynchronous task identifier is invalid.
errorTaskActive	The asynchronous task has not finished.
errorTaskQueued	The asynchronous task has been queued.
errorTaskSuspended	The asynchronous task has been suspended.
errorTaskFinished	The asynchronous task has finished.

Requirements

SocketTools Namespace | LastError Property | LastErrorString Property | OnError Event

NntpClient.NewsGroupAccess Enumeration

Specifies the newsgroup access modes that the NntpClient class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]
```
<Flags>
Public Enum NntpClient.NewsGroupAccess
```

[C#]
```
[Flags]
public enum NntpClient.NewsGroupAccess
```

Members

Member Name	Description	Value
groupReadOnly	The group is read-only and cannot be modified. Attempts to post articles to the newsgroup will result in an error.	0
groupReadWrite	Articles can be posted to the newsgroup. Even though a newsgroup is read-write, it may require that the client authenticate before being given permission to post articles to the server.	1
groupModerated	The newsgroup is moderated and articles can only be posted by the group moderator. To request that an article be posted to the newsgroup, you must email the message to the moderator.	2

Requirements

Namespace: SocketTools

Assembly: SocketTools.NntpClient (in SocketTools.NntpClient.dll)

See Also

SocketTools Namespace

NntpClient.NewsOptions Enumeration

Specifies the options that the NntpClient class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]

```
<Flags>
Public Enum NntpClient.NewsOptions
```

[C#]

```
[Flags]
public enum NntpClient.NewsOptions
```

Remarks

The NntpClient class uses the **NewsOptions** enumeration to specify one or more options to be used when establishing a connection with a remote host. Multiple options may be specified if necessary.

Members

Member Name	Description	Value
optionNone	No option specified.	0
optionDefault	The default connection option. This is the same as specifying **optionNone**.	0
optionTunnel	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established. This option also forces all connections to be outbound and enables the firewall compatibility features in the client.	1024
optionTrustedSite	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using either the SSL or TLS protocols.	2048
optionSecure	This option specifies the client should attempt to establish a secure connection with the server. Note that the server must support secure connections using either the SSL or TLS protocol.	4096
optionSecureFallback	This option specifies the client should permit the use of less secure cipher	32768

	suites for compatibility with legacy servers. If this option is specified, the client will permit connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.	
optionPreferIPv6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.	262144
optionFreeThread	This option specifies that class methods may be called from any thread, and not only the thread that established the connection. Using this option disables certain internal safety checks that are made by the class and may result in unexpected behavior unless you ensure that access to the class instance is synchronized across multiple threads.	524288

SocketTools Namespace

NntpClient.NewsStatus Enumeration

Specifies the status values that may be returned by the NntpClient class.

[Visual Basic]
```
Public Enum NntpClient.NewsStatus
```

[C#]
```
public enum NntpClient.NewsStatus
```

Remarks

The NntpClient class uses the **NewsStatus** enumeration to identify the current status of the client.

Members

Member Name	Description
statusUnused	A client session has not been created. Attempts to perform any network operations, such as sending or receiving data, will generate an error.
statusIdle	A client session has been created, but is not currently in use. A blocking socket operation can be executed at this point.
statusConnect	The client is in the process of establishing a connection with a remote host.
statusRead	The client is in the process of receiving data from a remote host.
statusWrite	The client is in the process of sending data to a remote host.
statusDisconnect	The client session is being closed and subsequent attempts to access the client will result in an error.

Requirements

Namespace: SocketTools

Assembly: SocketTools.NntpClient (in SocketTools.NntpClient.dll)

NntpClient.SecureCipherAlgorithm Enumeration

Specifies the encryption algorithms that the NntpClient class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]
```
<Flags>
Public Enum NntpClient.SecureCipherAlgorithm
```

[C#]
```
[Flags]
public enum NntpClient.SecureCipherAlgorithm
```

Remarks

The NntpClient class uses the **SecureCipherAlgorithm** enumeration to identify which encryption algorithm was selected when a secure connection was established with the remote host.

Members

Member Name	Description	Value
cipherNone	No cipher has been selected. A secure connection has not been established with the remote host.	0
cipherRC2	The RC2 block cipher was selected. This is a variable key length cipher which supports keys between 40- and 128-bits in length, in 8-bit increments.	1
cipherRC4	The RC4 stream cipher was selected. This is a variable key length cipher which supports keys between 40- and 128-bits in length, in 8-bit increments.	2
cipherRC5	The RC5 block cipher was selected. This is a variable key length cipher which supports keys up to 2040 bits, in 8-bit increments.	4
cipherDES	The DES (Data Encryption Standard) block cipher was selected. This is a fixed key length cipher using 56-bit keys.	8
cipherDES3	The Triple DES block cipher was selected. This cipher encrypts the data three times using different keys, effectively using a 168-bit key length.	16
cipherDESX	A variant of the DES block cipher which XORs an extra 64-bits of the key before and after the plaintext has been encrypted, increasing the key size to 184 bits.	32
cipherAES	The Advanced Encryption Standard	64

	cipher (also known as the Rijndael cipher) is a fixed block size cipher which use a key size of 128, 192 or 256 bits. This cipher is supported on Windows XP SP3 SP3 and later versions of the operating system.	
cipherSkipjack	The Skipjack block cipher was selected. This is a fixed key length cipher, using 80-bit keys.	128

NntpClient.SecureHashAlgorithm Enumeration

Specifies the hash algorithms that the NntpClient class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]

```
<Flags>
Public Enum NntpClient.SecureHashAlgorithm
```

[C#]

```
[Flags]
public enum NntpClient.SecureHashAlgorithm
```

Remarks

The NntpClient class uses the **SecureHashAlgorithm** enumeration to identify the message digest (hash) algorithm that was selected when a secure connection was established with the remote host.

Members

Member Name	Description	Value
hashNone	No hash algorithm has been selected. This is not a secure connection with the server.	0
hashMD5	The MD5 algorithm was selected. This algorithm produces a 128-bit message digest. This algorithm is no longer considered to be cryptographically secure.	1
hashSHA	The SHA-1 algorithm was selected. This algorithm produces a 160-bit message digest. This algorithm is no longer considered to be cryptographically secure.	2
hashSHA256	The SHA-256 algorithm was selected. This algorithm produces a 256-bit message digest.	4
hashSHA384	The SHA-384 algorithm was selected. This algorithm produces a 384-bit message digest.	8
hashSHA512	The SHA-512 algorithm was selected. This algorithm produces a 512-bit message digest.	16

Requirements

Namespace: SocketTools

Assembly: SocketTools.NntpClient (in SocketTools.NntpClient.dll)

SocketTools Namespace

NntpClient.SecureKeyAlgorithm Enumeration

Specifies the key exchange algorithms that the NntpClient class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]

```
<Flags>
Public Enum NntpClient.SecureKeyAlgorithm
```

[C#]

```
[Flags]
public enum NntpClient.SecureKeyAlgorithm
```

Remarks

The NntpClient class uses the **SecureKeyAlgorithm** enumeration to identify the key exchange algorithm that was selected when a secure connection was established with the remote host.

Members

Member Name	Description	Value
keyExchangeNone	No key exchange algorithm has been selected. This is not a secure connection with the server.	0
keyExchangeRSA	The RSA public key exchange algorithm has been selected.	1
keyExchangeKEA	The KEA public key exchange algorithm has been selected. This is an improved version of the Diffie-Hellman public key algorithm.	2
keyExchangeDH	The Diffie-Hellman public key exchange algorithm has been selected.	4
keyExchangeECDH	The Elliptic Curve Diffie-Hellman key exchange algorithm was selected. This is a variant of the Diffie-Hellman algorithm which uses elliptic curve cryptography. This key exchange algorithm is only supported on Windows XP SP3 SP3 and later versions of the operating system.	8

Requirements

Namespace: SocketTools

Assembly: SocketTools.NntpClient (in SocketTools.NntpClient.dll)

See Also

SocketTools Namespace

NntpClient.SecurityCertificate Enumeration

Specifies the security certificate status values that may be returned by the NntpClient class.

[Visual Basic]
```
Public Enum NntpClient.SecurityCertificate
```

[C#]
```
public enum NntpClient.SecurityCertificate
```

Remarks

The NntpClient class uses the **SecurityCertificate** enumeration to identify the current status of the certificate that was provided by the remote host when a secure connection was established.

Members

Member Name	Description
certificateNone	No certificate information is available. A secure connection was not established with the server.
certificateValid	The certificate is valid.
certificateNoMatch	The certificate is valid, however the domain name specified in the certificate does not match the domain name of the remote host. The application can examine the **CertificateSubject** property to determine the site the certificate was issued to.
certificateExpired	The certificate has expired and is no longer valid. The application can examine the **CertificateExpires** property to determine when the certificate expired.
certificateRevoked	The certificate has been revoked and is no longer valid. It is recommended that the application immediately terminate the connection if this status is returned.
certificateUntrusted	The certificate has not been issued by a trusted authority, or the certificate is not trusted on the local host. It is recommended that the application immediately terminate the connection if this status is returned.
certificateInvalid	The certificate is invalid. This typically indicates that the internal structure of the certificate is damaged. It is recommended that the application immediately terminate the connection if this status is returned.

Requirements

Namespace: SocketTools

Assembly: SocketTools.NntpClient (in SocketTools.NntpClient.dll)

See Also

SocketTools Namespace

NntpClient.SecurityProtocols Enumeration

Specifies the security protocols that the NntpClient class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

```
[Visual Basic]
<Flags>
Public Enum NntpClient.SecurityProtocols
```

```
[C#]
[Flags]
public enum NntpClient.SecurityProtocols
```

Remarks

The NntpClient class uses the **SecurityProtocols** enumeration to specify one or more security protocols to be used when establishing a connection with a remote host. Multiple protocols may be specified if necessary and the actual protocol used will be negotiated with the remote host. It is recommended that most applications use **protocolDefault** when creating a secure connection.

Members

Member Name	Description	Value
protocolNone	No security protocol will be used, a secure connection will not be established.	0
protocolSSL2	The SSL 2.0 protocol has been selected. This protocol has been deprecated and is no longer widely used. It is not recommended that this protocol be used when establishing secure connections.	1
protocolSSL3	The SSL 3.0 protocol has been selected. This protocol has been deprecated and is no longer widely used. It is not recommended that this protocol be used when establishing secure connections. In most cases, this protocol is only selected if TLS is not supported by the server.	2
protocolTLS10	The TLS 1.0 protocol has been selected. This version of the protocol is commonly used by older servers and is the only version of TLS supported on Windows platforms prior to Windows 7 SP1 and Windows Server 2008 R2.	4
protocolTLS11	The TLS 1.1 protocol has been selected. This version of TLS is supported on Windows 7 SP1 and Windows Server 2008 R2 and later versions of the	8

	operating system.	
protocolTLS12	The TLS 1.2 protocol has been selected. This is the default version of the protocol and is supported on Windows 7 SP1 and Windows Server 2008 R2 and later versions of Windows. It is recommended that you use this version of TLS.	16
protocolSSL	Any version of the Secure Sockets Layer (SSL) protocol should be used. The actual protocol version used will be negotiated with the remote host.	3
protocolTLS	Any version of the the Transport Layer Security (TLS) protocol should be used. The actual protocol version used will be negotiated with the remote host, with with preference for TLS 1.2.	28
protocolTLS1	Version 1.0, 1.1 or 1.2 of the the Transport Layer Security (TLS) protocol should be used. The actual protocol version used will be negotiated with the remote host, with preference for TLS 1.2.	28
protocolDefault	The default selection of security protocols will be used when establishing a connection. The TLS 1.2, 1.1 and 1.0 protocols will be negotiated with the host, in that order of preference. This option will always request the latest version of the preferred security protocols and is the recommended value.	16
protocolUnknown	An unknown or unsupported security protocol has been specified. This value indicates an error condition.	4096

Requirements

Namespace: SocketTools

Assembly: SocketTools.NntpClient (in SocketTools.NntpClient.dll)

NntpClient.TraceOptions Enumeration

Specifies the logging options that the NntpClient class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]

```
<Flags>
Public Enum NntpClient.TraceOptions
```

[C#]

```
[Flags]
public enum NntpClient.TraceOptions
```

Remarks

The NntpClient class uses the **TraceOptions** enumeration to specify what kind of debugging information is written to the trace logfile. These options are only meaningful when trace logging is enabled by setting the **Trace** property to **true**.

Members

Member Name	Description	Value
traceDefault	The default trace logging option. This is the same as specifying the **traceInfo** option.	0
traceInfo	All network function calls are written to the trace file. This is the default value.	0
traceError	Only those network function calls which fail are recorded in the trace file.	1
traceWarning	Only those network function calls which fail, or return values which indicate a warning, are recorded in the trace file.	2
traceHexDump	All network function calls are written to the trace file, plus all the data that is sent or received is displayed, in both ASCII and hexadecimal format.	4
traceProcess	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for multithreaded applications that are using worker threads.	4096

SocketTools Namespace

NntpClient.OnCommandEventHandler Delegate

Represents the method that will handle the OnCommand event.

[Visual Basic]

```
Public Delegate Sub NntpClient.OnCommandEventHandler( _
   ByVal sender As Object, _
   ByVal e As CommandEventArgs _
)
```

[C#]

```
public delegate void NntpClient.OnCommandEventHandler(
      object sender,
      CommandEventArgs e
   );
```

Parameters

sender

The source of the event.

e

A CommandEventArgs object that contains the event data.

Remarks

When you create an **OnCommandEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnCommandEventHandler** delegate declaration.

Requirements

Namespace: SocketTools

Assembly: SocketTools.NntpClient (in SocketTools.NntpClient.dll)

See Also

SocketTools Namespace

NntpClient.OnErrorEventHandler Delegate

Represents the method that will handle the OnError event.

[Visual Basic]

```
Public Delegate Sub NntpClient.OnErrorEventHandler( _
   ByVal sender As Object, _
   ByVal e As ErrorEventArgs _
)
```

[C#]

```
public delegate void NntpClient.OnErrorEventHandler(
      object sender,
      ErrorEventArgs e
   );
```

Parameters

sender

The source of the event.

e

An ErrorEventArgs that contains the event data.

Remarks

When you create an **OnErrorEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnErrorEventHandler** delegate declaration.

Requirements

Namespace: SocketTools

Assembly: SocketTools.NntpClient (in SocketTools.NntpClient.dll)

See Also

SocketTools Namespace

NntpClient.OnProgressEventHandler Delegate

Represents the method that will handle the OnProgress event.

[Visual Basic]

```
Public Delegate Sub NntpClient.OnProgressEventHandler( _
   ByVal sender As Object, _
   ByVal e As ProgressEventArgs _
)
```

[C#]

```
public delegate void NntpClient.OnProgressEventHandler(
      object sender,
      ProgressEventArgs e
   );
```

Parameters

sender

The source of the event.

e

A ProgressEventArgs that contains the event data.

Remarks

When you create an **OnProgressEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnProgressEventHandler** delegate declaration.

Requirements

Namespace: SocketTools

Assembly: SocketTools.NntpClient (in SocketTools.NntpClient.dll)

See Also

SocketTools Namespace

NntpClient.RuntimeLicenseAttribute Class

Attribute that defines the runtime license key for the class.

For a list of all members of this type, see NntpClient.RuntimeLicenseAttribute Members.

System.Object
  System.Attribute
    SocketTools.NntpClient.RuntimeLicenseAttribute

[Visual Basic]

```
<AttributeUsage(ValidOn:=AttributeTargets.Assembly, AllowMultiple:=False,
   Inherited:=True)>
Public Class NntpClient.RuntimeLicenseAttribute
    Inherits Attribute
```

[C#]

```
[AttributeUsage(ValidOn=AttributeTargets.Assembly, AllowMultiple=False,
   Inherited=True)]
public class NntpClient.RuntimeLicenseAttribute : Attribute
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

The RuntimeLicense attribute is used to define the runtime license key that will be used when an instance of the class is created. This attribute is defined in the assembly information module for the language, such as AssemblyInfo.cs when programming C#. The runtime license key must be defined if you wish to redistribute your application.

The runtime license key for your copy of SocketTools can be generated using the License Manager utility that is included with the product. Note that if you have installed an evaluation license, you will not have a runtime license key and cannot redistribute any applications which use the NntpClient class.

Example

```
<Assembly: SocketTools.NntpClient.RuntimeLicense("abcdefghijklmnop")>
```

```
[assembly: SocketTools.NntpClient.RuntimeLicense("abcdefghijklmnop")]
```

Requirements

Namespace: SocketTools

Assembly: SocketTools.NntpClient (in SocketTools.NntpClient.dll)

See Also

NntpClient.RuntimeLicenseAttribute Members | SocketTools Namespace

NntpClient.RuntimeLicenseAttribute Members

NntpClient.RuntimeLicenseAttribute overview

Public Instance Constructors

NntpClient.RuntimeLicenseAttribute Constructor	Constructor for the RuntimeLicense attribute which defines the runtime license key.

Public Instance Properties

LicenseKey	Returns the value of the runtime license key.
TypeId (inherited from Attribute)	When implemented in a derived class, gets a unique identifier for this Attribute.

Public Instance Methods

Equals (inherited from Attribute)	
GetHashCode (inherited from Attribute)	Returns the hash code for this instance.
GetType (inherited from Object)	Gets the Type of the current instance.
IsDefaultAttribute (inherited from Attribute)	When overridden in a derived class, returns an indication whether the value of this instance is the default value for the derived class.
Match (inherited from Attribute)	When overridden in a derived class, returns a value indicating whether this instance equals a specified object.
ToString (inherited from Object)	Returns a String that represents the current Object.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

NntpClient.RuntimeLicenseAttribute Class | SocketTools Namespace

NntpClient.RuntimeLicenseAttribute Constructor

Constructor for the RuntimeLicense attribute which defines the runtime license key.

[Visual Basic]

```
Public Sub New( _
   ByVal licenseKey As String _
)
```

[C#]

```
public NntpClient.RuntimeLicenseAttribute(
   string licenseKey
);
```

Parameters

licenseKey

A string argument which specifies the runtime license key which will be used to initialize the class library.

Remarks

The runtime license key for your copy of SocketTools can be generated using the License Manager utility that is included with the product. Note that if you have installed an evaluation license, you will not have a runtime license key and cannot redistribute any applications which use the NntpClient class.

See Also

NntpClient.RuntimeLicenseAttribute Class | SocketTools Namespace

NntpClient.RuntimeLicenseAttribute Properties

The properties of the **NntpClient.RuntimeLicenseAttribute** class are listed below. For a complete list of **NntpClient.RuntimeLicenseAttribute** class members, see the NntpClient.RuntimeLicenseAttribute Members topic.

Public Instance Properties

LicenseKey	Returns the value of the runtime license key.
TypeId (inherited from Attribute)	When implemented in a derived class, gets a unique identifier for this Attribute.

See Also

NntpClient.RuntimeLicenseAttribute Class | SocketTools Namespace

NntpClient.RuntimeLicenseAttribute.LicenseKey Property

Returns the value of the runtime license key.

[Visual Basic]

```
Public Property LicenseKey As String
```

[C#]

```
public string LicenseKey {get; set;}
```

Property Value

A string which contains the runtime license key.

See Also

NntpClient.RuntimeLicenseAttribute Class | SocketTools Namespace

NntpClientException Class

The exception that is thrown when a client error occurs.

For a list of all members of this type, see NntpClientException Members.

System.Object
  System.Exception
    System.ApplicationException
      SocketTools.NntpClientException

[Visual Basic]
```
Public Class NntpClientException
    Inherits ApplicationException
```

[C#]
```
public class NntpClientException : ApplicationException
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

A NntpClientException is thrown by the NntpClient class when an error occurs.

The default constructor for the NntpClientException class sets the **ErrorCode** property to the last client error that occurred.

Requirements

Namespace: SocketTools

Assembly: SocketTools.NntpClient (in SocketTools.NntpClient.dll)

See Also

NntpClientException Members | SocketTools Namespace

NntpClientException Members

NntpClientException overview

Public Instance Constructors

NntpClientException	Overloaded. Initializes a new instance of the NntpClientException class.

Public Instance Properties

ErrorCode	Gets a value which specifies the error that caused the exception.
HelpLink (inherited from Exception)	Gets or sets a link to the help file associated with this exception.
InnerException (inherited from Exception)	Gets the Exception instance that caused the current exception.
Message	Gets a value which describes the error that caused the exception.
Number	Gets a value which specifies the numeric value of the error that caused the exception.
Source (inherited from Exception)	Gets or sets the name of the application or the object that causes the error.
StackTrace (inherited from Exception)	Gets a string representation of the frames on the call stack at the time the current exception was thrown.
TargetSite (inherited from Exception)	Gets the method that throws the current exception.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetBaseException (inherited from Exception)	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetObjectData (inherited from Exception)	When overridden in a derived class, sets the SerializationInfo with information about the exception.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString	Creates and returns a string representation of the current exception.

Protected Instance Properties

HResult (inherited from Exception)	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

NntpClientException Class | SocketTools Namespace

NntpClientException Constructor

Initializes a new instance of the NntpClientException class with the last network error code.

Overload List

Initializes a new instance of the NntpClientException class with the last network error code.

public NntpClientException();

Initializes a new instance of the NntpClientException class with a specified error number.

public NntpClientException(int);

Initializes a new instance of the NntpClientException class with a specified error message.

public NntpClientException(string);

Initializes a new instance of the NntpClientException class with a specified error message and a reference to the inner exception that is the cause of this exception.

public NntpClientException(string,Exception);

See Also

NntpClientException Class | SocketTools Namespace

NntpClientException Constructor ()

Initializes a new instance of the NntpClientException class with the last network error code.

[Visual Basic]

```
Overloads Public Sub New()
```

[C#]

```
public NntpClientException();
```

Remarks

The ctor constructor sets the **ErrorCode** property to the last client error that occurred. For more information about the errors that may occur, refer to the NntpClient.ErrorCode enumeration.

See Also

NntpClientException Class | SocketTools Namespace | NntpClientException Constructor Overload List

NntpClientException Constructor (String)

Initializes a new instance of the NntpClientException class with a specified error message.

[Visual Basic]

```
Overloads Public Sub New( _
   ByVal message As String _
)
```

[C#]

```
public NntpClientException(
   string message
);
```

Parameters

message

The error message that explains the reason for the exception.

Remarks

The content of the ***message*** parameter is intended to be understood by humans. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

See Also

NntpClientException Class | SocketTools Namespace | NntpClientException Constructor Overload List

NntpClientException Constructor (String, Exception)

Initializes a new instance of the NntpClientException class with a specified error message and a reference to the inner exception that is the cause of this exception.

[Visual Basic]

```
Overloads Public Sub New( _
   ByVal message As String, _
   ByVal innerException As Exception _
)
```

[C#]

```
public NntpClientException(
   string message,
   Exception innerException
);
```

Parameters

message

The error message that explains the reason for the exception.

innerException

The exception that is the cause of the current exception. If the ***innerException*** parameter is not a null reference, the current exception is raised in a **catch** block that handles the inner exception.

Remarks

The content of the message parameter is intended to be understood by humans. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

An exception that is thrown as a direct result of a previous exception should include a reference to the previous exception in the **InnerException** property. The **InnerException** property returns the same value that is passed into the constructor, or a null reference if the **InnerException** property does not supply the inner exception value to the constructor.

See Also

NntpClientException Class | SocketTools Namespace | NntpClientException Constructor Overload List

NntpClientException Constructor (Int32)

Initializes a new instance of the NntpClientException class with a specified error number.

[Visual Basic]

```
Overloads Public Sub New( _
   ByVal code As Integer _
)
```

[C#]

```
public NntpClientException(
   int code
);
```

Parameters

code
An integer value which specifies an error code.

Remarks

This constructor sets the **ErrorCode** property to the specified error code. For more information about the errors that may occur, refer to the NntpClient.ErrorCode enumeration.

See Also

NntpClientException Class | SocketTools Namespace | NntpClientException Constructor Overload List

NntpClientException Properties

The properties of the **NntpClientException** class are listed below. For a complete list of **NntpClientException** class members, see the NntpClientException Members topic.

Public Instance Properties

ErrorCode	Gets a value which specifies the error that caused the exception.
HelpLink (inherited from Exception)	Gets or sets a link to the help file associated with this exception.
InnerException (inherited from Exception)	Gets the Exception instance that caused the current exception.
Message	Gets a value which describes the error that caused the exception.
Number	Gets a value which specifies the numeric value of the error that caused the exception.
Source (inherited from Exception)	Gets or sets the name of the application or the object that causes the error.
StackTrace (inherited from Exception)	Gets a string representation of the frames on the call stack at the time the current exception was thrown.
TargetSite (inherited from Exception)	Gets the method that throws the current exception.

Protected Instance Properties

HResult (inherited from Exception)	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception.

See Also

NntpClientException Class | SocketTools Namespace

NntpClientException.ErrorCode Property

Gets a value which specifies the error that caused the exception.

[Visual Basic]

```
Public ReadOnly Property ErrorCode As ErrorCode
```

[C#]

```
public NntpClient.ErrorCode ErrorCode {get;}
```

Property Value

Returns a NntpClient.ErrorCode enumeration value which specifies the error code.

Remarks

The **ErrorCode** property returns the error code that specifies the cause of the exception.

The default constructor for the NntpClientException class sets the error code to the last network error that occurred. For more information about the errors that may occur, refer to the NntpClient.ErrorCode enumeration.

See Also

NntpClientException Class | SocketTools Namespace

NntpClientException.Message Property

Gets a value which describes the error that caused the exception.

[Visual Basic]

```
Overrides Public ReadOnly Property Message As String
```

[C#]

```
public override string Message {get;}
```

Property Value

A string which describes the error that caused the exception.

Remarks

The **Message** property returns a string which describes the error that caused the exception.

See Also

NntpClientException Class | SocketTools Namespace

NntpClientException.Number Property

Gets a value which specifies the numeric value of the error that caused the exception.

[Visual Basic]

```
Public ReadOnly Property Number As Integer
```

[C#]

```
public int Number {get;}
```

Property Value

An integer value that specifies the error that caused the exception.

Remarks

The **Number** property returns an integer value which specifies the numeric value of the error that caused the exception. This value is the same as the values returned by the Windows Sockets API. For more information about socket error codes, see the Windows Socket Version 2 API error code documentation in MSDN.

See Also

NntpClientException Class | SocketTools Namespace

NntpClientException Methods

The methods of the **NntpClientException** class are listed below. For a complete list of **NntpClientException** class members, see the NntpClientException Members topic.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetBaseException (inherited from Exception)	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetObjectData (inherited from Exception)	When overridden in a derived class, sets the SerializationInfo with information about the exception.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString	Creates and returns a string representation of the current exception.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

NntpClientException Class | SocketTools Namespace

NntpClientException.ToString Method

Creates and returns a string representation of the current exception.

[Visual Basic]
```
Overrides Public Function ToString() As String
```

[C#]
```
public override string ToString();
```

Return Value

A string representation of the current exception.

Remarks

The **ToString** method returns a representation of the current exception that is intended to be understood by humans. Where the exception contains culture-sensitive data, the string representation returned by **ToString** is required to take into account the current system culture. Although there are no exact requirements for the format of the returned string, it should attempt to reflect the value of the object as perceived by the user.

This implementation of **ToString** obtains the numeric error code value and a description of the error that caused the current exception. If there is no error message or it is an empty string, then no error message is returned.

This method overrides **ApplicationException.ToString**.

NntpClientException Class | SocketTools Namespace

NetworkTime Class

Query a time server for the current time and synchronize the local system clock with that value.

For a list of all members of this type, see NetworkTime Members.

System.Object
  SocketTools.NetworkTime

[Visual Basic]
```
Public Class NetworkTime
    Implements IDisposable
```

[C#]
```
public class NetworkTime : IDisposable
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

The NetworkTime class library provides an interface for synchronizing the local system's time and date with that of a remote server. The time values returned are in in Coordinated Universal Time and be adjusted for the local host's timezone. The class enables developers to query a server for the current time and then update the system clock if desired.

Requirements

Namespace: SocketTools

Assembly: SocketTools.NetworkTime (in SocketTools.NetworkTime.dll)

See Also

NetworkTime Members | SocketTools Namespace

NetworkTime Members

NetworkTime overview

Public Static (Shared) Fields

timePortDefault	A constant value which specifies the default port number.
timeTimeout	A constant value which specifies the default timeout period.

Public Instance Constructors

NetworkTime Constructor	Initializes a new instance of the NetworkTime class.

Public Instance Properties

AutoResolve	Gets and sets a value that determines if host names and addresses are automatically resolved.
HostAddress	Gets and sets a value which specifies the Internet address used to establish a connection.
HostName	Gets and sets a value which specifies the host name used to establish a connection.
IsInitialized	Gets a value which indicates if the current instance of the class has been initialized successfully.
LastError	Gets and sets a value which specifies the last error that has occurred.
LastErrorString	Gets a value which describes the last error that has occurred.
LocalAddress	Gets the local Internet address that the client is bound to.
Localize	Gets and sets a value which specifies if the time should be adjusted for the current timezone.
LocalName	Gets a value which specifies the host name for the local system.
LocalPort	Gets the local port number the client is bound to.
Options	Gets and sets a value which specifies one or more client options.
RemotePort	Gets and sets a value which specifies the remote port number.
RemoteService	Gets and sets a value which specifies the remote service.
ThreadModel	Gets and sets a value which specifies the threading model for the class instance.
ThrowError	Gets and sets a value which specifies if method calls should throw exceptions when an error

	occurs.
Timeout	Gets and sets a value which specifies a timeout period in seconds.
Trace	Gets and sets a value which indicates if network function logging is enabled.
TraceFile	Gets and sets a value which specifies the name of the logfile.
TraceFlags	Gets and sets a value which specifies the client function tracing flags.
Version	Gets a value which returns the current version of the NetworkTime class library.

Public Instance Methods

AttachThread	Attach an instance of the class to the current thread
ConvertTime	Overloaded. Convert a network time value to a System.DateTime value.
Dispose	Overloaded. Releases all resources used by NetworkTime.
Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetTime	Overloaded. Get the current system date and time from the specified time server.
GetType (inherited from Object)	Gets the Type of the current instance.
Initialize	Overloaded. Initialize an instance of the NetworkTime class.
Reset	Reset the internal state of the object, resetting all properties to their default values.
SetTime	Overloaded. Set the local system clock to the specified System.DateTime value.
ToString (inherited from Object)	Returns a String that represents the current Object.
Uninitialize	Uninitialize the class library and release any resources allocated for the current thread.

Public Instance Events

OnCancel	Occurs when a blocking client operation is canceled.
OnError	Occurs when an client operation fails.
OnTimeout	Occurs when a blocking operation fails to complete before the timeout period elapses.

Protected Instance Methods

Dispose	Overloaded. Releases the unmanaged resources allocated by the NetworkTime class and optionally releases the managed resources.
Finalize	Destroys an instance of the class, releasing the resources allocated for the session and unloading the networking library.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

NetworkTime Properties

The properties of the **NetworkTime** class are listed below. For a complete list of **NetworkTime** class members, see the NetworkTime Members topic.

Public Instance Properties

AutoResolve	Gets and sets a value that determines if host names and addresses are automatically resolved.
HostAddress	Gets and sets a value which specifies the Internet address used to establish a connection.
HostName	Gets and sets a value which specifies the host name used to establish a connection.
IsInitialized	Gets a value which indicates if the current instance of the class has been initialized successfully.
LastError	Gets and sets a value which specifies the last error that has occurred.
LastErrorString	Gets a value which describes the last error that has occurred.
LocalAddress	Gets the local Internet address that the client is bound to.
Localize	Gets and sets a value which specifies if the time should be adjusted for the current timezone.
LocalName	Gets a value which specifies the host name for the local system.
LocalPort	Gets the local port number the client is bound to.
Options	Gets and sets a value which specifies one or more client options.
RemotePort	Gets and sets a value which specifies the remote port number.
RemoteService	Gets and sets a value which specifies the remote service.
ThreadModel	Gets and sets a value which specifies the threading model for the class instance.
ThrowError	Gets and sets a value which specifies if method calls should throw exceptions when an error occurs.
Timeout	Gets and sets a value which specifies a timeout period in seconds.
Trace	Gets and sets a value which indicates if network function logging is enabled.
TraceFile	Gets and sets a value which specifies the name of the logfile.

TraceFlags	Gets and sets a value which specifies the client function tracing flags.
Version	Gets a value which returns the current version of the NetworkTime class library.

NetworkTime Class | SocketTools Namespace

NetworkTime.AutoResolve Property

Gets and sets a value that determines if host names and addresses are automatically resolved.

[Visual Basic]

```
Public Property AutoResolve As Boolean
```

[C#]

```
public bool AutoResolve {get; set;}
```

Property Value

Returns **true** if host names are automatically resolved to Internet addresses. The default value is **false**.

Remarks

Setting the **AutoResolve** property determines if the class automatically resolves host names and addresses specified by the **HostName** and **HostAddress** properties. If set to **true**, setting the **HostName** property will cause the class to automatically determine the corresponding IP address and update the **HostAddress** property accordingly. Likewise, setting the **HostAddress** property will cause the class to determine the host name and update the **HostName** property. Setting this property to **false** prevents the class from resolving host names until a connection attempt is made.

It is important to note that setting the **HostName** or **HostAddress** property may cause the current thread to block, sometimes for several seconds, until the name or address is resolved. To prevent this behavior, set this property value to **false**.

See Also

NetworkTime Class | SocketTools Namespace

NetworkTime.HostAddress Property

Gets and sets a value which specifies the Internet address used to establish a connection.

[Visual Basic]
```
Public Property HostAddress As String
```

[C#]
```
public string HostAddress {get; set;}
```

Property Value

A string which specifies an Internet address.

Remarks

The **HostAddress** property can be used to set the Internet address for a remote system that you wish to communicate with. If the **AutoResolve** property is set to **true** and the address is assigned to a valid host name, the **HostName** property will be updated with that value.

See Also

NetworkTime Class | SocketTools Namespace

NetworkTime.HostName Property

Gets and sets a value which specifies the host name used to establish a connection.

[Visual Basic]

```
Public Property HostName As String
```

[C#]

```
public string HostName {get; set;}
```

Property Value

A string which specifies a host name.

Remarks

The **HostName** property can be used to set the host name for a remote system that you wish to communicate with. If the **AutoResolve** property is set to **true** and the name can be resolved to a valid Internet address, the **HostAddress** property will be updated with that value.

See Also

NetworkTime Class | SocketTools Namespace

NetworkTime.IsInitialized Property

Gets a value which indicates if the current instance of the class has been initialized successfully.

[Visual Basic]
```
Public ReadOnly Property IsInitialized As Boolean
```

[C#]
```
public bool IsInitialized {get;}
```

Property Value

Returns **true** if the class instance has been initialized; otherwise returns **false**.

Remarks

The **IsInitialized** property is used to determine if the current instance of the class has been initialized properly. Normally this is done automatically by the class constructor, however there are circumstances where the class may not be able to initialize itself.

The most common reasons that a class instance may not initialize correctly is that no runtime license key has been defined in the assembly or the license key provided is invalid. It may also indicate a problem with the system configuration or user access rights, such as not being able to load the required networking libraries or not being able to access the system registry.

See Also

NetworkTime Class | SocketTools Namespace

NetworkTime.LastError Property

Gets and sets a value which specifies the last error that has occurred.

[Visual Basic]

```
Public Property LastError As ErrorCode
```

[C#]

```
public NetworkTime.ErrorCode LastError {get; set;}
```

Property Value

Returns an ErrorCode enumeration value which specifies the last error code.

Remarks

The **LastError** property returns the error code associated with the last error that occurred for the current instance of the class. It is important to note that this value only has meaning if the previous method indicates that an error has actually occurred.

It is possible to explicitly clear the last error code by assigning the property to the value **ErrorCode.errorNone**.

The error code value can be cast to an integer value for display purposes if required. For a description of the error that can be displayed using a message box or some other similar mechanism, get the value of the **LastErrorString** property.

See Also

NetworkTime Class | SocketTools Namespace

NetworkTime.LastErrorString Property

Gets a value which describes the last error that has occurred.

[Visual Basic]

```
Public ReadOnly Property LastErrorString As String
```

[C#]

```
public string LastErrorString {get;}
```

Property Value

A string which describes the last error that has occurred.

Remarks

The **LastErrorString** property can be used to obtain a description of the last error that occurred for the current instance of the class. It is important to note that this value only has meaning if the previous method indicates that an error has actually occurred.

See Also

NetworkTime Class | SocketTools Namespace

NetworkTime.LocalAddress Property

Gets the local Internet address that the client is bound to.

[Visual Basic]

```
Public ReadOnly Property LocalAddress As String
```

[C#]

```
public string LocalAddress {get;}
```

Property Value

A string which specifies an Internet address.

Remarks

The **LocalAddress** property returns the local Internet address that the client is bound to when a connection is established with a remote host. This property may return either an IPv4 or IPv6 formatted address, depending on the type of connection that was established.

See Also

NetworkTime Class | SocketTools Namespace

NetworkTime.Localize Property

Gets and sets a value which specifies if the time should be adjusted for the current timezone.

[Visual Basic]

```
Public Property Localize As Boolean
```

[C#]

```
public bool Localize {get; set;}
```

Property Value

A boolean value which specifies if the time should be adjusted for the local timezone.

Remarks

The **Localize** property controls how date and time values are localized when the **GetTime** method is called. If the property is set to **true** the date and time will be adjusted to the current timezone. If the property is set to **false** the file date and time are returned as UTC (Coordinated Universal Time) values.

See Also

NetworkTime Class | SocketTools Namespace

NetworkTime.LocalName Property

Gets a value which specifies the host name for the local system.

[Visual Basic]

```
Public ReadOnly Property LocalName As String
```

[C#]

```
public string LocalName {get;}
```

Property Value

A string which specifies the local host name.

Remarks

The **LocalName** property returns the fully-qualified host name assigned to the local system. If the system has not been configured with an Internet domain name, then this property will return the NetBIOS name assigned to the local system.

See Also

NetworkTime Class | SocketTools Namespace

NetworkTime.LocalPort Property

Gets the local port number the client is bound to.

[Visual Basic]

```
Public ReadOnly Property LocalPort As Integer
```

[C#]

```
public int LocalPort {get;}
```

Property Value

An integer value which specifies a port number. The default value is 0.

Remarks

The **LocalPort** property is used to identify the local port number that the client is bound to to when a connection is established with a remote host.

See Also

NetworkTime Class | SocketTools Namespace

NetworkTime.RemotePort Property

Gets and sets a value which specifies the remote port number.

[Visual Basic]

```
Public Property RemotePort As Integer
```

[C#]

```
public int RemotePort {get; set;}
```

Property Value

An integer value which specifies a port number.

Remarks

The **RemotePort** property is used to set the port number that will be used to establish a connection with a remote host. If the port number specifies a well-known port, the **RemoteService** property will be updated with that name.

See Also

NetworkTime Class | SocketTools Namespace

NetworkTime.ThreadModel Property

Gets and sets a value which specifies the threading model for the class instance.

[Visual Basic]
```
Public Property ThreadModel As ThreadingModel
```

[C#]
```
public NetworkTime.ThreadingModel ThreadModel {get; set;}
```

Property Value

Returns one or more ThreadingModel enumeration value which specifies the threading model for the client. The default value for this property is **modelSingleThread**.

Remarks

The **ThreadModel** property specifies the threading model that is used by the class instance when a connection is established. The default value for this property is **modelSingleThread**, which specifies that only the thread that established the connection should be permitted to invoke methods. It is important to note that this threading model does not limit the application to a single thread of execution. When a session is established using the **Connect** method, that session is attached to the thread that created it. From that point on, until the session is terminated, only the owner may invoke methods in that instance of the class. The ownership of the class instance may be transferred from one thread to another using the **AttachThread** method.

Setting this property to **modelFreeThread** disables certain internal safety checks that are performed by the class and may result in unexpected behavior unless you ensure that access to the class instance is synchronized across multiple threads. The application must ensure that no two threads will attempt to invoke a blocking method at the same time. In other words, if one thread invokes a method, the application must ensure that another thread will not attempt to invoke any other method at the same time using the same instance of the class.

Changing the value of this property will not affect an active client session. The threading model must be specified prior to invoking the **Connect** method.

See Also

NetworkTime Class | SocketTools Namespace | AttachThread Method | ThreadingModel Enumeration | ThreadModel Attribute

NetworkTime.ThrowError Property

Gets and sets a value which specifies if method calls should throw exceptions when an error occurs.

[Visual Basic]

```
Public Property ThrowError As Boolean
```

[C#]

```
public bool ThrowError {get; set;}
```

Property Value

Returns **true** if method calls will generate exceptions when an error occurs; otherwise returns **false**. The default value is **false**.

Remarks

Error handling for when calling class methods can be done in either of two different styles, according to the value of this property.

If the **ThrowError** property is set to **false**, the application should check the return value of any method that is used, and report errors based upon the documented value of the return code. It is the responsibility of the application to interpret the error code, if it is desired to explain the error in addition to reporting it. This is the default behavior.

If the **ThrowError** property is set to **true**, then exceptions will be generated whenever a method call fails. The program must be written to catch these exceptions and take the appropriate action when an error occurs. Failure to handle an exception will cause the program to terminate abnormally.

Note that if an error occurs while a property is being read or modified, an exception will be raised regardless of the value of the **ThrowError** property.

See Also

NetworkTime Class | SocketTools Namespace

NetworkTime.Timeout Property

Gets and sets a value which specifies a timeout period in seconds.

[Visual Basic]

```
Public Property Timeout As Integer
```

[C#]

```
public int Timeout {get; set;}
```

Property Value

An integer value which specifies a timeout period in seconds.

Remarks

Setting the **Timeout** property specifies the number of seconds until a blocking operation fails and returns an error.

The timeout period is only used when the client is in blocking mode. Although this property can be changed when the client is in non-blocking mode, the value will be ignored until the client is returned to blocking mode.

For most applications it is recommended the timeout period be set between 10 and 20 seconds.

See Also

NetworkTime Class | SocketTools Namespace

NetworkTime.Trace Property

Gets and sets a value which indicates if network function logging is enabled.

[Visual Basic]
```
Public Property Trace As Boolean
```

[C#]
```
public bool Trace {get; set;}
```

Property Value

Returns **true** if network function tracing is enabled; otherwise returns **false**. The default value is **false**.

Remarks

The **Trace** property is used to enable (or disable) the tracing of network function calls. When enabled, each function call is logged to a file, including the function parameters, return value and error code if applicable. This facility can be enabled and disabled at run time, and the trace log file can be specified by setting the **TraceFile** property. All function calls that are being logged are appended to the trace file, if it exists. If no trace file exists when tracing is enabled, the trace file is created.

The tracing facility is available in all of the SocketTools networking classes and is enabled or disabled for an entire process. This means that once trace logging is enabled for a given component, all of the function calls made by the process using any of the SocketTools classes will be logged. For example, if you have an application using both the File Transfer Protocol and Post Office Protocol classes, and you set the **Trace** property to **true**, function calls made by both classes will be logged. Additionally, enabling a trace is cumulative, and tracing is not stopped until it is disabled for all classes used by the process.

If trace logging is not enabled, there is no negative impact on performance or throughput. Once enabled, application performance can degrade, especially in those situations in which multiple processes are being traced or the logfile is fairly large. Since logfiles can grow very quickly, even with modest applications, it is recommended that you delete the file when it is no longer needed.

When redistributing your application, make sure that you include the **SocketTools10.TraceLog.dll** module with your installation. If this library is not present, then no trace output will be generated and the value of the **Trace** property will be ignored. Only those function calls made by the SocketTools networking classes will be logged. Calls made directly to the Windows Sockets API, or calls made by other classes, will not be logged.

See Also

NetworkTime Class | SocketTools Namespace

NetworkTime.TraceFile Property

Gets and sets a value which specifies the name of the logfile.

[Visual Basic]

```
Public Property TraceFile As String
```

[C#]

```
public string TraceFile {get; set;}
```

Property Value

A string which specifies the name of the file.

Remarks

The **TraceFile** property is used to specify the name of the trace file that is created when network function tracing is enabled. If this property is set to an empty string (the default value), then a file named **SocketTools.log** is created in the system's temporary directory. If no temporary directory exists, then the file is created in the current working directory.

If the file exists, the trace output is appended to the file, otherwise the file is created. Since network function tracing is enabled per-process, the trace file is shared by all instances of the class being used. If multiple class instances have tracing enabled, the **TraceFile** property should be set to the same value for each instance. Since trace files can grow very quickly, even with modest applications, it is recommended that you delete the file when it is no longer needed.

The trace file has the following format:

```
 MyApp INF: WSAAsyncSelect(46, 0xcc4, 0x7e9, 0x27) returned 0 MyApp WRN:
connect(46, 192.0.0.1:1234, 16) returned -1 [10035] MyApp ERR: accept(46,
NULL, 0x0) returned -1 [10038]
```

The first column contains the name of the process that is being traced. The second column identifies if the trace record is reporting information, a warning, or an error. What follows is the name of the function being called, the arguments passed to the function and the function's return value. If a warning or error is reported, the error code is appended to the record (the value is placed inside brackets).

If parameters are passed as integer values, they are recorded in decimal. If the parameter or return value is a pointer (a memory address), it is recorded as a hexadecimal value preceded with "0x". A special type of pointer, called a null pointer, is recorded as NULL. Those functions which expect socket addresses are displayed in the following format:

```
aa.bb.cc.dd:nnnn
```

The first four numbers separated by periods represent the IP address, and the number following the colon represents the port number in host byte order. Note that in the second line of the above example, the control is attempting to connect to a system with the IP address 192.0.0.1 on port 1234.

Note that if the specified file cannot be created, or the user does not have permission to modify an existing file, the error is silently ignored and no trace output will be generated.

See Also

NetworkTime Class | SocketTools Namespace

NetworkTime.TraceFlags Property

Gets and sets a value which specifies the client function tracing flags.

[Visual Basic]

```
Public Property TraceFlags As TraceOptions
```

[C#]

```
public NetworkTime.TraceOptions TraceFlags {get; set;}
```

Property Value

A TraceOptions enumeration which specifies the amount of detail written to the trace logfile.

Remarks

The **TraceFlags** property is used to specify the type of information written to the trace file when network function tracing is enabled.

Because network function tracing is enabled per-process, the trace flags are shared by all instances of the class being used. If multiple class instances have tracing enabled, the **TraceFlags** property should be set to the same value for each instance. Changing the trace flags for any one instance of the class will affect the logging performed for all SocketTools classes used by the application.

Warnings are generated when a non-fatal error is returned by a network function. For example, if data is being written and the error **errorOperationWouldBlock** occurs, a warning is generated because the application simply needs to attempt to write the data at a later time.

See Also

NetworkTime Class | SocketTools Namespace

NetworkTime.Version Property

Gets a value which returns the current version of the NetworkTime class library.

[Visual Basic]
```
Public ReadOnly Property Version As String
```

[C#]
```
public string Version {get;}
```

Property Value

A string which specifies the version of the class library.

Remarks

The **Version** property returns a string which identifies the current version and build of the NetworkTime class library. This value can be used by an application for validation and debugging purposes.

See Also

NetworkTime Class | SocketTools Namespace

NetworkTime Methods

The methods of the **NetworkTime** class are listed below. For a complete list of **NetworkTime** class members, see the NetworkTime Members topic.

Public Instance Methods

AttachThread	Attach an instance of the class to the current thread
ConvertTime	Overloaded. Convert a network time value to a System.DateTime value.
Dispose	Overloaded. Releases all resources used by NetworkTime.
Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetTime	Overloaded. Get the current system date and time from the specified time server.
GetType (inherited from Object)	Gets the Type of the current instance.
Initialize	Overloaded. Initialize an instance of the NetworkTime class.
Reset	Reset the internal state of the object, resetting all properties to their default values.
SetTime	Overloaded. Set the local system clock to the specified System.DateTime value.
ToString (inherited from Object)	Returns a String that represents the current Object.
Uninitialize	Uninitialize the class library and release any resources allocated for the current thread.

Protected Instance Methods

Dispose	Overloaded. Releases the unmanaged resources allocated by the NetworkTime class and optionally releases the managed resources.
Finalize	Destroys an instance of the class, releasing the resources allocated for the session and unloading the networking library.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

NetworkTime.ConvertTime Method

Convert a System.DateTime value to a network time value.

Overload List

Convert a System.DateTime value to a network time value.

public bool ConvertTime(ref DateTime,ref long);

Convert a network time value to a System.DateTime value.

public bool ConvertTime(long,ref DateTime);

Convert a network time value to a System.DateTime value.

public bool ConvertTime(long,ref DateTime,bool);

See Also

NetworkTime Class | SocketTools Namespace

NetworkTime.ConvertTime Method (DateTime, Int64)

Convert a System.DateTime value to a network time value.

[Visual Basic]

```
Overloads Public Function ConvertTime( _
   ByRef dateTime As Date, _
   ByRef networkTime As Long _
) As Boolean
```

[C#]

```
public bool ConvertTime(
   ref DateTime dateTime,
   ref long networkTime
);
```

Parameters

dateTime

A **System.DateTime** structure passed by reference which will contain the date and time when the method returns.

networkTime

A long integer value which specifies the network time.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

Network time is expressed as the number of seconds that has elapsed since midnight, January 1, 1900 UTC.

See Also

NetworkTime Class | SocketTools Namespace | NetworkTime.ConvertTime Overload List

NetworkTime.ConvertTime Method (Int64, DateTime)

Convert a network time value to a System.DateTime value.

[Visual Basic]

```
Overloads Public Function ConvertTime( _
   ByVal networkTime As Long, _
   ByRef dateTime As Date _
) As Boolean
```

[C#]

```
public bool ConvertTime(
   long networkTime,
   ref DateTime dateTime
);
```

Parameters

networkTime

A long integer value which specifies the network time.

dateTime

A **System.DateTime** structure passed by reference which will contain the date and time when the method returns.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

If the **Localize** property is set to **true**, the network time value will be localized to the current timezone. If the property value is **false** the network time will be converted as-is.

Network time is expressed as the number of seconds that has elapsed since midnight, January 1, 1900 UTC.

See Also

NetworkTime Class | SocketTools Namespace | NetworkTime.ConvertTime Overload List

NetworkTime.ConvertTime Method (Int64, DateTime, Boolean)

Convert a network time value to a System.DateTime value.

[Visual Basic]

```
Overloads Public Function ConvertTime( _
   ByVal networkTime As Long, _
   ByRef dateTime As Date, _
   ByVal bLocalize As Boolean _
) As Boolean
```

[C#]

```
public bool ConvertTime(
   long networkTime,
   ref DateTime dateTime,
   bool bLocalize
);
```

Parameters

networkTime
A long integer value which specifies the network time.

dateTime
A **System.DateTime** structure passed by reference which will contain the date and time when the method returns.

bLocalize
A boolean value which specifies if the network time value should be localized for the current timezone.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

Network time is expressed as the number of seconds that has elapsed since midnight, January 1, 1900 UTC.

See Also

NetworkTime Class | SocketTools Namespace | NetworkTime.ConvertTime Overload List

NetworkTime.Dispose Method

Releases all resources used by NetworkTime.

Overload List

Releases all resources used by NetworkTime.

public void Dispose();

Releases the unmanaged resources allocated by the NetworkTime class and optionally releases the managed resources.

protected virtual void Dispose(bool);

See Also

NetworkTime Class | SocketTools Namespace

NetworkTime.Dispose Method ()

Releases all resources used by NetworkTime.

[Visual Basic]

```
NotOverridable Overloads Public Sub Dispose() _
    Implements IDisposable.Dispose
```

[C#]

```
public void Dispose();
```

Implements

IDisposable.Dispose

Remarks

The **Dispose** method terminates any active connection and explicitly releases the resources allocated for this instance of the class. In some cases, better performance can be achieved if the programmer explicitly releases resources when they are no longer being used. The **Dispose** method provides explicit control over these resources.

Unlike the **Uninitialize** method, once the **Dispose** method has been called, that instance of the class cannot be re-initialized and you should not attempt to access class properties or invoke any methods. Note that this method can be called even if other references to the object are active.

See Also

NetworkTime Class | SocketTools Namespace | NetworkTime.Dispose Overload List

NetworkTime.Dispose Method (Boolean)

Releases the unmanaged resources allocated by the NetworkTime class and optionally releases the managed resources.

[Visual Basic]

```
Overridable Overloads Protected Sub Dispose( _
   ByVal disposing As Boolean _
)
```

[C#]

```
protected virtual void Dispose(
   bool disposing
);
```

Parameters

disposing

A boolean value which should be specified as **true** to release both managed and unmanaged resources; **false** to release only unmanaged resources.

Remarks

The **Dispose** method terminates any active connection and explicitly releases the resources allocated for this instance of the class. In some cases, better performance can be achieved if the programmer explicitly releases resources when they are no longer being used. The **Dispose** method provides explicit control over these resources.

Unlike the **Uninitialize** method, once the **Dispose** method has been called, that instance of the class cannot be re-initialized and you should not attempt to access class properties or invoke any methods. Note that this method can be called even if other references to the object are active.

You should call **Dispose** in your derived class when you are finished using the derived class. The **Dispose** method leaves the derived class in an unusable state. After calling **Dispose**, you must release all references to the derived class and the **NetworkTime** class so the memory they were occupying can be reclaimed by garbage collection.

See Also

NetworkTime Class | SocketTools Namespace | NetworkTime.Dispose Overload List

NetworkTime.Finalize Method

Destroys an instance of the class, releasing the resources allocated for the session and unloading the networking library.

[Visual Basic]
```
Overrides Protected Sub Finalize()
```

[C#]
```
protected override void Finalize();
```

NetworkTime.GetTime Method

Get the current system date and time from a default time server.

Overload List

Get the current system date and time from a default time server.

public bool GetTime(ref DateTime);

Get the current system date and time from the time server.

public bool GetTime(ref long);

Get the current system date and time from the specified time server.

public bool GetTime(string,ref DateTime);

Get the current system date and time from the specified time server.

public bool GetTime(string,int,ref DateTime);

Get the current system date and time from the specified time server.

public bool GetTime(string,int,int,ref DateTime);

Get the current system date and time from the specified time server.

public bool GetTime(string,int,int,ref long);

Get the current system date and time from the specified time server.

public bool GetTime(string,int,ref long);

Get the current system date and time from the specified time server.

public bool GetTime(string,ref long);

NetworkTime.GetTime Method (DateTime)

Get the current system date and time from a default time server.

[Visual Basic]

```
Overloads Public Function GetTime( _
   ByRef dateTime As Date _
) As Boolean
```

[C#]

```
public bool GetTime(
   ref DateTime dateTime
);
```

Parameters

dateTime

A **System.DateTime** structure passed by reference which will contain the date and time returned by the server.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The time and date retrieved from the server will be returned as a **System.DateTime** value according to the user's current locale.

If the **HostName** or **HostAddress** property does not specify a server host name or address, a public timeserver will be automatically selected by default.

See Also

NetworkTime Class | SocketTools Namespace | NetworkTime.GetTime Overload List

NetworkTime.GetTime Method (Int64)

Get the current system date and time from the time server.

[Visual Basic]

```
Overloads Public Function GetTime( _
   ByRef networkTime As Long _
) As Boolean
```

[C#]

```
public bool GetTime(
   ref long networkTime
);
```

Parameters

networkTime

A **System.DateTime** structure passed by reference which will contain the date and time returned by the server.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

Network time is expressed as the number of seconds that has elapsed since midnight, January 1, 1900 UTC.

If the **HostName** or **HostAddress** property does not specify a server host name or address, a public timeserver will be automatically selected by default.

See Also

NetworkTime Class | SocketTools Namespace | NetworkTime.GetTime Overload List

NetworkTime.GetTime Method (String, DateTime)

Get the current system date and time from the specified time server.

```
[Visual Basic]
Overloads Public Function GetTime( _
   ByVal hostName As String, _
   ByRef dateTime As Date _
) As Boolean
```

```
[C#]
public bool GetTime(
   string hostName,
   ref DateTime dateTime
);
```

Parameters

hostName
A string which specifies the host name or address of the time server.

dateTime
A **System.DateTime** structure passed by reference which will contain the date and time returned by the server.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The time and date retrieved from the server will be returned as a **System.DateTime** value according to the user's current locale.

In the United States, the National Institute of Standards and Technology (NIST) hosts a number of public servers which can be used to obtain the current time:

Server Name	Location
time-a.nist.gov	Gaithersburg, Maryland
time-b.nist.gov	Gaithersburg, Maryland
time-nw.nist.gov	Redmond, Washington
time-a.timefreq.bldrdoc.gov	Boulder, Colorado
time-b.timefreq.bldrdoc.gov	Boulder, Colorado
time-c.timefreq.bldrdoc.gov	Boulder, Colorado

Time servers are also commonly maintained by Internet service providers and universities. If you are unable to obtain the time from a server, contact the system administrator to determine if they have the standard time service available on port 37.

See Also

NetworkTime Class | SocketTools Namespace | NetworkTime.GetTime Overload List

NetworkTime.GetTime Method (String, Int32, DateTime)

Get the current system date and time from the specified time server.

[Visual Basic]

```
Overloads Public Function GetTime( _
   ByVal hostName As String, _
   ByVal hostPort As Integer, _
   ByRef dateTime As Date _
) As Boolean
```

[C#]

```
public bool GetTime(
   string hostName,
   int hostPort,
   ref DateTime dateTime
);
```

Parameters

hostName
A string which specifies the host name or address of the time server.

hostPort
An integer value which specifies the port to connect to on the server. The default port value for a time server is port 37.

dateTime
A **System.DateTime** structure passed by reference which will contain the date and time returned by the server.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The time and date retrieved from the server will be returned as a **System.DateTime** value according to the user's current locale.

In the United States, the National Institute of Standards and Technology (NIST) hosts a number of public servers which can be used to obtain the current time:

Server Name	Location
time-a.nist.gov	Gaithersburg, Maryland
time-b.nist.gov	Gaithersburg, Maryland
time-nw.nist.gov	Redmond, Washington
time-a.timefreq.bldrdoc.gov	Boulder, Colorado
time-b.timefreq.bldrdoc.gov	Boulder, Colorado
time-c.timefreq.bldrdoc.gov	Boulder, Colorado

Time servers are also commonly maintained by Internet service providers and universities. If you are unable to obtain the time from a server, contact the system administrator to determine if they have the standard time service available on port 37.

NetworkTime.GetTime Method (String, Int32, Int32, DateTime)

Get the current system date and time from the specified time server.

[Visual Basic]

```
Overloads Public Function GetTime( _
   ByVal hostName As String, _
   ByVal hostPort As Integer, _
   ByVal timeout As Integer, _
   ByRef dateTime As Date _
) As Boolean
```

[C#]

```
public bool GetTime(
   string hostName,
   int hostPort,
   int timeout,
   ref DateTime dateTime
);
```

Parameters

hostName

A string which specifies the host name or address of the time server.

hostPort

An integer value which specifies the port to connect to on the server. The default port value for a time server is port 37.

timeout

An integer value which specifies the number of seconds until a blocking operation fails and returns an error.

dateTime

A **System.DateTime** structure passed by reference which will contain the date and time returned by the server.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The time and date retrieved from the server will be returned as a **System.DateTime** value according to the user's current locale.

In the United States, the National Institute of Standards and Technology (NIST) hosts a number of public servers which can be used to obtain the current time:

Server Name	Location
time-a.nist.gov	Gaithersburg, Maryland
time-b.nist.gov	Gaithersburg, Maryland
time-nw.nist.gov	Redmond, Washington
time-a.timefreq.bldrdoc.gov	Boulder, Colorado
time-b.timefreq.bldrdoc.gov	Boulder, Colorado

time-c.timefreq.bldrdoc.gov	Boulder, Colorado

Time servers are also commonly maintained by Internet service providers and universities. If you are unable to obtain the time from a server, contact the system administrator to determine if they have the standard time service available on port 37.

NetworkTime Class | SocketTools Namespace | NetworkTime.GetTime Overload List

NetworkTime.GetTime Method (String, Int32, Int32, Int64)

Get the current system date and time from the specified time server.

[Visual Basic]

```
Overloads Public Function GetTime( _
   ByVal hostName As String, _
   ByVal hostPort As Integer, _
   ByVal timeout As Integer, _
   ByRef networkTime As Long _
) As Boolean
```

[C#]

```
public bool GetTime(
   string hostName,
   int hostPort,
   int timeout,
   ref long networkTime
);
```

Parameters

hostName

A string which specifies the host name or address of the time server.

hostPort

An integer value which specifies the port to connect to on the server. The default port value for a time server is port 37.

timeout

An integer value which specifies the number of seconds until a blocking operation fails and returns an error. ///

networkTime

A long integer passed by reference which will contain the network time value returned by the server.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

Network time is expressed as the number of seconds that has elapsed since midnight, January 1, 1900 UTC.

In the United States, the National Institute of Standards and Technology (NIST) hosts a number of public servers which can be used to obtain the current time:

Server Name	Location
time-a.nist.gov	Gaithersburg, Maryland
time-b.nist.gov	Gaithersburg, Maryland
time-nw.nist.gov	Redmond, Washington
time-a.timefreq.bldrdoc.gov	Boulder, Colorado
time-b.timefreq.bldrdoc.gov	Boulder, Colorado
time-c.timefreq.bldrdoc.gov	Boulder, Colorado

Time servers are also commonly maintained by Internet service providers and universities. If you are unable to obtain the time from a server, contact the system administrator to determine if they have the standard time service available on port 37.

NetworkTime.GetTime Method (String, Int32, Int64)

Get the current system date and time from the specified time server.

[Visual Basic]

```
Overloads Public Function GetTime( _
   ByVal hostName As String, _
   ByVal hostPort As Integer, _
   ByRef networkTime As Long _
) As Boolean
```

[C#]

```
public bool GetTime(
   string hostName,
   int hostPort,
   ref long networkTime
);
```

Parameters

hostName
A string which specifies the host name or address of the time server.

hostPort
An integer value which specifies the port to connect to on the server. The default port value for a time server is port 37.

networkTime
A long integer passed by reference which will contain the network time value returned by the server.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

Network time is expressed as the number of seconds that has elapsed since midnight, January 1, 1900 UTC.

In the United States, the National Institute of Standards and Technology (NIST) hosts a number of public servers which can be used to obtain the current time:

Server Name	Location
time-a.nist.gov	Gaithersburg, Maryland
time-b.nist.gov	Gaithersburg, Maryland
time-nw.nist.gov	Redmond, Washington
time-a.timefreq.bldrdoc.gov	Boulder, Colorado
time-b.timefreq.bldrdoc.gov	Boulder, Colorado
time-c.timefreq.bldrdoc.gov	Boulder, Colorado

Time servers are also commonly maintained by Internet service providers and universities. If you are unable to obtain the time from a server, contact the system administrator to determine if they have the standard time service available on port 37.

NetworkTime Class | SocketTools Namespace | NetworkTime.GetTime Overload List

NetworkTime.GetTime Method (String, Int64)

Get the current system date and time from the specified time server.

```
[Visual Basic]
Overloads Public Function GetTime( _
   ByVal hostName As String, _
   ByRef networkTime As Long _
) As Boolean
```

```
[C#]
public bool GetTime(
   string hostName,
   ref long networkTime
);
```

Parameters

hostName
A string which specifies the host name or address of the time server.

networkTime
A long integer passed by reference which will contain the network time value returned by the server.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

Network time is expressed as the number of seconds that has elapsed since midnight, January 1, 1900 UTC.

In the United States, the National Institute of Standards and Technology (NIST) hosts a number of public servers which can be used to obtain the current time:

Server Name	Location
time-a.nist.gov	Gaithersburg, Maryland
time-b.nist.gov	Gaithersburg, Maryland
time-nw.nist.gov	Redmond, Washington
time-a.timefreq.bldrdoc.gov	Boulder, Colorado
time-b.timefreq.bldrdoc.gov	Boulder, Colorado
time-c.timefreq.bldrdoc.gov	Boulder, Colorado

Time servers are also commonly maintained by Internet service providers and universities. If you are unable to obtain the time from a server, contact the system administrator to determine if they have the standard time service available on port 37.

NetworkTime Class | SocketTools Namespace | NetworkTime.GetTime Overload List

NetworkTime.Initialize Method

Initialize an instance of the NetworkTime class.

Overload List

Initialize an instance of the NetworkTime class.

public bool Initialize();

Initialize an instance of the NetworkTime class.

public bool Initialize(string);

See Also

NetworkTime Class | SocketTools Namespace | Uninitialize Method

NetworkTime.Initialize Method ()

Initialize an instance of the NetworkTime class.

[Visual Basic]
```
Overloads Public Function Initialize() As Boolean
```

[C#]
```
public bool Initialize();
```

Return Value

A boolean value which specifies if the class was initialized successfully.

Remarks

The Initialize method can be used to explicitly initialize an instance of the NetworkTime class, loading the networking library and allocating resources for the current thread. Typically it is not necessary to explicitly call this method because the instance of the class is initialized by the class constructor. However, if the **Uninitialize** method is called, the class must be re-initialized before any other methods are called.

See Also

NetworkTime Class | SocketTools Namespace | NetworkTime.Initialize Overload List | Uninitialize Method

NetworkTime.Initialize Method (String)

Initialize an instance of the NetworkTime class.

[Visual Basic]

```
Overloads Public Function Initialize( _
   ByVal licenseKey As String _
) As Boolean
```

[C#]

```
public bool Initialize(
   string licenseKey
);
```

Return Value

A boolean value which specifies if the class was initialized successfully.

Remarks

The Initialize method can be used to explicitly initialize an instance of the NetworkTime class, loading the networking library and allocating resources for the current thread. Typically an application would define the license key as a custom attribute, however this method can be used to initialize the class directly.

The runtime license key for your copy of SocketTools can be generated using the License Manager utility that is included with the product. Note that if you have installed an evaluation license, you will not have a runtime license key and cannot redistribute any applications which use the NetworkTime class.

Example

The following example shows how to use the Initialize method to initialize an instance of the class. This example assumes that the license key string has been defined in code.

```
SocketTools.NetworkTime timeClient = new SocketTools.NetworkTime();

if (timeClient.Initialize(strLicenseKey) == false)
{
    MessageBox.Show(timeClient.LastErrorString, "Error",
                    MessageBoxButtons.OK, MessageBoxIcon.Exclamation);
    return;
}
```

```
Dim timeClient As New SocketTools.NetworkTime

If timeClient.Initialize(strLicenseKey) = False Then
    MsgBox(timeClient.LastErrorString, vbIconExclamation)
    Exit Sub
End If
```

See Also

NetworkTime Class | SocketTools Namespace | NetworkTime.Initialize Overload List | RuntimeLicenseAttribute Class | Uninitialize Method

NetworkTime.Reset Method

Reset the internal state of the object, resetting all properties to their default values.

[Visual Basic]

```
Public Sub Reset()
```

[C#]

```
public void Reset();
```

Remarks

The **Reset** method returns the object to its default state. If a socket has been allocated, it will be released and any active connections will be terminated. All properties will be reset to their default values.

See Also

NetworkTime Class | SocketTools Namespace

NetworkTime.SetTime Method

Set the local system clock to the current date and time as returned by the default timeserver.

Overload List

Set the local system clock to the current date and time as returned by the default timeserver.

public bool SetTime();

Set the local system clock to the specified System.DateTime value.

public bool SetTime(DateTime);

Set the local system clock to the specified network time value.

public bool SetTime(long);

Set the local system clock to the current date and time as returned by the specified timeserver.

public bool SetTime(string);

Set the local system clock to the current date and time as returned by the specified timeserver.

public bool SetTime(string,int);

Set the local system clock to the current date and time as returned by the specified timeserver.

public bool SetTime(string,int,int);

See Also

NetworkTime Class | SocketTools Namespace

NetworkTime.SetTime Method (DateTime)

Set the local system clock to the specified System.DateTime value.

[Visual Basic]

```
Overloads Public Function SetTime( _
   ByVal dateTime As Date _
) As Boolean
```

[C#]

```
public bool SetTime(
   DateTime dateTime
);
```

Parameters

dateTime

A **System.DateTime** structure which specifies the date and time the local system clock should be set to.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **SetTime** method causes the class to update the local system's clock to the specified date and time. It is required that the user have the appropriate privileges required to change the system clock, otherwise an error will be returned.

See Also

NetworkTime Class | SocketTools Namespace | NetworkTime.SetTime Overload List

NetworkTime.SetTime Method (Int64)

Set the local system clock to the specified network time value.

[Visual Basic]

```
Overloads Public Function SetTime( _
   ByVal networkTime As Long _
) As Boolean
```

[C#]

```
public bool SetTime(
   long networkTime
);
```

Parameters

networkTime

A long integer which specifies the date and time the local system clock should be set to.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **SetTime** method causes the class to update the local system's clock to the specified date and time. It is required that the user have the appropriate privileges required to change the system clock, otherwise an error will be returned.

Network time is expressed as the number of seconds that has elapsed since midnight, January 1, 1900 UTC.

See Also

NetworkTime Class | SocketTools Namespace | NetworkTime.SetTime Overload List

NetworkTime.Uninitialize Method

Uninitialize the class library and release any resources allocated for the current thread.

[Visual Basic]

```
Public Sub Uninitialize()
```

[C#]

```
public void Uninitialize();
```

Remarks

The **Uninitialize** method terminates any active connection, releases resources allocated for the current thread and unloads the networking library. After this method has been called, no further client operations may be performed until the class instance has been re-initialized.

If the **Initialize** method is explicitly called by the application, it should be matched by a call to the **Uninitialize** method when that instance of the class is no longer needed.

NetworkTime Class | SocketTools Namespace | Initialize Method

NetworkTime Events

The events of the **NetworkTime** class are listed below. For a complete list of **NetworkTime** class members, see the NetworkTime Members topic.

Public Instance Events

⚡ OnCancel	Occurs when a blocking client operation is canceled.
⚡ OnError	Occurs when an client operation fails.
⚡ OnTimeout	Occurs when a blocking operation fails to complete before the timeout period elapses.

See Also

NetworkTime Class | SocketTools Namespace

NetworkTime.OnCancel Event

Occurs when a blocking client operation is canceled.

[Visual Basic]

```
Public Event OnCancel As EventHandler
```

[C#]

```
public event EventHandler OnCancel;
```

Remarks

The **OnCancel** event is generated when a blocking client operation, such as sending or receiving data, is canceled with the **Cancel** method. To assist in determining which operation was canceled, check the value of the **Status** property.

See Also

NetworkTime Class | SocketTools Namespace

NetworkTime.OnError Event

Occurs when an client operation fails.

```
[Visual Basic]
Public Event OnError As OnErrorEventHandler
```

```
[C#]
public event OnErrorEventHandler OnError;
```

Event Data

The event handler receives an argument of type NetworkTime.ErrorEventArgs containing data related to this event. The following **NetworkTime.ErrorEventArgs** properties provide information specific to this event.

Property	Description
Description	Gets a value which describes the last error that has occurred.
Error	Gets a value which specifies the last error that has occurred.

Remarks

The **OnError** event occurs when a client operation fails.

See Also

NetworkTime Class | SocketTools Namespace

NetworkTime.ErrorEventArgs Class

Provides data for the OnError event.

For a list of all members of this type, see NetworkTime.ErrorEventArgs Members.

System.Object
  System.EventArgs
    SocketTools.NetworkTime.ErrorEventArgs

[Visual Basic]

```
Public Class NetworkTime.ErrorEventArgs
    Inherits EventArgs
```

[C#]

```
public class NetworkTime.ErrorEventArgs : EventArgs
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

ErrorEventArgs specifies the numeric error code and a description of the error that has occurred.

An OnError event occurs when a method fails.

Requirements

Namespace: SocketTools

Assembly: SocketTools.NetworkTime (in SocketTools.NetworkTime.dll)

NetworkTime.ErrorEventArgs Members | SocketTools Namespace

NetworkTime.ErrorEventArgs Members

NetworkTime.ErrorEventArgs overview

Public Instance Constructors

NetworkTime.ErrorEventArgs Constructor	Initializes a new instance of the NetworkTime.ErrorEventArgs class.

Public Instance Properties

Description	Gets a value which describes the last error that has occurred.
Error	Gets a value which specifies the last error that has occurred.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString (inherited from Object)	Returns a String that represents the current Object.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

NetworkTime.ErrorEventArgs Class | SocketTools Namespace

NetworkTime.ErrorEventArgs Constructor

Initializes a new instance of the NetworkTime.ErrorEventArgs class.

[Visual Basic]

```
Public Sub New()
```

[C#]

```
public NetworkTime.ErrorEventArgs();
```

See Also

NetworkTime.ErrorEventArgs Class | SocketTools Namespace

NetworkTime.ErrorEventArgs Properties

The properties of the **NetworkTime.ErrorEventArgs** class are listed below. For a complete list of **NetworkTime.ErrorEventArgs** class members, see the NetworkTime.ErrorEventArgs Members topic.

Public Instance Properties

Description	Gets a value which describes the last error that has occurred.
Error	Gets a value which specifies the last error that has occurred.

See Also

NetworkTime.ErrorEventArgs Class | SocketTools Namespace

NetworkTime.ErrorEventArgs.Description Property

Gets a value which describes the last error that has occurred.

[Visual Basic]

```
Public ReadOnly Property Description As String
```

[C#]

```
public string Description {get;}
```

Property Value

A string which describes the last error that has occurred.

See Also

NetworkTime.ErrorEventArgs Class | SocketTools Namespace | Error Property

NetworkTime.ErrorEventArgs.Error Property

Gets a value which specifies the last error that has occurred.

[Visual Basic]

```
Public ReadOnly Property Error As ErrorCode
```

[C#]

```
public NetworkTime.ErrorCode Error {get;}
```

Property Value

ErrorCode enumeration which specifies the error.

See Also

NetworkTime.ErrorEventArgs Class | SocketTools Namespace | Description Property

NetworkTime.OnTimeout Event

Occurs when a blocking operation fails to complete before the timeout period elapses.

[Visual Basic]

```
Public Event OnTimeout As EventHandler
```

[C#]

```
public event EventHandler OnTimeout;
```

Remarks

The **OnTimeout** event occurs when a blocking operation, such as sending or receiving data on the client, fails to complete before the specified timeout period elapses. The timeout period for a blocking operation can be adjusted by setting the **Timeout** property.

This event is only generated if the client is in blocking mode.

See Also

NetworkTime Class | SocketTools Namespace

NetworkTime.ErrorCode Enumeration

Specifies the error codes returned by the NetworkTime class.

[Visual Basic]
```
Public Enum NetworkTime.ErrorCode
```

[C#]
```
public enum NetworkTime.ErrorCode
```

Remarks

The NetworkTime class uses the **ErrorCode** enumeration to specify what error has occurred when a method fails. The current error code may be determined by checking the value of the **LastError** property.

Note that the last error code is only meaningful if the previous operation has failed.

Members

Member Name	Description
errorNone	No error.
errorNotHandleOwner	Handle not owned by the current thread.
errorFileNotFound	The specified file or directory does not exist.
errorFileNotCreated	The specified file could not be created.
errorOperationCanceled	The blocking operation has been canceled.
errorInvalidFileType	The specified file is a block or character device, not a regular file.
errorInvalidDevice	The specified file type is invalid or not a regular file.
errorTooManyParameters	The maximum number of function parameters has been exceeded.
errorInvalidFileName	The specified file name contains invalid characters or is too long.
errorInvalidFileHandle	Invalid file handle passed to function.
errorFileReadFailed	Unable to read data from the specified file.
errorFileWriteFailed	Unable to write data to the specified file.
errorOutOfMemory	Out of memory.
errorAccessDenied	Access denied.
errorInvalidParameter	Invalid argument passed to function.
errorClipboardUnavailable	The system clipboard is currently unavailable.
errorClipboardEmpty	The system clipboard is empty or does not contain any text data.
errorFileEmpty	The specified file does not contain any data.
errorFileExists	The specified file already exists.

errorEndOfFile	End of file.
errorDeviceNotFound	The specified device could not be found.
errorDirectoryNotFound	The specified directory could not be found.
errorInvalidbuffer	Invalid memory address passed to function.
errorBufferTooSmall	The specified buffer is not large enough to contain the data.
errorNoHandles	No more handles are available to this process.
errorOperationWouldBlock	The specified operation would block the current thread.
errorOperationInProgress	A blocking operation is currently in progress.
errorAlreadyInProgress	The specified operation is already in progress.
errorInvalidHandle	Invalid handle passed to function.
errorInvalidAddress	Invalid network address specified.
errorInvalidSize	Datagram is too large to fit in specified buffer.
errorInvalidProtocol	Invalid network protocol specified.
errorProtocolNotAvailable	The specified network protocol is not available.
errorProtocolNotSupported	The specified protocol is not supported.
errorSocketNotSupported	The specified socket type is not supported.
errorInvalidOption	The specified option is invalid.
errorProtocolFamily	Specified protocol family is not supported.
errorProtocolAddress	The specified address is invalid for this protocol family.
errorAddressInUse	The specified address is in use by another process.
errorAddressUnavailable	The specified address cannot be assigned.
errorNetworkUnavailable	The networking subsystem is unavailable.
errorNetworkUnreachable	The specified network is unreachable.
errorNetworkReset	Network dropped connection on remote reset.
errorConnectionAborted	Connection was aborted due to timeout or other failure.
errorConnectionReset	Connection was reset by remote network.
errorOutOfBuffers	No buffer space is available.
errorAlreadyConnected	Connection already established with remote host.
errorNotConnected	No connection established with remote host.
errorConnectionShutdown	Unable to send or receive data after connection shutdown.
errorOperationTimeout	The specified operation has timed out.
errorConnectionRefused	The connection has been refused by the remote host.

errorHostUnavailable	The specified host is unavailable.
errorHostUnreachable	Remote host is unreachable.
errorTooManyProcesses	Too many processes are using the networking subsystem.
errorTooManyThreads	Too many threads have been created by the current process.
errorTooManySessions	Too many client sessions have been created by the current process.
errorInternalFailure	An unexpected internal error has occurred.
errorNetworkNotReady	Network subsystem is not ready for communication.
errorInvalidVersion	This version of the operating system is not supported.
errorNetworkNotInitialized	The networking subsystem has not been initialized.
errorRemoteShutdown	The remote host has initiated a graceful shutdown sequence.
errorInvalidHostName	The specified hostname is invalid or could not be resolved.
errorHostNameNotFound	The specified hostname could not be found.
errorHostNameRefused	Unable to resolve hostname, request refused.
errorHostNameNotResolved	Unable to resolve hostname, no address for specified host.
errorInvalidLicense	The license for this product is invalid.
errorProductNotLicensed	This product is not licensed to perform this operation.
errorNotImplemented	This function has not been implemented on this platform.
errorUnknownLocalhost	Unable to determine local host name.
errorInvalidHostAddress	Invalid host address specified.
errorInvalidServicePort	Invalid service port number specified.
errorInvalidServiceName	Invalid or unknown service name specified.
errorInvalidEventId	Invalid event identifier specified.
errorOperationNotBlocking	No blocking operation in progress on this socket.
errorSecurityNotInitialized	Unable to initialize security interface for this process.
errorSecurityContext	Unable to establish security context for this session.
errorSecurityCredentials	Unable to open certificate store or establish security credentials.
errorSecurityCertificate	Unable to validate the certificate chain for this

	session.
errorSecurityDecryption	Unable to decrypt data stream.
errorSecurityEncryption	Unable to encrypt data stream.
errorOperationNotSupported	The specified operation is not supported.
errorInvalidProtocolVersion	Invalid application protocol version specified.
errorNoServerResponse	No data returned from server.
errorInvalidServerResponse	Invalid data returned from server.
errorUnexpectedServerResponse	Unexpected response code returned from server.
errorServerTransactionFailed	Server transaction failed.
errorServiceUnavailable	The service is currently unavailable.
errorServiceNotReady	The service is not ready, try again later.
errorServerResyncFailed	Unable to resynchronize with server.
errorInvalidProxyType	Invalid proxy server type specified.
errorProxyRequired	Resource must be accessed through specified proxy.
errorInvalidProxyLogin	Unable to login to proxy server using specified credentials.
errorProxyResyncFailed	Unable to resynchronize with proxy server.
errorInvalidCommand	Invalid command specified.
errorInvalidCommandParameter	Invalid command parameter specified.
errorInvalidCommandSequence	Invalid command sequence specified.
errorCommandNotImplemented	Specified command not implemented on this server.
errorCommandNotAuthorized	Specified command not authorized for the current user.
errorCommandAborted	Specified command was aborted by the remote host.
errorOptionNotSupported	The specified option is not supported on this server.
errorRequestNotCompleted	The current client request has not been completed.
errorInvalidUserName	The specified username is invalid.
errorInvalidPassword	The specified password is invalid.
errorInvalidAccount	The specified account name is invalid.
errorAccountRequired	Account name has not been specified.
errorInvalidAuthenticationType	Invalid authentication protocol specified.
errorAuthenticationRequired	User authentication is required.
errorProxyAuthenticationRequired	Proxy authentication required.

errorAlreadyAuthenticated	User has already been authenticated.
errorAuthenticationFailed	Unable to authenticate the specified user.
errorNetworkAdapter	Unable to determine network adapter configuration.
errorInvalidRecordType	Invalid record type specified.
errorInvalidRecordName	Invalid record name specified.
errorInvalidRecordData	Invalid record data specified.
errorConnectionOpen	Data connection already established.
errorConnectionClosed	Server closed data connection.
errorConnectionPassive	Data connection is passive.
errorConnectionFailed	Unable to open data connection to server.
errorInvalidSecurityLevel	Data connection cannot be opened with this security setting.
errorCachedTLSRequired	Data connection requires cached TLS session.
errorDataReadOnly	Data connection is read-only.
errorDataWriteOnly	Data connection is write-only.
errorEndOfData	End of data.
errorRemoteFileUnavailable	Remote file is unavailable.
errorInsufficientStorage	Insufficient storage on server.
errorStorageallocation	File exceeded storage allocation on server.
errorDirectoryExists	The specified directory already exists.
errorDirectoryEmpty	No files returned by the server for the specified directory.
errorEndOfDirectory	End of directory listing.
errorUnknownDirectoryFormat	Unknown directory format.
errorInvalidResource	Invalid resource name specified.
errorResourceRedirected	The specified resource has been redirected.
errorResourceRestricted	Access to this resource has been restricted.
errorResourceNotModified	The specified resource has not been modified.
errorResourceNotFound	The specified resource cannot be found.
errorResourceConflict	Request could not be completed due to the current state of the resource.
errorResourceRemoved	The specified resource has been permanently removed from this server.
errorContentLengthRequired	Request must include the content length.
errorRequestPrecondition	Request could not be completed due to server precondition.
errorUnsupportedMediaType	Request specified an unsupported media type.

errorInvalidContentRange	Content range specified for this resource is invalid.
errorInvalidMessagePart	Message is not multipart or an invalid message part was specified.
errorInvalidMessageHeader	The specified message header is invalid or has not been defined.
errorInvalidMessageBoundary	The multipart message boundary has not been defined.
errorNoFileAttachment	The current message part does not contain a file attachment.
errorUnknownFileType	The specified file type could not be determined.
errorDataNotEncoded	The specified data block could not be encoded.
errorDataNotDecoded	The specified data block could not be decoded.
errorFileNotEncoded	The specified file could not be encoded.
errorFileNotDecoded	The specified file could not be decoded.
errorNoMessageText	No message text.
errorInvalidCharacterSet	Invalid character set specified.
errorInvalidEncodingType	Invalid encoding type specified.
errorInvalidMessageNumber	Invalid message number specified.
errorNoReturnAddress	No valid return address specified.
errorNoValidRecipients	No valid recipients specified.
errorInvalidRecipient	The specified recipient address is invalid.
errorRelayNotAuthorized	The specified domain is invalid or server will not relay messages.
errorMailboxUnavailable	Specified mailbox is currently unavailable.
errorMailboxReadOnly	The selected mailbox cannot be modified.
errorMailboxNotSelected	No mailbox has been selected.
errorInvalidMailbox	Specified mailbox is invalid.
errorInvalidDomain	The specified domain name is invalid or not recognized.
errorInvalidSender	The specified sender address is invalid or not recognized.
errorMessageNotDelivered	Message not delivered to any of the specified recipients.
errorEndOfMessageData	No more message data available to be read
errorInvalidmessageSize	The specified message size is invalid.
errorMessageNotCreated	The message could not be created in the specified mailbox.
errorNoMoreMailboxes	No more mailboxes exist on this server.

errorInvalidEmulationType	The specified terminal emulation type is invalid.
errorInvalidFontHandle	The specified font handle is invalid.
errorInvalidFontName	The specified font name is invalid or unavailable.
errorInvalidPacketSize	The specified packet size is invalid.
errorInvalidPacketData	The specified packet data is invalid.
errorInvalidPacketId	The unique packet identifier is invalid.
errorPacketTTLExpired	The specified packet time-to-live period has expired.
errorInvalidNewsGroup	Invalid newsgroup specified.
errorNoNewsgroupSelected	No newsgroup selected.
errorEmptyNewsgroup	No articles in specified newsgroup.
errorInvalidArticle	Invalid article number specified.
errorNoArticleSelected	No article selected in the current newsgroup.
errorFirstArticle	First article in current newsgroup.
errorLastArticle	Last article in current newsgroup.
errorArticleExists	Unable to transfer article, article already exists.
errorArticleRejected	Unable to transfer article, article rejected.
errorArticleTransferFailed	Article transfer failed.
errorArticlePostingDenied	Posting is not permitted on this server.
errorArticlePostingFailed	Unable to post article on this server.
errorInvalidDateFormat	The specified date format is not recognized.
errorFeatureNotSupported	The specified feature is not supported on this server.
errorInvalidFormHandle	The specified form handle is invalid or a form has not been created.
errorInvalidFormAction	The specified form action is invalid or has not been specified.
errorInvalidFormMethod	The specified form method is invalid or not supported.
errorInvalidFormType	The specified form type is invalid or not supported.
errorInvalidFormField	The specified form field name is invalid or does not exist.
errorEmptyForm	The specified form does not contain any field values.
errorMaximumConnections	The maximum number of client connections exceeded.
errorThreadCreationFailed	Unable to create a new thread for the current process.
errorInvalidThreadHandle	The specified thread handle is no longer valid.

errorThreadTerminated	The specified thread has been terminated.
errorThreadDeadlock	The operation would result in the current thread becoming deadlocked.
errorInvalidClientMoniker	The specified moniker is not associated with any client session.
errorClientMonikerExists	The specified moniker has been assigned to another client session.
errorServerInactive	The specified server is not listening for client connections.
errorServerSuspended	The specified server is suspended and not accepting client connections.
errorNoMessageStore	No message store has been specified.
errorMessageStoreChanged	The message store has changed since it was last accessed.
errorMessageNotFound	No message was found that matches the specified criteria.
errorMessageDeleted	The specified message has been deleted.
errorFileChecksumMismatch	The local and remote file checksums do not match.
errorFileSizeMismatch	The local and remote file sizes do not match.
errorInvalidFeedUrl	The news feed URL is invalid or specifies an unsupported protocol.
errorInvalidFeedFormat	The internal format of the news feed is invalid.
errorInvalidFeedVersion	This version of the news feed is not supported.
errorChannelEmpty	There are no valid items found in this news feed.
errorInvalidItemNumber	The specified channel item identifier is invalid.
errorItemNotFound	The specified channel item could not be found.
errorItemEmpty	The specified channel item does not contain any data.
errorInvalidItemProperty	The specified item property name is invalid.
errorItemPropertyNotFound	The specified item property has not been defined.
errorInvalidChannelTitle	The channel title is invalid or has not been defined.
errorInvalidChannelLink	The channel hyperlink is invalid or has not been defined.
errorInvalidChannelDescription	The channel description is invalid or has not been defined.
errorInvalidItemText	The description for an item is invalid or has not been defined.
errorInvalidItemLink	The hyperlink for an item is invalid or has not been defined.

errorInvalidServiceType	The specified service type is invalid.
errorServiceSuspended	Access to the specified service has been suspended.
errorServiceRestricted	Access to the specified service has been restricted.
errorInvalidProviderName	The specified provider name is invalid or unknown.
errorInvalidPhoneNumber	The specified phone number is invalid or not supported in this region.
errorGatewayNotFound	A message gateway cannot be found for the specified provider.
errorMessageTooLong	The message exceeds the maximum number of characters permitted.
errorInvalidProviderData	The request returned invalid or incomplete service provider data.
errorInvalidGatewayData	The request returned invalid or incomplete message gateway data.
errorMultipleProviders	The request has returned multiple service providers.
errorProviderNotFound	The specified service provider could not be found.
errorInvalidMessageService	The specified message is not supported with this service type.
errorInvalidMessageFormat	The specified message format is invalid.
errorInvalidConfiguration	The specified configuration options are invalid.
errorServerActive	The requested action is not permitted while the server is active.
errorServerPortBound	Unable to obtain exclusive use of the specified local port.
errorInvalidClientSession	The specified client identifier is invalid for this session.
errorClientNotIdentified	The specified client has not provided user credentials.
errorInvalidClientState	The requested action cannot be performed at this time.
errorInvalidResultCode	The specified result code is not valid for this protocol
errorCommandRequired	The specified command is required and cannot be disabled.
errorCommandDisabled	The specified command has been disabled.
errorCommandSequence	The command cannot be processed at this time.
errorCommandCompleted	The previous command has completed.
errorInvalidProgramName	The specified program name is invalid or unrecognized.

errorInvalidRequestHeader	The request header contains one or more invalid values.
errorInvalidVirtualHost	The specified virtual host name is invalid.
errorVirtualHostNotFound	The specified virtual host does not exist.
errorTooManyVirtualHosts	Too many virtual hosts created for this server.
errorInvalidVirtualPath	The specified virtual path name is invalid.
errorVirtualPathNotFound	The specified virtual path does not exist.
errorTooManyVirtualPaths	Too many virtual paths created for this server.
errorInvalidTask	The asynchronous task identifier is invalid.
errorTaskActive	The asynchronous task has not finished.
errorTaskQueued	The asynchronous task has been queued.
errorTaskSuspended	The asynchronous task has been suspended.
errorTaskFinished	The asynchronous task has finished.

Requirements

Namespace: SocketTools

Assembly: SocketTools.NetworkTime (in SocketTools.NetworkTime.dll)

See Also

SocketTools Namespace | LastError Property | LastErrorString Property | OnError Event

NetworkTime.TraceOptions Enumeration

Specifies the logging options that the NetworkTime class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

```
[Visual Basic]
<Flags>
Public Enum NetworkTime.TraceOptions
```

```
[C#]
[Flags]
public enum NetworkTime.TraceOptions
```

Remarks

The NetworkTime class uses the **TraceOptions** enumeration to specify what kind of debugging information is written to the trace logfile. These options are only meaningful when trace logging is enabled by setting the **Trace** property to **true**.

Members

Member Name	Description	Value
traceDefault	The default trace logging option. This is the same as specifying the **traceInfo** option.	0
traceInfo	All network function calls are written to the trace file. This is the default value.	0
traceError	Only those network function calls which fail are recorded in the trace file.	1
traceWarning	Only those network function calls which fail, or return values which indicate a warning, are recorded in the trace file.	2
traceHexDump	All network function calls are written to the trace file, plus all the data that is sent or received is displayed, in both ASCII and hexadecimal format.	4
traceProcess	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for multithreaded applications that are using worker threads.	4096

Requirements

Namespace: SocketTools

Assembly: SocketTools.NetworkTime (in SocketTools.NetworkTime.dll)

See Also

SocketTools Namespace

NetworkTime.OnErrorEventHandler Delegate

Represents the method that will handle the OnError event.

[Visual Basic]

```
Public Delegate Sub NetworkTime.OnErrorEventHandler( _
   ByVal sender As Object, _
   ByVal e As ErrorEventArgs _
)
```

[C#]

```
public delegate void NetworkTime.OnErrorEventHandler(
      object sender,
      ErrorEventArgs e
   );
```

Parameters

sender
The source of the event.

e
An ErrorEventArgs that contains the event data.

Remarks

When you create an **OnErrorEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnErrorEventHandler** delegate declaration.

Requirements

Namespace: SocketTools

Assembly: SocketTools.NetworkTime (in SocketTools.NetworkTime.dll)

See Also

SocketTools Namespace

NetworkTime.RuntimeLicenseAttribute Class

Attribute that defines the runtime license key for the class.

For a list of all members of this type, see NetworkTime.RuntimeLicenseAttribute Members.

System.Object
  System.Attribute
    SocketTools.NetworkTime.RuntimeLicenseAttribute

[Visual Basic]

```
<AttributeUsage(ValidOn:=AttributeTargets.Assembly, AllowMultiple:=False,
   Inherited:=True)>
Public Class NetworkTime.RuntimeLicenseAttribute
    Inherits Attribute
```

[C#]

```
[AttributeUsage(ValidOn=AttributeTargets.Assembly, AllowMultiple=False,
   Inherited=True)]
public class NetworkTime.RuntimeLicenseAttribute : Attribute
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

The RuntimeLicense attribute is used to define the runtime license key that will be used when an instance of the class is created. This attribute is defined in the assembly information module for the language, such as AssemblyInfo.cs when programming C#. The runtime license key must be defined if you wish to redistribute your application.

The runtime license key for your copy of SocketTools can be generated using the License Manager utility that is included with the product. Note that if you have installed an evaluation license, you will not have a runtime license key and cannot redistribute any applications which use the NetworkTime class.

Example

```
<Assembly: SocketTools.NetworkTime.RuntimeLicense("abcdefghijklmnop")>
```

```
[assembly: SocketTools.NetworkTime.RuntimeLicense("abcdefghijklmnop")]
```

Requirements

Namespace: SocketTools

Assembly: SocketTools.NetworkTime (in SocketTools.NetworkTime.dll)

See Also

NetworkTime.RuntimeLicenseAttribute Members | SocketTools Namespace

NetworkTime.RuntimeLicenseAttribute Members

NetworkTime.RuntimeLicenseAttribute overview

Public Instance Constructors

NetworkTime.RuntimeLicenseAttribute Constructor	Constructor for the RuntimeLicense attribute which defines the runtime license key.

Public Instance Properties

LicenseKey	Returns the value of the runtime license key.
TypeId (inherited from Attribute)	When implemented in a derived class, gets a unique identifier for this Attribute.

Public Instance Methods

Equals (inherited from Attribute)	
GetHashCode (inherited from Attribute)	Returns the hash code for this instance.
GetType (inherited from Object)	Gets the Type of the current instance.
IsDefaultAttribute (inherited from Attribute)	When overridden in a derived class, returns an indication whether the value of this instance is the default value for the derived class.
Match (inherited from Attribute)	When overridden in a derived class, returns a value indicating whether this instance equals a specified object.
ToString (inherited from Object)	Returns a String that represents the current Object.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

NetworkTime.RuntimeLicenseAttribute Class | SocketTools Namespace

NetworkTime.RuntimeLicenseAttribute Constructor

Constructor for the RuntimeLicense attribute which defines the runtime license key.

[Visual Basic]

```
Public Sub New( _
   ByVal licenseKey As String _
)
```

[C#]

```
public NetworkTime.RuntimeLicenseAttribute(
   string licenseKey
);
```

Parameters

licenseKey

A string argument which specifies the runtime license key which will be used to initialize the class library.

Remarks

The runtime license key for your copy of SocketTools can be generated using the License Manager utility that is included with the product. Note that if you have installed an evaluation license, you will not have a runtime license key and cannot redistribute any applications which use the NetworkTime class.

NetworkTime.RuntimeLicenseAttribute Class | SocketTools Namespace

NetworkTime.RuntimeLicenseAttribute Properties

The properties of the **NetworkTime.RuntimeLicenseAttribute** class are listed below. For a complete list of **NetworkTime.RuntimeLicenseAttribute** class members, see the NetworkTime.RuntimeLicenseAttribute Members topic.

Public Instance Properties

LicenseKey	Returns the value of the runtime license key.
TypeId (inherited from Attribute)	When implemented in a derived class, gets a unique identifier for this Attribute.

See Also

NetworkTime.RuntimeLicenseAttribute Class | SocketTools Namespace

NetworkTime.RuntimeLicenseAttribute.LicenseKey Property

Returns the value of the runtime license key.

[Visual Basic]

```
Public Property LicenseKey As String
```

[C#]

```
public string LicenseKey {get; set;}
```

Property Value

A string which contains the runtime license key.

See Also

NetworkTime.RuntimeLicenseAttribute Class | SocketTools Namespace

NetworkTimeException Class

The exception that is thrown when a client error occurs.

For a list of all members of this type, see NetworkTimeException Members.

System.Object
  System.Exception
    System.ApplicationException
      SocketTools.NetworkTimeException

[Visual Basic]

```
Public Class NetworkTimeException
    Inherits ApplicationException
```

[C#]

```
public class NetworkTimeException : ApplicationException
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

A NetworkTimeException is thrown by the NetworkTime class when an error occurs.

The default constructor for the NetworkTimeException class sets the **ErrorCode** property to the last client error that occurred.

Requirements

Namespace: SocketTools

Assembly: SocketTools.NetworkTime (in SocketTools.NetworkTime.dll)

NetworkTimeException Members

NetworkTimeException overview

Public Instance Constructors

NetworkTimeException	Overloaded. Initializes a new instance of the NetworkTimeException class.

Public Instance Properties

ErrorCode	Gets a value which specifies the error that caused the exception.
HelpLink (inherited from Exception)	Gets or sets a link to the help file associated with this exception.
InnerException (inherited from Exception)	Gets the Exception instance that caused the current exception.
Message	Gets a value which describes the error that caused the exception.
Number	Gets a value which specifies the numeric value of the error that caused the exception.
Source (inherited from Exception)	Gets or sets the name of the application or the object that causes the error.
StackTrace (inherited from Exception)	Gets a string representation of the frames on the call stack at the time the current exception was thrown.
TargetSite (inherited from Exception)	Gets the method that throws the current exception.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetBaseException (inherited from Exception)	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetObjectData (inherited from Exception)	When overridden in a derived class, sets the SerializationInfo with information about the exception.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString	Creates and returns a string representation of the current exception.

Protected Instance Properties

HResult (inherited from Exception)	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

NetworkTimeException Class | SocketTools Namespace

NetworkTimeException Constructor

Initializes a new instance of the NetworkTimeException class with the last network error code.

Overload List

Initializes a new instance of the NetworkTimeException class with the last network error code.

public NetworkTimeException();

Initializes a new instance of the NetworkTimeException class with a specified error number.

public NetworkTimeException(int);

Initializes a new instance of the NetworkTimeException class with a specified error message.

public NetworkTimeException(string);

Initializes a new instance of the NetworkTimeException class with a specified error message and a reference to the inner exception that is the cause of this exception.

public NetworkTimeException(string,Exception);

See Also

NetworkTimeException Class | SocketTools Namespace

NetworkTimeException Constructor ()

Initializes a new instance of the NetworkTimeException class with the last network error code.

[Visual Basic]

```
Overloads Public Sub New()
```

[C#]

```
public NetworkTimeException();
```

Remarks

The ctor constructor sets the **ErrorCode** property to the last client error that occurred. For more information about the errors that may occur, refer to the NetworkTime.ErrorCode enumeration.

See Also

NetworkTimeException Class | SocketTools Namespace | NetworkTimeException Constructor Overload List

NetworkTimeException Constructor (String)

Initializes a new instance of the NetworkTimeException class with a specified error message.

[Visual Basic]

```
Overloads Public Sub New( _
   ByVal message As String _
)
```

[C#]

```
public NetworkTimeException(
   string message
);
```

Parameters

message

The error message that explains the reason for the exception.

Remarks

The content of the ***message*** parameter is intended to be understood by humans. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

See Also

NetworkTimeException Class | SocketTools Namespace | NetworkTimeException Constructor Overload List

NetworkTimeException Constructor (String, Exception)

Initializes a new instance of the NetworkTimeException class with a specified error message and a reference to the inner exception that is the cause of this exception.

```
[Visual Basic]
Overloads Public Sub New( _
   ByVal message As String, _
   ByVal innerException As Exception _
)
```

```
[C#]
public NetworkTimeException(
   string message,
   Exception innerException
);
```

Parameters

message

The error message that explains the reason for the exception.

innerException

The exception that is the cause of the current exception. If the ***innerException*** parameter is not a null reference, the current exception is raised in a **catch** block that handles the inner exception.

Remarks

The content of the message parameter is intended to be understood by humans. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

An exception that is thrown as a direct result of a previous exception should include a reference to the previous exception in the **InnerException** property. The **InnerException** property returns the same value that is passed into the constructor, or a null reference if the **InnerException** property does not supply the inner exception value to the constructor.

See Also

NetworkTimeException Class | SocketTools Namespace | NetworkTimeException Constructor Overload List

NetworkTimeException Constructor (Int32)

Initializes a new instance of the NetworkTimeException class with a specified error number.

[Visual Basic]

```
Overloads Public Sub New( _
   ByVal code As Integer _
)
```

[C#]

```
public NetworkTimeException(
   int code
);
```

Parameters

code

An integer value which specifies an error code.

Remarks

This constructor sets the **ErrorCode** property to the specified error code. For more information about the errors that may occur, refer to the NetworkTime.ErrorCode enumeration.

See Also

NetworkTimeException Class | SocketTools Namespace | NetworkTimeException Constructor Overload List

NetworkTimeException Properties

The properties of the **NetworkTimeException** class are listed below. For a complete list of **NetworkTimeException** class members, see the NetworkTimeException Members topic.

Public Instance Properties

ErrorCode	Gets a value which specifies the error that caused the exception.
HelpLink (inherited from Exception)	Gets or sets a link to the help file associated with this exception.
InnerException (inherited from Exception)	Gets the Exception instance that caused the current exception.
Message	Gets a value which describes the error that caused the exception.
Number	Gets a value which specifies the numeric value of the error that caused the exception.
Source (inherited from Exception)	Gets or sets the name of the application or the object that causes the error.
StackTrace (inherited from Exception)	Gets a string representation of the frames on the call stack at the time the current exception was thrown.
TargetSite (inherited from Exception)	Gets the method that throws the current exception.

Protected Instance Properties

HResult (inherited from Exception)	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception.

See Also

NetworkTimeException Class | SocketTools Namespace

NetworkTimeException.ErrorCode Property

Gets a value which specifies the error that caused the exception.

[Visual Basic]

```
Public ReadOnly Property ErrorCode As ErrorCode
```

[C#]

```
public NetworkTime.ErrorCode ErrorCode {get;}
```

Property Value

Returns a NetworkTime.ErrorCode enumeration value which specifies the error code.

Remarks

The **ErrorCode** property returns the error code that specifies the cause of the exception.

The default constructor for the NetworkTimeException class sets the error code to the last network error that occurred. For more information about the errors that may occur, refer to the NetworkTime.ErrorCode enumeration.

See Also

NetworkTimeException Class | SocketTools Namespace

NetworkTimeException.Message Property

Gets a value which describes the error that caused the exception.

[Visual Basic]

```
Overrides Public ReadOnly Property Message As String
```

[C#]

```
public override string Message {get;}
```

Property Value

A string which describes the error that caused the exception.

Remarks

The **Message** property returns a string which describes the error that caused the exception.

See Also

NetworkTimeException Class | SocketTools Namespace

NetworkTimeException.Number Property

Gets a value which specifies the numeric value of the error that caused the exception.

[Visual Basic]

```
Public ReadOnly Property Number As Integer
```

[C#]

```
public int Number {get;}
```

Property Value

An integer value that specifies the error that caused the exception.

Remarks

The **Number** property returns an integer value which specifies the numeric value of the error that caused the exception. This value is the same as the values returned by the Windows Sockets API. For more information about socket error codes, see the Windows Socket Version 2 API error code documentation in MSDN.

See Also

NetworkTimeException Class | SocketTools Namespace

NetworkTimeException Methods

The methods of the **NetworkTimeException** class are listed below. For a complete list of **NetworkTimeException** class members, see the NetworkTimeException Members topic.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetBaseException (inherited from Exception)	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetObjectData (inherited from Exception)	When overridden in a derived class, sets the SerializationInfo with information about the exception.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString	Creates and returns a string representation of the current exception.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

NetworkTimeException Class | SocketTools Namespace

NetworkTimeException.ToString Method

Creates and returns a string representation of the current exception.

[Visual Basic]

```
Overrides Public Function ToString() As String
```

[C#]

```
public override string ToString();
```

Return Value

A string representation of the current exception.

Remarks

The **ToString** method returns a representation of the current exception that is intended to be understood by humans. Where the exception contains culture-sensitive data, the string representation returned by **ToString** is required to take into account the current system culture. Although there are no exact requirements for the format of the returned string, it should attempt to reflect the value of the object as perceived by the user.

This implementation of **ToString** obtains the numeric error code value and a description of the error that caused the current exception. If there is no error message or it is an empty string, then no error message is returned.

This method overrides **ApplicationException.ToString**.

NetworkTimeException Class | SocketTools Namespace

NewsFeed Class

Retrieve and process the contents of a syndicated news feed.

For a list of all members of this type, see NewsFeed Members.

System.Object
  SocketTools.NewsFeed

[Visual Basic]
```
Public Class NewsFeed
    Implements IDisposable
```

[C#]
```
public class NewsFeed : IDisposable
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

Really Simple Syndication (RSS) is a collection of standardized formats that are used to publish information about content that is frequently changed. A news feed is published in XML format, which contains one or more items that includes summary text, hyperlinks to source content and additional metadata that is used to describe the item. News feeds can be used for a variety of purposes, including providing updates for weblogs, news headlines, video and audio content. RSS can also be used for other purposes, such as a software updates, where new updates are listed as items in the feed.

News feeds can be accessed remotely from a web server, or locally as an XML formatted text file. The source of the feed is determined by the URI scheme that is specified. If the http or https scheme is specified, then the feed is retrieved from a web server. If the file scheme is used, the feed is considered to be local and is accessed from the disk or local network. The **SocketTools.NewsFeed** class provides an interface that enables you to open a feed by URL and iterate through each of the items in the feed or search for a specific feed item. The class can also be used to parse a string that contains XML data in RSS format, where the feed may have been retrieved from other sources such as a database.

Requirements

Namespace: SocketTools

Assembly: SocketTools.NewsFeed (in SocketTools.NewsFeed.dll)

See Also

NewsFeed Members | SocketTools Namespace

NewsFeed Members

NewsFeed overview

Public Static (Shared) Fields

feedPortDefault	A constant value which specifies the default port number.
feedPortSecure	A constant value which specifies the default port number for a secure connection.
feedTimeout	A constant value which specifies the default timeout period.

Public Instance Constructors

NewsFeed Constructor	Initializes a new instance of the NewsFeed class.

Public Instance Properties

Category	Gets a value which specifies the category or categories that the channel belongs to.
Copyright	Gets a value which specifies a copyright notice for the content.
Description	Gets a value which describes the news feed channel.
Editor	Gets a value which identifies the person responsible for managing the content of the news feed.
FeedVersion	Gets a value which identifies the version of the news feed.
Generator	Gets a value which identifies the application that was used to create the news feed.
ImageLink	Gets a value which specifies a URL to the website corresponding to the news feed.
ImageTitle	Gets a value which describes the image associated with the news feed.
ImageUrl	Gets a value which specifies a URL for the image associated with the news feed.
IsInitialized	Gets a value which indicates if the current instance of the class has been initialized successfully.
ItemAuthor	Gets a value which identifies the author of the current news feed item.
ItemComments	Gets a value which specifies a URL that links to further discussion about the current item.
ItemCount	Gets value which specifies the number of news items in the channel.

ItemEnclosure	Gets a value which specifies a URL that links to a file related to the item.
ItemGuid	Gets a value which uniquely identifies the current news item in the channel.
ItemId	Gets an numeric value which identifies the current news item in the channel.
ItemLink	Gets a value which specifies a URL that links to additional information related to the current item.
ItemPublished	Gets a value which specifies the date and time the current news item was published.
ItemSource	Gets a value which identifies the source of the current news item.
ItemText	Gets a value which provides a summary or description of the current news item.
ItemTitle	Gets a value which specifies a title for the current news item.
Language	Gets a value which identifies the language the news feed is written in.
LastBuild	Gets a value which specifies the date and time that the content of the news feed was last modified.
LastError	Gets and sets a value which specifies the last error that has occurred.
LastErrorString	Gets a value which describes the last error that has occurred.
LinkUrl	Gets a value which specifies a URL to the website corresponding to the channel.
LocalFeed	Gets a value which specifies if the news feed was opened on the local system.
Options	Gets and sets a value which specifies one or more client options.
Published	Gets a value which specifies the date and time that the news feed was published.
ThrowError	Gets and sets a value which specifies if method calls should throw exceptions when an error occurs.
Timeout	Gets and sets a value which specifies a timeout period in seconds.
TimeToLive	Gets a value which specifies the frequency in seconds at which the feed should be refreshed.
Title	Gets a value which specifies the name of the news feed channel.
Trace	Gets and sets a value which indicates if network function logging is enabled.

TraceFile	Gets and sets a value which specifies the name of the logfile.
TraceFlags	Gets and sets a value which specifies the client function tracing flags.
URL	Gets and sets a value which specifies the current news feed URL.
Version	Gets a value which returns the current version of the NewsFeed class library.
Webmaster	Gets a value which identifies the person responsible for technical issues related to the news feed.

Public Instance Methods

Close	Close the current news feed.
Dispose	Overloaded. Releases all resources used by NewsFeed.
Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
FindItem	Search for an item in the news feed channel which matches the unique identifier.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetItem	Set the current news item to the specified item number.
GetProperty	Overloaded. Get the value of a property for the specified item in the news feed.
GetType (inherited from Object)	Gets the Type of the current instance.
Initialize	Overloaded. Initialize an instance of the NewsFeed class.
Open	Overloaded. Open the specified news feed and load the first news item.
Parse	Overloaded. Parse the contents of a news feed and load the first news item.
Refresh	Refresh the current news feed, reloading the news channel items.
Reset	Reset the internal state of the object, resetting all properties to their default values.
Store	Store the contents of the news feed in an XML formatted text file.
ToString (inherited from Object)	Returns a String that represents the current Object.
Uninitialize	Uninitialize the class library and release any

	resources allocated for the current thread.

Public Instance Events

OnError	Occurs when an client operation fails.

Protected Instance Methods

Dispose	Overloaded. Releases the unmanaged resources allocated by the NewsFeed class and optionally releases the managed resources.
Finalize	Destroys an instance of the class, releasing the resources allocated for the session and unloading the networking library.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

NewsFeed Properties

The properties of the **NewsFeed** class are listed below. For a complete list of **NewsFeed** class members, see the NewsFeed Members topic.

Public Instance Properties

Category	Gets a value which specifies the category or categories that the channel belongs to.
Copyright	Gets a value which specifies a copyright notice for the content.
Description	Gets a value which describes the news feed channel.
Editor	Gets a value which identifies the person responsible for managing the content of the news feed.
FeedVersion	Gets a value which identifies the version of the news feed.
Generator	Gets a value which identifies the application that was used to create the news feed.
ImageLink	Gets a value which specifies a URL to the website corresponding to the news feed.
ImageTitle	Gets a value which describes the image associated with the news feed.
ImageUrl	Gets a value which specifies a URL for the image associated with the news feed.
IsInitialized	Gets a value which indicates if the current instance of the class has been initialized successfully.
ItemAuthor	Gets a value which identifies the author of the current news feed item.
ItemComments	Gets a value which specifies a URL that links to further discussion about the current item.
ItemCount	Gets value which specifies the number of news items in the channel.
ItemEnclosure	Gets a value which specifies a URL that links to a file related to the item.
ItemGuid	Gets a value which uniquely identifies the current news item in the channel.
ItemId	Gets an numeric value which identifies the current news item in the channel.
ItemLink	Gets a value which specifies a URL that links to additional information related to the current item.
ItemPublished	Gets a value which specifies the date and time the current news item was published.

ItemSource	Gets a value which identifies the source of the current news item.
ItemText	Gets a value which provides a summary or description of the current news item.
ItemTitle	Gets a value which specifies a title for the current news item.
Language	Gets a value which identifies the language the news feed is written in.
LastBuild	Gets a value which specifies the date and time that the content of the news feed was last modified.
LastError	Gets and sets a value which specifies the last error that has occurred.
LastErrorString	Gets a value which describes the last error that has occurred.
LinkUrl	Gets a value which specifies a URL to the website corresponding to the channel.
LocalFeed	Gets a value which specifies if the news feed was opened on the local system.
Options	Gets and sets a value which specifies one or more client options.
Published	Gets a value which specifies the date and time that the news feed was published.
ThrowError	Gets and sets a value which specifies if method calls should throw exceptions when an error occurs.
Timeout	Gets and sets a value which specifies a timeout period in seconds.
TimeToLive	Gets a value which specifies the frequency in seconds at which the feed should be refreshed.
Title	Gets a value which specifies the name of the news feed channel.
Trace	Gets and sets a value which indicates if network function logging is enabled.
TraceFile	Gets and sets a value which specifies the name of the logfile.
TraceFlags	Gets and sets a value which specifies the client function tracing flags.
URL	Gets and sets a value which specifies the current news feed URL.
Version	Gets a value which returns the current version of the NewsFeed class library.
Webmaster	Gets a value which identifies the person

	responsible for technical issues related to the news feed.

NewsFeed.FeedVersion Property

Gets a value which identifies the version of the news feed.

[Visual Basic]

```
Public ReadOnly Property FeedVersion As String
```

[C#]

```
public string FeedVersion {get;}
```

See Also

NewsFeed Class | SocketTools Namespace

NewsFeed.Generator Property

Gets a value which identifies the application that was used to create the news feed.

[Visual Basic]
```
Public ReadOnly Property Generator As String
```

[C#]
```
public string Generator {get;}
```

See Also

NewsFeed Class | SocketTools Namespace

NewsFeed.ImageLink Property

Gets a value which specifies a URL to the website corresponding to the news feed.

[Visual Basic]

```
Public ReadOnly Property ImageLink As String
```

[C#]

```
public string ImageLink {get;}
```

See Also

NewsFeed Class | SocketTools Namespace

NewsFeed.ImageTitle Property

Gets a value which describes the image associated with the news feed.

[Visual Basic]

```
Public ReadOnly Property ImageTitle As String
```

[C#]

```
public string ImageTitle {get;}
```

See Also

NewsFeed Class | SocketTools Namespace

NewsFeed.ImageUrl Property

Gets a value which specifies a URL for the image associated with the news feed.

[Visual Basic]

```
Public ReadOnly Property ImageUrl As String
```

[C#]

```
public string ImageUrl {get;}
```

See Also

NewsFeed Class | SocketTools Namespace

NewsFeed.ItemAuthor Property

Gets a value which identifies the author of the current news feed item.

[Visual Basic]

```
Public ReadOnly Property ItemAuthor As String
```

[C#]

```
public string ItemAuthor {get;}
```

See Also

NewsFeed Class | SocketTools Namespace

NewsFeed.ItemComments Property

Gets a value which specifies a URL that links to further discussion about the current item.

[Visual Basic]

```
Public ReadOnly Property ItemComments As String
```

[C#]

```
public string ItemComments {get;}
```

See Also

NewsFeed Class | SocketTools Namespace

NewsFeed.ItemCount Property

Gets value which specifies the number of news items in the channel.

[Visual Basic]
```
Public ReadOnly Property ItemCount As Integer
```

[C#]
```
public int ItemCount {get;}
```

See Also

NewsFeed Class | SocketTools Namespace

NewsFeed.ItemEnclosure Property

Gets a value which specifies a URL that links to a file related to the item.

[Visual Basic]

```
Public ReadOnly Property ItemEnclosure As String
```

[C#]

```
public string ItemEnclosure {get;}
```

Remarks

This is similar to an attachment in an email message, however instead of the item containing the contents of the attached file, it only specifies a link to the file. Enclosures are most commonly used with podcasting where an item is linked to an audio or video file, however the link may reference any type of file. If there is no enclosure specified for the current item, this property will return an empty string.

See Also

NewsFeed Class | SocketTools Namespace

NewsFeed.ItemGuid Property

Gets a value which uniquely identifies the current news item in the channel.

[Visual Basic]

```
Public ReadOnly Property ItemGuid As String
```

[C#]

```
public string ItemGuid {get;}
```

Remarks

If this property is defined, it is guaranteed to be a unique, persistent value. It is important to note that this string does not have to be a standard GUID reference number, it can be any unique string. In many cases it is the same value as the hyperlink returned by the **ItemLink** property, although an application should never depend on this behavior. If there is no unique identifier associated with the current item, this property will return an empty string.

See Also

NewsFeed Class | SocketTools Namespace

NewsFeed.ItemId Property

Gets an numeric value which identifies the current news item in the channel.

[Visual Basic]

```
Public ReadOnly Property ItemId As Integer
```

[C#]

```
public int ItemId {get;}
```

Remarks

The value returned by this property is an index into the list of available news items. It is not persistent and the ID for a specific news item may change when the news feed is refreshed or opened at a later point. To uniquely identify a news item in the channel, use the **ItemGuid** property.

See Also

NewsFeed Class | SocketTools Namespace

NewsFeed.ItemLink Property

Gets a value which specifies a URL that links to additional information related to the current item.

[Visual Basic]
```
Public ReadOnly Property ItemLink As String
```

[C#]
```
public string ItemLink {get;}
```

See Also

NewsFeed Class | SocketTools Namespace

NewsFeed.ItemPublished Property

Gets a value which specifies the date and time the current news item was published.

[Visual Basic]

```
Public ReadOnly Property ItemPublished As String
```

[C#]

```
public string ItemPublished {get;}
```

See Also

NewsFeed Class | SocketTools Namespace

NewsFeed.ItemSource Property

Gets a value which identifies the source of the current news item.

[Visual Basic]

```
Public ReadOnly Property ItemSource As String
```

[C#]

```
public string ItemSource {get;}
```

Remarks

If the news item specifies a source, it will be the URL for the original news feed that contained it. This is typically used to propagate credit for news items that are aggregated by a third-party and re-published in their own channel. If the source is not specified, this property will return an empty string.

See Also

NewsFeed Class | SocketTools Namespace

NewsFeed.ItemText Property

Gets a value which provides a summary or description of the current news item.

[Visual Basic]

```
Public ReadOnly Property ItemText As String
```

[C#]

```
public string ItemText {get;}
```

Remarks

This may property may return either plain text or HTML formatted text. If no text has been specified for the current item, this property will return an empty string.

See Also

NewsFeed Class | SocketTools Namespace

NewsFeed.ItemTitle Property

Gets a value which specifies a title for the current news item.

[Visual Basic]

```
Public ReadOnly Property ItemTitle As String
```

[C#]

```
public string ItemTitle {get;}
```

See Also

NewsFeed Class | SocketTools Namespace

NewsFeed.Language Property

Gets a value which identifies the language the news feed is written in.

[Visual Basic]

```
Public ReadOnly Property Language As String
```

[C#]

```
public string Language {get;}
```

Remarks

This property typically returns standardized language codes, however the value actually returned depends on the content of the feed. If the news feed does not define this property, then it is generally presumed to be written in English.

See Also

NewsFeed Class | SocketTools Namespace

NewsFeed.LastBuild Property

Gets a value which specifies the date and time that the content of the news feed was last modified.

[Visual Basic]

```
Public ReadOnly Property LastBuild As String
```

[C#]

```
public string LastBuild {get;}
```

See Also

NewsFeed Class | SocketTools Namespace

NewsFeed.LastError Property

Gets and sets a value which specifies the last error that has occurred.

[Visual Basic]

```
Public Property LastError As ErrorCode
```

[C#]

```
public NewsFeed.ErrorCode LastError {get; set;}
```

Property Value

Returns an ErrorCode enumeration value which specifies the last error code.

Remarks

The **LastError** property returns the error code associated with the last error that occurred for the current instance of the class. It is important to note that this value only has meaning if the previous method indicates that an error has actually occurred.

It is possible to explicitly clear the last error code by assigning the property to the value **ErrorCode.errorNone**.

The error code value can be cast to an integer value for display purposes if required. For a description of the error that can be displayed using a message box or some other similar mechanism, get the value of the **LastErrorString** property.

See Also

NewsFeed Class | SocketTools Namespace

NewsFeed.LastErrorString Property

Gets a value which describes the last error that has occurred.

[Visual Basic]

```
Public ReadOnly Property LastErrorString As String
```

[C#]

```
public string LastErrorString {get;}
```

Property Value

A string which describes the last error that has occurred.

Remarks

The **LastErrorString** property can be used to obtain a description of the last error that occurred for the current instance of the class. It is important to note that this value only has meaning if the previous method indicates that an error has actually occurred.

See Also

NewsFeed Class | SocketTools Namespace

NewsFeed.LinkUrl Property

Gets a value which specifies a URL to the website corresponding to the channel.

[Visual Basic]

```
Public ReadOnly Property LinkUrl As String
```

[C#]

```
public string LinkUrl {get;}
```

Remarks

This property does not return the URL of the news feed itself. Typically it is a link to the home page of the site which owns the news feed. If a link has not been specified in the news feed, this property will return an empty string. Note that strictly conforming news feeds require a valid link.

See Also

NewsFeed Class | SocketTools Namespace

NewsFeed.LocalFeed Property

Gets a value which specifies if the news feed was opened on the local system.

[Visual Basic]

```
Public ReadOnly Property LocalFeed As Boolean
```

[C#]

```
public bool LocalFeed {get;}
```

See Also

NewsFeed Class | SocketTools Namespace

NewsFeed.Options Property

Gets and sets a value which specifies one or more client options.

[Visual Basic]
```
Public Property Options As NewsFeedOptions
```

[C#]
```
public NewsFeed.NewsFeedOptions Options {get; set;}
```

Property Value

Returns one or more NewsFeedOptions enumeration flags which specify the options for the client. The default value for this property is **optionNone**.

Remarks

The **Options** property specifies one or more default options options which are used when opening a news feed using the **Open** method.

See Also

NewsFeed Class | SocketTools Namespace

NewsFeed.Published Property

Gets a value which specifies the date and time that the news feed was published.

[Visual Basic]

```
Public ReadOnly Property Published As String
```

[C#]

```
public string Published {get;}
```

Remarks

The value returned by this property is not necessarily the date that the news feed was last modified. For example, a feed that is associated with a weekly print publication may update this value once per week. If a publish date has not been specified for the feed, this property will return an empty string.

See Also

NewsFeed Class | SocketTools Namespace

NewsFeed.ThrowError Property

Gets and sets a value which specifies if method calls should throw exceptions when an error occurs.

[Visual Basic]
```
Public Property ThrowError As Boolean
```

[C#]
```
public bool ThrowError {get; set;}
```

Property Value

Returns **true** if method calls will generate exceptions when an error occurs; otherwise returns **false**. The default value is **false**.

Remarks

Error handling for when calling class methods can be done in either of two different styles, according to the value of this property.

If the **ThrowError** property is set to **false**, the application should check the return value of any method that is used, and report errors based upon the documented value of the return code. It is the responsibility of the application to interpret the error code, if it is desired to explain the error in addition to reporting it. This is the default behavior.

If the **ThrowError** property is set to **true**, then exceptions will be generated whenever a method call fails. The program must be written to catch these exceptions and take the appropriate action when an error occurs. Failure to handle an exception will cause the program to terminate abnormally.

Note that if an error occurs while a property is being read or modified, an exception will be raised regardless of the value of the **ThrowError** property.

See Also

NewsFeed Class | SocketTools Namespace

NewsFeed.Timeout Property

Gets and sets a value which specifies a timeout period in seconds.

[Visual Basic]

```
Public Property Timeout As Integer
```

[C#]

```
public int Timeout {get; set;}
```

Property Value

An integer value which specifies a timeout period in seconds.

Remarks

Setting the **Timeout** property specifies the number of seconds until a blocking operation fails and returns an error.

The timeout period is only used when the client is in blocking mode. Although this property can be changed when the client is in non-blocking mode, the value will be ignored until the client is returned to blocking mode.

For most applications it is recommended the timeout period be set between 10 and 20 seconds.

See Also

NewsFeed Class | SocketTools Namespace

NewsFeed.TimeToLive Property

Gets a value which specifies the frequency in seconds at which the feed should be refreshed.

[Visual Basic]

```
Public ReadOnly Property TimeToLive As Integer
```

[C#]

```
public int TimeToLive {get;}
```

Property Value

An integer value that specifies the frequency in seconds at which the feed should be refreshed to obtain updated information. Not all feeds specify a time-to-live, in which case this member will have a value of zero.

Remarks

The value of the **TimeToLive** property should be considered advisory, and not all news feeds will provide this value. If the news feed does provide this value, it is recommended that you consider it to be the minimum interval at which you will poll the site for updates to the feed.

To update the contents of the current feed, use the **Refresh** method.

See Also

NewsFeed Class | SocketTools Namespace | Refresh Method

NewsFeed.Title Property

Gets a value which specifies the name of the news feed channel.

[Visual Basic]

```
Public ReadOnly Property Title As String
```

[C#]

```
public string Title {get;}
```

Remarks

If the content of the news feed corresponds to a website, this is value returned by this property is typically the same as the title of the website. If a title has not been specified, this property will return an empty string. Note that a strictly conforming news feed requires a title.

See Also

NewsFeed Class | SocketTools Namespace

NewsFeed.Trace Property

Gets and sets a value which indicates if network function logging is enabled.

[Visual Basic]
```
Public Property Trace As Boolean
```

[C#]
```
public bool Trace {get; set;}
```

Property Value

Returns **true** if network function tracing is enabled; otherwise returns **false**. The default value is **false**.

Remarks

The **Trace** property is used to enable (or disable) the tracing of network function calls. When enabled, each function call is logged to a file, including the function parameters, return value and error code if applicable. This facility can be enabled and disabled at run time, and the trace log file can be specified by setting the **TraceFile** property. All function calls that are being logged are appended to the trace file, if it exists. If no trace file exists when tracing is enabled, the trace file is created.

The tracing facility is available in all of the SocketTools networking classes and is enabled or disabled for an entire process. This means that once trace logging is enabled for a given component, all of the function calls made by the process using any of the SocketTools classes will be logged. For example, if you have an application using both the File Transfer Protocol and Post Office Protocol classes, and you set the **Trace** property to **true**, function calls made by both classes will be logged. Additionally, enabling a trace is cumulative, and tracing is not stopped until it is disabled for all classes used by the process.

If trace logging is not enabled, there is no negative impact on performance or throughput. Once enabled, application performance can degrade, especially in those situations in which multiple processes are being traced or the logfile is fairly large. Since logfiles can grow very quickly, even with modest applications, it is recommended that you delete the file when it is no longer needed.

When redistributing your application, make sure that you include the **SocketTools10.TraceLog.dll** module with your installation. If this library is not present, then no trace output will be generated and the value of the **Trace** property will be ignored. Only those function calls made by the SocketTools networking classes will be logged. Calls made directly to the Windows Sockets API, or calls made by other classes, will not be logged.

See Also

NewsFeed Class | SocketTools Namespace

NewsFeed.TraceFile Property

Gets and sets a value which specifies the name of the logfile.

[Visual Basic]

```
Public Property TraceFile As String
```

[C#]

```
public string TraceFile {get; set;}
```

Property Value

A string which specifies the name of the file.

Remarks

The **TraceFile** property is used to specify the name of the trace file that is created when network function tracing is enabled. If this property is set to an empty string (the default value), then a file named **SocketTools.log** is created in the system's temporary directory. If no temporary directory exists, then the file is created in the current working directory.

If the file exists, the trace output is appended to the file, otherwise the file is created. Since network function tracing is enabled per-process, the trace file is shared by all instances of the class being used. If multiple class instances have tracing enabled, the **TraceFile** property should be set to the same value for each instance. Since trace files can grow very quickly, even with modest applications, it is recommended that you delete the file when it is no longer needed.

The trace file has the following format:

```
 MyApp INF: WSAAsyncSelect(46, 0xcc4, 0x7e9, 0x27) returned 0 MyApp WRN:
connect(46, 192.0.0.1:1234, 16) returned -1 [10035] MyApp ERR: accept(46,
NULL, 0x0) returned -1 [10038]
```

The first column contains the name of the process that is being traced. The second column identifies if the trace record is reporting information, a warning, or an error. What follows is the name of the function being called, the arguments passed to the function and the function's return value. If a warning or error is reported, the error code is appended to the record (the value is placed inside brackets).

If parameters are passed as integer values, they are recorded in decimal. If the parameter or return value is a pointer (a memory address), it is recorded as a hexadecimal value preceded with "0x". A special type of pointer, called a null pointer, is recorded as NULL. Those functions which expect socket addresses are displayed in the following format:

```
aa.bb.cc.dd:nnnn
```

The first four numbers separated by periods represent the IP address, and the number following the colon represents the port number in host byte order. Note that in the second line of the above example, the control is attempting to connect to a system with the IP address 192.0.0.1 on port 1234.

Note that if the specified file cannot be created, or the user does not have permission to modify an existing file, the error is silently ignored and no trace output will be generated.

See Also

NewsFeed Class | SocketTools Namespace

NewsFeed.TraceFlags Property

Gets and sets a value which specifies the client function tracing flags.

[Visual Basic]
```
Public Property TraceFlags As TraceOptions
```

[C#]
```
public NewsFeed.TraceOptions TraceFlags {get; set;}
```

Property Value

A TraceOptions enumeration which specifies the amount of detail written to the trace logfile.

Remarks

The **TraceFlags** property is used to specify the type of information written to the trace file when network function tracing is enabled.

Because network function tracing is enabled per-process, the trace flags are shared by all instances of the class being used. If multiple class instances have tracing enabled, the **TraceFlags** property should be set to the same value for each instance. Changing the trace flags for any one instance of the class will affect the logging performed for all SocketTools classes used by the application.

Warnings are generated when a non-fatal error is returned by a network function. For example, if data is being written and the error **errorOperationWouldBlock** occurs, a warning is generated because the application simply needs to attempt to write the data at a later time.

See Also

NewsFeed Class | SocketTools Namespace

NewsFeed.URL Property

Gets and sets a value which specifies the current news feed URL.

[Visual Basic]

```
Public Property URL As String
```

[C#]

```
public string URL {get; set;}
```

See Also

NewsFeed Class | SocketTools Namespace

NewsFeed.Version Property

Gets a value which returns the current version of the NewsFeed class library.

[Visual Basic]

```
Public ReadOnly Property Version As String
```

[C#]

```
public string Version {get;}
```

Property Value

A string which specifies the version of the class library.

Remarks

The **Version** property returns a string which identifies the current version and build of the NewsFeed class library. This value can be used by an application for validation and debugging purposes.

See Also

NewsFeed Class | SocketTools Namespace

NewsFeed.Webmaster Property

Gets a value which identifies the person responsible for technical issues related to the news feed.

[Visual Basic]

```
Public ReadOnly Property Webmaster As String
```

[C#]

```
public string Webmaster {get;}
```

Remarks

If this value is defined in the news feed, it is typically the email address of a system administrator responsible for the server that hosts the news feed. If the webmaster is not specified, this property will return an empty string.

See Also

NewsFeed Class | SocketTools Namespace

NewsFeed Methods

The methods of the **NewsFeed** class are listed below. For a complete list of **NewsFeed** class members, see the NewsFeed Members topic.

Public Instance Methods

Close	Close the current news feed.
Dispose	Overloaded. Releases all resources used by NewsFeed.
Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
FindItem	Search for an item in the news feed channel which matches the unique identifier.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetItem	Set the current news item to the specified item number.
GetProperty	Overloaded. Get the value of a property for the specified item in the news feed.
GetType (inherited from Object)	Gets the Type of the current instance.
Initialize	Overloaded. Initialize an instance of the NewsFeed class.
Open	Overloaded. Open the specified news feed and load the first news item.
Parse	Overloaded. Parse the contents of a news feed and load the first news item.
Refresh	Refresh the current news feed, reloading the news channel items.
Reset	Reset the internal state of the object, resetting all properties to their default values.
Store	Store the contents of the news feed in an XML formatted text file.
ToString (inherited from Object)	Returns a String that represents the current Object.
Uninitialize	Uninitialize the class library and release any resources allocated for the current thread.

Protected Instance Methods

Dispose	Overloaded. Releases the unmanaged resources allocated by the NewsFeed class and optionally releases the managed resources.
Finalize	Destroys an instance of the class, releasing the resources allocated for the session and unloading

	the networking library.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

NewsFeed Class | SocketTools Namespace

NewsFeed.Close Method

Close the current news feed.

[Visual Basic]

```
Public Function Close() As Boolean
```

[C#]

```
public bool Close();
```

Return Value

A boolean value which specifies if the news feed was closed successfully. A return value of true indicates success, while a return value of false indicates failure. If the method fails, the value of the **LastError** property can be used to determine cause of the failure.

Remarks

The **Close** method must be called whenever the application has completed processing the news feed. It is important to note that information about the current news feed item will be cleared whenever this method is called, resetting the channel and item related properties back to their default values.

See Also

NewsFeed Class | SocketTools Namespace | Open Method | Parse Method

NewsFeed.FindItem Method

Search for an item in the news feed channel which matches the unique identifier.

```
[Visual Basic]
Public Function FindItem( _
   ByVal itemGuid As String _
) As Boolean
```

```
[C#]
public bool FindItem(
   string itemGuid
);
```

Parameters

itemGuid

A string value which specifies the unique identifier for the news item that is being searched for.

Return Value

A boolean value that specifies if the news item was found. A return value of true indicates success, while a return value of false indicates failure. If the method fails, the value of the **LastError** property can be used to determine cause of the failure.

Remarks

If this method returns true, the current news item is changed to the item that was found and property values such as **ItemLink** and **ItemText** will be updated. If this method returns false, the current news item is not changed.

It is recommended that you use this method with news feeds that are using version 2.0 or later of the RSS specification. If the feed uses an earlier version, items may not include a GUID property. It is also possible that a feed may omit the GUID property even though it is considered a requirement for the current RSS specification. For the broadest compatibility with all news feeds, an application should not depend on being able to search for a specific news feed item by its GUID.

See Also

NewsFeed Class | SocketTools Namespace | ItemGuid Property | GetItem Method

NewsFeed.GetItem Method

Set the current news item to the specified item number.

[Visual Basic]

```
Public Function GetItem( _
   ByVal itemId As Integer _
) As Boolean
```

[C#]

```
public bool GetItem(
   int itemId
);
```

Parameters

itemId

An integer value which specifies item in the news feed channel.

Return Value

A boolean value that specifies if the news item was found. A return value of true indicates success, while a return value of false indicates failure. If the method fails, the value of the **LastError** property can be used to determine cause of the failure.

Remarks

The item number is an index into the list of available news items in the current news feed. The first news item is one, and it increments for each additional item in the feed. If ***itemId*** parameter is zero or specifies a value larger than the number of items in the feed, this method will fail.

If this method returns true, the current news item is changed to the specified value and property values such as **ItemLink** and **ItemText** will be updated. If this method returns false, the current news item is not changed.

If this method fails, it typically indicates that the ***itemId*** parameter is invalid or that the feed does not contain any valid news items. The **ItemCount** property can be used to determine the number of items contained in the news feed channel.

NewsFeed Class | SocketTools Namespace | GetItem

NewsFeed.GetProperty Method (Int32, String, String, String)

Get the value of a property for the specified item in the news feed.

[Visual Basic]

```
Overloads Public Function GetProperty( _
   ByVal itemId As Integer, _
   ByVal propName As String, _
   ByVal propAttribute As String, _
   ByRef propValue As String _
) As Boolean
```

[C#]

```
public bool GetProperty(
   int itemId,
   string propName,
   string propAttribute,
   ref string propValue
);
```

Parameters

itemId
An integer value which specifies the item in the news feed channel.

propName
A string value which specifies the property name.

propAttribute
A string value which specifies the property attribute.

propValue
A string value passed by reference that will contain the property value when the method returns.

Return Value

A boolean value that specifies if the property attribute was found. A return value of true indicates success, while a return value of false indicates failure. If the method fails, the value of the **LastError** property can be used to determine cause of the failure.

Remarks

The **GetProperty** method is primarily used with custom item properties that may be used with extensions to the news feed. The standard properties for an news feed item such as the title, link and description can be access using properties such as **ItemTitle**, **ItemLink** and **ItemText**. However, if items in the feed contain custom properties that are not part of the standard RSS format, this method can be used to obtain those values.

The item number is an index into the list of available news items in the current news feed. The first news item is one, and it increments for each additional item in the feed. If *itemId* parameter is zero or specifies a value larger than the number of items in the feed, this method will fail.

NewsFeed.Initialize Method

Initialize an instance of the NewsFeed class.

Overload List

Initialize an instance of the NewsFeed class.

public bool Initialize();

Initialize an instance of the NewsFeed class.

public bool Initialize(string);

See Also

NewsFeed Class | SocketTools Namespace | Uninitialize Method

NewsFeed.Initialize Method ()

Initialize an instance of the NewsFeed class.

[Visual Basic]
```
Overloads Public Function Initialize() As Boolean
```

[C#]
```
public bool Initialize();
```

Return Value

A boolean value which specifies if the class was initialized successfully.

Remarks

The Initialize method can be used to explicitly initialize an instance of the NewsFeed class, loading the networking library and allocating resources for the current thread. Typically it is not necessary to explicitly call this method because the instance of the class is initialized by the class constructor. However, if the **Uninitialize** method is called, the class must be re-initialized before any other methods are called.

See Also

NewsFeed Class | SocketTools Namespace | NewsFeed.Initialize Overload List | Uninitialize Method

NewsFeed.Initialize Method (String)

Initialize an instance of the NewsFeed class.

[Visual Basic]
```
Overloads Public Function Initialize( _
   ByVal licenseKey As String _
) As Boolean
```

[C#]
```
public bool Initialize(
   string licenseKey
);
```

Return Value

A boolean value which specifies if the class was initialized successfully.

Remarks

The Initialize method can be used to explicitly initialize an instance of the NewsFeed class, loading the networking library and allocating resources for the current thread. Typically an application would define the license key as a custom attribute, however this method can be used to initialize the class directly.

The runtime license key for your copy of SocketTools can be generated using the License Manager utility that is included with the product. Note that if you have installed an evaluation license, you will not have a runtime license key and cannot redistribute any applications which use the NewsFeed class.

Example

The following example shows how to use the Initialize method to initialize an instance of the class. This example assumes that the license key string has been defined in code.

```
SocketTools.NewsFeed newsFeed = new SocketTools.NewsFeed();

if (newsFeed.Initialize(strLicenseKey) == false)
{
    MessageBox.Show(newsFeed.LastErrorString, "Error",
                    MessageBoxButtons.OK, MessageBoxIcon.Exclamation);
    return;
}
```

```
Dim newsFeed As New SocketTools.NewsFeed

If newsFeed.Initialize(strLicenseKey) = False Then
    MsgBox(newsFeed.LastErrorString, vbIconExclamation)
    Exit Sub
End If
```

NewsFeed Class | SocketTools Namespace | NewsFeed.Initialize Overload List | RuntimeLicenseAttribute Class | Uninitialize Method

NewsFeed.Open Method

Open the specified news feed and load the first news item.

Overload List

Open the specified news feed and load the first news item.

public bool Open(string);

Open the specified news feed and load the first news item.

public bool Open(string,int);

Open the specified news feed and load the first news item.

public bool Open(string,int,NewsFeedOptions);

See Also

NewsFeed Class | SocketTools Namespace | Parse Method

NewsFeed.Open Method (String, Int32, NewsFeedOptions)

Open the specified news feed and load the first news item.

[Visual Basic]

```
Overloads Public Function Open( _
   ByVal feedUrl As String, _
   ByVal timeout As Integer, _
   ByVal options As NewsFeedOptions _
) As Boolean
```

[C#]

```
public bool Open(
   string feedUrl,
   int timeout,
   NewsFeedOptions options
);
```

Parameters

feedUrl

A string value which specifies the URL for the news feed. To access a news feed on a web server, a standard http or https URL may be used. To access a file on the local system or network share, a file name or file URL may be specified.

timeout

The number of seconds that the client will wait for a response before failing the operation. This parameter is ignored if the ***feedUrl*** parameter specifies a local file name or URL.

options

One or more NewsFeedOptions enumeration flags which specify the options for the client. The default value for this property is **optionNone**.

Return Value

A boolean value that specifies if the news feed was opened. A return value of true indicates success, while a return value of false indicates failure. If the method fails, the value of the **LastError** property can be used to determine cause of the failure.

Remarks

A news feed may be local or remote, depending on the URL that is specified. If a local file name or file URL is specified for the feed, then it is opened locally and no network access is required. If an http or https URL is specified, then the **Open** method will attempt to download the feed from the remote host and store it temporarily on the local system. Accessing a remote feed requires that the application has permission to establish a connection with the remote host and will cause the application to block until the feed has been downloaded, the operation times out or an error occurs.

Although the **Open** method will meet the needs of most applications, if you require more complex functionality such as retrieving the feed asynchronously in the background or event notifications for large transfers, you can use the **SocketTools.HttpClient** class to download the news feed and then use the **Parse** method to parse the contents.

See Also

NewsFeed Class | SocketTools Namespace | NewsFeed.Open Overload List | Parse Method

NewsFeed.Open Method (String, Int32)

Open the specified news feed and load the first news item.

[Visual Basic]

```
Overloads Public Function Open( _
   ByVal feedUrl As String, _
   ByVal timeout As Integer _
) As Boolean
```

[C#]

```
public bool Open(
   string feedUrl,
   int timeout
);
```

Parameters

feedUrl

A string value which specifies the URL for the news feed. To access a news feed on a web server, a standard http or https URL may be used. To access a file on the local system or network share, a file name or file URL may be specified.

timeout

The number of seconds that the client will wait for a response before failing the operation. This parameter is ignored if the ***feedUrl*** parameter specifies a local file name or URL.

Return Value

A boolean value that specifies if the news feed was opened. A return value of true indicates success, while a return value of false indicates failure. If the method fails, the value of the **LastError** property can be used to determine cause of the failure.

Remarks

A news feed may be local or remote, depending on the URL that is specified. If a local file name or file URL is specified for the feed, then it is opened locally and no network access is required. If an http or https URL is specified, then the **Open** method will attempt to download the feed from the remote host and store it temporarily on the local system. Accessing a remote feed requires that the application has permission to establish a connection with the remote host and will cause the application to block until the feed has been downloaded, the operation times out or an error occurs.

Although the **Open** method will meet the needs of most applications, if you require more complex functionality such as retrieving the feed asynchronously in the background or event notifications for large transfers, you can use the **SocketTools.HttpClient** class to download the news feed and then use the **Parse** method to parse the contents.

NewsFeed.Open Method (String)

Open the specified news feed and load the first news item.

[Visual Basic]

```
Overloads Public Function Open( _
   ByVal feedUrl As String _
) As Boolean
```

[C#]

```
public bool Open(
   string feedUrl
);
```

Parameters

feedUrl

A string value which specifies the URL for the news feed. To access a news feed on a web server, a standard http or https URL may be used. To access a file on the local system or network share, a file name or file URL may be specified.

Return Value

A boolean value that specifies if the news feed was opened. A return value of true indicates success, while a return value of false indicates failure. If the method fails, the value of the **LastError** property can be used to determine cause of the failure.

Remarks

A news feed may be local or remote, depending on the URL that is specified. If a local file name or file URL is specified for the feed, then it is opened locally and no network access is required. If an http or https URL is specified, then the **Open** method will attempt to download the feed from the remote host and store it temporarily on the local system. Accessing a remote feed requires that the application has permission to establish a connection with the remote host and will cause the application to block until the feed has been downloaded, the operation times out or an error occurs.

Although the **Open** method will meet the needs of most applications, if you require more complex functionality such as retrieving the feed asynchronously in the background or event notifications for large transfers, you can use the **SocketTools.HttpClient** class to download the news feed and then use the **Parse** method to parse the contents.

NewsFeed.Parse Method

Parse the contents of a news feed and load the first news item.

Overload List

Parse the contents of a news feed and load the first news item.

public bool Parse(string);

Parse the contents of a news feed and load the first news item.

public bool Parse(string,NewsFeedOptions);

See Also

NewsFeed Class | SocketTools Namespace

NewsFeed.Parse Method (String, NewsFeedOptions)

Parse the contents of a news feed and load the first news item.

[Visual Basic]

```
Overloads Public Function Parse( _
   ByVal feedXml As String, _
   ByVal options As NewsFeedOptions _
) As Boolean
```

[C#]

```
public bool Parse(
   string feedXml,
   NewsFeedOptions options
);
```

Parameters

feedXml

A string which contains the contents of the news feed. The string must contain XML formatted data that conforms to the RSS standard specification and cannot specify an empty string.

options

One or more NewsFeedOptions enumeration flags which specify the options for the client. The default value for this property is **optionNone**.

Return Value

A boolean value that specifies if the contents of the ***feedXml*** parameter could be parsed. A return value of true indicates success, while a return value of false indicates failure. If the method fails, the value of the **LastError** property can be used to determine cause of the failure.

Remarks

The **Parse** method is an alternative to the **Open** method, enabling the application to process a news feed from alternative sources such as a database or compressed file. It is important to note that the string which contains the news feed XML must be properly formatted and conform to the RSS standard specification.

See Also

NewsFeed Class | SocketTools Namespace | NewsFeed.Parse Overload List

NewsFeed.Parse Method (String)

Parse the contents of a news feed and load the first news item.

[Visual Basic]

```
Overloads Public Function Parse( _
   ByVal feedXml As String _
) As Boolean
```

[C#]

```
public bool Parse(
   string feedXml
);
```

Parameters

feedXml

A string which contains the contents of the news feed. The string must contain XML formatted data that conforms to the RSS standard specification and cannot specify an empty string.

Return Value

A boolean value that specifies if the contents of the ***feedXml*** parameter could be parsed. A return value of true indicates success, while a return value of false indicates failure. If the method fails, the value of the **LastError** property can be used to determine cause of the failure.

Remarks

The **Parse** method is an alternative to the **Open** method, enabling the application to process a news feed from alternative sources such as a database or compressed file. It is important to note that the string which contains the news feed XML must be properly formatted and conform to the RSS standard specification.

See Also

NewsFeed Class | SocketTools Namespace | NewsFeed.Parse Overload List

NewsFeed.Refresh Method

Refresh the current news feed, reloading the news channel items.

[Visual Basic]
```
Public Function Refresh() As Boolean
```

[C#]
```
public bool Refresh();
```

Return Value

A boolean value that specifies if the news feed was refreshed. A return value of true indicates success, while a return value of false indicates failure. If the method fails, the value of the **LastError** property can be used to determine cause of the failure.

Remarks

When the **Refresh** method is called, the news feed is reloaded from the original source and the items in the channel are updated. For news feeds that are frequently updated, the **TimeToLive** property can provide a hint to the application as to how frequently the feed should be refreshed.

If the news feed was originally opened using an http or https URL, this function will download the updated feed from the remote host and store it temporarily on the local system. Accessing a remote feed requires that the application has permission to establish a connection with the remote host and will cause the application to block until the feed has been downloaded, the operation times out or an error occurs. The same timeout period and options will be used as when the feed was originally opened.

The **Refresh** method should only be used if the feed was opened using the **Open** method, otherwise the method will fail with an error indicating that the operation is not supported.

It is important that the application does not make any assumptions about the number of news items in the channel, or the content associated with those items after the **Refresh** method has been called. For example, never assume that the number of items in the news feed remains the same, or that the item IDs for each item remains the same. If you need to find a specific item in the news feed, use the **FindItem** method.

See Also

NewsFeed Class | SocketTools Namespace | FindItem Method | Open Method

NewsFeed.Reset Method

Reset the internal state of the object, resetting all properties to their default values.

[Visual Basic]

```
Public Sub Reset()
```

[C#]

```
public void Reset();
```

Remarks

The **Reset** method returns the object to its default state. If a socket has been allocated, it will be released and any active connections will be terminated. All properties will be reset to their default values.

See Also

NewsFeed Class | SocketTools Namespace

NewsFeed.Store Method

Store the contents of the news feed in an XML formatted text file.

[Visual Basic]

```
Public Function Store( _
   ByVal fileName As String _
) As Boolean
```

[C#]

```
public bool Store(
   string fileName
);
```

Parameters

fileName

A string value which specifies the name of the file on the local system. The contents of the news feed will be stored in this file. If the file does not exist, it will be created; otherwise it will overwrite the contents of the file.

Return Value

A boolean value that specifies if the news feed was stored on the local system or network. A return value of true indicates success, while a return value of false indicates failure. If the method fails, the value of the **LastError** property can be used to determine cause of the failure.

See Also

NewsFeed Class | SocketTools Namespace | Open Method | Parse Method

NewsFeed.Uninitialize Method

Uninitialize the class library and release any resources allocated for the current thread.

[Visual Basic]

```
Public Sub Uninitialize()
```

[C#]

```
public void Uninitialize();
```

Remarks

The **Uninitialize** method terminates any active connection, releases resources allocated for the current thread and unloads the networking library. After this method has been called, no further client operations may be performed until the class instance has been re-initialized.

If the **Initialize** method is explicitly called by the application, it should be matched by a call to the **Uninitialize** method when that instance of the class is no longer needed.

NewsFeed Class | SocketTools Namespace | Initialize Method

NewsFeed Events

The events of the **NewsFeed** class are listed below. For a complete list of **NewsFeed** class members, see the NewsFeed Members topic.

Public Instance Events

⚡ OnError	Occurs when an client operation fails.

See Also

NewsFeed Class | SocketTools Namespace

NewsFeed.OnError Event

Occurs when an client operation fails.

[Visual Basic]
```
Public Event OnError As OnErrorEventHandler
```

[C#]
```
public event OnErrorEventHandler OnError;
```

Event Data

The event handler receives an argument of type NewsFeed.ErrorEventArgs containing data related to this event. The following **NewsFeed.ErrorEventArgs** properties provide information specific to this event.

Property	Description
Description	Gets a value which describes the last error that has occurred.
Error	Gets a value which specifies the last error that has occurred.

Remarks

The **OnError** event occurs when a client operation fails.

See Also

NewsFeed Class | SocketTools Namespace

NewsFeed.ErrorEventArgs Class

Provides data for the OnError event.

For a list of all members of this type, see NewsFeed.ErrorEventArgs Members.

System.Object
  System.EventArgs
    SocketTools.NewsFeed.ErrorEventArgs

[Visual Basic]

```
Public Class NewsFeed.ErrorEventArgs
    Inherits EventArgs
```

[C#]

```
public class NewsFeed.ErrorEventArgs : EventArgs
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

ErrorEventArgs specifies the numeric error code and a description of the error that has occurred.

An OnError event occurs when a method fails.

Requirements

Namespace: SocketTools

Assembly: SocketTools.NewsFeed (in SocketTools.NewsFeed.dll)

NewsFeed.ErrorEventArgs Members

NewsFeed.ErrorEventArgs overview

Public Instance Constructors

NewsFeed.ErrorEventArgs Constructor	Initializes a new instance of the NewsFeed.ErrorEventArgs class.

Public Instance Properties

Description	Gets a value which describes the last error that has occurred.
Error	Gets a value which specifies the last error that has occurred.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString (inherited from Object)	Returns a String that represents the current Object.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

NewsFeed.ErrorEventArgs Class | SocketTools Namespace

NewsFeed.ErrorEventArgs Constructor

Initializes a new instance of the NewsFeed.ErrorEventArgs class.

[Visual Basic]

```
Public Sub New()
```

[C#]

```
public NewsFeed.ErrorEventArgs();
```

See Also

NewsFeed.ErrorEventArgs Class | SocketTools Namespace

NewsFeed.ErrorEventArgs Properties

The properties of the **NewsFeed.ErrorEventArgs** class are listed below. For a complete list of **NewsFeed.ErrorEventArgs** class members, see the NewsFeed.ErrorEventArgs Members topic.

Public Instance Properties

Description	Gets a value which describes the last error that has occurred.
Error	Gets a value which specifies the last error that has occurred.

See Also

NewsFeed.ErrorEventArgs Class | SocketTools Namespace

NewsFeed.ErrorEventArgs.Description Property

Gets a value which describes the last error that has occurred.

[Visual Basic]

```
Public ReadOnly Property Description As String
```

[C#]

```
public string Description {get;}
```

Property Value

A string which describes the last error that has occurred.

See Also

NewsFeed.ErrorEventArgs Class | SocketTools Namespace | Error Property

NewsFeed.ErrorEventArgs.Error Property

Gets a value which specifies the last error that has occurred.

[Visual Basic]

```
Public ReadOnly Property Error As ErrorCode
```

[C#]

```
public NewsFeed.ErrorCode Error {get;}
```

Property Value

ErrorCode enumeration which specifies the error.

See Also

NewsFeed.ErrorEventArgs Class | SocketTools Namespace | Description Property

NewsFeed.ErrorCode Enumeration

Specifies the error codes returned by the NewsFeed class.

[Visual Basic]
```
Public Enum NewsFeed.ErrorCode
```

[C#]
```
public enum NewsFeed.ErrorCode
```

Remarks

The NewsFeed class uses the **ErrorCode** enumeration to specify what error has occurred when a method fails. The current error code may be determined by checking the value of the **LastError** property.

Note that the last error code is only meaningful if the previous operation has failed.

Members

Member Name	Description
errorNone	No error.
errorNotHandleOwner	Handle not owned by the current thread.
errorFileNotFound	The specified file or directory does not exist.
errorFileNotCreated	The specified file could not be created.
errorOperationCanceled	The blocking operation has been canceled.
errorInvalidFileType	The specified file is a block or character device, not a regular file.
errorInvalidDevice	The specified file type is invalid or not a regular file.
errorTooManyParameters	The maximum number of function parameters has been exceeded.
errorInvalidFileName	The specified file name contains invalid characters or is too long.
errorInvalidFileHandle	Invalid file handle passed to function.
errorFileReadFailed	Unable to read data from the specified file.
errorFileWriteFailed	Unable to write data to the specified file.
errorOutOfMemory	Out of memory.
errorAccessDenied	Access denied.
errorInvalidParameter	Invalid argument passed to function.
errorClipboardUnavailable	The system clipboard is currently unavailable.
errorClipboardEmpty	The system clipboard is empty or does not contain any text data.
errorFileEmpty	The specified file does not contain any data.
errorFileExists	The specified file already exists.

errorEndOfFile	End of file.
errorDeviceNotFound	The specified device could not be found.
errorDirectoryNotFound	The specified directory could not be found.
errorInvalidbuffer	Invalid memory address passed to function.
errorBufferTooSmall	The specified buffer is not large enough to contain the data.
errorNoHandles	No more handles are available to this process.
errorOperationWouldBlock	The specified operation would block the current thread.
errorOperationInProgress	A blocking operation is currently in progress.
errorAlreadyInProgress	The specified operation is already in progress.
errorInvalidHandle	Invalid handle passed to function.
errorInvalidAddress	Invalid network address specified.
errorInvalidSize	Datagram is too large to fit in specified buffer.
errorInvalidProtocol	Invalid network protocol specified.
errorProtocolNotAvailable	The specified network protocol is not available.
errorProtocolNotSupported	The specified protocol is not supported.
errorSocketNotSupported	The specified socket type is not supported.
errorInvalidOption	The specified option is invalid.
errorProtocolFamily	Specified protocol family is not supported.
errorProtocolAddress	The specified address is invalid for this protocol family.
errorAddressInUse	The specified address is in use by another process.
errorAddressUnavailable	The specified address cannot be assigned.
errorNetworkUnavailable	The networking subsystem is unavailable.
errorNetworkUnreachable	The specified network is unreachable.
errorNetworkReset	Network dropped connection on remote reset.
errorConnectionAborted	Connection was aborted due to timeout or other failure.
errorConnectionReset	Connection was reset by remote network.
errorOutOfBuffers	No buffer space is available.
errorAlreadyConnected	Connection already established with remote host.
errorNotConnected	No connection established with remote host.
errorConnectionShutdown	Unable to send or receive data after connection shutdown.
errorOperationTimeout	The specified operation has timed out.
errorConnectionRefused	The connection has been refused by the remote host.

errorHostUnavailable	The specified host is unavailable.
errorHostUnreachable	Remote host is unreachable.
errorTooManyProcesses	Too many processes are using the networking subsystem.
errorTooManyThreads	Too many threads have been created by the current process.
errorTooManySessions	Too many client sessions have been created by the current process.
errorInternalFailure	An unexpected internal error has occurred.
errorNetworkNotReady	Network subsystem is not ready for communication.
errorInvalidVersion	This version of the operating system is not supported.
errorNetworkNotInitialized	The networking subsystem has not been initialized.
errorRemoteShutdown	The remote host has initiated a graceful shutdown sequence.
errorInvalidHostName	The specified hostname is invalid or could not be resolved.
errorHostNameNotFound	The specified hostname could not be found.
errorHostNameRefused	Unable to resolve hostname, request refused.
errorHostNameNotResolved	Unable to resolve hostname, no address for specified host.
errorInvalidLicense	The license for this product is invalid.
errorProductNotLicensed	This product is not licensed to perform this operation.
errorNotImplemented	This function has not been implemented on this platform.
errorUnknownLocalhost	Unable to determine local host name.
errorInvalidHostAddress	Invalid host address specified.
errorInvalidServicePort	Invalid service port number specified.
errorInvalidServiceName	Invalid or unknown service name specified.
errorInvalidEventId	Invalid event identifier specified.
errorOperationNotBlocking	No blocking operation in progress on this socket.
errorSecurityNotInitialized	Unable to initialize security interface for this process.
errorSecurityContext	Unable to establish security context for this session.
errorSecurityCredentials	Unable to open certificate store or establish security credentials.
errorSecurityCertificate	Unable to validate the certificate chain for this

	session.
errorSecurityDecryption	Unable to decrypt data stream.
errorSecurityEncryption	Unable to encrypt data stream.
errorOperationNotSupported	The specified operation is not supported.
errorInvalidProtocolVersion	Invalid application protocol version specified.
errorNoServerResponse	No data returned from server.
errorInvalidServerResponse	Invalid data returned from server.
errorUnexpectedServerResponse	Unexpected response code returned from server.
errorServerTransactionFailed	Server transaction failed.
errorServiceUnavailable	The service is currently unavailable.
errorServiceNotReady	The service is not ready, try again later.
errorServerResyncFailed	Unable to resynchronize with server.
errorInvalidProxyType	Invalid proxy server type specified.
errorProxyRequired	Resource must be accessed through specified proxy.
errorInvalidProxyLogin	Unable to login to proxy server using specified credentials.
errorProxyResyncFailed	Unable to resynchronize with proxy server.
errorInvalidCommand	Invalid command specified.
errorInvalidCommandParameter	Invalid command parameter specified.
errorInvalidCommandSequence	Invalid command sequence specified.
errorCommandNotImplemented	Specified command not implemented on this server.
errorCommandNotAuthorized	Specified command not authorized for the current user.
errorCommandAborted	Specified command was aborted by the remote host.
errorOptionNotSupported	The specified option is not supported on this server.
errorRequestNotCompleted	The current client request has not been completed.
errorInvalidUserName	The specified username is invalid.
errorInvalidPassword	The specified password is invalid.
errorInvalidAccount	The specified account name is invalid.
errorAccountRequired	Account name has not been specified.
errorInvalidAuthenticationType	Invalid authentication protocol specified.
errorAuthenticationRequired	User authentication is required.
errorProxyAuthenticationRequired	Proxy authentication required.

errorAlreadyAuthenticated	User has already been authenticated.
errorAuthenticationFailed	Unable to authenticate the specified user.
errorNetworkAdapter	Unable to determine network adapter configuration.
errorInvalidRecordType	Invalid record type specified.
errorInvalidRecordName	Invalid record name specified.
errorInvalidRecordData	Invalid record data specified.
errorConnectionOpen	Data connection already established.
errorConnectionClosed	Server closed data connection.
errorConnectionPassive	Data connection is passive.
errorConnectionFailed	Unable to open data connection to server.
errorInvalidSecurityLevel	Data connection cannot be opened with this security setting.
errorCachedTLSRequired	Data connection requires cached TLS session.
errorDataReadOnly	Data connection is read-only.
errorDataWriteOnly	Data connection is write-only.
errorEndOfData	End of data.
errorRemoteFileUnavailable	Remote file is unavailable.
errorInsufficientStorage	Insufficient storage on server.
errorStorageallocation	File exceeded storage allocation on server.
errorDirectoryExists	The specified directory already exists.
errorDirectoryEmpty	No files returned by the server for the specified directory.
errorEndOfDirectory	End of directory listing.
errorUnknownDirectoryFormat	Unknown directory format.
errorInvalidResource	Invalid resource name specified.
errorResourceRedirected	The specified resource has been redirected.
errorResourceRestricted	Access to this resource has been restricted.
errorResourceNotModified	The specified resource has not been modified.
errorResourceNotFound	The specified resource cannot be found.
errorResourceConflict	Request could not be completed due to the current state of the resource.
errorResourceRemoved	The specified resource has been permanently removed from this server.
errorContentLengthRequired	Request must include the content length.
errorRequestPrecondition	Request could not be completed due to server precondition.
errorUnsupportedMediaType	Request specified an unsupported media type.

errorInvalidContentRange	Content range specified for this resource is invalid.
errorInvalidMessagePart	Message is not multipart or an invalid message part was specified.
errorInvalidMessageHeader	The specified message header is invalid or has not been defined.
errorInvalidMessageBoundary	The multipart message boundary has not been defined.
errorNoFileAttachment	The current message part does not contain a file attachment.
errorUnknownFileType	The specified file type could not be determined.
errorDataNotEncoded	The specified data block could not be encoded.
errorDataNotDecoded	The specified data block could not be decoded.
errorFileNotEncoded	The specified file could not be encoded.
errorFileNotDecoded	The specified file could not be decoded.
errorNoMessageText	No message text.
errorInvalidCharacterSet	Invalid character set specified.
errorInvalidEncodingType	Invalid encoding type specified.
errorInvalidMessageNumber	Invalid message number specified.
errorNoReturnAddress	No valid return address specified.
errorNoValidRecipients	No valid recipients specified.
errorInvalidRecipient	The specified recipient address is invalid.
errorRelayNotAuthorized	The specified domain is invalid or server will not relay messages.
errorMailboxUnavailable	Specified mailbox is currently unavailable.
errorMailboxReadOnly	The selected mailbox cannot be modified.
errorMailboxNotSelected	No mailbox has been selected.
errorInvalidMailbox	Specified mailbox is invalid.
errorInvalidDomain	The specified domain name is invalid or not recognized.
errorInvalidSender	The specified sender address is invalid or not recognized.
errorMessageNotDelivered	Message not delivered to any of the specified recipients.
errorEndOfMessageData	No more message data available to be read
errorInvalidmessageSize	The specified message size is invalid.
errorMessageNotCreated	The message could not be created in the specified mailbox.
errorNoMoreMailboxes	No more mailboxes exist on this server.

errorInvalidEmulationType	The specified terminal emulation type is invalid.
errorInvalidFontHandle	The specified font handle is invalid.
errorInvalidFontName	The specified font name is invalid or unavailable.
errorInvalidPacketSize	The specified packet size is invalid.
errorInvalidPacketData	The specified packet data is invalid.
errorInvalidPacketId	The unique packet identifier is invalid.
errorPacketTTLExpired	The specified packet time-to-live period has expired.
errorInvalidNewsGroup	Invalid newsgroup specified.
errorNoNewsgroupSelected	No newsgroup selected.
errorEmptyNewsgroup	No articles in specified newsgroup.
errorInvalidArticle	Invalid article number specified.
errorNoArticleSelected	No article selected in the current newsgroup.
errorFirstArticle	First article in current newsgroup.
errorLastArticle	Last article in current newsgroup.
errorArticleExists	Unable to transfer article, article already exists.
errorArticleRejected	Unable to transfer article, article rejected.
errorArticleTransferFailed	Article transfer failed.
errorArticlePostingDenied	Posting is not permitted on this server.
errorArticlePostingFailed	Unable to post article on this server.
errorInvalidDateFormat	The specified date format is not recognized.
errorFeatureNotSupported	The specified feature is not supported on this server.
errorInvalidFormHandle	The specified form handle is invalid or a form has not been created.
errorInvalidFormAction	The specified form action is invalid or has not been specified.
errorInvalidFormMethod	The specified form method is invalid or not supported.
errorInvalidFormType	The specified form type is invalid or not supported.
errorInvalidFormField	The specified form field name is invalid or does not exist.
errorEmptyForm	The specified form does not contain any field values.
errorMaximumConnections	The maximum number of client connections exceeded.
errorThreadCreationFailed	Unable to create a new thread for the current process.
errorInvalidThreadHandle	The specified thread handle is no longer valid.

errorThreadTerminated	The specified thread has been terminated.
errorThreadDeadlock	The operation would result in the current thread becoming deadlocked.
errorInvalidClientMoniker	The specified moniker is not associated with any client session.
errorClientMonikerExists	The specified moniker has been assigned to another client session.
errorServerInactive	The specified server is not listening for client connections.
errorServerSuspended	The specified server is suspended and not accepting client connections.
errorNoMessageStore	No message store has been specified.
errorMessageStoreChanged	The message store has changed since it was last accessed.
errorMessageNotFound	No message was found that matches the specified criteria.
errorMessageDeleted	The specified message has been deleted.
errorFileChecksumMismatch	The local and remote file checksums do not match.
errorFileSizeMismatch	The local and remote file sizes do not match.
errorInvalidFeedUrl	The news feed URL is invalid or specifies an unsupported protocol.
errorInvalidFeedFormat	The internal format of the news feed is invalid.
errorInvalidFeedVersion	This version of the news feed is not supported.
errorChannelEmpty	There are no valid items found in this news feed.
errorInvalidItemNumber	The specified channel item identifier is invalid.
errorItemNotFound	The specified channel item could not be found.
errorItemEmpty	The specified channel item does not contain any data.
errorInvalidItemProperty	The specified item property name is invalid.
errorItemPropertyNotFound	The specified item property has not been defined.
errorInvalidChannelTitle	The channel title is invalid or has not been defined.
errorInvalidChannelLink	The channel hyperlink is invalid or has not been defined.
errorInvalidChannelDescription	The channel description is invalid or has not been defined.
errorInvalidItemText	The description for an item is invalid or has not been defined.
errorInvalidItemLink	The hyperlink for an item is invalid or has not been defined.

errorInvalidServiceType	The specified service type is invalid.
errorServiceSuspended	Access to the specified service has been suspended.
errorServiceRestricted	Access to the specified service has been restricted.
errorInvalidProviderName	The specified provider name is invalid or unknown.
errorInvalidPhoneNumber	The specified phone number is invalid or not supported in this region.
errorGatewayNotFound	A message gateway cannot be found for the specified provider.
errorMessageTooLong	The message exceeds the maximum number of characters permitted.
errorInvalidProviderData	The request returned invalid or incomplete service provider data.
errorInvalidGatewayData	The request returned invalid or incomplete message gateway data.
errorMultipleProviders	The request has returned multiple service providers.
errorProviderNotFound	The specified service provider could not be found.
errorInvalidMessageService	The specified message is not supported with this service type.
errorInvalidMessageFormat	The specified message format is invalid.
errorInvalidConfiguration	The specified configuration options are invalid.
errorServerActive	The requested action is not permitted while the server is active.
errorServerPortBound	Unable to obtain exclusive use of the specified local port.
errorInvalidClientSession	The specified client identifier is invalid for this session.
errorClientNotIdentified	The specified client has not provided user credentials.
errorInvalidClientState	The requested action cannot be performed at this time.
errorInvalidResultCode	The specified result code is not valid for this protocol
errorCommandRequired	The specified command is required and cannot be disabled.
errorCommandDisabled	The specified command has been disabled.
errorCommandSequence	The command cannot be processed at this time.
errorCommandCompleted	The previous command has completed.
errorInvalidProgramName	The specified program name is invalid or unrecognized.

errorInvalidRequestHeader	The request header contains one or more invalid values.
errorInvalidVirtualHost	The specified virtual host name is invalid.
errorVirtualHostNotFound	The specified virtual host does not exist.
errorTooManyVirtualHosts	Too many virtual hosts created for this server.
errorInvalidVirtualPath	The specified virtual path name is invalid.
errorVirtualPathNotFound	The specified virtual path does not exist.
errorTooManyVirtualPaths	Too many virtual paths created for this server.
errorInvalidTask	The asynchronous task identifier is invalid.
errorTaskActive	The asynchronous task has not finished.
errorTaskQueued	The asynchronous task has been queued.
errorTaskSuspended	The asynchronous task has been suspended.
errorTaskFinished	The asynchronous task has finished.

Requirements

Namespace: SocketTools

Assembly: SocketTools.NewsFeed (in SocketTools.NewsFeed.dll)

See Also

SocketTools Namespace | LastError Property | LastErrorString Property | OnError Event

NewsFeed.TraceOptions Enumeration

Specifies the logging options that the NewsFeed class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]
```
<Flags>
Public Enum NewsFeed.TraceOptions
```

[C#]
```
[Flags]
public enum NewsFeed.TraceOptions
```

Remarks

The NewsFeed class uses the **TraceOptions** enumeration to specify what kind of debugging information is written to the trace logfile. These options are only meaningful when trace logging is enabled by setting the **Trace** property to **true**.

Members

Member Name	Description	Value
traceDefault	The default trace logging option. This is the same as specifying the **traceInfo** option.	0
traceInfo	All network function calls are written to the trace file. This is the default value.	0
traceError	Only those network function calls which fail are recorded in the trace file.	1
traceWarning	Only those network function calls which fail, or return values which indicate a warning, are recorded in the trace file.	2
traceHexDump	All network function calls are written to the trace file, plus all the data that is sent or received is displayed, in both ASCII and hexadecimal format.	4
traceProcess	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for multithreaded applications that are using worker threads.	4096

Requirements

Namespace: SocketTools

Assembly: SocketTools.NewsFeed (in SocketTools.NewsFeed.dll)

See Also

SocketTools Namespace

NewsFeed.OnErrorEventHandler Delegate

Represents the method that will handle the OnError event.

[Visual Basic]

```
Public Delegate Sub NewsFeed.OnErrorEventHandler( _
   ByVal sender As Object, _
   ByVal e As ErrorEventArgs _
)
```

[C#]

```
public delegate void NewsFeed.OnErrorEventHandler(
      object sender,
      ErrorEventArgs e
   );
```

Parameters

sender
The source of the event.

e
An ErrorEventArgs that contains the event data.

Remarks

When you create an **OnErrorEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnErrorEventHandler** delegate declaration.

Requirements

Namespace: SocketTools

Assembly: SocketTools.NewsFeed (in SocketTools.NewsFeed.dll)

SocketTools Namespace

NewsFeed.RuntimeLicenseAttribute Class

Attribute that defines the runtime license key for the class.

For a list of all members of this type, see NewsFeed.RuntimeLicenseAttribute Members.

System.Object
  System.Attribute
    SocketTools.NewsFeed.RuntimeLicenseAttribute

[Visual Basic]

```
<AttributeUsage(ValidOn:=AttributeTargets.Assembly, AllowMultiple:=False,
   Inherited:=True)>
Public Class NewsFeed.RuntimeLicenseAttribute
    Inherits Attribute
```

[C#]

```
[AttributeUsage(ValidOn=AttributeTargets.Assembly, AllowMultiple=False,
   Inherited=True)]
public class NewsFeed.RuntimeLicenseAttribute : Attribute
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

The RuntimeLicense attribute is used to define the runtime license key that will be used when an instance of the class is created. This attribute is defined in the assembly information module for the language, such as AssemblyInfo.cs when programming C#. The runtime license key must be defined if you wish to redistribute your application.

The runtime license key for your copy of SocketTools can be generated using the License Manager utility that is included with the product. Note that if you have installed an evaluation license, you will not have a runtime license key and cannot redistribute any applications which use the NewsFeed class.

Example

```
<Assembly: SocketTools.NewsFeed.RuntimeLicense("abcdefghijklmnop")>
```

```
[assembly: SocketTools.NewsFeed.RuntimeLicense("abcdefghijklmnop")]
```

Requirements

Namespace: SocketTools

Assembly: SocketTools.NewsFeed (in SocketTools.NewsFeed.dll)

NewsFeed.RuntimeLicenseAttribute overview

Public Instance Constructors

NewsFeed.RuntimeLicenseAttribute Constructor	Constructor for the RuntimeLicense attribute which defines the runtime license key.

Public Instance Properties

LicenseKey	Returns the value of the runtime license key.
TypeId (inherited from Attribute)	When implemented in a derived class, gets a unique identifier for this Attribute.

Public Instance Methods

Equals (inherited from Attribute)	
GetHashCode (inherited from Attribute)	Returns the hash code for this instance.
GetType (inherited from Object)	Gets the Type of the current instance.
IsDefaultAttribute (inherited from Attribute)	When overridden in a derived class, returns an indication whether the value of this instance is the default value for the derived class.
Match (inherited from Attribute)	When overridden in a derived class, returns a value indicating whether this instance equals a specified object.
ToString (inherited from Object)	Returns a String that represents the current Object.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

NewsFeed.RuntimeLicenseAttribute Class | SocketTools Namespace

NewsFeed.RuntimeLicenseAttribute Constructor

Constructor for the RuntimeLicense attribute which defines the runtime license key.

```
[Visual Basic]
Public Sub New( _
   ByVal licenseKey As String _
)
```

```
[C#]
public NewsFeed.RuntimeLicenseAttribute(
   string licenseKey
);
```

Parameters

licenseKey

A string argument which specifies the runtime license key which will be used to initialize the class library.

Remarks

The runtime license key for your copy of SocketTools can be generated using the License Manager utility that is included with the product. Note that if you have installed an evaluation license, you will not have a runtime license key and cannot redistribute any applications which use the NewsFeed class.

NewsFeed.RuntimeLicenseAttribute Class | SocketTools Namespace

NewsFeed.RuntimeLicenseAttribute Properties

The properties of the **NewsFeed.RuntimeLicenseAttribute** class are listed below. For a complete list of **NewsFeed.RuntimeLicenseAttribute** class members, see the NewsFeed.RuntimeLicenseAttribute Members topic.

Public Instance Properties

LicenseKey	Returns the value of the runtime license key.
TypeId (inherited from Attribute)	When implemented in a derived class, gets a unique identifier for this Attribute.

See Also

NewsFeed.RuntimeLicenseAttribute Class | SocketTools Namespace

NewsFeed.RuntimeLicenseAttribute.LicenseKey Property

Returns the value of the runtime license key.

[Visual Basic]

```
Public Property LicenseKey As String
```

[C#]

```
public string LicenseKey {get; set;}
```

Property Value

A string which contains the runtime license key.

See Also

NewsFeed.RuntimeLicenseAttribute Class | SocketTools Namespace

NewsFeedException Class

The exception that is thrown when a client error occurs.

For a list of all members of this type, see NewsFeedException Members.

System.Object
  System.Exception
    System.ApplicationException
      SocketTools.NewsFeedException

[Visual Basic]

```
Public Class NewsFeedException
    Inherits ApplicationException
```

[C#]

```
public class NewsFeedException : ApplicationException
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

A NewsFeedException is thrown by the NewsFeed class when an error occurs.

The default constructor for the NewsFeedException class sets the **ErrorCode** property to the last client error that occurred.

Requirements

Namespace: SocketTools

Assembly: SocketTools.NewsFeed (in SocketTools.NewsFeed.dll)

NewsFeedException Members

NewsFeedException overview

Public Instance Constructors

NewsFeedException	Overloaded. Initializes a new instance of the NewsFeedException class.

Public Instance Properties

ErrorCode	Gets a value which specifies the error that caused the exception.
HelpLink (inherited from Exception)	Gets or sets a link to the help file associated with this exception.
InnerException (inherited from Exception)	Gets the Exception instance that caused the current exception.
Message	Gets a value which describes the error that caused the exception.
Number	Gets a value which specifies the numeric value of the error that caused the exception.
Source (inherited from Exception)	Gets or sets the name of the application or the object that causes the error.
StackTrace (inherited from Exception)	Gets a string representation of the frames on the call stack at the time the current exception was thrown.
TargetSite (inherited from Exception)	Gets the method that throws the current exception.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetBaseException (inherited from Exception)	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetObjectData (inherited from Exception)	When overridden in a derived class, sets the SerializationInfo with information about the exception.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString	Creates and returns a string representation of the current exception.

Protected Instance Properties

HResult (inherited from Exception)	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

NewsFeedException Class | SocketTools Namespace

NewsFeedException Constructor

Initializes a new instance of the NewsFeedException class with the last network error code.

Overload List

Initializes a new instance of the NewsFeedException class with the last network error code.

```
public NewsFeedException();
```

Initializes a new instance of the NewsFeedException class with a specified error number.

```
public NewsFeedException(int);
```

Initializes a new instance of the NewsFeedException class with a specified error message.

```
public NewsFeedException(string);
```

Initializes a new instance of the NewsFeedException class with a specified error message and a reference to the inner exception that is the cause of this exception.

```
public NewsFeedException(string,Exception);
```

See Also

NewsFeedException Class | SocketTools Namespace

NewsFeedException Constructor ()

Initializes a new instance of the NewsFeedException class with the last network error code.

[Visual Basic]

```
Overloads Public Sub New()
```

[C#]

```
public NewsFeedException();
```

Remarks

The ctor constructor sets the **ErrorCode** property to the last client error that occurred. For more information about the errors that may occur, refer to the NewsFeed.ErrorCode enumeration.

See Also

NewsFeedException Class | SocketTools Namespace | NewsFeedException Constructor Overload List

NewsFeedException Constructor (String)

Initializes a new instance of the NewsFeedException class with a specified error message.

[Visual Basic]

```
Overloads Public Sub New( _
   ByVal message As String _
)
```

[C#]

```
public NewsFeedException(
   string message
);
```

Parameters

message

The error message that explains the reason for the exception.

Remarks

The content of the ***message*** parameter is intended to be understood by humans. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

See Also

NewsFeedException Class | SocketTools Namespace | NewsFeedException Constructor Overload List

NewsFeedException Constructor (String, Exception)

Initializes a new instance of the NewsFeedException class with a specified error message and a reference to the inner exception that is the cause of this exception.

[Visual Basic]

```
Overloads Public Sub New( _
   ByVal message As String, _
   ByVal innerException As Exception _
)
```

[C#]

```
public NewsFeedException(
   string message,
   Exception innerException
);
```

Parameters

message
The error message that explains the reason for the exception.

innerException
The exception that is the cause of the current exception. If the ***innerException*** parameter is not a null reference, the current exception is raised in a **catch** block that handles the inner exception.

Remarks

The content of the message parameter is intended to be understood by humans. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

An exception that is thrown as a direct result of a previous exception should include a reference to the previous exception in the **InnerException** property. The **InnerException** property returns the same value that is passed into the constructor, or a null reference if the **InnerException** property does not supply the inner exception value to the constructor.

See Also

NewsFeedException Class | SocketTools Namespace | NewsFeedException Constructor Overload List

NewsFeedException Constructor (Int32)

Initializes a new instance of the NewsFeedException class with a specified error number.

[Visual Basic]

```
Overloads Public Sub New( _
   ByVal code As Integer _
)
```

[C#]

```
public NewsFeedException(
   int code
);
```

Parameters

code

An integer value which specifies an error code.

Remarks

This constructor sets the **ErrorCode** property to the specified error code. For more information about the errors that may occur, refer to the NewsFeed.ErrorCode enumeration.

See Also

NewsFeedException Class | SocketTools Namespace | NewsFeedException Constructor Overload List

NewsFeedException Properties

The properties of the **NewsFeedException** class are listed below. For a complete list of **NewsFeedException** class members, see the NewsFeedException Members topic.

Public Instance Properties

ErrorCode	Gets a value which specifies the error that caused the exception.
HelpLink (inherited from Exception)	Gets or sets a link to the help file associated with this exception.
InnerException (inherited from Exception)	Gets the Exception instance that caused the current exception.
Message	Gets a value which describes the error that caused the exception.
Number	Gets a value which specifies the numeric value of the error that caused the exception.
Source (inherited from Exception)	Gets or sets the name of the application or the object that causes the error.
StackTrace (inherited from Exception)	Gets a string representation of the frames on the call stack at the time the current exception was thrown.
TargetSite (inherited from Exception)	Gets the method that throws the current exception.

Protected Instance Properties

HResult (inherited from Exception)	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception.

See Also

NewsFeedException Class | SocketTools Namespace

NewsFeedException.ErrorCode Property

Gets a value which specifies the error that caused the exception.

[Visual Basic]

```
Public ReadOnly Property ErrorCode As ErrorCode
```

[C#]

```
public NewsFeed.ErrorCode ErrorCode {get;}
```

Property Value

Returns a NewsFeed.ErrorCode enumeration value which specifies the error code.

Remarks

The **ErrorCode** property returns the error code that specifies the cause of the exception.

The default constructor for the NewsFeedException class sets the error code to the last network error that occurred. For more information about the errors that may occur, refer to the NewsFeed.ErrorCode enumeration.

See Also

NewsFeedException Class | SocketTools Namespace

NewsFeedException.Message Property

Gets a value which describes the error that caused the exception.

[Visual Basic]

```
Overrides Public ReadOnly Property Message As String
```

[C#]

```
public override string Message {get;}
```

Property Value

A string which describes the error that caused the exception.

Remarks

The **Message** property returns a string which describes the error that caused the exception.

See Also

NewsFeedException Class | SocketTools Namespace

NewsFeedException.Number Property

Gets a value which specifies the numeric value of the error that caused the exception.

[Visual Basic]

```
Public ReadOnly Property Number As Integer
```

[C#]

```
public int Number {get;}
```

Property Value

An integer value that specifies the error that caused the exception.

Remarks

The **Number** property returns an integer value which specifies the numeric value of the error that caused the exception. This value is the same as the values returned by the Windows Sockets API. For more information about socket error codes, see the Windows Socket Version 2 API error code documentation in MSDN.

See Also

NewsFeedException Class | SocketTools Namespace

NewsFeedException Methods

The methods of the **NewsFeedException** class are listed below. For a complete list of **NewsFeedException** class members, see the NewsFeedException Members topic.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetBaseException (inherited from Exception)	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetObjectData (inherited from Exception)	When overridden in a derived class, sets the SerializationInfo with information about the exception.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString	Creates and returns a string representation of the current exception.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

NewsFeedException Class | SocketTools Namespace

NewsFeedException.ToString Method

Creates and returns a string representation of the current exception.

[Visual Basic]

```
Overrides Public Function ToString() As String
```

[C#]

```
public override string ToString();
```

Return Value

A string representation of the current exception.

Remarks

The **ToString** method returns a representation of the current exception that is intended to be understood by humans. Where the exception contains culture-sensitive data, the string representation returned by **ToString** is required to take into account the current system culture. Although there are no exact requirements for the format of the returned string, it should attempt to reflect the value of the object as perceived by the user.

This implementation of **ToString** obtains the numeric error code value and a description of the error that caused the current exception. If there is no error message or it is an empty string, then no error message is returned.

This method overrides **ApplicationException.ToString**.

NewsFeedException Class | SocketTools Namespace

PopClient Class

Implements the Post Office Protocol.

For a list of all members of this type, see PopClient Members.

System.Object
 SocketTools.PopClient

[Visual Basic]

```
Public Class PopClient
    Implements IDisposable
```

[C#]

```
public class PopClient : IDisposable
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

The Post Office Protocol (POP3) provides access to a user's new email messages on a mail server. Methods are provided for listing available messages and then retrieving those messages, storing them either in files or in memory. Once a user's messages have been downloaded to the local system, they are typically removed from the server. This is the most popular email protocol used by Internet Service Providers (ISPs) and the PopClient class provides a complete interface for managing a user's mailbox. This class is typically used in conjunction with the SocketTools.MailMessage class, which is used to process the messages that are retrieved from the server.

This class supports secure connections using the standard SSL and TLS protocols. Both implicit and explicit SSL connections can be established, enabling the class to work with a wide variety of servers.

Requirements

Namespace: SocketTools

Assembly: SocketTools.PopClient (in SocketTools.PopClient.dll)

See Also

PopClient Members | SocketTools Namespace

PopClient Members

PopClient overview

Public Static (Shared) Fields

popPortDefault	A constant value which specifies the default port number.
popPortSecure	A constant value which specifies the default port number for a secure connection.
popTimeout	A constant value which specifies the default timeout period.

Public Instance Constructors

PopClient Constructor	Initializes a new instance of the PopClient class.

Public Instance Properties

Authentication	Gets and sets the method used to authenticate the user.
AutoResolve	Gets and sets a value that determines if host names and addresses are automatically resolved.
BearerToken	Gets and sets the bearer token used with OAuth 2.0 authentication.
Blocking	Gets and sets a value which indicates if the client is in blocking mode.
CertificateExpires	Get a value that specifies the date that the security certificate expires.
CertificateIssued	Get a value that specifies the date that the security certificate was issued.
CertificateIssuer	Get a value that provides information about the organization that issued the certificate.
CertificateName	Gets and sets a value that specifies the name of the client certificate.
CertificatePassword	Gets and sets the password associated with the client certificate.
CertificateStatus	Gets a value which indicates the status of the security certificate returned by the remote host.
CertificateStore	Gets and sets a value that specifies the name of the local certificate store.
CertificateSubject	Gets a value that provides information about the organization that the server certificate was issued to.
CertificateUser	Gets and sets the user that owns the client certificate.

CipherStrength	Gets a value that indicates the length of the key used by the encryption algorithm for a secure connection.
Handle	Gets a value that specifies the client handle allocated for the current session.
HashStrength	Gets a value which specifies the length of the message digest that was selected for a secure connection.
HeaderField	Gets and sets the current header field name.
HeaderValue	Gets the value of the current header field.
HostAddress	Gets and sets a value which specifies the Internet address used to establish a connection.
HostName	Gets and sets a value which specifies the host name used to establish a connection.
IsBlocked	Gets a value which indicates if the current thread is performing a blocking client operation.
IsConnected	Gets a value which indicates if a connection to the remote host has been established.
IsInitialized	Gets a value which indicates if the current instance of the class has been initialized successfully.
IsReadable	Gets a value which indicates if there is data available to be read from the socket connection to the server.
IsWritable	Gets a value which indicates if data can be written to the client without blocking.
LastError	Gets and sets a value which specifies the last error that has occurred.
LastErrorString	Gets a value which describes the last error that has occurred.
LastMessage	Gets the number of the last message available in the current mailbox.
LocalAddress	Gets the local Internet address that the client is bound to.
LocalName	Gets a value which specifies the host name for the local system.
LocalPort	Gets the local port number the client is bound to.
MailboxSize	Gets the size of the current mailbox.
Message	Gets and sets the current message number.
MessageCount	Gets the number of messages available in the mailbox.
MessageFrom	Gets the address of the user who sent the message.

MessageSize	Gets the size of the current message in bytes.
MessageUID	Gets the UID for the current message.
Options	Gets and sets a value which specifies one or more client options.
Password	Gets and sets the password used to authenticate the client.
RemotePort	Gets and sets a value which specifies the remote port number.
RemoteService	Gets and sets a value which specifies the remote service.
ResultCode	Gets a value which specifies the result of the last command executed by the server.
ResultString	Gets a string value which describes the result of the previous command.
Secure	Gets and sets a value which specifies if a secure connection is established.
SecureCipher	Gets a value that specifies the encryption algorithm used for a secure connection.
SecureHash	Gets a value that specifies the message digest algorithm used for a secure connection.
SecureKeyExchange	Gets a value that specifies the key exchange algorithm used for a secure connection.
SecureProtocol	Gets and sets a value which specifies the protocol used for a secure connection.
Status	Gets a value which specifies the current status of the client.
ThreadModel	Gets and sets a value which specifies the threading model for the class instance.
ThrowError	Gets and sets a value which specifies if method calls should throw exceptions when an error occurs.
Timeout	Gets and sets a value which specifies a timeout period in seconds.
Trace	Gets and sets a value which indicates if network function logging is enabled.
TraceFile	Gets and sets a value which specifies the name of the logfile.
TraceFlags	Gets and sets a value which specifies the client function tracing flags.
UserName	Gets and sets the username used to authenticate the client session.
Version	Gets a value which returns the current version of

	the PopClient class library.

Public Instance Methods

AttachThread	Attach an instance of the class to the current thread
Cancel	Cancel the current blocking client operation.
ChangePassword	Change the mailbox password for the current user.
CloseMessage	Closes the current message.
Command	Overloaded. Send a custom command to the server.
Connect	Overloaded. Establish a connection with a remote host.
DeleteMessage	Overloaded. Flags a message for deletion from the current mailbox.
Disconnect	Terminate the connection with a remote host.
Dispose	Overloaded. Releases all resources used by PopClient.
Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetHeader	Overloaded. Returns the value of a header field from the specified message.
GetHeaders	Overloaded. Retrieves the headers for the specified message from the server.
GetMessage	Overloaded. Retrieve a message from the server and return the contents in a byte array.
GetType (inherited from Object)	Gets the Type of the current instance.
Initialize	Overloaded. Initialize an instance of the PopClient class.
OpenMessage	Overloaded. Open the specified message for reading.
Read	Overloaded. Read data from the server and store it in a byte array.
Reset	Reset the internal state of the object, resetting all properties to their default values.
SendMessage	Overloaded. Submits a message to the mail server for delivery.
StoreMessage	Overloaded. Retrieve a message from the current mailbox and store it in a file on the local system.
ToString (inherited from Object)	Returns a String that represents the current Object.

Uninitialize	Uninitialize the class library and release any resources allocated for the current thread.
Write	Overloaded. Write one or more bytes of data to the server.

Public Instance Events

OnCancel	Occurs when a blocking client operation is canceled.
OnConnect	Occurs when a connection is established with the remote host.
OnDisconnect	Occurs when the remote host disconnects from the local system.
OnError	Occurs when an client operation fails.
OnProgress	Occurs as a data stream is being read or written to the client.
OnRead	Occurs when data is available to be read from the client.
OnTimeout	Occurs when a blocking operation fails to complete before the timeout period elapses.
OnWrite	Occurs when data can be written to the client.

Protected Instance Methods

Dispose	Overloaded. Releases the unmanaged resources allocated by the PopClient class and optionally releases the managed resources.
Finalize	Destroys an instance of the class, releasing the resources allocated for the session and unloading the networking library.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

PopClient Properties

The properties of the **PopClient** class are listed below. For a complete list of **PopClient** class members, see the PopClient Members topic.

Public Instance Properties

Authentication	Gets and sets the method used to authenticate the user.
AutoResolve	Gets and sets a value that determines if host names and addresses are automatically resolved.
BearerToken	Gets and sets the bearer token used with OAuth 2.0 authentication.
Blocking	Gets and sets a value which indicates if the client is in blocking mode.
CertificateExpires	Get a value that specifies the date that the security certificate expires.
CertificateIssued	Get a value that specifies the date that the security certificate was issued.
CertificateIssuer	Get a value that provides information about the organization that issued the certificate.
CertificateName	Gets and sets a value that specifies the name of the client certificate.
CertificatePassword	Gets and sets the password associated with the client certificate.
CertificateStatus	Gets a value which indicates the status of the security certificate returned by the remote host.
CertificateStore	Gets and sets a value that specifies the name of the local certificate store.
CertificateSubject	Gets a value that provides information about the organization that the server certificate was issued to.
CertificateUser	Gets and sets the user that owns the client certificate.
CipherStrength	Gets a value that indicates the length of the key used by the encryption algorithm for a secure connection.
Handle	Gets a value that specifies the client handle allocated for the current session.
HashStrength	Gets a value which specifies the length of the message digest that was selected for a secure connection.
HeaderField	Gets and sets the current header field name.
HeaderValue	Gets the value of the current header field.

HostAddress	Gets and sets a value which specifies the Internet address used to establish a connection.
HostName	Gets and sets a value which specifies the host name used to establish a connection.
IsBlocked	Gets a value which indicates if the current thread is performing a blocking client operation.
IsConnected	Gets a value which indicates if a connection to the remote host has been established.
IsInitialized	Gets a value which indicates if the current instance of the class has been initialized successfully.
IsReadable	Gets a value which indicates if there is data available to be read from the socket connection to the server.
IsWritable	Gets a value which indicates if data can be written to the client without blocking.
LastError	Gets and sets a value which specifies the last error that has occurred.
LastErrorString	Gets a value which describes the last error that has occurred.
LastMessage	Gets the number of the last message available in the current mailbox.
LocalAddress	Gets the local Internet address that the client is bound to.
LocalName	Gets a value which specifies the host name for the local system.
LocalPort	Gets the local port number the client is bound to.
MailboxSize	Gets the size of the current mailbox.
Message	Gets and sets the current message number.
MessageCount	Gets the number of messages available in the mailbox.
MessageFrom	Gets the address of the user who sent the message.
MessageSize	Gets the size of the current message in bytes.
MessageUID	Gets the UID for the current message.
Options	Gets and sets a value which specifies one or more client options.
Password	Gets and sets the password used to authenticate the client.
RemotePort	Gets and sets a value which specifies the remote port number.
RemoteService	Gets and sets a value which specifies the remote service.

ResultCode	Gets a value which specifies the result of the last command executed by the server.
ResultString	Gets a string value which describes the result of the previous command.
Secure	Gets and sets a value which specifies if a secure connection is established.
SecureCipher	Gets a value that specifies the encryption algorithm used for a secure connection.
SecureHash	Gets a value that specifies the message digest algorithm used for a secure connection.
SecureKeyExchange	Gets a value that specifies the key exchange algorithm used for a secure connection.
SecureProtocol	Gets and sets a value which specifies the protocol used for a secure connection.
Status	Gets a value which specifies the current status of the client.
ThreadModel	Gets and sets a value which specifies the threading model for the class instance.
ThrowError	Gets and sets a value which specifies if method calls should throw exceptions when an error occurs.
Timeout	Gets and sets a value which specifies a timeout period in seconds.
Trace	Gets and sets a value which indicates if network function logging is enabled.
TraceFile	Gets and sets a value which specifies the name of the logfile.
TraceFlags	Gets and sets a value which specifies the client function tracing flags.
UserName	Gets and sets the username used to authenticate the client session.
Version	Gets a value which returns the current version of the PopClient class library.

See Also

PopClient Class | SocketTools Namespace

PopClient.Authentication Property

Gets and sets the method used to authenticate the user.

[Visual Basic]
```
Public Property Authentication As PopAuthentication
```

[C#]
```
public PopClient.PopAuthentication Authentication {get; set;}
```

Property Value

A PopAuthentication enumeration value which specifies the authentication method.

Remarks

The **authLogin** and **authPlain** authentication methods require the mail server support the Simple Authentication and Security Layer (SASL) AUTH command as defined in RFC 5034. Most modern mail servers do support one or both of these methods, and they are generally preferred over the **authPassword** method when possible. However, for backwards compatibility with legacy servers, the class will default to using **authPassword** for client authentication.

The **authXOAuth2** and **authBearer** authentication methods are similar, but they are not interchangeable. Both use an OAuth 2.0 bearer token to authenticate the client session, but they differ in how the token is presented to the server. It is currently preferable to use the XOAUTH2 method because it is more widely available and some service providers do not yet support the OAUTHBEARER method.

See Also

PopClient Class | SocketTools Namespace | BearerToken Poperty | Password Property | UserName Property

PopClient.AutoResolve Property

Gets and sets a value that determines if host names and addresses are automatically resolved.

[Visual Basic]

```
Public Property AutoResolve As Boolean
```

[C#]

```
public bool AutoResolve {get; set;}
```

Property Value

Returns **true** if host names are automatically resolved to Internet addresses. The default value is **false**.

Remarks

Setting the **AutoResolve** property determines if the class automatically resolves host names and addresses specified by the **HostName** and **HostAddress** properties. If set to **true**, setting the **HostName** property will cause the class to automatically determine the corresponding IP address and update the **HostAddress** property accordingly. Likewise, setting the **HostAddress** property will cause the class to determine the host name and update the **HostName** property. Setting this property to **false** prevents the class from resolving host names until a connection attempt is made.

It is important to note that setting the **HostName** or **HostAddress** property may cause the current thread to block, sometimes for several seconds, until the name or address is resolved. To prevent this behavior, set this property value to **false**.

See Also

PopClient Class | SocketTools Namespace

PopClient.BearerToken Property

Gets and sets the bearer token used with OAuth 2.0 authentication.

[Visual Basic]
```
Public Property BearerToken As String
```

[C#]
```
public string BearerToken {get; set;}
```

Property Value

Returns a string which contains the bearer token. Assigning a value to this property sets the curent authentication type to use OAuth 2.0 authentication and updates the bearer token.

Remarks

Assigning a value to the **BearerToken** property will automatically change the current authentication method to use OAuth 2.0 if necessary.

You should only use an OAuth 2.0 authentication method if you understand the process of how to request the access token. Obtaining a bearer token requires registering your application with the mail service provider (e.g.: Microsoft or Google), getting a unique client ID associated with your application and then requesting the bearer token using the appropriate scope for the service. Obtaining the initial token will typically involve interactive confirmation on the part of the user, requiring they grant permission to your application to access their mail account.

Your application should not store the bearer token for later use. They usually have a relatively short lifespan, typically about an hour, and are designed to be used with the current client session. You should specify offline access as part of the OAuth 2.0 scope, and store the refresh token provided by the service. The refresh token has a much onger validity period and can be used to obtain a new access token when needed.

If the current authentication method does not use OAuth 2.0, this property will return an empty string and you should use the **Password** property to obtain the current user password.

See Also

PopClient Class | SocketTools Namespace | Authentication Property | Password Property | UserName Property

PopClient.Blocking Property

Gets and sets a value which indicates if the client is in blocking mode.

[Visual Basic]

```
Public Property Blocking As Boolean
```

[C#]

```
public bool Blocking {get; set;}
```

Property Value

Returns **true** if the client is in blocking mode; otherwise it returns **false**. The default value is **true**.

Remarks

Setting the **Blocking** property determines if client operations complete synchronously or asynchronously. If set to **true**, then each client operation (such as sending or receiving data) will return when the operation has completed or timed-out. If set to **false**, client operations will return immediately. If the operation would result in the client blocking (such as attempting to read data when no data has been sent by the remote host), an error is generated.

It is important to note that certain events, such as **OnDisconnect, OnRead** and **OnWrite** are only fired if the client is in non-blocking mode.

See Also

PopClient Class | SocketTools Namespace

PopClient.CertificateExpires Property

Get a value that specifies the date that the security certificate expires.

[Visual Basic]

```
Public ReadOnly Property CertificateExpires As String
```

[C#]

```
public string CertificateExpires {get;}
```

Property Value

A string which specifies a date using the local date and time format.

Remarks

The **CertificateExpires** property returns a string that specifies the date and time that the security certificate expires. This property will return an empty string if a secure connection has not been established with the remote host.

See Also

PopClient Class | SocketTools Namespace

PopClient.CertificateIssued Property

Get a value that specifies the date that the security certificate was issued.

[Visual Basic]

```
Public ReadOnly Property CertificateIssued As String
```

[C#]

```
public string CertificateIssued {get;}
```

Property Value

A string which specifies a date using the local date and time format.

Remarks

The **CertificateIssued** property returns a string that specifies the date and time that the security certificate was issued. This property will return an empty string if a secure connection has not been established with the remote host.

See Also

PopClient Class | SocketTools Namespace

PopClient.CertificateIssuer Property

Get a value that provides information about the organization that issued the certificate.

[Visual Basic]

```
Public ReadOnly Property CertificateIssuer As String
```

[C#]

```
public string CertificateIssuer {get;}
```

Property Value

A string that contains a comma separated list of name value pairs.

Remarks

The **CertificateIssuer** property returns a string that contains information about the organization that issued the server certificate. The string value is a comma separated list of tagged name and value pairs. In the nomenclature of the X.500 standard, each of these pairs are called a relative distinguished name (RDN), and when concatenated together, forms the issuer's distinguished name (DN). For example:

```
C=US, O="RSA Data Security, Inc.", OU=Secure Server Certification Authority
```

To obtain a specific value, such as the name of the issuer or the issuer's country, the application must parse the string returned by this property. Some of the common tokens used in the distinguished name are:

Token	Description
C	The ISO standard two character country code.
S	The name of the state or province.
L	The name of the city or locality.
O	The name of the company or organization.
OU	The name of the department or organizational unit
CN	The common name; with X.509 certificates, this is the domain name of the site the certificate was issued for.

This property will return an empty string if a secure connection has not been established with the remote host.

See Also

PopClient Class | SocketTools Namespace

PopClient.CertificateName Property

Gets and sets a value that specifies the name of the client certificate.

[Visual Basic]

```
Public Property CertificateName As String
```

[C#]

```
public string CertificateName {get; set;}
```

Property Value

A string which specifies the certificate name.

Remarks

The **CertificateName** property is used to specify the name of a client certificate to use when establishing a secure connection. It is only required that you set this property value if the server requires a client certificate for authentication. If this property is not set, a client certificate will not be provided to the server. If a certificate name is specified, the certificate must have a private key associated with it, otherwise the connection attempt will fail because the control will be unable to create a security context for the session.

When the certificate store is searched for a matching certificate, it will first search for any certificate with a friendly name that matches the property value. If no valid certificate is found, it will then search for a certificate with a matching common name.

Certificates may be installed and viewed on the local system using the Certificate Manager that is included with the Windows operating system. For more information, refer to the documentation for the Microsoft Management Console.

See Also

PopClient Class | SocketTools Namespace | CertificateStore Property | Secure Property

PopClient.CertificateStatus Property

Gets a value which indicates the status of the security certificate returned by the remote host.

[Visual Basic]

```
Public ReadOnly Property CertificateStatus As SecurityCertificate
```

[C#]

```
public PopClient.SecurityCertificate CertificateStatus {get;}
```

Property Value

A SecurityCertificate enumeration value which specifies the status of the certificate.

Remarks

The **CertificateStatus** property is used to determine the status of the security certificate returned by the remote host when a secure connection has been established. This property value should be checked after the connection to the server has completed, but prior to beginning a transaction.

Note that if the certificate cannot be validated, the secure connection will not be automatically terminated. It is the responsibility of your application to determine the best course of action to take if the certificate is invalid. Even if the security certificate cannot be validated, the data exchanged with the remote host will still be encrypted.

See Also

PopClient Class | SocketTools Namespace

PopClient.CertificateStore Property

Gets and sets a value that specifies the name of the local certificate store.

[Visual Basic]
```
Public Property CertificateStore As String
```

[C#]
```
public string CertificateStore {get; set;}
```

Property Value

A string which specifies the certificate store name. The default value is the current user's personal certificate store.

Remarks

The **CertificateStore** property is used to specify the name of the certificate store which contains the security certificate to use when establishing a secure connection. The certificate may either be stored in the registry or in a file. If the certificate is stored in the registry, then this property should be set to one of the following predefined values:

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as VeriSign and Thawte act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. If a certificate store is not specified, this is the default value that is used.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as VeriSign and Thawte are installed as part of the operating system and periodically updated by Microsoft.

In most cases the client certificate will be installed in the user's personal certificate store, and therefore it is not necessary to set this property value because that is the default location that will be used to search for the certificate. This property is only used if the **CertificateName** property is also set to a valid certificate name.

If you are using a local certificate store, with the certificate and private key stored in the registry, you can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU" for the current user, or "HKLM" for the local machine. For example, a certificate store name of "HKLM:MY" would specify the personal certificate store for the local machine, rather than the current user. If neither prefix is specified, it will default to the certificate store for the current user.

This property may also be used to specify a file that contains the client certificate. In this case, the property should specify the full path to the file and must contain both the certificate and private key in PKCS12

format. If the file is protected by a password, the **CertificatePassword** property must also be set to specify the password.

See Also

PopClient Class | SocketTools Namespace | CertificatePassword Property | Secure Property

PopClient.CertificateSubject Property

Gets a value that provides information about the organization that the server certificate was issued to.

[Visual Basic]

```
Public ReadOnly Property CertificateSubject As String
```

[C#]

```
public string CertificateSubject {get;}
```

Property Value

A string that contains a comma separated list of name value pairs.

Remarks

The **CertificateSubject** property returns a string that contains information about the organization that the server certificate was issued to. The string value is a comma separated list of tagged name and value pairs. In the nomenclature of the X.500 standard, each of these pairs are called a relative distinguished name (RDN), and when concatenated together, forms the issuer's distinguished name (DN). For example:

```
C=US, O="RSA Data Security, Inc.", OU=Secure Server Certification Authority
```

To obtain a specific value, such as the name of the issuer or the issuer's country, the application must parse the string returned by this property. Some of the common tokens used in the distinguished name are:

Token	Description
C	The ISO standard two character country code.
S	The name of the state or province.
L	The name of the city or locality.
O	The name of the company or organization.
OU	The name of the department or organizational unit
CN	The common name; with X.509 certificates, this is the domain name of the site the certificate was issued for.

This property will return an empty string if a secure connection has not been established with the remote host.

See Also

PopClient Class | SocketTools Namespace

PopClient.CipherStrength Property

Gets a value that indicates the length of the key used by the encryption algorithm for a secure connection.

[Visual Basic]

```
Public ReadOnly Property CipherStrength As Integer
```

[C#]

```
public int CipherStrength {get;}
```

Property Value

An integer value which specifies the encryption key length if a secure connection has been established; otherwise a value of 0 is returned.

Remarks

The **CipherStrength** property returns the number of bits in the key used to encrypt the secure data stream. Common values returned by this property are 128 and 256. A key length of 40 or 56 bits is considered insecure and subject to brute force attacks. 128-bit and 256-bit keys are considered secure. If this property returns a value of 0, this means that a secure connection has not been established with the remote host.

See Also

PopClient Class | SocketTools Namespace

PopClient.Handle Property

Gets a value that specifies the client handle allocated for the current session.

[Visual Basic]

```
Public ReadOnly Property Handle As Integer
```

[C#]

```
public int Handle {get;}
```

Property Value

An integer which represents a client handle. If there is no active connection, a value of -1 is returned.

Remarks

The **Handle** property specifies the numeric descriptor of the current client session.

See Also

PopClient Class | SocketTools Namespace

PopClient.HashStrength Property

Gets a value which specifies the length of the message digest that was selected for a secure connection.

[Visual Basic]

```
Public ReadOnly Property HashStrength As Integer
```

[C#]

```
public int HashStrength {get;}
```

Property Value

An integer value which specifies the length of the message digest if a secure connection has been established; otherwise a value of 0 is returned.

Remarks

The **HashStrength** property returns the number of bits used in the message digest (hash) that was selected. Common values returned by this property are 128 and 160. If this property returns a value of 0, this means that a secure connection has not been established with the remote host.

See Also

PopClient Class | SocketTools Namespace

PopClient.HeaderField Property

Gets and sets the current header field name.

[Visual Basic]
```
Public Property HeaderField As String
```

[C#]
```
public string HeaderField {get; set;}
```

Property Value

A string which specifies the current header field name.

Remarks

The **HeaderField** property returns the name of the current header field. Setting this property causes the control to determine if that header field exists, and if it does, to update the **HeaderValue** property with its value. This property can be used to obtain the value of any header in the current message.

See Also

PopClient Class | SocketTools Namespace

PopClient.HeaderValue Property

Gets the value of the current header field.

[Visual Basic]

```
Public ReadOnly Property HeaderValue As String
```

[C#]

```
public string HeaderValue {get;}
```

Property Value

A string which specifies the value of the current header field.

Remarks

The **HeaderValue** property returns the value of the header field specified by the **HeaderField** property. This property can be used to obtain the value of any header in the current message.

See Also

PopClient Class | SocketTools Namespace

PopClient.HostAddress Property

Gets and sets a value which specifies the Internet address used to establish a connection.

[Visual Basic]

```
Public Property HostAddress As String
```

[C#]

```
public string HostAddress {get; set;}
```

Property Value

A string which specifies an Internet address.

Remarks

The **HostAddress** property can be used to set the Internet address for a remote system that you wish to communicate with. If the **AutoResolve** property is set to **true** and the address is assigned to a valid host name, the **HostName** property will be updated with that value.

See Also

PopClient Class | SocketTools Namespace

PopClient.HostName Property

Gets and sets a value which specifies the host name used to establish a connection.

[Visual Basic]

```
Public Property HostName As String
```

[C#]

```
public string HostName {get; set;}
```

Property Value

A string which specifies a host name.

Remarks

The **HostName** property can be used to set the host name for a remote system that you wish to communicate with. If the **AutoResolve** property is set to **true** and the name can be resolved to a valid Internet address, the **HostAddress** property will be updated with that value.

See Also

PopClient Class | SocketTools Namespace

PopClient.IsBlocked Property

Gets a value which indicates if the current thread is performing a blocking client operation.

[Visual Basic]
```
Public ReadOnly Property IsBlocked As Boolean
```

[C#]
```
public bool IsBlocked {get;}
```

Property Value

Returns **true** if the current thread is blocking, otherwise returns **false**.

Remarks

The **IsBlocked** property returns **true** if the current thread is blocked performing an operation. Because the Windows Sockets API only permits one blocking operation per thread of execution, this property should be checked before starting any blocking operation in response to an event.

If the **IsBlocked** property returns **false**, this means there are no blocking operations on the current thread at that time. However, this does not guarantee that the next client operation will not fail. An application should always check the return value from a client operation and check the value of the **LastError** property if an error occurs.

Note that this property will return **true** if there is any blocking operation being performed by the current thread, regardless of whether this specific instance of the class is responsible for the blocking operation or not.

See Also

PopClient Class | SocketTools Namespace

PopClient.IsConnected Property

Gets a value which indicates if a connection to the remote host has been established.

[Visual Basic]

```
Public ReadOnly Property IsConnected As Boolean
```

[C#]

```
public bool IsConnected {get;}
```

Property Value

Returns **true** if the connection has been established; otherwise returns **false**.

Remarks

The **IsConnected** property can only be used to indicate if there is still a logical connection to the remote host. It cannot be used to detect abnormal conditions such as the remote host aborting the connection, the physical network connection being lost or other critical errors.

See Also

PopClient Class | SocketTools Namespace

PopClient.IsInitialized Property

Gets a value which indicates if the current instance of the class has been initialized successfully.

[Visual Basic]
```
Public ReadOnly Property IsInitialized As Boolean
```

[C#]
```
public bool IsInitialized {get;}
```

Property Value

Returns **true** if the class instance has been initialized; otherwise returns **false**.

Remarks

The **IsInitialized** property is used to determine if the current instance of the class has been initialized properly. Normally this is done automatically by the class constructor, however there are circumstances where the class may not be able to initialize itself.

The most common reasons that a class instance may not initialize correctly is that no runtime license key has been defined in the assembly or the license key provided is invalid. It may also indicate a problem with the system configuration or user access rights, such as not being able to load the required networking libraries or not being able to access the system registry.

See Also

PopClient Class | SocketTools Namespace

PopClient.IsReadable Property

Gets a value which indicates if there is data available to be read from the socket connection to the server.

[Visual Basic]
```
Public ReadOnly Property IsReadable As Boolean
```

[C#]
```
public bool IsReadable {get;}
```

Property Value

Returns **true** if there is data available to be read; otherwise returns **false**.

Remarks

The **IsReadable** property returns **true** if data can be read from the client without blocking. For non-blocking sessions, this property can be checked before the application attempts to read the client. Note that even if this property does return **true** indicating that there is data available to be read, applications should always check the return value from the **Read** method.

See Also

PopClient Class | SocketTools Namespace

PopClient.IsWritable Property

Gets a value which indicates if data can be written to the client without blocking.

[Visual Basic]

```
Public ReadOnly Property IsWritable As Boolean
```

[C#]

```
public bool IsWritable {get;}
```

Property Value

Returns **true** if data can be written to the client; otherwise returns **false**.

Remarks

The **IsWritable** property returns **true** if data can be written to the client without blocking. For non-blocking sessions, this property can be checked before the application attempts to write data to the client. Note that even if this property does return **true** indicating that data can be written to the client, applications should always check the return value from the **Write** method.

See Also

PopClient Class | SocketTools Namespace

PopClient.LastError Property

Gets and sets a value which specifies the last error that has occurred.

[Visual Basic]

```
Public Property LastError As ErrorCode
```

[C#]

```
public PopClient.ErrorCode LastError {get; set;}
```

Property Value

Returns an ErrorCode enumeration value which specifies the last error code.

Remarks

The **LastError** property returns the error code associated with the last error that occurred for the current instance of the class. It is important to note that this value only has meaning if the previous method indicates that an error has actually occurred.

It is possible to explicitly clear the last error code by assigning the property to the value **ErrorCode.errorNone**.

The error code value can be cast to an integer value for display purposes if required. For a description of the error that can be displayed using a message box or some other similar mechanism, get the value of the **LastErrorString** property.

See Also

PopClient Class | SocketTools Namespace

PopClient.LastErrorString Property

Gets a value which describes the last error that has occurred.

[Visual Basic]

```
Public ReadOnly Property LastErrorString As String
```

[C#]

```
public string LastErrorString {get;}
```

Property Value

A string which describes the last error that has occurred.

Remarks

The **LastErrorString** property can be used to obtain a description of the last error that occurred for the current instance of the class. It is important to note that this value only has meaning if the previous method indicates that an error has actually occurred.

See Also

PopClient Class | SocketTools Namespace

PopClient.LastMessage Property

Gets the number of the last message available in the current mailbox.

[Visual Basic]

```
Public ReadOnly Property LastMessage As Integer
```

[C#]

```
public int LastMessage {get;}
```

Property Value

An integer value which specifies the number of messages.

Remarks

The **LastMessage** property returns the number of the last message available in the currently selected mailbox. This value may be different than the value returned by the **MessageCount** property if one or more messages have been deleted. This is because the **MessageCount** property returns the number of available messages, and this value will decrement whenever a message is flagged for deletion. The **LastMessage** property value is constant and will always return the last message number in the mailbox, regardless if any messages have been deleted.

See Also

PopClient Class | SocketTools Namespace

PopClient.LocalAddress Property

Gets the local Internet address that the client is bound to.

[Visual Basic]

```
Public ReadOnly Property LocalAddress As String
```

[C#]

```
public string LocalAddress {get;}
```

Property Value

A string which specifies an Internet address.

Remarks

The **LocalAddress** property returns the local Internet address that the client is bound to when a connection is established with a remote host. This property may return either an IPv4 or IPv6 formatted address, depending on the type of connection that was established.

See Also

PopClient Class | SocketTools Namespace

PopClient.LocalName Property

Gets a value which specifies the host name for the local system.

[Visual Basic]

```
Public ReadOnly Property LocalName As String
```

[C#]

```
public string LocalName {get;}
```

Property Value

A string which specifies the local host name.

Remarks

The **LocalName** property returns the fully-qualified host name assigned to the local system. If the system has not been configured with an Internet domain name, then this property will return the NetBIOS name assigned to the local system.

See Also

PopClient Class | SocketTools Namespace

PopClient.LocalPort Property

Gets the local port number the client is bound to.

[Visual Basic]

```
Public ReadOnly Property LocalPort As Integer
```

[C#]

```
public int LocalPort {get;}
```

Property Value

An integer value which specifies a port number. The default value is 0.

Remarks

The **LocalPort** property is used to identify the local port number that the client is bound to to when a connection is established with a remote host.

See Also

PopClient Class | SocketTools Namespace

PopClient.MailboxSize Property

Gets the size of the current mailbox.

[Visual Basic]

```
Public ReadOnly Property MailboxSize As Integer
```

[C#]

```
public int MailboxSize {get;}
```

Property Value

An integer value which specifies the size of the mailbox in bytes.

Remarks

The **MailboxSize** property returns the combined size in bytes of all of the available messages in the current mailbox. Note that as messages are deleted from the mailbox, this property value will decrease.

See Also

PopClient Class | SocketTools Namespace

PopClient.Message Property

Gets and sets the current message number.

[Visual Basic]

```
Public Property Message As Integer
```

[C#]

```
public int Message {get; set;}
```

Property Value

An integer value which specifies the current message number.

Remarks

The **Message** property sets or returns the message number for the currently selected mailbox. Message numbers range from 1 through the number of messages available on the server, as returned by the **MessageCount** property. Setting the **Message** property to an invalid message number will generate an exception.

See Also

PopClient Class | SocketTools Namespace

PopClient.MessageCount Property

Gets the number of messages available in the mailbox.

[Visual Basic]
```
Public ReadOnly Property MessageCount As Integer
```

[C#]
```
public int MessageCount {get;}
```

Property Value

An integer value which specifies the number of messages.

Remarks

The **MessageCount** property returns the number of messages available to be retrieved from the current mailbox.

See Also

PopClient Class | SocketTools Namespace

PopClient.MessageFrom Property

Gets the address of the user who sent the message.

[Visual Basic]
```
Public ReadOnly Property MessageFrom As String
```

[C#]
```
public string MessageFrom {get;}
```

Property Value

A string which specifies the email address of the user who sent the message.

Remarks

The **MessageFrom** property returns the address of the user who sent the current message. This property requires that the mail server support either the XSENDER or the XTND XLST command in order to determine who the sender is. The XSENDER command returns an authenticated address, as used with the Netscape SMTP authentication method. If this command is not supported, or the sender's address was not authenticated, then the XTND XLST command is used to return the value of the From header field in the message. If this command is not supported, the property will return an empty string.

See Also

PopClient Class | SocketTools Namespace

PopClient.MessageSize Property

Gets the size of the current message in bytes.

[Visual Basic]

```
Public ReadOnly Property MessageSize As Integer
```

[C#]

```
public int MessageSize {get;}
```

Property Value

An integer value which specifies the size of the message.

Remarks

The **MessageSize** property returns the size of the current message in bytes. The size includes the header and body portion of the message.

See Also

PopClient Class | SocketTools Namespace

PopClient.MessageUID Property

Gets the UID for the current message.

[Visual Basic]

```
Public ReadOnly Property MessageUID As String
```

[C#]

```
public string MessageUID {get;}
```

Property Value

An string value which specifies the current message UID.

Remarks

The **MessageID** property returns a string which uniquely identifies the message on the server. The identifier is assigned by the mail server, and retains the same value across multiple client sessions. This value is typically used when the client wants to leave a message on the mail server, but does not wish to retrieve the message contents multiple times. For example, the client can store the unique ID for each message that it retrieves, but does not delete from the server. The next time that it connects to the mail server, it compares the unique ID of a message against the stored values. If there is a match, the client knows that the message has already been retrieved, and does not need to do so again.

This property requires that the server support the optional UIDL command. If the command is not supported, this property will always return an empty string. Note that the unique ID for the message is not the same as the Message-ID header field in the message itself.

See Also

PopClient Class | SocketTools Namespace

PopClient.Options Property

Gets and sets a value which specifies one or more client options.

[Visual Basic]
```
Public Property Options As PopOptions
```

[C#]
```
public PopClient.PopOptions Options {get; set;}
```

Property Value

Returns one or more PopOptions enumeration flags which specify the options for the client. The default value for this property is **popOptionNone**.

Remarks

The **Options** property specifies one or more default options options which are used when establishing a connection using the **Connect** method.

See Also

PopClient Class | SocketTools Namespace

PopClient.Password Property

Gets and sets the password used to authenticate the client.

[Visual Basic]
```
Public Property Password As String
```

[C#]
```
public string Password {get; set;}
```

Property Value

A string which specifies the password.

Remarks

The **Password** property specifies the password used to authenticate the client session. This property is used as the default value for the **Connect** method if no password is specified as an argument.

Refer to the **Authentication** property for more information on the available authentication methods. If you are using the OAuth 2.0 authentication method, this property should not be set to the user's password. Instead, you should set the **BearerToken** property to the OAuth 2.0 bearer token issued by the mail service provider. Note that these access tokens can be much larger than your typical password and are only valid for a limited period of time.

You can use the **Password** property to specify an OAuth 2.0 bearer token. However, it is recommended that you use the **BearerToken** property instead of assigning it to this property. It will ensure compatibility with future versions of the class and make it clear in your code you are using an OAuth 2.0 bearer token and not a password. If the **AuthType** property specifies one of the OAuth 2.0 authentication methods, this property will return the bearer token.

See Also

PopClient Class | SocketTools Namespace | Authentication Property | BearerToken Property | UserName Property | Connect Method

PopClient.RemotePort Property

Gets and sets a value which specifies the remote port number.

[Visual Basic]

```
Public Property RemotePort As Integer
```

[C#]

```
public int RemotePort {get; set;}
```

Property Value

An integer value which specifies a port number.

Remarks

The **RemotePort** property is used to set the port number that will be used to establish a connection with a remote host. If the port number specifies a well-known port, the **RemoteService** property will be updated with that name.

See Also

PopClient Class | SocketTools Namespace

PopClient.ResultCode Property

Gets a value which specifies the result of the last command executed by the server.

[Visual Basic]
```
Public ReadOnly Property ResultCode As Boolean
```

[C#]
```
public bool ResultCode {get;}
```

Property Value

A boolean value which specifies the result of the last command executed on the server. A return value of **true** specifies that the previous command executed successfully. A return value of **false** specifies that the command failed.

Remarks

Unlike other protocols which typically return a numeric result code, the POP3 protocol returns a value that indicates only success or failure. If a failure occurs, the client should check the value of the **ResultString** property for any additional information as to what may have caused the failure.

See Also

PopClient Class | SocketTools Namespace

PopClient.ResultString Property

Gets a string value which describes the result of the previous command.

[Visual Basic]

```
Public ReadOnly Property ResultString As String
```

[C#]

```
public string ResultString {get;}
```

Property Value

A string which describes the result of the previous command executed on the server.

Remarks

The **ResultString** property returns the result string from the last action taken by the client. This string is generated by the remote server, and typically is used to describe the result code. For example, if an error is indicated by the result code, the result string may describe the condition that caused the error.

See Also

PopClient Class | SocketTools Namespace

PopClient.Secure Property

Gets and sets a value which specifies if a secure connection is established.

[Visual Basic]

```
Public Property Secure As Boolean
```

[C#]

```
public bool Secure {get; set;}
```

Property Value

Returns **true** if a secure connection is established; otherwise returns **false**. The default value is **false**.

Remarks

The **Secure** property determines if a secure connection is established with the remote host. The default value for this property is **false**, which specifies that a standard connection to the server is used. To establish a secure connection, the application should set this property value to **true** prior to calling the **Connect** method. Once the connection has been established, the client may exchange data with the server as with standard connections.

It is strongly recommended that any application that sets this property **true** use error handling to trap an errors that may occur. If the control is unable to initialize the security libraries, or otherwise cannot create a secure session for the client, an exception may be generated when this property value is set.

See Also

PopClient Class | SocketTools Namespace

PopClient.SecureCipher Property

Gets a value that specifies the encryption algorithm used for a secure connection.

[Visual Basic]

```
Public ReadOnly Property SecureCipher As SecureCipherAlgorithm
```

[C#]

```
public PopClient.SecureCipherAlgorithm SecureCipher {get;}
```

Property Value

A SecureCipherAlgorithm enumeration value which identifies the algorithm.

Remarks

The **SecureCipher** property returns a value which identifies the algorithm used to encrypt the data stream. If a secure connection has not been established, this property will return a value of **cipherNone**.

See Also

PopClient Class | SocketTools Namespace

PopClient.SecureHash Property

Gets a value that specifies the message digest algorithm used for a secure connection.

[Visual Basic]

```
Public ReadOnly Property SecureHash As SecureHashAlgorithm
```

[C#]

```
public PopClient.SecureHashAlgorithm SecureHash {get;}
```

Property Value

A SecureHashAlgorithm enumeration value which identifies the algorithm.

Remarks

The **SecureHash** property returns a value which identifies the message digest (hash) algorithm that was selected when a secure connection was established. If a secure connection has not been established, this property will return a value of **hashNone**.

See Also

PopClient Class | SocketTools Namespace

PopClient.SecureKeyExchange Property

Gets a value that specifies the key exchange algorithm used for a secure connection.

[Visual Basic]

```
Public ReadOnly Property SecureKeyExchange As SecureKeyAlgorithm
```

[C#]

```
public PopClient.SecureKeyAlgorithm SecureKeyExchange {get;}
```

Property Value

A SecureKeyAlgorithm enumeration value which identifies the algorithm.

Remarks

The **SecureKeyExchange** property returns a value which identifies the key exchange algorithm that was selected when a secure connection was established. If a secure connection has not been established, this property will return a value of **keyExchangeNone**.

See Also

PopClient Class | SocketTools Namespace

PopClient.SecureProtocol Property

Gets and sets a value which specifies the protocol used for a secure connection.

[Visual Basic]
```
Public Property SecureProtocol As SecurityProtocols
```

[C#]
```
public PopClient.SecurityProtocols SecureProtocol {get; set;}
```

Property Value

A SecurityProtocols enumeration value which identifies the protocol to be used when establishing a secure connection.

Remarks

The **SecureProtocol** property can be used to specify the security protocol to be used when establishing a secure connection with a server or accepting a secure connection from a client. By default, the class will attempt to use either SSL v3 or TLS v1 to establish the connection, with the appropriate protocol automatically selected based on the capabilities of the remote host. It is recommended that you only change this property value if you fully understand the implications of doing so. Assigning a value to this property will override the default protocol and force the class to attempt to use only the protocol specified.

Multiple security protocols may be specified by combining them using a bitwise **or** operator. After a connection has been established, this property will identify the protocol that was selected. Attempting to set this property after a connection has been established will result in an exception being thrown. This property should only be set after setting the **Secure** property to **true** and before calling the **Accept** or **Connect** methods.

In some cases, a server may only accept a secure connection if the TLS v1 protocol is specified. If the security protocol is not compatible with the server, then the connection will fail with an error indicating that the control is unable to establish a security context for the session. In this case, try assigning the property to **protocolTLS1** and attempt the connection again.

See Also

PopClient Class | SocketTools Namespace

PopClient.Status Property

Gets a value which specifies the current status of the client.

[Visual Basic]

```
Public ReadOnly Property Status As PopStatus
```

[C#]

```
public PopClient.PopStatus Status {get;}
```

Property Value

A PopStatus enumeration value which specifies the current client status.

Remarks

The **Status** property returns the current status of the client. This property can be used to check on blocking connections to determine if the client is interacting with the remote host before taking some action.

See Also

PopClient Class | SocketTools Namespace

PopClient.ThreadModel Property

Gets and sets a value which specifies the threading model for the class instance.

[Visual Basic]
```
Public Property ThreadModel As ThreadingModel
```

[C#]
```
public PopClient.ThreadingModel ThreadModel {get; set;}
```

Property Value

Returns one or more ThreadingModel enumeration value which specifies the threading model for the client. The default value for this property is **modelSingleThread**.

Remarks

The **ThreadModel** property specifies the threading model that is used by the class instance when a connection is established. The default value for this property is **modelSingleThread**, which specifies that only the thread that established the connection should be permitted to invoke methods. It is important to note that this threading model does not limit the application to a single thread of execution. When a session is established using the **Connect** method, that session is attached to the thread that created it. From that point on, until the session is terminated, only the owner may invoke methods in that instance of the class. The ownership of the class instance may be transferred from one thread to another using the **AttachThread** method.

Setting this property to **modelFreeThread** disables certain internal safety checks that are performed by the class and may result in unexpected behavior unless you ensure that access to the class instance is synchronized across multiple threads. The application must ensure that no two threads will attempt to invoke a blocking method at the same time. In other words, if one thread invokes a method, the application must ensure that another thread will not attempt to invoke any other method at the same time using the same instance of the class.

Changing the value of this property will not affect an active client session. The threading model must be specified prior to invoking the **Connect** method.

See Also

PopClient Class | SocketTools Namespace | AttachThread Method | ThreadingModel Enumeration | ThreadModel Attribute

PopClient.ThrowError Property

Gets and sets a value which specifies if method calls should throw exceptions when an error occurs.

[Visual Basic]

```
Public Property ThrowError As Boolean
```

[C#]

```
public bool ThrowError {get; set;}
```

Property Value

Returns **true** if method calls will generate exceptions when an error occurs; otherwise returns **false**. The default value is **false**.

Remarks

Error handling for when calling class methods can be done in either of two different styles, according to the value of this property.

If the **ThrowError** property is set to **false**, the application should check the return value of any method that is used, and report errors based upon the documented value of the return code. It is the responsibility of the application to interpret the error code, if it is desired to explain the error in addition to reporting it. This is the default behavior.

If the **ThrowError** property is set to **true**, then exceptions will be generated whenever a method call fails. The program must be written to catch these exceptions and take the appropriate action when an error occurs. Failure to handle an exception will cause the program to terminate abnormally.

Note that if an error occurs while a property is being read or modified, an exception will be raised regardless of the value of the **ThrowError** property.

See Also

PopClient Class | SocketTools Namespace

PopClient.Timeout Property

Gets and sets a value which specifies a timeout period in seconds.

[Visual Basic]

```
Public Property Timeout As Integer
```

[C#]

```
public int Timeout {get; set;}
```

Property Value

An integer value which specifies a timeout period in seconds.

Remarks

Setting the **Timeout** property specifies the number of seconds until a blocking operation fails and returns an error.

The timeout period is only used when the client is in blocking mode. Although this property can be changed when the client is in non-blocking mode, the value will be ignored until the client is returned to blocking mode.

For most applications it is recommended the timeout period be set between 10 and 20 seconds.

See Also

PopClient Class | SocketTools Namespace

PopClient.Trace Property

Gets and sets a value which indicates if network function logging is enabled.

[Visual Basic]

```
Public Property Trace As Boolean
```

[C#]

```
public bool Trace {get; set;}
```

Property Value

Returns **true** if network function tracing is enabled; otherwise returns **false**. The default value is **false**.

Remarks

The **Trace** property is used to enable (or disable) the tracing of network function calls. When enabled, each function call is logged to a file, including the function parameters, return value and error code if applicable. This facility can be enabled and disabled at run time, and the trace log file can be specified by setting the **TraceFile** property. All function calls that are being logged are appended to the trace file, if it exists. If no trace file exists when tracing is enabled, the trace file is created.

The tracing facility is available in all of the SocketTools networking classes and is enabled or disabled for an entire process. This means that once trace logging is enabled for a given component, all of the function calls made by the process using any of the SocketTools classes will be logged. For example, if you have an application using both the File Transfer Protocol and Post Office Protocol classes, and you set the **Trace** property to **true**, function calls made by both classes will be logged. Additionally, enabling a trace is cumulative, and tracing is not stopped until it is disabled for all classes used by the process.

If trace logging is not enabled, there is no negative impact on performance or throughput. Once enabled, application performance can degrade, especially in those situations in which multiple processes are being traced or the logfile is fairly large. Since logfiles can grow very quickly, even with modest applications, it is recommended that you delete the file when it is no longer needed.

When redistributing your application, make sure that you include the **SocketTools10.TraceLog.dll** module with your installation. If this library is not present, then no trace output will be generated and the value of the **Trace** property will be ignored. Only those function calls made by the SocketTools networking classes will be logged. Calls made directly to the Windows Sockets API, or calls made by other classes, will not be logged.

See Also

PopClient Class | SocketTools Namespace

PopClient.TraceFile Property

Gets and sets a value which specifies the name of the logfile.

[Visual Basic]

```
Public Property TraceFile As String
```

[C#]

```
public string TraceFile {get; set;}
```

Property Value

A string which specifies the name of the file.

Remarks

The **TraceFile** property is used to specify the name of the trace file that is created when network function tracing is enabled. If this property is set to an empty string (the default value), then a file named **SocketTools.log** is created in the system's temporary directory. If no temporary directory exists, then the file is created in the current working directory.

If the file exists, the trace output is appended to the file, otherwise the file is created. Since network function tracing is enabled per-process, the trace file is shared by all instances of the class being used. If multiple class instances have tracing enabled, the **TraceFile** property should be set to the same value for each instance. Since trace files can grow very quickly, even with modest applications, it is recommended that you delete the file when it is no longer needed.

The trace file has the following format:

```
 MyApp INF: WSAAsyncSelect(46, 0xcc4, 0x7e9, 0x27) returned 0 MyApp WRN:
connect(46, 192.0.0.1:1234, 16) returned -1 [10035] MyApp ERR: accept(46,
NULL, 0x0) returned -1 [10038]
```

The first column contains the name of the process that is being traced. The second column identifies if the trace record is reporting information, a warning, or an error. What follows is the name of the function being called, the arguments passed to the function and the function's return value. If a warning or error is reported, the error code is appended to the record (the value is placed inside brackets).

If parameters are passed as integer values, they are recorded in decimal. If the parameter or return value is a pointer (a memory address), it is recorded as a hexadecimal value preceded with "0x". A special type of pointer, called a null pointer, is recorded as NULL. Those functions which expect socket addresses are displayed in the following format:

```
aa.bb.cc.dd:nnnn
```

The first four numbers separated by periods represent the IP address, and the number following the colon represents the port number in host byte order. Note that in the second line of the above example, the control is attempting to connect to a system with the IP address 192.0.0.1 on port 1234.

Note that if the specified file cannot be created, or the user does not have permission to modify an existing file, the error is silently ignored and no trace output will be generated.

See Also

PopClient Class | SocketTools Namespace

PopClient.TraceFlags Property

Gets and sets a value which specifies the client function tracing flags.

[Visual Basic]

```
Public Property TraceFlags As TraceOptions
```

[C#]

```
public PopClient.TraceOptions TraceFlags {get; set;}
```

Property Value

A TraceOptions enumeration which specifies the amount of detail written to the trace logfile.

Remarks

The **TraceFlags** property is used to specify the type of information written to the trace file when network function tracing is enabled.

Because network function tracing is enabled per-process, the trace flags are shared by all instances of the class being used. If multiple class instances have tracing enabled, the **TraceFlags** property should be set to the same value for each instance. Changing the trace flags for any one instance of the class will affect the logging performed for all SocketTools classes used by the application.

Warnings are generated when a non-fatal error is returned by a network function. For example, if data is being written and the error **errorOperationWouldBlock** occurs, a warning is generated because the application simply needs to attempt to write the data at a later time.

See Also

PopClient Class | SocketTools Namespace

PopClient.UserName Property

Gets and sets the username used to authenticate the client session.

[Visual Basic]

```
Public Property UserName As String
```

[C#]

```
public string UserName {get; set;}
```

Property Value

A string which specifies the username.

Remarks

If a username is not specified when the **Connect** method is called, the value of this property will be used as the default username when establishing a connection with the server.

See Also

PopClient Class | SocketTools Namespace | BearerToken Property | Password Property

PopClient.Version Property

Gets a value which returns the current version of the PopClient class library.

[Visual Basic]

```
Public ReadOnly Property Version As String
```

[C#]

```
public string Version {get;}
```

Property Value

A string which specifies the version of the class library.

Remarks

The **Version** property returns a string which identifies the current version and build of the PopClient class library. This value can be used by an application for validation and debugging purposes.

PopClient Class | SocketTools Namespace

PopClient Methods

The methods of the **PopClient** class are listed below. For a complete list of **PopClient** class members, see the PopClient Members topic.

Public Instance Methods

AttachThread	Attach an instance of the class to the current thread
Cancel	Cancel the current blocking client operation.
ChangePassword	Change the mailbox password for the current user.
CloseMessage	Closes the current message.
Command	Overloaded. Send a custom command to the server.
Connect	Overloaded. Establish a connection with a remote host.
DeleteMessage	Overloaded. Flags a message for deletion from the current mailbox.
Disconnect	Terminate the connection with a remote host.
Dispose	Overloaded. Releases all resources used by PopClient.
Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetHeader	Overloaded. Returns the value of a header field from the specified message.
GetHeaders	Overloaded. Retrieves the headers for the specified message from the server.
GetMessage	Overloaded. Retrieve a message from the server and return the contents in a byte array.
GetType (inherited from Object)	Gets the Type of the current instance.
Initialize	Overloaded. Initialize an instance of the PopClient class.
OpenMessage	Overloaded. Open the specified message for reading.
Read	Overloaded. Read data from the server and store it in a byte array.
Reset	Reset the internal state of the object, resetting all properties to their default values.
SendMessage	Overloaded. Submits a message to the mail server for delivery.

StoreMessage	Overloaded. Retrieve a message from the current mailbox and store it in a file on the local system.
ToString (inherited from Object)	Returns a String that represents the current Object.
Uninitialize	Uninitialize the class library and release any resources allocated for the current thread.
Write	Overloaded. Write one or more bytes of data to the server.

Protected Instance Methods

Dispose	Overloaded. Releases the unmanaged resources allocated by the PopClient class and optionally releases the managed resources.
Finalize	Destroys an instance of the class, releasing the resources allocated for the session and unloading the networking library.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

PopClient Class | SocketTools Namespace

PopClient.AttachThread Method

Attach an instance of the class to the current thread

[Visual Basic]
```
Public Function AttachThread() As Boolean
```

[C#]
```
public bool AttachThread();
```

Return Value

A boolean value which specifies if the client could be attached to the current thread. If this method returns **false**, the client could not be attached to the thread and the application should check the value of the LastError property to determine the cause of the failure.

Remarks

When an instance of the class is created it is associated with the current thread that created it. Normally, if another thread attempts to perform an operation using that instance, an error is returned. This is used to ensure that other threads cannot interfere with an operation being performed by the owner thread. In some cases, it may be desirable for one thread in an application to create an instance of the class, establish a connection and then pass that instance to another worker thread. The **AttachThread** method can be used to change the ownership of the class instance to the new worker thread.

This method should be called by the new thread immediately after it has been created, and if the new thread does not release the handle itself, the ownership of the handle should be restored by the original thread. Under no circumstances should **AttachThread** be used to forcibly destroy an instance of a class allocated by another thread while a blocking operation is in progress. To cancel a blocking operation, use the **Cancel** method and then delete the class instance after the blocking function exits and control is returned to the current thread.

See Also

PopClient Class | SocketTools Namespace

PopClient.Cancel Method

Cancel the current blocking client operation.

[Visual Basic]
```
Public Sub Cancel()
```

[C#]
```
public void Cancel();
```

Remarks

When the **Cancel** method is called, the blocking client operation will not immediately fail. An internal flag is set which causes the blocking operation to exit with an error. This means that the application cannot cancel an operation and immediately perform some other blocking function. Instead it must allow the calling stack to unwind, returning back to the blocking operation before making any further function calls.

PopClient.ChangePassword Method

Change the mailbox password for the current user.

[Visual Basic]

```
Public Function ChangePassword( _
   ByVal userName As String, _
   ByVal oldPassword As String, _
   ByVal newPassword As String _
) As Boolean
```

[C#]

```
public bool ChangePassword(
   string userName,
   string oldPassword,
   string newPassword
);
```

Parameters

userName
A string which specifies the username for which the password will be changed.

oldPassword
A string which specifies the current password.

newPassword
A string which specifies the new password.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **ChangePassword** method changes the current password that will be used to authenticate the user. Once the password has been changed, the **Password** property will be updated with the new password.

Note that in order to change the user's mailbox password, the server must be running the poppass service on port 106, on the same server. Because passwords are transmitted as clear text (unencrypted), this service is not considered secure and may not be available.

PopClient.CloseMessage Method

Closes the current message.

[Visual Basic]
```
Public Function CloseMessage() As Boolean
```

[C#]
```
public bool CloseMessage();
```

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **CloseMessage** method closes the current message. If there is any remaining data left to be read from the message, it will be read and discarded.

PopClient.Command Method (String)

Send a custom command to the server.

[Visual Basic]

```
Overloads Public Function Command( _
   ByVal command As String _
) As Boolean
```

[C#]

```
public bool Command(
   string command
);
```

Parameters

command

A string which specifies the command to send. Valid commands vary based on the Internet protocol and the type of server that the client is connected to. Consult the protocol standard and/or the technical reference documentation for the server to determine what commands may be issued by a client application.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **Command** method sends a command to the remote host and processes the result code sent back in response to that command. This method can be used to send custom commands to a server to take advantage of features or capabilities that may not be supported internally by the class library.

To determine the specific status code returned by the server, check the value of the **ResultCode** property after the method returns.

See Also

PopClient Class | SocketTools Namespace | PopClient.Command Overload List

PopClient.Command Method (String, Boolean)

Send a custom command to the server.

[Visual Basic]

```
Overloads Public Function Command( _
   ByVal command As String, _
   ByVal isMultiLine As Boolean _
) As Boolean
```

[C#]

```
public bool Command(
   string command,
   bool isMultiLine
);
```

Parameters

command

A string which specifies the command to send. Valid commands vary based on the Internet protocol and the type of server that the client is connected to. Consult the protocol standard and/or the technical reference documentation for the server to determine what commands may be issued by a client application.

isMultiLine

A boolean value which specifies if the command will result in multiple lines of output from the server. For more information about a specific command, consult the standards documentation for the protocol.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **Command** method sends a command to the remote host and processes the result code sent back in response to that command. This method can be used to send custom commands to a server to take advantage of features or capabilities that may not be supported internally by the class library.

The *isMultiLine* parameter is used by the method to determine if multiple lines of data will be returned by the server as the result of a command. Unlike a single line response, which consists of a result code and result string, a multi-line response consists of one or more lines of text, terminated by a special end-of-data marker.

To determine the specific status code returned by the server, check the value of the **ResultCode** property after the method returns.

PopClient.Command Method (String, String)

Send a custom command to the server.

[Visual Basic]

```
Overloads Public Function Command( _
   ByVal command As String, _
   ByVal parameters As String _
) As Boolean
```

[C#]

```
public bool Command(
   string command,
   string parameters
);
```

Parameters

command

A string which specifies the command to send. Valid commands vary based on the Internet protocol and the type of server that the client is connected to. Consult the protocol standard and/or the technical reference documentation for the server to determine what commands may be issued by a client application.

parameters

An string which specifies one or more parameters to be sent along with the command. If more than one parameter is required, they must be separated by a single space character. Consult the protocol standard and/or technical reference documentation for the server to determine what parameters should be provided when issuing a specific command.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **Command** method sends a command to the remote host and processes the result code sent back in response to that command. This method can be used to send custom commands to a server to take advantage of features or capabilities that may not be supported internally by the class library.

To determine the specific status code returned by the server, check the value of the **ResultCode** property after the method returns.

PopClient Class | SocketTools Namespace

PopClient.Connect Method ()

Establish a connection with a remote host.

[Visual Basic]

```
Overloads Public Function Connect() As Boolean
```

[C#]

```
public bool Connect();
```

Return Value

A boolean value which specifies if the connection has been established. If the client is in blocking mode, a return value of **true** indicates that the connection has completed and the application may send and receive data from the remote host. If the client is in non-blocking mode, a return value of **true** indicates that the client has successfully created a socket and the connection is in progress.

When a non-blocking connection has completed, the OnConnect event will be fired. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

Remarks

This method establishes a connection using assigned property values.

The value of the **HostName** or **HostAddress** property will be used to determine the host name or address to connect to.

The value of the **RemotePort** property will be used to determine the port number to connect to.

The value of the **Timeout** property will be used to specify the timeout period.

The value of the **Options** property will be used to specify the default options for the connection.

PopClient.Connect Method (String)

Establish a connection with a remote host.

[Visual Basic]

```
Overloads Public Function Connect( _
   ByVal hostName As String _
) As Boolean
```

[C#]

```
public bool Connect(
   string hostName
);
```

Parameters

hostName

A string which specifies the remote host to establish a connection with. This may specify a host name or an Internet address in dot-notation.

Return Value

A boolean value which specifies if the connection has been established. If the client is in blocking mode, a return value of **true** indicates that the connection has completed and the application may send and receive data from the remote host. If the client is in non-blocking mode, a return value of **true** indicates that the client has successfully created a socket and the connection is in progress.

When a non-blocking connection has completed, the OnConnect event will be fired. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

PopClient.Connect Method (String, Int32)

Establish a connection with a remote host.

[Visual Basic]

```
Overloads Public Function Connect( _
   ByVal hostName As String, _
   ByVal hostPort As Integer _
) As Boolean
```

[C#]

```
public bool Connect(
   string hostName,
   int hostPort
);
```

Parameters

hostName

A string which specifies the remote host to establish a connection with. This may specify a host name or an Internet address in dot-notation.

hostPort

An integer which specifies the port number for the connection. This value must be greater than zero and the maximum valid port number is 65535.

Return Value

A boolean value which specifies if the connection has been established. If the client is in blocking mode, a return value of **true** indicates that the connection has completed and the application may send and receive data from the remote host. If the client is in non-blocking mode, a return value of **true** indicates that the client has successfully created a socket and the connection is in progress.

When a non-blocking connection has completed, the OnConnect event will be fired. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

```
Overloads Public Function Connect( _
   ByVal hostName As String, _
   ByVal hostPort As Integer, _
   ByVal timeout As Integer _
) As Boolean
```

[C#]

```
public bool Connect(
   string hostName,
   int hostPort,
   int timeout
);
```

Parameters

hostName

A string which specifies the remote host to establish a connection with. This may specify a host name or an Internet address in dot-notation.

hostPort

An integer which specifies the port number for the connection. This value must be greater than zero and the maximum valid port number is 65535.

timeout

An integer value that specifies the number of seconds that the method will wait for the connection to complete before failing the operation and returning to the caller. This value is only meaningful for blocking connections.

Return Value

A boolean value which specifies if the connection has been established. If the client is in blocking mode, a return value of **true** indicates that the connection has completed and the application may send and receive data from the remote host. If the client is in non-blocking mode, a return value of **true** indicates that the client has successfully created a socket and the connection is in progress.

When a non-blocking connection has completed, the OnConnect event will be fired. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

PopClient.Connect Method (String, Int32, String, String)

Establish a connection with a remote host.

[Visual Basic]

```
Overloads Public Function Connect( _
   ByVal hostName As String, _
   ByVal hostPort As Integer, _
   ByVal userName As String, _
   ByVal userPassword As String _
) As Boolean
```

[C#]

```
public bool Connect(
   string hostName,
   int hostPort,
   string userName,
   string userPassword
);
```

Parameters

hostName
A string which specifies the remote host to establish a connection with. This may specify a host name or an Internet address in dot-notation.

hostPort
An integer which specifies the port number for the connection. This value must be greater than zero and the maximum valid port number is 65535.

userName
A string which specifies the username which will be used to authenticate the client session with the remote host.

userPassword
A string which specifies the password which will be used to authenticate the client session with the remote host. If an OAuth 2.0 authentication method has been specified, this parameter should specify the bearer token.

Return Value

A boolean value which specifies if the connection has been established. If the client is in blocking mode, a return value of **true** indicates that the connection has completed and the application may send and receive data from the remote host. If the client is in non-blocking mode, a return value of **true** indicates that the client has successfully created a socket and the connection is in progress.

When a non-blocking connection has completed, the OnConnect event will be fired. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

PopClient.Connect Method (String, String, String)

Establish a connection with a remote host.

[Visual Basic]

```
Overloads Public Function Connect( _
   ByVal hostName As String, _
   ByVal userName As String, _
   ByVal userPassword As String _
) As Boolean
```

[C#]

```
public bool Connect(
   string hostName,
   string userName,
   string userPassword
);
```

Parameters

hostName

A string which specifies the remote host to establish a connection with. This may specify a host name or an Internet address in dot-notation.

userName

A string which specifies the username which will be used to authenticate the client session with the remote host.

userPassword

A string which specifies the password which will be used to authenticate the client session with the remote host. If an OAuth 2.0 authentication method has been specified, this parameter should specify the bearer token.

Return Value

A boolean value which specifies if the connection has been established. If the client is in blocking mode, a return value of **true** indicates that the connection has completed and the application may send and receive data from the remote host. If the client is in non-blocking mode, a return value of **true** indicates that the client has successfully created a socket and the connection is in progress.

When a non-blocking connection has completed, the OnConnect event will be fired. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

PopClient.DeleteMessage Method

Flags the current message for deletion from the mailbox.

Overload List

Flags the current message for deletion from the mailbox.

public bool DeleteMessage();

Flags a message for deletion from the current mailbox.

public bool DeleteMessage(int);

See Also

PopClient Class | SocketTools Namespace

PopClient.DeleteMessage Method ()

Flags the current message for deletion from the mailbox.

[Visual Basic]

```
Overloads Public Function DeleteMessage() As Boolean
```

[C#]

```
public bool DeleteMessage();
```

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

This method only flags the message for deletion. The message is not actually deleted until the client disconnects from the server, however the deleted message will no longer be accessible to the client. To prevent deleted messages from actually being removed from the mailbox, call the **Reset** method.

See Also

PopClient Class | SocketTools Namespace | PopClient.DeleteMessage Overload List

PopClient.DeleteMessage Method (Int32)

Flags a message for deletion from the current mailbox.

[Visual Basic]

```
Overloads Public Function DeleteMessage( _
   ByVal messageId As Integer _
) As Boolean
```

[C#]

```
public bool DeleteMessage(
   int messageId
);
```

Parameters

messageId

Number of message to delete from the server. This value must be greater than zero. The first message in the mailbox is message number one.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

This method only flags the message for deletion. The message is not actually deleted until the client disconnects from the server, however the deleted message will no longer be accessible to the client. To prevent deleted messages from actually being removed from the mailbox, call the **Reset** method.

See Also

PopClient Class | SocketTools Namespace | PopClient.DeleteMessage Overload List

PopClient.Disconnect Method

Terminate the connection with a remote host.

[Visual Basic]

```
Public Sub Disconnect()
```

[C#]

```
public void Disconnect();
```

Remarks

The **Disconnect** method terminates the connection with the remote host and releases the client handle allocated by the class. Note that the socket is not immediately released when the connection is terminated and will enter a wait state for two minutes. After the time wait period has elapsed, the client will be released by the operating system. This is a normal safety mechanism to handle any packets that may arrive after the connection has been closed.

PopClient Class | SocketTools Namespace

PopClient.Dispose Method

Releases all resources used by PopClient.

Overload List

Releases all resources used by PopClient.

public void Dispose();

Releases the unmanaged resources allocated by the PopClient class and optionally releases the managed resources.

protected virtual void Dispose(bool);

See Also

PopClient Class | SocketTools Namespace

PopClient.Dispose Method ()

Releases all resources used by PopClient.

[Visual Basic]
```
NotOverridable Overloads Public Sub Dispose() _
    Implements IDisposable.Dispose
```

[C#]
```
public void Dispose();
```

Implements

IDisposable.Dispose

Remarks

The **Dispose** method terminates any active connection and explicitly releases the resources allocated for this instance of the class. In some cases, better performance can be achieved if the programmer explicitly releases resources when they are no longer being used. The **Dispose** method provides explicit control over these resources.

Unlike the **Uninitialize** method, once the **Dispose** method has been called, that instance of the class cannot be re-initialized and you should not attempt to access class properties or invoke any methods. Note that this method can be called even if other references to the object are active.

See Also

PopClient Class | SocketTools Namespace | PopClient.Dispose Overload List

PopClient.Dispose Method (Boolean)

Releases the unmanaged resources allocated by the PopClient class and optionally releases the managed resources.

[Visual Basic]

```
Overridable Overloads Protected Sub Dispose( _
   ByVal disposing As Boolean _
)
```

[C#]

```
protected virtual void Dispose(
   bool disposing
);
```

Parameters

disposing

A boolean value which should be specified as **true** to release both managed and unmanaged resources; **false** to release only unmanaged resources.

Remarks

The **Dispose** method terminates any active connection and explicitly releases the resources allocated for this instance of the class. In some cases, better performance can be achieved if the programmer explicitly releases resources when they are no longer being used. The **Dispose** method provides explicit control over these resources.

Unlike the **Uninitialize** method, once the **Dispose** method has been called, that instance of the class cannot be re-initialized and you should not attempt to access class properties or invoke any methods. Note that this method can be called even if other references to the object are active.

You should call **Dispose** in your derived class when you are finished using the derived class. The **Dispose** method leaves the derived class in an unusable state. After calling **Dispose**, you must release all references to the derived class and the **PopClient** class so the memory they were occupying can be reclaimed by garbage collection.

PopClient.GetHeader Method

Returns the value of a header field from the specified message.

Overload List

Returns the value of a header field from the specified message.

public bool GetHeader(int,string,ref string);

Returns the value of a header field from the current message.

public bool GetHeader(string,ref string);

See Also

PopClient Class | SocketTools Namespace

PopClient.GetHeader Method (Int32, String, String)

Returns the value of a header field from the specified message.

[Visual Basic]

```
Overloads Public Function GetHeader( _
   ByVal messageId As Integer, _
   ByVal headerName As String, _
   ByRef headerValue As String _
) As Boolean
```

[C#]

```
public bool GetHeader(
   int messageId,
   string headerName,
   ref string headerValue
);
```

Parameters

messageId
An integer value that specifies the message to retrieve the header value from. This value must be greater than zero. The first message in the mailbox is message number one.

headerName
A string which specifies the message header to retrieve.

headerValue
A string passed by reference which will contain the value of the specified message header if the method is successful.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetHeader** method returns the value of a header field from the specified message. This allows an application to be able to easily determine the value of a header such as the sender, or the subject of the message. Any header field, including non-standard extensions, may be returned by this method.

See Also

PopClient Class | SocketTools Namespace | PopClient.GetHeader Overload List

PopClient.GetHeader Method (String, String)

Returns the value of a header field from the current message.

[Visual Basic]

```
Overloads Public Function GetHeader( _
   ByVal headerName As String, _
   ByRef headerValue As String _
) As Boolean
```

[C#]

```
public bool GetHeader(
   string headerName,
   ref string headerValue
);
```

Parameters

headerName
A string which specifies the message header to retrieve.

headerValue
A string passed by reference which will contain the value of the specified message header if the method is successful.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetHeader** method returns the value of a header field from the current message. This allows an application to be able to easily determine the value of a header such as the sender, or the subject of the message. Any header field, including non-standard extensions, may be returned by this method.

The current message number is specified by the value of the **Message** property.

PopClient Class | SocketTools Namespace | PopClient.GetHeader Overload List

PopClient.GetHeaders Method

Retrieves the headers for the current message from the server.

Overload List

Retrieves the headers for the current message from the server.

public bool GetHeaders(byte[],ref int);

Retrieves the headers for the specified message from the server.

public bool GetHeaders(int,byte[],ref int);

Retrieves the headers for the specified message from the server.

public bool GetHeaders(int,ref string);

Retrieves the headers for the current message from the server.

public bool GetHeaders(ref string);

See Also

PopClient Class | SocketTools Namespace

PopClient.GetHeaders Method (Byte[], Int32)

Retrieves the headers for the current message from the server.

[Visual Basic]

```
Overloads Public Function GetHeaders( _
   ByVal buffer As Byte(), _
   ByRef length As Integer _
) As Boolean
```

[C#]

```
public bool GetHeaders(
   byte[] buffer,
   ref int length
);
```

Parameters

buffer

A byte array that will contain the message data when the method returns.

length

An integer value which specifies the maximum number of bytes of data to write. This value cannot be larger than the size of the buffer specified by the caller.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetHeaders** method is used to retrieve the message headers from the server and copy it into a local buffer. This method will cause the current thread to block until the article transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

Note that the header data will be from the first part of the message, not from any additional sections of a multipart message. In other words, the headers such as From, To, Subject and Date will be returned in the buffer. To retrieve the headers from a specific section of a multipart message, you can use the **GetMessage** method and specify the **ImapSections.sectionHeader** option.

The current message number is specified by the value of the **Message** property.

See Also

PopClient Class | SocketTools Namespace | PopClient.GetHeaders Overload List

PopClient.GetHeaders Method (Int32, Byte[], Int32)

Retrieves the headers for the specified message from the server.

[Visual Basic]

```
Overloads Public Function GetHeaders( _
   ByVal messageId As Integer, _
   ByVal buffer As Byte(), _
   ByRef length As Integer _
) As Boolean
```

[C#]

```
public bool GetHeaders(
   int messageId,
   byte[] buffer,
   ref int length
);
```

Parameters

messageId

Number of article to retrieve from the server. This value must be greater than zero. The first message in the mailbox is message number one.

buffer

A byte array that will contain the message data when the method returns.

length

An integer value which specifies the maximum number of bytes of data to write. This value cannot be larger than the size of the buffer specified by the caller.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetHeaders** method is used to retrieve the message headers from the server and copy it into a local buffer. This method will cause the current thread to block until the article transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

Note that the header data will be from the first part of the message, not from any additional sections of a multipart message. In other words, the headers such as From, To, Subject and Date will be returned in the buffer. To retrieve the headers from a specific section of a multipart message, you can use the **GetMessage** method and specify the **ImapSections.sectionHeader** option.

PopClient Class | SocketTools Namespace

PopClient.GetMessage Method (Byte[], Int32)

Retrieve the current message from the server and return the contents in a byte array.

[Visual Basic]

```
Overloads Public Function GetMessage( _
   ByVal buffer As Byte(), _
   ByRef length As Integer _
) As Boolean
```

[C#]

```
public bool GetMessage(
   byte[] buffer,
   ref int length
);
```

Parameters

buffer

A byte array that the message data will be stored in.

length

An integer value passed by reference which specifies the maximum number of bytes of data to read. This value cannot be larger than the size of the buffer specified by the caller. When the method returns, this parameter will be updated with the actual number of bytes copied into the array.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetMessage** method is used to retrieve the current message from the server and copy it into a local buffer. This method will cause the current thread to block until the message transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

PopClient.GetMessage Method (Int32, Byte[], Int32)

Retrieve a message from the server and return the contents in a byte array.

[Visual Basic]

```
Overloads Public Function GetMessage( _
   ByVal messageId As Integer, _
   ByVal buffer As Byte(), _
   ByRef length As Integer _
) As Boolean
```

[C#]

```
public bool GetMessage(
   int messageId,
   byte[] buffer,
   ref int length
);
```

Parameters

messageId
Number of article to retrieve from the server. This value must be greater than zero. The first message in the mailbox is message number one.

buffer
A byte array that the message data will be stored in.

length
An integer value passed by reference which specifies the maximum number of bytes of data to read. This value cannot be larger than the size of the buffer specified by the caller. When the method returns, this parameter will be updated with the actual number of bytes copied into the array.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetMessage** method is used to retrieve a message from the server and copy it into a local buffer. This method will cause the current thread to block until the message transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

Retrieve a message from the server and return the contents in a string.

[Visual Basic]

```
Overloads Public Function GetMessage( _
   ByVal messageId As Integer, _
   ByRef buffer As String _
) As Boolean
```

[C#]

```
public bool GetMessage(
   int messageId,
   ref string buffer
);
```

Parameters

messageId

Number of article to retrieve from the server. This value must be greater than zero. The first message in the mailbox is message number one.

buffer

A string passed by reference that will contain the message data when the method returns.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetMessage** method is used to retrieve a message from the server and copy it into a local buffer. This method will cause the current thread to block until the message transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

PopClient Class | SocketTools Namespace | PopClient.GetMessage Overload List

PopClient.GetMessage Method (String)

Retrieve the current message from the server and return the contents in a string.

[Visual Basic]

```
Overloads Public Function GetMessage( _
   ByRef buffer As String _
) As Boolean
```

[C#]

```
public bool GetMessage(
   ref string buffer
);
```

Parameters

buffer

A string passed by reference that will contain the message data when the method returns.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetMessage** method is used to retrieve the current message from the server and copy it into a local buffer. This method will cause the current thread to block until the message transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

The current message number is specified by the value of the **Message** property.

PopClient.Initialize Method

Initialize an instance of the PopClient class.

Overload List

Initialize an instance of the PopClient class.

public bool Initialize();

Initialize an instance of the PopClient class.

public bool Initialize(string);

See Also

PopClient Class | SocketTools Namespace | Uninitialize Method

PopClient.Initialize Method ()

Initialize an instance of the PopClient class.

[Visual Basic]
```
Overloads Public Function Initialize() As Boolean
```

[C#]
```
public bool Initialize();
```

Return Value

A boolean value which specifies if the class was initialized successfully.

Remarks

The Initialize method can be used to explicitly initialize an instance of the PopClient class, loading the networking library and allocating resources for the current thread. Typically it is not necessary to explicitly call this method because the instance of the class is initialized by the class constructor. However, if the **Uninitialize** method is called, the class must be re-initialized before any other methods are called.

See Also

PopClient Class | SocketTools Namespace | PopClient.Initialize Overload List | Uninitialize Method

PopClient.Initialize Method (String)

Initialize an instance of the PopClient class.

[Visual Basic]
```
Overloads Public Function Initialize( _
   ByVal licenseKey As String _
) As Boolean
```

[C#]
```
public bool Initialize(
   string licenseKey
);
```

Return Value

A boolean value which specifies if the class was initialized successfully.

Remarks

The Initialize method can be used to explicitly initialize an instance of the PopClient class, loading the networking library and allocating resources for the current thread. Typically an application would define the license key as a custom attribute, however this method can be used to initialize the class directly.

The runtime license key for your copy of SocketTools can be generated using the License Manager utility that is included with the product. Note that if you have installed an evaluation license, you will not have a runtime license key and cannot redistribute any applications which use the PopClient class.

Example

The following example shows how to use the Initialize method to initialize an instance of the class. This example assumes that the license key string has been defined in code.

```
SocketTools.PopClient popClient = new SocketTools.PopClient();

if (popClient.Initialize(strLicenseKey) == false)
{
    MessageBox.Show(popClient.LastErrorString, "Error",
                    MessageBoxButtons.OK, MessageBoxIcon.Exclamation);
    return;
}
```

```
Dim popClient As New SocketTools.PopClient

If popClient.Initialize(strLicenseKey) = False Then
    MsgBox(popClient.LastErrorString, vbIconExclamation)
    Exit Sub
End If
```

PopClient.OpenMessage Method

Open the current message for reading.

Overload List

Open the current message for reading.

public bool OpenMessage();

Open the specified message for reading.

public bool OpenMessage(int);

See Also

PopClient Class | SocketTools Namespace

PopClient.OpenMessage Method ()

Open the current message for reading.

[Visual Basic]

```
Overloads Public Function OpenMessage() As Boolean
```

[C#]

```
public bool OpenMessage();
```

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **OpenMessage** method opens the current message in the mailbox. The client can then read the contents of the message using the **Read** method, and once all of the data has been read, the message should be closed by calling the **CloseMessage** method.

The current message number is specified by the value of the **Message** property.

See Also

PopClient Class | SocketTools Namespace | PopClient.OpenMessage Overload List

PopClient.OpenMessage Method (Int32)

Open the specified message for reading.

[Visual Basic]

```
Overloads Public Function OpenMessage( _
   ByVal messageId As Integer _
) As Boolean
```

[C#]

```
public bool OpenMessage(
   int messageId
);
```

Parameters

messageId

Number of article to retrieve from the server. This value must be greater than zero. The first message in the mailbox is message number one.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **OpenMessage** method opens a message in the current mailbox. The client can then read the contents of the message using the **Read** method, and once all of the data has been read, the message should be closed by calling the **CloseMessage** method.

PopClient Class | SocketTools Namespace | PopClient.OpenMessage Overload List

PopClient.Read Method

Read data from the server and store it in a byte array.

Overload List

Read data from the server and store it in a byte array.

public int Read(byte[]);

Read data from the server and store it in a byte array.

public int Read(byte[],int);

Read data from the server and store it in a string.

public int Read(ref string);

Read data from the server and store it in a string.

public int Read(ref string,int);

See Also

PopClient Class | SocketTools Namespace

PopClient.Read Method (Byte[])

Read data from the server and store it in a byte array.

```
[Visual Basic]
Overloads Public Function Read( _
   ByVal buffer As Byte() _
) As Integer
```

```
[C#]
public int Read(
   byte[] buffer
);
```

Parameters

buffer

A byte array that the data will be stored in.

Return Value

An integer value which specifies the number of bytes actually read from the server. A return value of zero specifies that the remote host has closed the connection and there is no more data available to be read. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Read** method returns data that has been read from the server, up to the size of the byte array passed to the method. If no data is available to be read, an error will be generated if the client is in non-blocking mode. If the client is in blocking mode, the program will stop until data is received from the server or the connection is closed.

See Also

PopClient Class | SocketTools Namespace | PopClient.Read Overload List

PopClient.Read Method (Byte[], Int32)

Read data from the server and store it in a byte array.

[Visual Basic]

```
Overloads Public Function Read( _
   ByVal buffer As Byte(), _
   ByVal length As Integer _
) As Integer
```

[C#]

```
public int Read(
   byte[] buffer,
   int length
);
```

Parameters

buffer

A byte array that the data will be stored in.

length

An integer value which specifies the maximum number of bytes of data to read. This value cannot be larger than the size of the buffer specified by the caller.

Return Value

An integer value which specifies the number of bytes actually read from the server. A return value of zero specifies that the remote host has closed the connection and there is no more data available to be read. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Read** method returns data that has been read from the server, up to the number of bytes specified. If no data is available to be read, an error will be generated if the client is in non-blocking mode. If the client is in blocking mode, the program will stop until data is received from the server or the connection is closed.

See Also

PopClient Class | SocketTools Namespace | PopClient.Read Overload List

PopClient.Read Method (String)

Read data from the server and store it in a string.

[Visual Basic]

```
Overloads Public Function Read( _
   ByRef buffer As String _
) As Integer
```

[C#]

```
public int Read(
   ref string buffer
);
```

Parameters

buffer

A string that will contain the data read from the client.

Return Value

An integer value which specifies the number of bytes actually read from the server. A return value of zero specifies that the remote host has closed the connection and there is no more data available to be read. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Read** method returns data that has been read from the server, up to a maximum of 4096 bytes. If no data is available to be read, an error will be generated if the client is in non-blocking mode. If the client is in blocking mode, the program will stop until data is received from the server or the connection is closed.

This method should only be used if the remote host is sending data that consists of printable characters. Binary data should be read using the method that accepts a byte array as the buffer parameter.

See Also

PopClient Class | SocketTools Namespace | PopClient.Read Overload List

PopClient.Read Method (String, Int32)

Read data from the server and store it in a string.

```
[Visual Basic]
Overloads Public Function Read( _
   ByRef buffer As String, _
   ByVal length As Integer _
) As Integer
```

```
[C#]
public int Read(
   ref string buffer,
   int length
);
```

Parameters

buffer

A string that will contain the data read from the client.

length

An integer value which specifies the maximum number of bytes of data to read.

Return Value

An integer value which specifies the number of bytes actually read from the server. A return value of zero specifies that the remote host has closed the connection and there is no more data available to be read. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Read** method returns data that has been read from the server, up to the number of bytes specified. If no data is available to be read, an error will be generated if the client is in non-blocking mode. If the client is in blocking mode, the program will stop until data is received from the server or the connection is closed.

This method should only be used if the remote host is sending data that consists of printable characters. Binary data should be read using the method that accepts a byte array as the buffer parameter.

PopClient.SendMessage Method

Submits a message to the mail server for delivery.

Overload List

Submits a message to the mail server for delivery.

public bool SendMessage(byte[],int);

Submits a message to the mail server for delivery.

public bool SendMessage(string);

See Also

PopClient Class | SocketTools Namespace

PopClient.SendMessage Method (Byte[], Int32)

Submits a message to the mail server for delivery.

[Visual Basic]

```
Overloads Public Function SendMessage( _
   ByVal buffer As Byte(), _
   ByVal length As Integer _
) As Boolean
```

[C#]

```
public bool SendMessage(
   byte[] buffer,
   int length
);
```

Parameters

buffer
A byte array which contains the message to be submitted for delivery.

length
An integer value which specifies the maximum number of bytes of data to send. This value cannot be larger than the size of the buffer specified by the caller.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **SendMessage** method submits a message to the mail server for delivery. The message format must comply with the RFC 822 standard, with the header and body separated by a blank line, and each line terminated with carriage-return/linefeed characters.

This method will cause the current thread to block until the message transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

Note that this method requires that the server support the XTND XMIT command. Although using this method to send mail has the advantage that the sender is authenticated (because the user must first login to the server), it is not widely supported. For general purpose mail delivery service, it is recommended that an application use the Simple Mail Transfer Protocol (SMTP).

PopClient Class | SocketTools Namespace | PopClient.SendMessage Overload List

PopClient.SendMessage Method (String)

Submits a message to the mail server for delivery.

[Visual Basic]

```
Overloads Public Function SendMessage( _
   ByVal buffer As String _
) As Boolean
```

[C#]

```
public bool SendMessage(
   string buffer
);
```

Parameters

buffer

A string which contains the message to be submitted for delivery.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **SendMessage** method submits a message to the mail server for delivery. The message format must comply with the RFC 822 standard, with the header and body separated by a blank line, and each line terminated with carriage-return/linefeed characters.

This method will cause the current thread to block until the message transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

Note that this method requires that the server support the XTND XMIT command. Although using this method to send mail has the advantage that the sender is authenticated (because the user must first login to the server), it is not widely supported. For general purpose mail delivery service, it is recommended that an application use the Simple Mail Transfer Protocol (SMTP).

PopClient.StoreMessage Method

Retrieve a message from the current mailbox and store it in a file on the local system.

Overload List

Retrieve a message from the current mailbox and store it in a file on the local system.

public bool StoreMessage(int,string);

Retrieve the current message and store it in a file on the local system.

public bool StoreMessage(string);

See Also

PopClient Class | SocketTools Namespace

PopClient.StoreMessage Method (Int32, String)

Retrieve a message from the current mailbox and store it in a file on the local system.

[Visual Basic]

```
Overloads Public Function StoreMessage( _
   ByVal messageId As Integer, _
   ByVal fileName As String _
) As Boolean
```

[C#]

```
public bool StoreMessage(
   int messageId,
   string fileName
);
```

Parameters

messageId

Number of message to retrieve. This value must be greater than zero. The first message in the mailbox is message number one.

fileName

A string which specifies the file that the message will be stored in. If the file does not exist, it will be created. If the file does exist, it will be overwritten with the contents of the message.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **StoreMessage** method retrieves a message from the server and stores it in a file on the local system. The contents of the message is stored as a text file, using the specified file name. This method will cause the current thread to block until the message transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

Retrieve the current message and store it in a file on the local system.

[Visual Basic]

```
Overloads Public Function StoreMessage( _
   ByVal fileName As String _
) As Boolean
```

[C#]

```
public bool StoreMessage(
   string fileName
);
```

Parameters

fileName

A string which specifies the file that the message will be stored in. If the file does not exist, it will be created. If the file does exist, it will be overwritten with the contents of the message.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **StoreMessage** method retrieves the current message from the server and stores it in a file on the local system. The contents of the message is stored as a text file, using the specified file name. This method will cause the current thread to block until the message transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

The current message number is specified by the value of the **Message** property.

See Also

PopClient Class | SocketTools Namespace | PopClient.StoreMessage Overload List

PopClient.Uninitialize Method

Uninitialize the class library and release any resources allocated for the current thread.

[Visual Basic]

```
Public Sub Uninitialize()
```

[C#]

```
public void Uninitialize();
```

Remarks

The **Uninitialize** method terminates any active connection, releases resources allocated for the current thread and unloads the networking library. After this method has been called, no further client operations may be performed until the class instance has been re-initialized.

If the **Initialize** method is explicitly called by the application, it should be matched by a call to the **Uninitialize** method when that instance of the class is no longer needed.

PopClient Class | SocketTools Namespace | Initialize Method

PopClient.Write Method

Write one or more bytes of data to the server.

Overload List

Write one or more bytes of data to the server.

public int Write(byte[]);

Write one or more bytes of data to the server.

public int Write(byte[],int);

Write a string of characters to the server.

public int Write(string);

Write a string of characters to the server.

public int Write(string,int);

See Also

PopClient Class | SocketTools Namespace

PopClient.Write Method (Byte[])

Write one or more bytes of data to the server.

[Visual Basic]

```
Overloads Public Function Write( _
   ByVal buffer As Byte() _
) As Integer
```

[C#]

```
public int Write(
   byte[] buffer
);
```

Parameters

buffer

A byte array that contains the data to be written to the server.

Return Value

An integer value which specifies the number of bytes actually written to the server. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Write** method sends one or more bytes of data to the server. If there is enough room in the client's internal send buffer to accommodate all of the data, it is copied to the send buffer and control immediately returns to the caller. If amount of data exceeds the available buffer space and the client is in blocking mode, then the method will block until the data can be sent. If the client is in non-blocking mode and the send buffer is full, an error will occur.

See Also

PopClient Class | SocketTools Namespace | PopClient.Write Overload List

PopClient.Write Method (Byte[], Int32)

Write one or more bytes of data to the server.

[Visual Basic]

```
Overloads Public Function Write( _
   ByVal buffer As Byte(), _
   ByVal length As Integer _
) As Integer
```

[C#]

```
public int Write(
   byte[] buffer,
   int length
);
```

Parameters

buffer
A byte array that contains the data to be written to the server.

length
An integer value which specifies the maximum number of bytes of data to write. This value cannot be larger than the size of the buffer specified by the caller.

Return Value

An integer value which specifies the number of bytes actually written to the server. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Write** method sends one or more bytes of data to the server. If there is enough room in the client's internal send buffer to accommodate all of the data, it is copied to the send buffer and control immediately returns to the caller. If amount of data exceeds the available buffer space and the client is in blocking mode, then the method will block until the data can be sent. If the client is in non-blocking mode and the send buffer is full, an error will occur.

See Also

PopClient Class | SocketTools Namespace | PopClient.Write Overload List

PopClient.Write Method (String)

Write a string of characters to the server.

[Visual Basic]

```
Overloads Public Function Write( _
   ByVal buffer As String _
) As Integer
```

[C#]

```
public int Write(
   string buffer
);
```

Parameters

buffer

A string which contains the data to be written to the server.

Return Value

An integer value which specifies the number of characters actually written to the server. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Write** method sends a string of characters to the server. If there is enough room in the client's internal send buffer to accommodate all of the data, it is copied to the send buffer and control immediately returns to the caller. If amount of data exceeds the available buffer space and the client is in blocking mode, then the method will block until the data can be sent. If the client is in non-blocking mode and the send buffer is full, an error will occur.

See Also

PopClient Class | SocketTools Namespace | PopClient.Write Overload List

PopClient.Write Method (String, Int32)

Write a string of characters to the server.

[Visual Basic]

```
Overloads Public Function Write( _
   ByVal buffer As String, _
   ByVal length As Integer _
) As Integer
```

[C#]

```
public int Write(
   string buffer,
   int length
);
```

Parameters

buffer

A string which contains the data to be written to the server.

length

An integer value which specifies the maximum number of characters to write. This value cannot be larger than the length of the string specified by the caller.

Return Value

An integer value which specifies the number of characters actually written to the server. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Write** method sends a string of characters to the server. If there is enough room in the client's internal send buffer to accommodate all of the data, it is copied to the send buffer and control immediately returns to the caller. If amount of data exceeds the available buffer space and the client is in blocking mode, then the method will block until the data can be sent. If the client is in non-blocking mode and the send buffer is full, an error will occur.

PopClient Events

The events of the **PopClient** class are listed below. For a complete list of **PopClient** class members, see the PopClient Members topic.

Public Instance Events

⚡ OnCancel	Occurs when a blocking client operation is canceled.
⚡ OnConnect	Occurs when a connection is established with the remote host.
⚡ OnDisconnect	Occurs when the remote host disconnects from the local system.
⚡ OnError	Occurs when an client operation fails.
⚡ OnProgress	Occurs as a data stream is being read or written to the client.
⚡ OnRead	Occurs when data is available to be read from the client.
⚡ OnTimeout	Occurs when a blocking operation fails to complete before the timeout period elapses.
⚡ OnWrite	Occurs when data can be written to the client.

See Also

PopClient Class | SocketTools Namespace

PopClient.OnCancel Event

Occurs when a blocking client operation is canceled.

[Visual Basic]

```
Public Event OnCancel As EventHandler
```

[C#]

```
public event EventHandler OnCancel;
```

Remarks

The **OnCancel** event is generated when a blocking client operation, such as sending or receiving data, is canceled with the **Cancel** method. To assist in determining which operation was canceled, check the value of the **Status** property.

See Also

PopClient Class | SocketTools Namespace

PopClient.OnConnect Event

Occurs when a connection is established with the remote host.

[Visual Basic]

```
Public Event OnConnect As EventHandler
```

[C#]

```
public event EventHandler OnConnect;
```

Remarks

The **OnConnect** event occurs when a connection is made with a remote host as a result of a **Connect** method call. When the **Connect** method is called and the **Blocking** property is set to **false**, a socket is created but the connection is not actually established until after this event occurs. Between the time connection process is started and this event fires, no operation may be performed on the client other than calling the **Disconnect** method.

This event is only generated if the client is in non-blocking mode.

See Also

PopClient Class | SocketTools Namespace

PopClient.OnDisconnect Event

Occurs when the remote host disconnects from the local system.

[Visual Basic]

```
Public Event OnDisconnect As EventHandler
```

[C#]

```
public event EventHandler OnDisconnect;
```

Remarks

The **OnDisconnect** event occurs when the remote host closes its connection, terminating the client session with the application. Because there may still be data in the client receive buffers, you should continue to read data from the client until the **Read** method returns a value of 0. Once all of the data has been read, you should call the **Disconnect** method to close the local socket and release the resources allocated for the client.

This event is only generated if the client is in non-blocking mode.

See Also

PopClient Class | SocketTools Namespace

PopClient.OnError Event

Occurs when an client operation fails.

[Visual Basic]
```
Public Event OnError As OnErrorEventHandler
```

[C#]
```
public event OnErrorEventHandler OnError;
```

Event Data

The event handler receives an argument of type PopClient.ErrorEventArgs containing data related to this event. The following **PopClient.ErrorEventArgs** properties provide information specific to this event.

Property	Description
Description	Gets a value which describes the last error that has occurred.
Error	Gets a value which specifies the last error that has occurred.

Remarks

The **OnError** event occurs when a client operation fails.

See Also

PopClient Class | SocketTools Namespace

PopClient.ErrorEventArgs Class

Provides data for the OnError event.

For a list of all members of this type, see PopClient.ErrorEventArgs Members.

System.Object
  System.EventArgs
    SocketTools.PopClient.ErrorEventArgs

[Visual Basic]

```
Public Class PopClient.ErrorEventArgs
    Inherits EventArgs
```

[C#]

```
public class PopClient.ErrorEventArgs : EventArgs
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

ErrorEventArgs specifies the numeric error code and a description of the error that has occurred.

An OnError event occurs when a method fails.

Requirements

Namespace: SocketTools

Assembly: SocketTools.PopClient (in SocketTools.PopClient.dll)

See Also

PopClient.ErrorEventArgs Members | SocketTools Namespace

PopClient.ErrorEventArgs Members

PopClient.ErrorEventArgs overview

Public Instance Constructors

PopClient.ErrorEventArgs Constructor	Initializes a new instance of the PopClient.ErrorEventArgs class.

Public Instance Properties

Description	Gets a value which describes the last error that has occurred.
Error	Gets a value which specifies the last error that has occurred.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString (inherited from Object)	Returns a String that represents the current Object.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

PopClient.ErrorEventArgs Class | SocketTools Namespace

PopClient.ErrorEventArgs Constructor

Initializes a new instance of the PopClient.ErrorEventArgs class.

[Visual Basic]
```
Public Sub New()
```

[C#]
```
public PopClient.ErrorEventArgs();
```

See Also

PopClient.ErrorEventArgs Class | SocketTools Namespace

PopClient.ErrorEventArgs Properties

The properties of the **PopClient.ErrorEventArgs** class are listed below. For a complete list of **PopClient.ErrorEventArgs** class members, see the PopClient.ErrorEventArgs Members topic.

Public Instance Properties

Description	Gets a value which describes the last error that has occurred.
Error	Gets a value which specifies the last error that has occurred.

See Also

PopClient.ErrorEventArgs Class | SocketTools Namespace

PopClient.ErrorEventArgs.Description Property

Gets a value which describes the last error that has occurred.

[Visual Basic]

```
Public ReadOnly Property Description As String
```

[C#]

```
public string Description {get;}
```

Property Value

A string which describes the last error that has occurred.

See Also

PopClient.ErrorEventArgs Class | SocketTools Namespace | Error Property

PopClient.ErrorEventArgs.Error Property

Gets a value which specifies the last error that has occurred.

[Visual Basic]

```
Public ReadOnly Property Error As ErrorCode
```

[C#]

```
public PopClient.ErrorCode Error {get;}
```

Property Value

ErrorCode enumeration which specifies the error.

See Also

PopClient.ErrorEventArgs Class | SocketTools Namespace | Description Property

PopClient.OnProgress Event

Occurs as a data stream is being read or written to the client.

[Visual Basic]
```
Public Event OnProgress As OnProgressEventHandler
```

[C#]
```
public event OnProgressEventHandler OnProgress;
```

Event Data

The event handler receives an argument of type PopClient.ProgressEventArgs containing data related to this event. The following **PopClient.ProgressEventArgs** properties provide information specific to this event.

Property	Description
BytesCopied	Gets a value which specifies the number of bytes of data that has been read or written.
BytesTotal	Gets a value which specifies the total number of bytes in the data stream.
Message	Gets the message number.
Percent	Gets a value which specifies the percentage of data that has been read or written.

Remarks

The **OnProgress** event occurs as a data stream is being read or written to the client. If large amounts of data are being read or written, this event can be used to update a progress bar or other user-interface component to provide the user with some visual feedback on the progress of the operation.

See Also

PopClient Class | SocketTools Namespace

PopClient.ProgressEventArgs Class

Provides data for the OnProgress event.

For a list of all members of this type, see PopClient.ProgressEventArgs Members.

System.Object
  System.EventArgs
    SocketTools.PopClient.ProgressEventArgs

[Visual Basic]
```
Public Class PopClient.ProgressEventArgs
    Inherits EventArgs
```

[C#]
```
public class PopClient.ProgressEventArgs : EventArgs
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

ProgressEventArgs specifies the number of bytes copied from the data stream, the total number of bytes in the data stream and a completion percentage.

The OnProgress event occurs as a data stream is being read or written to the client.

Requirements

Namespace: SocketTools

Assembly: SocketTools.PopClient (in SocketTools.PopClient.dll)

PopClient.ProgressEventArgs Properties

The properties of the **PopClient.ProgressEventArgs** class are listed below. For a complete list of **PopClient.ProgressEventArgs** class members, see the PopClient.ProgressEventArgs Members topic.

Public Instance Properties

BytesCopied	Gets a value which specifies the number of bytes of data that has been read or written.
BytesTotal	Gets a value which specifies the total number of bytes in the data stream.
Message	Gets the message number.
Percent	Gets a value which specifies the percentage of data that has been read or written.

See Also

PopClient.ProgressEventArgs Class | SocketTools Namespace

PopClient.ProgressEventArgs.BytesCopied Property

Gets a value which specifies the number of bytes of data that has been read or written.

[Visual Basic]
```
Public ReadOnly Property BytesCopied As Integer
```

[C#]
```
public int BytesCopied {get;}
```

Property Value

An integer value which specifies the number of bytes of data.

Remarks

The **BytesCopied** property specifies the number of bytes that have been read from the client and stored in the local stream buffer, or written from the stream buffer to the client.

See Also

PopClient.ProgressEventArgs Class | SocketTools Namespace | BytesTotal Property | Percent Property

PopClient.ProgressEventArgs.BytesTotal Property

Gets a value which specifies the total number of bytes in the data stream.

[Visual Basic]

```
Public ReadOnly Property BytesTotal As Integer
```

[C#]

```
public int BytesTotal {get;}
```

Property Value

An integer value which specifies the number of bytes of data.

Remarks

The **BytesTotal** property specifies the total amount of data being read from the client and stored in the data stream, or written from the data stream to the client. If the amount of data was unknown or unspecified at the time the method call was made, then this value will always be the same as the **BytesCopied** property.

See Also

PopClient.ProgressEventArgs Class | SocketTools Namespace | BytesCopied Property | Percent Property

PopClient.ProgressEventArgs.Message Property

Gets the message number.

[Visual Basic]
```
Public ReadOnly Property Message As Integer
```

[C#]
```
public int Message {get;}
```

Property Value

An integer value which specifies the message number.

Remarks

The **Message** property specifies the message number for the current message that is being downloaded from the mail server to the local host. If the **OnProgress** event occurs while message data is being uploaded to the server, this property will return a value of zero.

See Also

PopClient.ProgressEventArgs Class | SocketTools Namespace

PopClient.ProgressEventArgs.Percent Property

Gets a value which specifies the percentage of data that has been read or written.

[Visual Basic]

```
Public ReadOnly Property Percent As Integer
```

[C#]

```
public int Percent {get;}
```

Property Value

An integer value which specifies a percentage.

Remarks

The **Percent** property specifies the percentage of data that has been transmitted, expressed as an integer value between 0 and 100, inclusive. If the maximum size of the data stream was not specified by the caller, this value will always be 100.

See Also

PopClient.ProgressEventArgs Class | SocketTools Namespace | BytesCopied Property | BytesTotal Property

PopClient.OnRead Event

Occurs when data is available to be read from the client.

[Visual Basic]
```
Public Event OnRead As EventHandler
```

[C#]
```
public event EventHandler OnRead;
```

Remarks

The **OnRead** event occurs when data is available to be read from the client. This event is level-triggered, which means that once this event fires, it will not occur again until some data has been read from the client. This design prevents an application from being flooded with event notifications. It is recommended that your application read all of the available data from the server and store it in a local buffer for processing. See the example below.

This event is only generated if the client is in non-blocking mode.

Example

```
Private Sub Socket_OnRead(ByVal sender As Object, ByVal e As System.EventArgs)
Handles Socket.OnRead
    Dim strBuffer As String
    Dim nRead As Integer

    Do
        ' Read up to m_nBufferSize bytes of data from the server
        nRead = Socket.Read(strBuffer, m_nBufferSize)

        If nRead > 0 Then
            ' Append the data to an internal buffer for processing
            m_dataBuffer = m_dataBuffer + strBuffer
        End If
    Loop Until nRead < 1

    ProcessData()
End Sub
```

See Also

PopClient Class | SocketTools Namespace

PopClient.OnTimeout Event

Occurs when a blocking operation fails to complete before the timeout period elapses.

[Visual Basic]

```
Public Event OnTimeout As EventHandler
```

[C#]

```
public event EventHandler OnTimeout;
```

Remarks

The **OnTimeout** event occurs when a blocking operation, such as sending or receiving data on the client, fails to complete before the specified timeout period elapses. The timeout period for a blocking operation can be adjusted by setting the **Timeout** property.

This event is only generated if the client is in blocking mode.

See Also

PopClient Class | SocketTools Namespace

PopClient.OnWrite Event

Occurs when data can be written to the client.

[Visual Basic]

```
Public Event OnWrite As EventHandler
```

[C#]

```
public event EventHandler OnWrite;
```

Remarks

The **OnWrite** event occurs when the application can write data to the client. This event will typically occur when a connection is first established with the remote host, and after the **Write** method has failed because there was insufficient memory available in the client send buffers. In the second case, when some of the buffered data has been successfully sent to the remote host and there is space available in the send buffers, this event is used to signal the application that it may attempt to send more data.

This event is only generated if the client is in non-blocking mode.

See Also

PopClient Class | SocketTools Namespace

PopClient.ErrorCode Enumeration

Specifies the error codes returned by the PopClient class.

[Visual Basic]
```
Public Enum PopClient.ErrorCode
```

[C#]
```
public enum PopClient.ErrorCode
```

Remarks

The PopClient class uses the **ErrorCode** enumeration to specify what error has occurred when a method fails. The current error code may be determined by checking the value of the **LastError** property.

Note that the last error code is only meaningful if the previous operation has failed.

Members

Member Name	Description
errorNone	No error.
errorNotHandleOwner	Handle not owned by the current thread.
errorFileNotFound	The specified file or directory does not exist.
errorFileNotCreated	The specified file could not be created.
errorOperationCanceled	The blocking operation has been canceled.
errorInvalidFileType	The specified file is a block or character device, not a regular file.
errorInvalidDevice	The specified file type is invalid or not a regular file.
errorTooManyParameters	The maximum number of function parameters has been exceeded.
errorInvalidFileName	The specified file name contains invalid characters or is too long.
errorInvalidFileHandle	Invalid file handle passed to function.
errorFileReadFailed	Unable to read data from the specified file.
errorFileWriteFailed	Unable to write data to the specified file.
errorOutOfMemory	Out of memory.
errorAccessDenied	Access denied.
errorInvalidParameter	Invalid argument passed to function.
errorClipboardUnavailable	The system clipboard is currently unavailable.
errorClipboardEmpty	The system clipboard is empty or does not contain any text data.
errorFileEmpty	The specified file does not contain any data.
errorFileExists	The specified file already exists.

errorEndOfFile	End of file.
errorDeviceNotFound	The specified device could not be found.
errorDirectoryNotFound	The specified directory could not be found.
errorInvalidbuffer	Invalid memory address passed to function.
errorBufferTooSmall	The specified buffer is not large enough to contain the data.
errorNoHandles	No more handles are available to this process.
errorOperationWouldBlock	The specified operation would block the current thread.
errorOperationInProgress	A blocking operation is currently in progress.
errorAlreadyInProgress	The specified operation is already in progress.
errorInvalidHandle	Invalid handle passed to function.
errorInvalidAddress	Invalid network address specified.
errorInvalidSize	Datagram is too large to fit in specified buffer.
errorInvalidProtocol	Invalid network protocol specified.
errorProtocolNotAvailable	The specified network protocol is not available.
errorProtocolNotSupported	The specified protocol is not supported.
errorSocketNotSupported	The specified socket type is not supported.
errorInvalidOption	The specified option is invalid.
errorProtocolFamily	Specified protocol family is not supported.
errorProtocolAddress	The specified address is invalid for this protocol family.
errorAddressInUse	The specified address is in use by another process.
errorAddressUnavailable	The specified address cannot be assigned.
errorNetworkUnavailable	The networking subsystem is unavailable.
errorNetworkUnreachable	The specified network is unreachable.
errorNetworkReset	Network dropped connection on remote reset.
errorConnectionAborted	Connection was aborted due to timeout or other failure.
errorConnectionReset	Connection was reset by remote network.
errorOutOfBuffers	No buffer space is available.
errorAlreadyConnected	Connection already established with remote host.
errorNotConnected	No connection established with remote host.
errorConnectionShutdown	Unable to send or receive data after connection shutdown.
errorOperationTimeout	The specified operation has timed out.
errorConnectionRefused	The connection has been refused by the remote host.

errorHostUnavailable	The specified host is unavailable.
errorHostUnreachable	Remote host is unreachable.
errorTooManyProcesses	Too many processes are using the networking subsystem.
errorTooManyThreads	Too many threads have been created by the current process.
errorTooManySessions	Too many client sessions have been created by the current process.
errorInternalFailure	An unexpected internal error has occurred.
errorNetworkNotReady	Network subsystem is not ready for communication.
errorInvalidVersion	This version of the operating system is not supported.
errorNetworkNotInitialized	The networking subsystem has not been initialized.
errorRemoteShutdown	The remote host has initiated a graceful shutdown sequence.
errorInvalidHostName	The specified hostname is invalid or could not be resolved.
errorHostNameNotFound	The specified hostname could not be found.
errorHostNameRefused	Unable to resolve hostname, request refused.
errorHostNameNotResolved	Unable to resolve hostname, no address for specified host.
errorInvalidLicense	The license for this product is invalid.
errorProductNotLicensed	This product is not licensed to perform this operation.
errorNotImplemented	This function has not been implemented on this platform.
errorUnknownLocalhost	Unable to determine local host name.
errorInvalidHostAddress	Invalid host address specified.
errorInvalidServicePort	Invalid service port number specified.
errorInvalidServiceName	Invalid or unknown service name specified.
errorInvalidEventId	Invalid event identifier specified.
errorOperationNotBlocking	No blocking operation in progress on this socket.
errorSecurityNotInitialized	Unable to initialize security interface for this process.
errorSecurityContext	Unable to establish security context for this session.
errorSecurityCredentials	Unable to open certificate store or establish security credentials.
errorSecurityCertificate	Unable to validate the certificate chain for this

	session.
errorSecurityDecryption	Unable to decrypt data stream.
errorSecurityEncryption	Unable to encrypt data stream.
errorOperationNotSupported	The specified operation is not supported.
errorInvalidProtocolVersion	Invalid application protocol version specified.
errorNoServerResponse	No data returned from server.
errorInvalidServerResponse	Invalid data returned from server.
errorUnexpectedServerResponse	Unexpected response code returned from server.
errorServerTransactionFailed	Server transaction failed.
errorServiceUnavailable	The service is currently unavailable.
errorServiceNotReady	The service is not ready, try again later.
errorServerResyncFailed	Unable to resynchronize with server.
errorInvalidProxyType	Invalid proxy server type specified.
errorProxyRequired	Resource must be accessed through specified proxy.
errorInvalidProxyLogin	Unable to login to proxy server using specified credentials.
errorProxyResyncFailed	Unable to resynchronize with proxy server.
errorInvalidCommand	Invalid command specified.
errorInvalidCommandParameter	Invalid command parameter specified.
errorInvalidCommandSequence	Invalid command sequence specified.
errorCommandNotImplemented	Specified command not implemented on this server.
errorCommandNotAuthorized	Specified command not authorized for the current user.
errorCommandAborted	Specified command was aborted by the remote host.
errorOptionNotSupported	The specified option is not supported on this server.
errorRequestNotCompleted	The current client request has not been completed.
errorInvalidUserName	The specified username is invalid.
errorInvalidPassword	The specified password is invalid.
errorInvalidAccount	The specified account name is invalid.
errorAccountRequired	Account name has not been specified.
errorInvalidAuthenticationType	Invalid authentication protocol specified.
errorAuthenticationRequired	User authentication is required.
errorProxyAuthenticationRequired	Proxy authentication required.

errorAlreadyAuthenticated	User has already been authenticated.
errorAuthenticationFailed	Unable to authenticate the specified user.
errorNetworkAdapter	Unable to determine network adapter configuration.
errorInvalidRecordType	Invalid record type specified.
errorInvalidRecordName	Invalid record name specified.
errorInvalidRecordData	Invalid record data specified.
errorConnectionOpen	Data connection already established.
errorConnectionClosed	Server closed data connection.
errorConnectionPassive	Data connection is passive.
errorConnectionFailed	Unable to open data connection to server.
errorInvalidSecurityLevel	Data connection cannot be opened with this security setting.
errorCachedTLSRequired	Data connection requires cached TLS session.
errorDataReadOnly	Data connection is read-only.
errorDataWriteOnly	Data connection is write-only.
errorEndOfData	End of data.
errorRemoteFileUnavailable	Remote file is unavailable.
errorInsufficientStorage	Insufficient storage on server.
errorStorageallocation	File exceeded storage allocation on server.
errorDirectoryExists	The specified directory already exists.
errorDirectoryEmpty	No files returned by the server for the specified directory.
errorEndOfDirectory	End of directory listing.
errorUnknownDirectoryFormat	Unknown directory format.
errorInvalidResource	Invalid resource name specified.
errorResourceRedirected	The specified resource has been redirected.
errorResourceRestricted	Access to this resource has been restricted.
errorResourceNotModified	The specified resource has not been modified.
errorResourceNotFound	The specified resource cannot be found.
errorResourceConflict	Request could not be completed due to the current state of the resource.
errorResourceRemoved	The specified resource has been permanently removed from this server.
errorContentLengthRequired	Request must include the content length.
errorRequestPrecondition	Request could not be completed due to server precondition.
errorUnsupportedMediaType	Request specified an unsupported media type.

errorInvalidContentRange	Content range specified for this resource is invalid.
errorInvalidMessagePart	Message is not multipart or an invalid message part was specified.
errorInvalidMessageHeader	The specified message header is invalid or has not been defined.
errorInvalidMessageBoundary	The multipart message boundary has not been defined.
errorNoFileAttachment	The current message part does not contain a file attachment.
errorUnknownFileType	The specified file type could not be determined.
errorDataNotEncoded	The specified data block could not be encoded.
errorDataNotDecoded	The specified data block could not be decoded.
errorFileNotEncoded	The specified file could not be encoded.
errorFileNotDecoded	The specified file could not be decoded.
errorNoMessageText	No message text.
errorInvalidCharacterSet	Invalid character set specified.
errorInvalidEncodingType	Invalid encoding type specified.
errorInvalidMessageNumber	Invalid message number specified.
errorNoReturnAddress	No valid return address specified.
errorNoValidRecipients	No valid recipients specified.
errorInvalidRecipient	The specified recipient address is invalid.
errorRelayNotAuthorized	The specified domain is invalid or server will not relay messages.
errorMailboxUnavailable	Specified mailbox is currently unavailable.
errorMailboxReadOnly	The selected mailbox cannot be modified.
errorMailboxNotSelected	No mailbox has been selected.
errorInvalidMailbox	Specified mailbox is invalid.
errorInvalidDomain	The specified domain name is invalid or not recognized.
errorInvalidSender	The specified sender address is invalid or not recognized.
errorMessageNotDelivered	Message not delivered to any of the specified recipients.
errorEndOfMessageData	No more message data available to be read
errorInvalidmessageSize	The specified message size is invalid.
errorMessageNotCreated	The message could not be created in the specified mailbox.
errorNoMoreMailboxes	No more mailboxes exist on this server.

errorInvalidEmulationType	The specified terminal emulation type is invalid.
errorInvalidFontHandle	The specified font handle is invalid.
errorInvalidFontName	The specified font name is invalid or unavailable.
errorInvalidPacketSize	The specified packet size is invalid.
errorInvalidPacketData	The specified packet data is invalid.
errorInvalidPacketId	The unique packet identifier is invalid.
errorPacketTTLExpired	The specified packet time-to-live period has expired.
errorInvalidNewsGroup	Invalid newsgroup specified.
errorNoNewsgroupSelected	No newsgroup selected.
errorEmptyNewsgroup	No articles in specified newsgroup.
errorInvalidArticle	Invalid article number specified.
errorNoArticleSelected	No article selected in the current newsgroup.
errorFirstArticle	First article in current newsgroup.
errorLastArticle	Last article in current newsgroup.
errorArticleExists	Unable to transfer article, article already exists.
errorArticleRejected	Unable to transfer article, article rejected.
errorArticleTransferFailed	Article transfer failed.
errorArticlePostingDenied	Posting is not permitted on this server.
errorArticlePostingFailed	Unable to post article on this server.
errorInvalidDateFormat	The specified date format is not recognized.
errorFeatureNotSupported	The specified feature is not supported on this server.
errorInvalidFormHandle	The specified form handle is invalid or a form has not been created.
errorInvalidFormAction	The specified form action is invalid or has not been specified.
errorInvalidFormMethod	The specified form method is invalid or not supported.
errorInvalidFormType	The specified form type is invalid or not supported.
errorInvalidFormField	The specified form field name is invalid or does not exist.
errorEmptyForm	The specified form does not contain any field values.
errorMaximumConnections	The maximum number of client connections exceeded.
errorThreadCreationFailed	Unable to create a new thread for the current process.
errorInvalidThreadHandle	The specified thread handle is no longer valid.

errorThreadTerminated	The specified thread has been terminated.
errorThreadDeadlock	The operation would result in the current thread becoming deadlocked.
errorInvalidClientMoniker	The specified moniker is not associated with any client session.
errorClientMonikerExists	The specified moniker has been assigned to another client session.
errorServerInactive	The specified server is not listening for client connections.
errorServerSuspended	The specified server is suspended and not accepting client connections.
errorNoMessageStore	No message store has been specified.
errorMessageStoreChanged	The message store has changed since it was last accessed.
errorMessageNotFound	No message was found that matches the specified criteria.
errorMessageDeleted	The specified message has been deleted.
errorFileChecksumMismatch	The local and remote file checksums do not match.
errorFileSizeMismatch	The local and remote file sizes do not match.
errorInvalidFeedUrl	The news feed URL is invalid or specifies an unsupported protocol.
errorInvalidFeedFormat	The internal format of the news feed is invalid.
errorInvalidFeedVersion	This version of the news feed is not supported.
errorChannelEmpty	There are no valid items found in this news feed.
errorInvalidItemNumber	The specified channel item identifier is invalid.
errorItemNotFound	The specified channel item could not be found.
errorItemEmpty	The specified channel item does not contain any data.
errorInvalidItemProperty	The specified item property name is invalid.
errorItemPropertyNotFound	The specified item property has not been defined.
errorInvalidChannelTitle	The channel title is invalid or has not been defined.
errorInvalidChannelLink	The channel hyperlink is invalid or has not been defined.
errorInvalidChannelDescription	The channel description is invalid or has not been defined.
errorInvalidItemText	The description for an item is invalid or has not been defined.
errorInvalidItemLink	The hyperlink for an item is invalid or has not been defined.

errorInvalidServiceType	The specified service type is invalid.
errorServiceSuspended	Access to the specified service has been suspended.
errorServiceRestricted	Access to the specified service has been restricted.
errorInvalidProviderName	The specified provider name is invalid or unknown.
errorInvalidPhoneNumber	The specified phone number is invalid or not supported in this region.
errorGatewayNotFound	A message gateway cannot be found for the specified provider.
errorMessageTooLong	The message exceeds the maximum number of characters permitted.
errorInvalidProviderData	The request returned invalid or incomplete service provider data.
errorInvalidGatewayData	The request returned invalid or incomplete message gateway data.
errorMultipleProviders	The request has returned multiple service providers.
errorProviderNotFound	The specified service provider could not be found.
errorInvalidMessageService	The specified message is not supported with this service type.
errorInvalidMessageFormat	The specified message format is invalid.
errorInvalidConfiguration	The specified configuration options are invalid.
errorServerActive	The requested action is not permitted while the server is active.
errorServerPortBound	Unable to obtain exclusive use of the specified local port.
errorInvalidClientSession	The specified client identifier is invalid for this session.
errorClientNotIdentified	The specified client has not provided user credentials.
errorInvalidClientState	The requested action cannot be performed at this time.
errorInvalidResultCode	The specified result code is not valid for this protocol
errorCommandRequired	The specified command is required and cannot be disabled.
errorCommandDisabled	The specified command has been disabled.
errorCommandSequence	The command cannot be processed at this time.
errorCommandCompleted	The previous command has completed.
errorInvalidProgramName	The specified program name is invalid or unrecognized.

errorInvalidRequestHeader	The request header contains one or more invalid values.
errorInvalidVirtualHost	The specified virtual host name is invalid.
errorVirtualHostNotFound	The specified virtual host does not exist.
errorTooManyVirtualHosts	Too many virtual hosts created for this server.
errorInvalidVirtualPath	The specified virtual path name is invalid.
errorVirtualPathNotFound	The specified virtual path does not exist.
errorTooManyVirtualPaths	Too many virtual paths created for this server.
errorInvalidTask	The asynchronous task identifier is invalid.
errorTaskActive	The asynchronous task has not finished.
errorTaskQueued	The asynchronous task has been queued.
errorTaskSuspended	The asynchronous task has been suspended.
errorTaskFinished	The asynchronous task has finished.

PopClient.PopAuthentication Enumeration

Specifies the authentication methods supported by the PopClient class.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]

```
<Flags>
Public Enum PopClient.PopAuthentication
```

[C#]

```
[Flags]
public enum PopClient.PopAuthentication
```

Members

Member Name	Description	Value
authDefault	The default authentication scheme which sends the username and password as cleartext to the server. Because the user credentials are not encrypted, this method should only be used over a secure connection. This is the same as specifying **authPassword** as the authentication method.	0
authPassword	The username and password is sent to the server using the USER and PASS commands. This authentication method is supported by most servers and is the default authentication type. The credentials are not encrypted and this method should only be used over secure connections.	0
authApop	The APOP authentication method which uses an MD5 digest of the password. This method has been deprecated is not supported by all servers. It should only be used if required by legacy mail servers which do not support the SASL authentication methods.	1
authLogin	This authentication type will use the LOGIN method to authenticate the client session. This encodes the username and password in a specific format, but the credentials are not encrypted. It should be used over a secure connection. The server must support the Simple Authentication and Security Layer (SASL) mechanism as defined in RFC 4422.	3
authPlain	This authentication type will use the	4

	PLAIN method to authenticate the client session. This encodes the username and password in a specific format, but the credentials are not encrypted. It should be used over a secure connection. The server must support the PLAIN Simple Authentication and Security Layer (SASL) mechanism as defined in RFC 4616.	
authXOAuth2	This authentication type will use the XOAUTH2 method to authenticate the client session. This authentication method does not require the user password, instead the BearerToken property must specify the OAuth 2.0 bearer token issued by the service provider.	6
authBearer	This authentication type will use the OAUTHBEARER method to authenticate the client session as defined in RFC 7628. This authentication method does not require the user password, instead the BearerToken property must specify the OAuth 2.0 bearer token issued by the service provider.	7

Requirements

Namespace: SocketTools

Assembly: SocketTools.PopClient (in SocketTools.PopClient.dll)

See Also

SocketTools Namespace

PopClient.PopOptions Enumeration

Specifies the options that the PopClient class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]

```
<Flags>
Public Enum PopClient.PopOptions
```

[C#]

```
[Flags]
public enum PopClient.PopOptions
```

Remarks

The PopClient class uses the **PopOptions** enumeration to specify one or more options to be used when establishing a connection with a remote host. Multiple options may be specified if necessary.

Members

Member Name	Description	Value
optionNone	No option specified.	0
optionDefault	The default connection option. This is the same as specifying **optionNone**.	0
optionLineBreak	Message data that is received from the server is read as individual lines of text terminated by a carriage return and linefeed control sequence. This option can be useful for applications that need to use the lower level network I/O functions and must process the message text on a line-by-line basis. This option is not recommended for most applications because it can have a negative impact on performance when retrieving large messages from the server.	1
optionTunnel	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established. This option also forces all connections to be outbound and enables the firewall compatibility features in the client.	1024
optionTrustedSite	This option specifies the server is	2048

	trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using either the SSL or TLS protocols.	
optionSecure	This option specifies the client should attempt to establish a secure connection with the server. The server must support secure connections using either the SSL or TLS protocol.	4096
optionExplicitSSL	This option specifies the client should attempt to establish a secure explicit SSL session. The initial connection to the server is not encrypted, and the client will attempt to negotiate a secure connection by sending the STLS command to the server. Some servers may require this option when connecting to the server on ports other than the default secure port of 995.	4096
optionImplicitSSL	This option specifies the client should attempt to establish a secure implicit SSL session. The SSL handshake is initiated immediately after the connection to the server has been established.	8192
optionSecureFallback	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will permit connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.	32768
optionPreferIPv6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.	262144
optionFreeThread	This option specifies that class methods may be called from any thread, and not only the thread that established the connection. Using this option disables	524288

	certain internal safety checks that are made by the class and may result in unexpected behavior unless you ensure that access to the class instance is synchronized across multiple threads.

PopClient.PopStatus Enumeration

Specifies the status values that may be returned by the PopClient class.

[Visual Basic]
```
Public Enum PopClient.PopStatus
```

[C#]
```
public enum PopClient.PopStatus
```

Remarks

The PopClient class uses the **PopStatus** enumeration to identify the current status of the client.

Members

Member Name	Description
statusUnused	A client session has not been created. Attempts to perform any network operations, such as sending or receiving data, will generate an error.
statusIdle	A client session has been created, but is not currently in use. A blocking socket operation can be executed at this point.
statusConnect	The client is in the process of establishing a connection with a remote host.
statusRead	The client is in the process of receiving data from a remote host.
statusWrite	The client is in the process of sending data to a remote host.
statusDisconnect	The client session is being closed and subsequent attempts to access the client will result in an error.

SocketTools Namespace

PopClient.SecureCipherAlgorithm Enumeration

Specifies the encryption algorithms that the PopClient class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

```
[Visual Basic]
<Flags>
Public Enum PopClient.SecureCipherAlgorithm
```

```
[C#]
[Flags]
public enum PopClient.SecureCipherAlgorithm
```

Remarks

The PopClient class uses the **SecureCipherAlgorithm** enumeration to identify which encryption algorithm was selected when a secure connection was established with the remote host.

Members

Member Name	Description	Value
cipherNone	No cipher has been selected. A secure connection has not been established with the remote host.	0
cipherRC2	The RC2 block cipher was selected. This is a variable key length cipher which supports keys between 40- and 128-bits in length, in 8-bit increments.	1
cipherRC4	The RC4 stream cipher was selected. This is a variable key length cipher which supports keys between 40- and 128-bits in length, in 8-bit increments.	2
cipherRC5	The RC5 block cipher was selected. This is a variable key length cipher which supports keys up to 2040 bits, in 8-bit increments.	4
cipherDES	The DES (Data Encryption Standard) block cipher was selected. This is a fixed key length cipher using 56-bit keys.	8
cipherDES3	The Triple DES block cipher was selected. This cipher encrypts the data three times using different keys, effectively using a 168-bit key length.	16
cipherDESX	A variant of the DES block cipher which XORs an extra 64-bits of the key before and after the plaintext has been encrypted, increasing the key size to 184 bits.	32
cipherAES	The Advanced Encryption Standard	64

	cipher (also known as the Rijndael cipher) is a fixed block size cipher which use a key size of 128, 192 or 256 bits. This cipher is supported on Windows XP SP3 SP3 and later versions of the operating system.	
cipherSkipjack	The Skipjack block cipher was selected. This is a fixed key length cipher, using 80-bit keys.	128

PopClient.SecureHashAlgorithm Enumeration

Specifies the hash algorithms that the PopClient class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]

```
<Flags>
Public Enum PopClient.SecureHashAlgorithm
```

[C#]

```
[Flags]
public enum PopClient.SecureHashAlgorithm
```

Remarks

The PopClient class uses the **SecureHashAlgorithm** enumeration to identify the message digest (hash) algorithm that was selected when a secure connection was established with the remote host.

Members

Member Name	Description	Value
hashNone	No hash algorithm has been selected. This is not a secure connection with the server.	0
hashMD5	The MD5 algorithm was selected. This algorithm produces a 128-bit message digest. This algorithm is no longer considered to be cryptographically secure.	1
hashSHA	The SHA-1 algorithm was selected. This algorithm produces a 160-bit message digest. This algorithm is no longer considered to be cryptographically secure.	2
hashSHA256	The SHA-256 algorithm was selected. This algorithm produces a 256-bit message digest.	4
hashSHA384	The SHA-384 algorithm was selected. This algorithm produces a 384-bit message digest.	8
hashSHA512	The SHA-512 algorithm was selected. This algorithm produces a 512-bit message digest.	16

Requirements

Namespace: SocketTools

Assembly: SocketTools.PopClient (in SocketTools.PopClient.dll)

PopClient.SecureKeyAlgorithm Enumeration

Specifies the key exchange algorithms that the PopClient class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]

```
<Flags>
Public Enum PopClient.SecureKeyAlgorithm
```

[C#]

```
[Flags]
public enum PopClient.SecureKeyAlgorithm
```

Remarks

The PopClient class uses the **SecureKeyAlgorithm** enumeration to identify the key exchange algorithm that was selected when a secure connection was established with the remote host.

Members

Member Name	Description	Value
keyExchangeNone	No key exchange algorithm has been selected. This is not a secure connection with the server.	0
keyExchangeRSA	The RSA public key exchange algorithm has been selected.	1
keyExchangeKEA	The KEA public key exchange algorithm has been selected. This is an improved version of the Diffie-Hellman public key algorithm.	2
keyExchangeDH	The Diffie-Hellman public key exchange algorithm has been selected.	4
keyExchangeECDH	The Elliptic Curve Diffie-Hellman key exchange algorithm was selected. This is a variant of the Diffie-Hellman algorithm which uses elliptic curve cryptography. This key exchange algorithm is only supported on Windows XP SP3 SP3 and later versions of the operating system.	8

Requirements

Namespace: SocketTools

Assembly: SocketTools.PopClient (in SocketTools.PopClient.dll)

SocketTools Namespace

PopClient.SecurityCertificate Enumeration

Specifies the security certificate status values that may be returned by the PopClient class.

[Visual Basic]
```
Public Enum PopClient.SecurityCertificate
```

[C#]
```
public enum PopClient.SecurityCertificate
```

Remarks

The PopClient class uses the **SecurityCertificate** enumeration to identify the current status of the certificate that was provided by the remote host when a secure connection was established.

Members

Member Name	Description
certificateNone	No certificate information is available. A secure connection was not established with the server.
certificateValid	The certificate is valid.
certificateNoMatch	The certificate is valid, however the domain name specified in the certificate does not match the domain name of the remote host. The application can examine the **CertificateSubject** property to determine the site the certificate was issued to.
certificateExpired	The certificate has expired and is no longer valid. The application can examine the **CertificateExpires** property to determine when the certificate expired.
certificateRevoked	The certificate has been revoked and is no longer valid. It is recommended that the application immediately terminate the connection if this status is returned.
certificateUntrusted	The certificate has not been issued by a trusted authority, or the certificate is not trusted on the local host. It is recommended that the application immediately terminate the connection if this status is returned.
certificateInvalid	The certificate is invalid. This typically indicates that the internal structure of the certificate is damaged. It is recommended that the application immediately terminate the connection if this status is returned.

Requirements

Namespace: SocketTools

Assembly: SocketTools.PopClient (in SocketTools.PopClient.dll)

SocketTools Namespace

PopClient.SecurityProtocols Enumeration

Specifies the security protocols that the PopClient class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]

```
<Flags>
Public Enum PopClient.SecurityProtocols
```

[C#]

```
[Flags]
public enum PopClient.SecurityProtocols
```

Remarks

The PopClient class uses the **SecurityProtocols** enumeration to specify one or more security protocols to be used when establishing a connection with a remote host. Multiple protocols may be specified if necessary and the actual protocol used will be negotiated with the remote host. It is recommended that most applications use **protocolDefault** when creating a secure connection.

Members

Member Name	Description	Value
protocolNone	No security protocol will be used, a secure connection will not be established.	0
protocolSSL2	The SSL 2.0 protocol has been selected. This protocol has been deprecated and is no longer widely used. It is not recommended that this protocol be used when establishing secure connections.	1
protocolSSL3	The SSL 3.0 protocol has been selected. This protocol has been deprecated and is no longer widely used. It is not recommended that this protocol be used when establishing secure connections. In most cases, this protocol is only selected if TLS is not supported by the server.	2
protocolTLS10	The TLS 1.0 protocol has been selected. This version of the protocol is commonly used by older servers and is the only version of TLS supported on Windows platforms prior to Windows 7 SP1 and Windows Server 2008 R2.	4
protocolTLS11	The TLS 1.1 protocol has been selected. This version of TLS is supported on Windows 7 SP1 and Windows Server 2008 R2 and later versions of the	8

	operating system.	
protocolTLS12	The TLS 1.2 protocol has been selected. This is the default version of the protocol and is supported on Windows 7 SP1 and Windows Server 2008 R2 and later versions of Windows. It is recommended that you use this version of TLS.	16
protocolSSL	Any version of the Secure Sockets Layer (SSL) protocol should be used. The actual protocol version used will be negotiated with the remote host.	3
protocolTLS	Any version of the the Transport Layer Security (TLS) protocol should be used. The actual protocol version used will be negotiated with the remote host, with with preference for TLS 1.2.	28
protocolTLS1	Version 1.0, 1.1 or 1.2 of the the Transport Layer Security (TLS) protocol should be used. The actual protocol version used will be negotiated with the remote host, with preference for TLS 1.2.	28
protocolDefault	The default selection of security protocols will be used when establishing a connection. The TLS 1.2, 1.1 and 1.0 protocols will be negotiated with the host, in that order of preference. This option will always request the latest version of the preferred security protocols and is the recommended value.	16
protocolUnknown	An unknown or unsupported security protocol has been specified. This value indicates an error condition.	4096

SocketTools Namespace

PopClient.TraceOptions Enumeration

Specifies the logging options that the PopClient class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]

```
<Flags>
Public Enum PopClient.TraceOptions
```

[C#]

```
[Flags]
public enum PopClient.TraceOptions
```

Remarks

The PopClient class uses the **TraceOptions** enumeration to specify what kind of debugging information is written to the trace logfile. These options are only meaningful when trace logging is enabled by setting the **Trace** property to **true**.

Members

Member Name	Description	Value
traceDefault	The default trace logging option. This is the same as specifying the **traceInfo** option.	0
traceInfo	All network function calls are written to the trace file. This is the default value.	0
traceError	Only those network function calls which fail are recorded in the trace file.	1
traceWarning	Only those network function calls which fail, or return values which indicate a warning, are recorded in the trace file.	2
traceHexDump	All network function calls are written to the trace file, plus all the data that is sent or received is displayed, in both ASCII and hexadecimal format.	4
traceProcess	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for multithreaded applications that are using worker threads.	4096

Requirements

Namespace: SocketTools

Assembly: SocketTools.PopClient (in SocketTools.PopClient.dll)

SocketTools Namespace

PopClient.OnErrorEventHandler Delegate

Represents the method that will handle the OnError event.

[Visual Basic]

```
Public Delegate Sub PopClient.OnErrorEventHandler( _
   ByVal sender As Object, _
   ByVal e As ErrorEventArgs _
)
```

[C#]

```
public delegate void PopClient.OnErrorEventHandler(
      object sender,
      ErrorEventArgs e
   );
```

Parameters

sender
The source of the event.

e
An ErrorEventArgs that contains the event data.

Remarks

When you create an **OnErrorEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnErrorEventHandler** delegate declaration.

Requirements

Namespace: SocketTools

Assembly: SocketTools.PopClient (in SocketTools.PopClient.dll)

SocketTools Namespace

PopClient.OnProgressEventHandler Delegate

Represents the method that will handle the OnProgress event.

[Visual Basic]

```
Public Delegate Sub PopClient.OnProgressEventHandler( _
   ByVal sender As Object, _
   ByVal e As ProgressEventArgs _
)
```

[C#]

```
public delegate void PopClient.OnProgressEventHandler(
      object sender,
      ProgressEventArgs e
   );
```

Parameters

sender

The source of the event.

e

A ProgressEventArgs that contains the event data.

Remarks

When you create an **OnProgressEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnProgressEventHandler** delegate declaration.

SocketTools Namespace

PopClientException Class

The exception that is thrown when a client error occurs.

For a list of all members of this type, see PopClientException Members.

System.Object
  System.Exception
    System.ApplicationException
      SocketTools.PopClientException

[Visual Basic]

```
Public Class PopClientException
    Inherits ApplicationException
```

[C#]

```
public class PopClientException : ApplicationException
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

A PopClientException is thrown by the PopClient class when an error occurs.

The default constructor for the PopClientException class sets the **ErrorCode** property to the last client error that occurred.

Requirements

Namespace: SocketTools

Assembly: SocketTools.PopClient (in SocketTools.PopClient.dll)

PopClientException Members

PopClientException overview

Public Instance Constructors

PopClientException	Overloaded. Initializes a new instance of the PopClientException class.

Public Instance Properties

ErrorCode	Gets a value which specifies the error that caused the exception.
HelpLink (inherited from Exception)	Gets or sets a link to the help file associated with this exception.
InnerException (inherited from Exception)	Gets the Exception instance that caused the current exception.
Message	Gets a value which describes the error that caused the exception.
Number	Gets a value which specifies the numeric value of the error that caused the exception.
Source (inherited from Exception)	Gets or sets the name of the application or the object that causes the error.
StackTrace (inherited from Exception)	Gets a string representation of the frames on the call stack at the time the current exception was thrown.
TargetSite (inherited from Exception)	Gets the method that throws the current exception.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetBaseException (inherited from Exception)	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetObjectData (inherited from Exception)	When overridden in a derived class, sets the SerializationInfo with information about the exception.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString	Creates and returns a string representation of the current exception.

Protected Instance Properties

HResult (inherited from Exception)	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

PopClientException Class | SocketTools Namespace

PopClientException Constructor

Initializes a new instance of the PopClientException class with the last network error code.

Overload List

Initializes a new instance of the PopClientException class with the last network error code.

```
public PopClientException();
```

Initializes a new instance of the PopClientException class with a specified error number.

```
public PopClientException(int);
```

Initializes a new instance of the PopClientException class with a specified error message.

```
public PopClientException(string);
```

Initializes a new instance of the PopClientException class with a specified error message and a reference to the inner exception that is the cause of this exception.

```
public PopClientException(string,Exception);
```

See Also

PopClientException Class | SocketTools Namespace

PopClientException Constructor ()

Initializes a new instance of the PopClientException class with the last network error code.

[Visual Basic]
```
Overloads Public Sub New()
```

[C#]
```
public PopClientException();
```

Remarks

The ctor constructor sets the **ErrorCode** property to the last client error that occurred. For more information about the errors that may occur, refer to the PopClient.ErrorCode enumeration.

PopClientException Class | SocketTools Namespace | PopClientException Constructor Overload List

PopClientException Constructor (String)

Initializes a new instance of the PopClientException class with a specified error message.

[Visual Basic]

```
Overloads Public Sub New( _
   ByVal message As String _
)
```

[C#]

```
public PopClientException(
   string message
);
```

Parameters

message

The error message that explains the reason for the exception.

Remarks

The content of the ***message*** parameter is intended to be understood by humans. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

See Also

PopClientException Class | SocketTools Namespace | PopClientException Constructor Overload List

PopClientException Constructor (String, Exception)

Initializes a new instance of the PopClientException class with a specified error message and a reference to the inner exception that is the cause of this exception.

[Visual Basic]

```
Overloads Public Sub New( _
   ByVal message As String, _
   ByVal innerException As Exception _
)
```

[C#]

```
public PopClientException(
   string message,
   Exception innerException
);
```

Parameters

message

The error message that explains the reason for the exception.

innerException

The exception that is the cause of the current exception. If the ***innerException*** parameter is not a null reference, the current exception is raised in a **catch** block that handles the inner exception.

Remarks

The content of the message parameter is intended to be understood by humans. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

An exception that is thrown as a direct result of a previous exception should include a reference to the previous exception in the **InnerException** property. The **InnerException** property returns the same value that is passed into the constructor, or a null reference if the **InnerException** property does not supply the inner exception value to the constructor.

See Also

PopClientException Class | SocketTools Namespace | PopClientException Constructor Overload List

PopClientException Constructor (Int32)

Initializes a new instance of the PopClientException class with a specified error number.

[Visual Basic]

```
Overloads Public Sub New( _
   ByVal code As Integer _
)
```

[C#]

```
public PopClientException(
   int code
);
```

Parameters

code

An integer value which specifies an error code.

Remarks

This constructor sets the **ErrorCode** property to the specified error code. For more information about the errors that may occur, refer to the PopClient.ErrorCode enumeration.

See Also

PopClientException Class | SocketTools Namespace | PopClientException Constructor Overload List

PopClientException Properties

The properties of the **PopClientException** class are listed below. For a complete list of **PopClientException** class members, see the PopClientException Members topic.

Public Instance Properties

ErrorCode	Gets a value which specifies the error that caused the exception.
HelpLink (inherited from Exception)	Gets or sets a link to the help file associated with this exception.
InnerException (inherited from Exception)	Gets the Exception instance that caused the current exception.
Message	Gets a value which describes the error that caused the exception.
Number	Gets a value which specifies the numeric value of the error that caused the exception.
Source (inherited from Exception)	Gets or sets the name of the application or the object that causes the error.
StackTrace (inherited from Exception)	Gets a string representation of the frames on the call stack at the time the current exception was thrown.
TargetSite (inherited from Exception)	Gets the method that throws the current exception.

Protected Instance Properties

HResult (inherited from Exception)	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception.

See Also

PopClientException Class | SocketTools Namespace

PopClientException.ErrorCode Property

Gets a value which specifies the error that caused the exception.

[Visual Basic]

```
Public ReadOnly Property ErrorCode As ErrorCode
```

[C#]

```
public PopClient.ErrorCode ErrorCode {get;}
```

Property Value

Returns a PopClient.ErrorCode enumeration value which specifies the error code.

Remarks

The **ErrorCode** property returns the error code that specifies the cause of the exception.

The default constructor for the PopClientException class sets the error code to the last network error that occurred. For more information about the errors that may occur, refer to the PopClient.ErrorCode enumeration.

See Also

PopClientException Class | SocketTools Namespace

PopClientException.Message Property

Gets a value which describes the error that caused the exception.

[Visual Basic]

```
Overrides Public ReadOnly Property Message As String
```

[C#]

```
public override string Message {get;}
```

Property Value

A string which describes the error that caused the exception.

Remarks

The **Message** property returns a string which describes the error that caused the exception.

See Also

PopClientException Class | SocketTools Namespace

PopClientException.Number Property

Gets a value which specifies the numeric value of the error that caused the exception.

[Visual Basic]

```
Public ReadOnly Property Number As Integer
```

[C#]

```
public int Number {get;}
```

Property Value

An integer value that specifies the error that caused the exception.

Remarks

The **Number** property returns an integer value which specifies the numeric value of the error that caused the exception. This value is the same as the values returned by the Windows Sockets API. For more information about socket error codes, see the Windows Socket Version 2 API error code documentation in MSDN.

See Also

PopClientException Class | SocketTools Namespace

PopClientException Methods

The methods of the **PopClientException** class are listed below. For a complete list of **PopClientException** class members, see the PopClientException Members topic.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetBaseException (inherited from Exception)	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetObjectData (inherited from Exception)	When overridden in a derived class, sets the SerializationInfo with information about the exception.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString	Creates and returns a string representation of the current exception.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

PopClientException Class | SocketTools Namespace

PopClientException.ToString Method

Creates and returns a string representation of the current exception.

[Visual Basic]
```
Overrides Public Function ToString() As String
```

[C#]
```
public override string ToString();
```

Return Value

A string representation of the current exception.

Remarks

The **ToString** method returns a representation of the current exception that is intended to be understood by humans. Where the exception contains culture-sensitive data, the string representation returned by **ToString** is required to take into account the current system culture. Although there are no exact requirements for the format of the returned string, it should attempt to reflect the value of the object as perceived by the user.

This implementation of **ToString** obtains the numeric error code value and a description of the error that caused the current exception. If there is no error message or it is an empty string, then no error message is returned.

This method overrides **ApplicationException.ToString**.

PopClientException Class | SocketTools Namespace

PopClient.RuntimeLicenseAttribute Class

Attribute that defines the runtime license key for the class.

For a list of all members of this type, see PopClient.RuntimeLicenseAttribute Members.

System.Object
  System.Attribute
    SocketTools.PopClient.RuntimeLicenseAttribute

[Visual Basic]

```
<AttributeUsage(ValidOn:=AttributeTargets.Assembly, AllowMultiple:=False,
   Inherited:=True)>
Public Class PopClient.RuntimeLicenseAttribute
    Inherits Attribute
```

[C#]

```
[AttributeUsage(ValidOn=AttributeTargets.Assembly, AllowMultiple=False,
   Inherited=True)]
public class PopClient.RuntimeLicenseAttribute : Attribute
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

The RuntimeLicense attribute is used to define the runtime license key that will be used when an instance of the class is created. This attribute is defined in the assembly information module for the language, such as AssemblyInfo.cs when programming C#. The runtime license key must be defined if you wish to redistribute your application.

The runtime license key for your copy of SocketTools can be generated using the License Manager utility that is included with the product. Note that if you have installed an evaluation license, you will not have a runtime license key and cannot redistribute any applications which use the PopClient class.

Example

```
<Assembly: SocketTools.PopClient.RuntimeLicense("abcdefghijklmnop")>
```

```
[assembly: SocketTools.PopClient.RuntimeLicense("abcdefghijklmnop")]
```

Requirements

Namespace: SocketTools

Assembly: SocketTools.PopClient (in SocketTools.PopClient.dll)

See Also

PopClient.RuntimeLicenseAttribute Members | SocketTools Namespace

PopClient.RuntimeLicenseAttribute Members

PopClient.RuntimeLicenseAttribute overview

Public Instance Constructors

PopClient.RuntimeLicenseAttribute Constructor	Constructor for the RuntimeLicense attribute which defines the runtime license key.

Public Instance Properties

LicenseKey	Returns the value of the runtime license key.
TypeId (inherited from Attribute)	When implemented in a derived class, gets a unique identifier for this Attribute.

Public Instance Methods

Equals (inherited from Attribute)	
GetHashCode (inherited from Attribute)	Returns the hash code for this instance.
GetType (inherited from Object)	Gets the Type of the current instance.
IsDefaultAttribute (inherited from Attribute)	When overridden in a derived class, returns an indication whether the value of this instance is the default value for the derived class.
Match (inherited from Attribute)	When overridden in a derived class, returns a value indicating whether this instance equals a specified object.
ToString (inherited from Object)	Returns a String that represents the current Object.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

PopClient.RuntimeLicenseAttribute Class | SocketTools Namespace

PopClient.RuntimeLicenseAttribute Constructor

Constructor for the RuntimeLicense attribute which defines the runtime license key.

[Visual Basic]

```
Public Sub New( _
   ByVal licenseKey As String _
)
```

[C#]

```
public PopClient.RuntimeLicenseAttribute(
   string licenseKey
);
```

Parameters

licenseKey

A string argument which specifies the runtime license key which will be used to initialize the class library.

Remarks

The runtime license key for your copy of SocketTools can be generated using the License Manager utility that is included with the product. Note that if you have installed an evaluation license, you will not have a runtime license key and cannot redistribute any applications which use the PopClient class.

See Also

PopClient.RuntimeLicenseAttribute Class | SocketTools Namespace

PopClient.RuntimeLicenseAttribute Properties

The properties of the **PopClient.RuntimeLicenseAttribute** class are listed below. For a complete list of **PopClient.RuntimeLicenseAttribute** class members, see the PopClient.RuntimeLicenseAttribute Members topic.

Public Instance Properties

LicenseKey	Returns the value of the runtime license key.
TypeId (inherited from Attribute)	When implemented in a derived class, gets a unique identifier for this Attribute.

See Also

PopClient.RuntimeLicenseAttribute Class | SocketTools Namespace

PopClient.RuntimeLicenseAttribute.LicenseKey Property

Returns the value of the runtime license key.

[Visual Basic]
```
Public Property LicenseKey As String
```

[C#]
```
public string LicenseKey {get; set;}
```

Property Value

A string which contains the runtime license key.

See Also

PopClient.RuntimeLicenseAttribute Class | SocketTools Namespace

RshClient Class

Implements the Remote Shell and Remote Login protocols.

For a list of all members of this type, see RshClient Members.

System.Object
  SocketTools.RshClient

[Visual Basic]
```
Public Class RshClient
    Implements IDisposable
```

[C#]
```
public class RshClient : IDisposable
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

The RshClient class is used to execute a command on a server and return the output of that command to the client. This is most commonly used with UNIX based servers, although there are implementations of remote command servers for the Windows operating system. The class supports both the rsh and rshell remote execution protocols and provides functions which can be used to search the data stream for specific sequences of characters. This makes it extremely easy to write Windows applications which serve as light-weight client interfaces to commands being executed on a UNIX server or another Windows system. The class can also be used to establish a remote terminal session using the rlogin protocol, which is similar to how the Telnet protocol functions.

Requirements

Namespace: SocketTools

Assembly: SocketTools.RshClient (in SocketTools.RshClient.dll)

See Also

RshClient Members | SocketTools Namespace

RshClient Members

RshClient overview

Public Static (Shared) Fields

rshPortExecute	A constant value which specifies the default port number for the rexec service.
rshPortLogin	A constant value which specifies the default port number for the rlogin service.
rshPortShell	A constant value which specifies the default port number for the rshell service.
rshTimeout	A constant value which specifies the default timeout period.

Public Instance Constructors

RshClient Constructor	Initializes a new instance of the RshClient class.

Public Instance Properties

AutoResolve	Gets and sets a value that determines if host names and addresses are automatically resolved.
Blocking	Gets and sets a value which indicates if the client is in blocking mode.
CodePage	Gets and sets the code page used when reading and writing text.
Command	Gets and sets a value which specifies the command to be executed on the remote host.
HostAddress	Gets and sets a value which specifies the Internet address used to establish a connection.
HostName	Gets and sets a value which specifies the host name used to establish a connection.
IsBlocked	Gets a value which indicates if the current thread is performing a blocking client operation.
IsConnected	Gets a value which indicates if a connection to the remote host has been established.
IsInitialized	Gets a value which indicates if the current instance of the class has been initialized successfully.
IsReadable	Gets a value which indicates if there is data available to be read from the socket connection to the server.
IsWritable	Gets a value which indicates if data can be written to the client without blocking.
LastError	Gets and sets a value which specifies the last error that has occurred.

LastErrorString	Gets a value which describes the last error that has occurred.
LocalAddress	Gets the local Internet address that the client is bound to.
LocalName	Gets a value which specifies the host name for the local system.
LocalPort	Gets the local port number the client is bound to.
Options	Gets and sets a value which specifies one or more client options.
Password	Gets and sets the password used to authenticate the client session.
RemotePort	Gets and sets a value which specifies the remote port number.
RemoteService	Gets and sets a value which specifies the remote service.
Status	Gets a value which specifies the current status of the client.
Terminal	Gets and sets the terminal type used for a remote login session.
ThreadModel	Gets and sets a value which specifies the threading model for the class instance.
ThrowError	Gets and sets a value which specifies if method calls should throw exceptions when an error occurs.
Timeout	Gets and sets a value which specifies a timeout period in seconds.
Trace	Gets and sets a value which indicates if network function logging is enabled.
TraceFile	Gets and sets a value which specifies the name of the logfile.
TraceFlags	Gets and sets a value which specifies the client function tracing flags.
UserName	Gets and sets the username used to authenticate the client session.
Version	Gets a value which returns the current version of the RshClient class library.

Public Instance Methods

AttachThread	Attach an instance of the class to the current thread
Cancel	Cancel the current blocking client operation.
Disconnect	Terminate the connection with a remote host.

Dispose	Overloaded. Releases all resources used by RshClient.
Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
Execute	Overloaded. Execute the specified command on the remote host.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from Object)	Gets the Type of the current instance.
Initialize	Overloaded. Initialize an instance of the RshClient class.
Login	Overloaded. Establish an interactive terminal session for the specified user.
Read	Overloaded. Read data from the server and store it in a byte array.
Reset	Reset the internal state of the object, resetting all properties to their default values.
Search	Overloaded. Search for a specific character sequence in the data stream.
ToString (inherited from Object)	Returns a String that represents the current Object.
Uninitialize	Uninitialize the class library and release any resources allocated for the current thread.
Write	Overloaded. Write one or more bytes of data to the server.

Public Instance Events

OnCancel	Occurs when a blocking client operation is canceled.
OnConnect	Occurs when a connection is established with the remote host.
OnDisconnect	Occurs when the remote host disconnects from the local system.
OnError	Occurs when an client operation fails.
OnRead	Occurs when data is available to be read from the client.
OnTimeout	Occurs when a blocking operation fails to complete before the timeout period elapses.
OnWrite	Occurs when data can be written to the client.

Protected Instance Methods

Dispose	Overloaded. Releases the unmanaged resources allocated by the RshClient class and optionally

	releases the managed resources.
Finalize	Destroys an instance of the class, releasing the resources allocated for the session and unloading the networking library.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

Trace	Gets and sets a value which indicates if network function logging is enabled.
TraceFile	Gets and sets a value which specifies the name of the logfile.
TraceFlags	Gets and sets a value which specifies the client function tracing flags.
UserName	Gets and sets the username used to authenticate the client session.
Version	Gets a value which returns the current version of the RshClient class library.

See Also

RshClient Class | SocketTools Namespace

RshClient.AutoResolve Property

Gets and sets a value that determines if host names and addresses are automatically resolved.

[Visual Basic]
```
Public Property AutoResolve As Boolean
```

[C#]
```
public bool AutoResolve {get; set;}
```

Property Value

Returns **true** if host names are automatically resolved to Internet addresses. The default value is **false**.

Remarks

Setting the **AutoResolve** property determines if the class automatically resolves host names and addresses specified by the **HostName** and **HostAddress** properties. If set to **true**, setting the **HostName** property will cause the class to automatically determine the corresponding IP address and update the **HostAddress** property accordingly. Likewise, setting the **HostAddress** property will cause the class to determine the host name and update the **HostName** property. Setting this property to **false** prevents the class from resolving host names until a connection attempt is made.

It is important to note that setting the **HostName** or **HostAddress** property may cause the current thread to block, sometimes for several seconds, until the name or address is resolved. To prevent this behavior, set this property value to **false**.

See Also

RshClient Class | SocketTools Namespace

RshClient.Blocking Property

Gets and sets a value which indicates if the client is in blocking mode.

[Visual Basic]

```
Public Property Blocking As Boolean
```

[C#]

```
public bool Blocking {get; set;}
```

Property Value

Returns **true** if the client is in blocking mode; otherwise it returns **false**. The default value is **true**.

Remarks

Setting the **Blocking** property determines if client operations complete synchronously or asynchronously. If set to **true**, then each client operation (such as sending or receiving data) will return when the operation has completed or timed-out. If set to **false**, client operations will return immediately. If the operation would result in the client blocking (such as attempting to read data when no data has been sent by the remote host), an error is generated.

It is important to note that certain events, such as **OnDisconnect, OnRead** and **OnWrite** are only fired if the client is in non-blocking mode.

See Also

RshClient Class | SocketTools Namespace

RshClient.CodePage Property

Gets and sets the code page used when reading and writing text.

[Visual Basic]

```
Public Property CodePage As Integer
```

[C#]

```
public int CodePage {get; set;}
```

Property Value

An integer value which specifies the current code page. A value of zero specifies the default code page for the current locale should be used. To preserve the original Unicode text, you can use code page 65001 which specifies UTF-8 character encoding.

Remarks

All data which is exchanged over a socket is sent and received as 8-bit bytes, typically referred to as "octets" in networking terminology. However, strings in .NET are Unicode where each character is represented by 16 bits. To send and receive data using strings, these Unicode strings are converted to a stream of bytes.

By default, strings are converted to an array of bytes using the code page for the current locale, mapping the 16-bit Unicode characters to bytes. Similarly, when reading data from the socket into a string buffer, the stream of bytes received from the remote host are converted to Unicode before they are returned to your application.

If you are exchanging text with another system and it appears to corrupted or characters are being replaced with question marks or other symbols, it is likely the system is sending text which is using a different character encoding. Most services use UTF-8 encoding to represent non-ASCII characters and selecting the UTF-8 code page will typically resolve the issue.

Strings are only guaranteed to be safe when sending and receiving text. Using a string data type is not recommended when reading or writing binary data to a socket. If possible, you should always use a byte array as the buffer parameter for the Read and Write methods whenever you are exchanging binary data.

For backwards compatibility, this class defaults to using the code page for the current locale. This property value directly corresponds to Windows code page identifiers, and will accept any valid code page supported by the .NET Framework. Setting this property to an invalid code page will generate an exception.

See Also

RshClient Class | SocketTools Namespace

RshClient.HostAddress Property

Gets and sets a value which specifies the Internet address used to establish a connection.

[Visual Basic]

```
Public Property HostAddress As String
```

[C#]

```
public string HostAddress {get; set;}
```

Property Value

A string which specifies an Internet address.

Remarks

The **HostAddress** property can be used to set the Internet address for a remote system that you wish to communicate with. If the **AutoResolve** property is set to **true** and the address is assigned to a valid host name, the **HostName** property will be updated with that value.

See Also

RshClient Class | SocketTools Namespace

RshClient.HostName Property

Gets and sets a value which specifies the host name used to establish a connection.

[Visual Basic]

```
Public Property HostName As String
```

[C#]

```
public string HostName {get; set;}
```

Property Value

A string which specifies a host name.

Remarks

The **HostName** property can be used to set the host name for a remote system that you wish to communicate with. If the **AutoResolve** property is set to **true** and the name can be resolved to a valid Internet address, the **HostAddress** property will be updated with that value.

See Also

RshClient Class | SocketTools Namespace

RshClient.IsBlocked Property

Gets a value which indicates if the current thread is performing a blocking client operation.

[Visual Basic]
```
Public ReadOnly Property IsBlocked As Boolean
```

[C#]
```
public bool IsBlocked {get;}
```

Property Value

Returns **true** if the current thread is blocking, otherwise returns **false**.

Remarks

The **IsBlocked** property returns **true** if the current thread is blocked performing an operation. Because the Windows Sockets API only permits one blocking operation per thread of execution, this property should be checked before starting any blocking operation in response to an event.

If the **IsBlocked** property returns **false**, this means there are no blocking operations on the current thread at that time. However, this does not guarantee that the next client operation will not fail. An application should always check the return value from a client operation and check the value of the **LastError** property if an error occurs.

Note that this property will return **true** if there is any blocking operation being performed by the current thread, regardless of whether this specific instance of the class is responsible for the blocking operation or not.

See Also

RshClient Class | SocketTools Namespace

RshClient.IsConnected Property

Gets a value which indicates if a connection to the remote host has been established.

[Visual Basic]

```
Public ReadOnly Property IsConnected As Boolean
```

[C#]

```
public bool IsConnected {get;}
```

Property Value

Returns **true** if the connection has been established; otherwise returns **false**.

Remarks

The **IsConnected** property can only be used to indicate if there is still a logical connection to the remote host. It cannot be used to detect abnormal conditions such as the remote host aborting the connection, the physical network connection being lost or other critical errors.

See Also

RshClient Class | SocketTools Namespace

RshClient.IsInitialized Property

Gets a value which indicates if the current instance of the class has been initialized successfully.

[Visual Basic]

```
Public ReadOnly Property IsInitialized As Boolean
```

[C#]

```
public bool IsInitialized {get;}
```

Property Value

Returns **true** if the class instance has been initialized; otherwise returns **false**.

Remarks

The **IsInitialized** property is used to determine if the current instance of the class has been initialized properly. Normally this is done automatically by the class constructor, however there are circumstances where the class may not be able to initialize itself.

The most common reasons that a class instance may not initialize correctly is that no runtime license key has been defined in the assembly or the license key provided is invalid. It may also indicate a problem with the system configuration or user access rights, such as not being able to load the required networking libraries or not being able to access the system registry.

See Also

RshClient Class | SocketTools Namespace

RshClient.IsReadable Property

Gets a value which indicates if there is data available to be read from the socket connection to the server.

[Visual Basic]

```
Public ReadOnly Property IsReadable As Boolean
```

[C#]

```
public bool IsReadable {get;}
```

Property Value

Returns **true** if there is data available to be read; otherwise returns **false**.

Remarks

The **IsReadable** property returns **true** if data can be read from the client without blocking. For non-blocking sessions, this property can be checked before the application attempts to read the client. Note that even if this property does return **true** indicating that there is data available to be read, applications should always check the return value from the **Read** method.

See Also

RshClient Class | SocketTools Namespace

RshClient.IsWritable Property

Gets a value which indicates if data can be written to the client without blocking.

[Visual Basic]

```
Public ReadOnly Property IsWritable As Boolean
```

[C#]

```
public bool IsWritable {get;}
```

Property Value

Returns **true** if data can be written to the client; otherwise returns **false**.

Remarks

The **IsWritable** property returns **true** if data can be written to the client without blocking. For non-blocking sessions, this property can be checked before the application attempts to write data to the client. Note that even if this property does return **true** indicating that data can be written to the client, applications should always check the return value from the **Write** method.

See Also

RshClient Class | SocketTools Namespace

RshClient.LastError Property

Gets and sets a value which specifies the last error that has occurred.

[Visual Basic]
```
Public Property LastError As ErrorCode
```

[C#]
```
public RshClient.ErrorCode LastError {get; set;}
```

Property Value

Returns an ErrorCode enumeration value which specifies the last error code.

Remarks

The **LastError** property returns the error code associated with the last error that occurred for the current instance of the class. It is important to note that this value only has meaning if the previous method indicates that an error has actually occurred.

It is possible to explicitly clear the last error code by assigning the property to the value **ErrorCode.errorNone**.

The error code value can be cast to an integer value for display purposes if required. For a description of the error that can be displayed using a message box or some other similar mechanism, get the value of the **LastErrorString** property.

See Also

RshClient Class | SocketTools Namespace

RshClient.LastErrorString Property

Gets a value which describes the last error that has occurred.

[Visual Basic]

```
Public ReadOnly Property LastErrorString As String
```

[C#]

```
public string LastErrorString {get;}
```

Property Value

A string which describes the last error that has occurred.

Remarks

The **LastErrorString** property can be used to obtain a description of the last error that occurred for the current instance of the class. It is important to note that this value only has meaning if the previous method indicates that an error has actually occurred.

See Also

RshClient Class | SocketTools Namespace

RshClient.LocalAddress Property

Gets the local Internet address that the client is bound to.

[Visual Basic]
```
Public ReadOnly Property LocalAddress As String
```

[C#]
```
public string LocalAddress {get;}
```

Property Value

A string which specifies an Internet address.

Remarks

The **LocalAddress** property returns the local Internet address that the client is bound to when a connection is established with a remote host. This property may return either an IPv4 or IPv6 formatted address, depending on the type of connection that was established.

RshClient Class | SocketTools Namespace

RshClient.LocalName Property

Gets a value which specifies the host name for the local system.

[Visual Basic]
```
Public ReadOnly Property LocalName As String
```

[C#]
```
public string LocalName {get;}
```

Property Value

A string which specifies the local host name.

Remarks

The **LocalName** property returns the fully-qualified host name assigned to the local system. If the system has not been configured with an Internet domain name, then this property will return the NetBIOS name assigned to the local system.

See Also

RshClient Class | SocketTools Namespace

RshClient.LocalPort Property

Gets the local port number the client is bound to.

[Visual Basic]
```
Public ReadOnly Property LocalPort As Integer
```

[C#]
```
public int LocalPort {get;}
```

Property Value

An integer value which specifies a port number. The default value is 0.

Remarks

The **LocalPort** property is used to identify the local port number that the client is bound to to when a connection is established with a remote host.

See Also

RshClient Class | SocketTools Namespace

RshClient.Options Property

Gets and sets a value which specifies one or more client options.

[Visual Basic]

```
Public Property Options As RemoteOptions
```

[C#]

```
public RshClient.RemoteOptions Options {get; set;}
```

Property Value

Returns one or more RemoteOptions enumeration flags which specify the options for the client. The default value for this property is **rshOptionNone**.

Remarks

The **Options** property specifies one or more default options options which are used when establishing a connection using the **Connect** method.

See Also

RshClient Class | SocketTools Namespace

RshClient.Password Property

Gets and sets the password used to authenticate the client session.

[Visual Basic]
```
Public Property Password As String
```

[C#]
```
public string Password {get; set;}
```

Property Value

A string which specifies the password.

Remarks

If a password is not specified when the **Execute** method is called, the value of this property will be used as the default password when establishing a connection with the server.

See Also

RshClient Class | SocketTools Namespace

RshClient.RemotePort Property

Gets and sets a value which specifies the remote port number.

[Visual Basic]

```
Public Property RemotePort As Integer
```

[C#]

```
public int RemotePort {get; set;}
```

Property Value

An integer value which specifies a port number.

Remarks

The **RemotePort** property is used to set the port number that will be used to establish a connection with a remote host. If the port number specifies a well-known port, the **RemoteService** property will be updated with that name.

See Also

RshClient Class | SocketTools Namespace

RshClient.Status Property

Gets a value which specifies the current status of the client.

[Visual Basic]

```
Public ReadOnly Property Status As RemoteStatus
```

[C#]

```
public RshClient.RemoteStatus Status {get;}
```

Property Value

A RemoteStatus enumeration value which specifies the current client status.

Remarks

The **Status** property returns the current status of the client. This property can be used to check on blocking connections to determine if the client is interacting with the remote host before taking some action.

See Also

RshClient Class | SocketTools Namespace

RshClient.Terminal Property

Gets and sets the terminal type used for a remote login session.

[Visual Basic]

```
Public Property Terminal As String
```

[C#]

```
public string Terminal {get; set;}
```

Property Value

A string which specifies the terminal type.

Remarks

The **Terminal** property specifies the terminal type of the remote host for display purposes. On UNIX based systems, the terminal name corresponds to a termcap or terminfo entry as set in the TERM environment variable. On Windows based systems which implement the rlogin service, this property may be ignored and the server will assume that the client is capable of displaying ANSI escape sequences. On VMS systems, the terminal name should correspond to the terminal type used with the SET TERMINAL/DEVICE command.

If this property is set to an empty string and no terminal type is specified when the **Login** method is called, a default terminal type named "unknown" will be used. On most UNIX and VMS systems this defines a terminal which is not capable of cursor positioning using control or escape sequences. This terminal type may not be recognized and an error may be displayed when the user logs in indicating that the terminal type is invalid.

Refer to the documentation for the server system to determine what terminal type names are available to you. Remember that on UNIX systems, the terminal type is case-sensitive. Some of the more common terminal types are:

Terminal	Description
ansi	This terminal type is usually available on UNIX based servers. This specifies that the client is capable of displaying standard ANSI escape sequences for cursor control.
dumb	This terminal type typically specifies a terminal display which does not support control or escape sequences for cursor positioning. If you do not want escape sequences embedded in the data stream and the server returns an error if the terminal type is not specified, try using this terminal type.
pcansi	This terminal type is usually available on UNIX based servers. This specifies that the client is a using a PC terminal emulator that supports basic ANSI escape sequences for cursor control. This may also enable escape sequences which can set the display colors.
vt100	This terminal type is usually available on UNIX and VMS based servers. On some VMS systems this

	string may need to be specified as DEC-VT100. This specifies that the client is capable of emulating a DEC VT100 terminal. The VT100 supports many of the same cursor control sequences as an ANSI terminal.
vt220	This terminal type is usually available on UNIX and VMS based servers. On some VMS systems this string may need to be specified as DEC-VT220. This specifies that the client is capable of emulating a DEC VT220 terminal, which is a later version of the VT100.
vt320	This terminal type is usually available on UNIX and VMS based servers. On some VMS systems this string may need to be specified as DEC-VT320. This specifies that the client is capable of emulating a DEC VT320 terminal, which is similar to the VT100 and VT220 and provides advanced features such as the ability to set display colors.
xterm	This terminal type is may be available on UNIX based servers which have X Windows installed. This specifies that the client is a using the X Windows xterm emulator which supports standard ANSI escape sequences for cursor control.

RshClient Class | SocketTools Namespace

RshClient.ThreadModel Property

Gets and sets a value which specifies the threading model for the class instance.

[Visual Basic]
```
Public Property ThreadModel As ThreadingModel
```

[C#]
```
public RshClient.ThreadingModel ThreadModel {get; set;}
```

Property Value

Returns one or more ThreadingModel enumeration value which specifies the threading model for the client. The default value for this property is **modelSingleThread**.

Remarks

The **ThreadModel** property specifies the threading model that is used by the class instance when a connection is established. The default value for this property is **modelSingleThread**, which specifies that only the thread that established the connection should be permitted to invoke methods. It is important to note that this threading model does not limit the application to a single thread of execution. When a session is established using the **Connect** method, that session is attached to the thread that created it. From that point on, until the session is terminated, only the owner may invoke methods in that instance of the class. The ownership of the class instance may be transferred from one thread to another using the **AttachThread** method.

Setting this property to **modelFreeThread** disables certain internal safety checks that are performed by the class and may result in unexpected behavior unless you ensure that access to the class instance is synchronized across multiple threads. The application must ensure that no two threads will attempt to invoke a blocking method at the same time. In other words, if one thread invokes a method, the application must ensure that another thread will not attempt to invoke any other method at the same time using the same instance of the class.

Changing the value of this property will not affect an active client session. The threading model must be specified prior to invoking the **Connect** method.

See Also

RshClient Class | SocketTools Namespace | AttachThread Method | ThreadingModel Enumeration | ThreadModel Attribute

RshClient.ThrowError Property

Gets and sets a value which specifies if method calls should throw exceptions when an error occurs.

[Visual Basic]
```
Public Property ThrowError As Boolean
```

[C#]
```
public bool ThrowError {get; set;}
```

Property Value

Returns **true** if method calls will generate exceptions when an error occurs; otherwise returns **false**. The default value is **false**.

Remarks

Error handling for when calling class methods can be done in either of two different styles, according to the value of this property.

If the **ThrowError** property is set to **false**, the application should check the return value of any method that is used, and report errors based upon the documented value of the return code. It is the responsibility of the application to interpret the error code, if it is desired to explain the error in addition to reporting it. This is the default behavior.

If the **ThrowError** property is set to **true**, then exceptions will be generated whenever a method call fails. The program must be written to catch these exceptions and take the appropriate action when an error occurs. Failure to handle an exception will cause the program to terminate abnormally.

Note that if an error occurs while a property is being read or modified, an exception will be raised regardless of the value of the **ThrowError** property.

See Also

RshClient Class | SocketTools Namespace

RshClient.Timeout Property

Gets and sets a value which specifies a timeout period in seconds.

[Visual Basic]

```
Public Property Timeout As Integer
```

[C#]

```
public int Timeout {get; set;}
```

Property Value

An integer value which specifies a timeout period in seconds.

Remarks

Setting the **Timeout** property specifies the number of seconds until a blocking operation fails and returns an error.

The timeout period is only used when the client is in blocking mode. Although this property can be changed when the client is in non-blocking mode, the value will be ignored until the client is returned to blocking mode.

For most applications it is recommended the timeout period be set between 10 and 20 seconds.

See Also

RshClient Class | SocketTools Namespace

RshClient.Trace Property

Gets and sets a value which indicates if network function logging is enabled.

[Visual Basic]

```
Public Property Trace As Boolean
```

[C#]

```
public bool Trace {get; set;}
```

Property Value

Returns **true** if network function tracing is enabled; otherwise returns **false**. The default value is **false**.

Remarks

The **Trace** property is used to enable (or disable) the tracing of network function calls. When enabled, each function call is logged to a file, including the function parameters, return value and error code if applicable. This facility can be enabled and disabled at run time, and the trace log file can be specified by setting the **TraceFile** property. All function calls that are being logged are appended to the trace file, if it exists. If no trace file exists when tracing is enabled, the trace file is created.

The tracing facility is available in all of the SocketTools networking classes and is enabled or disabled for an entire process. This means that once trace logging is enabled for a given component, all of the function calls made by the process using any of the SocketTools classes will be logged. For example, if you have an application using both the File Transfer Protocol and Post Office Protocol classes, and you set the **Trace** property to **true**, function calls made by both classes will be logged. Additionally, enabling a trace is cumulative, and tracing is not stopped until it is disabled for all classes used by the process.

If trace logging is not enabled, there is no negative impact on performance or throughput. Once enabled, application performance can degrade, especially in those situations in which multiple processes are being traced or the logfile is fairly large. Since logfiles can grow very quickly, even with modest applications, it is recommended that you delete the file when it is no longer needed.

When redistributing your application, make sure that you include the **SocketTools10.TraceLog.dll** module with your installation. If this library is not present, then no trace output will be generated and the value of the **Trace** property will be ignored. Only those function calls made by the SocketTools networking classes will be logged. Calls made directly to the Windows Sockets API, or calls made by other classes, will not be logged.

See Also

RshClient Class | SocketTools Namespace

RshClient.TraceFile Property

Gets and sets a value which specifies the name of the logfile.

[Visual Basic]

```
Public Property TraceFile As String
```

[C#]

```
public string TraceFile {get; set;}
```

Property Value

A string which specifies the name of the file.

Remarks

The **TraceFile** property is used to specify the name of the trace file that is created when network function tracing is enabled. If this property is set to an empty string (the default value), then a file named **SocketTools.log** is created in the system's temporary directory. If no temporary directory exists, then the file is created in the current working directory.

If the file exists, the trace output is appended to the file, otherwise the file is created. Since network function tracing is enabled per-process, the trace file is shared by all instances of the class being used. If multiple class instances have tracing enabled, the **TraceFile** property should be set to the same value for each instance. Since trace files can grow very quickly, even with modest applications, it is recommended that you delete the file when it is no longer needed.

The trace file has the following format:

```
 MyApp INF: WSAAsyncSelect(46, 0xcc4, 0x7e9, 0x27) returned 0 MyApp WRN:
connect(46, 192.0.0.1:1234, 16) returned -1 [10035] MyApp ERR: accept(46,
NULL, 0x0) returned -1 [10038]
```

The first column contains the name of the process that is being traced. The second column identifies if the trace record is reporting information, a warning, or an error. What follows is the name of the function being called, the arguments passed to the function and the function's return value. If a warning or error is reported, the error code is appended to the record (the value is placed inside brackets).

If parameters are passed as integer values, they are recorded in decimal. If the parameter or return value is a pointer (a memory address), it is recorded as a hexadecimal value preceded with "0x". A special type of pointer, called a null pointer, is recorded as NULL. Those functions which expect socket addresses are displayed in the following format:

```
aa.bb.cc.dd:nnnn
```

The first four numbers separated by periods represent the IP address, and the number following the colon represents the port number in host byte order. Note that in the second line of the above example, the control is attempting to connect to a system with the IP address 192.0.0.1 on port 1234.

Note that if the specified file cannot be created, or the user does not have permission to modify an existing file, the error is silently ignored and no trace output will be generated.

See Also

RshClient Class | SocketTools Namespace

RshClient.TraceFlags Property

Gets and sets a value which specifies the client function tracing flags.

[Visual Basic]

```
Public Property TraceFlags As TraceOptions
```

[C#]

```
public RshClient.TraceOptions TraceFlags {get; set;}
```

Property Value

A TraceOptions enumeration which specifies the amount of detail written to the trace logfile.

Remarks

The **TraceFlags** property is used to specify the type of information written to the trace file when network function tracing is enabled.

Because network function tracing is enabled per-process, the trace flags are shared by all instances of the class being used. If multiple class instances have tracing enabled, the **TraceFlags** property should be set to the same value for each instance. Changing the trace flags for any one instance of the class will affect the logging performed for all SocketTools classes used by the application.

Warnings are generated when a non-fatal error is returned by a network function. For example, if data is being written and the error **errorOperationWouldBlock** occurs, a warning is generated because the application simply needs to attempt to write the data at a later time.

See Also

RshClient Class | SocketTools Namespace

RshClient.UserName Property

Gets and sets the username used to authenticate the client session.

[Visual Basic]

```
Public Property UserName As String
```

[C#]

```
public string UserName {get; set;}
```

Property Value

A string which specifies the username.

Remarks

If a username is not specified when the **Execute** or **Login** method is called, the value of this property will be used as the default username when establishing a connection with the server.

See Also

RshClient Class | SocketTools Namespace

RshClient.Version Property

Gets a value which returns the current version of the RshClient class library.

[Visual Basic]
```
Public ReadOnly Property Version As String
```

[C#]
```
public string Version {get;}
```

Property Value

A string which specifies the version of the class library.

Remarks

The **Version** property returns a string which identifies the current version and build of the RshClient class library. This value can be used by an application for validation and debugging purposes.

See Also

RshClient Class | SocketTools Namespace

RshClient Methods

The methods of the **RshClient** class are listed below. For a complete list of **RshClient** class members, see the RshClient Members topic.

Public Instance Methods

AttachThread	Attach an instance of the class to the current thread
Cancel	Cancel the current blocking client operation.
Disconnect	Terminate the connection with a remote host.
Dispose	Overloaded. Releases all resources used by RshClient.
Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
Execute	Overloaded. Execute the specified command on the remote host.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from Object)	Gets the Type of the current instance.
Initialize	Overloaded. Initialize an instance of the RshClient class.
Login	Overloaded. Establish an interactive terminal session for the specified user.
Read	Overloaded. Read data from the server and store it in a byte array.
Reset	Reset the internal state of the object, resetting all properties to their default values.
Search	Overloaded. Search for a specific character sequence in the data stream.
ToString (inherited from Object)	Returns a String that represents the current Object.
Uninitialize	Uninitialize the class library and release any resources allocated for the current thread.
Write	Overloaded. Write one or more bytes of data to the server.

Protected Instance Methods

Dispose	Overloaded. Releases the unmanaged resources allocated by the RshClient class and optionally releases the managed resources.
Finalize	Destroys an instance of the class, releasing the resources allocated for the session and unloading the networking library.

MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

RshClient Class | SocketTools Namespace

RshClient.AttachThread Method

Attach an instance of the class to the current thread

[Visual Basic]
```
Public Function AttachThread() As Boolean
```

[C#]
```
public bool AttachThread();
```

Return Value

A boolean value which specifies if the client could be attached to the current thread. If this method returns **false**, the client could not be attached to the thread and the application should check the value of the LastError property to determine the cause of the failure.

Remarks

When an instance of the class is created it is associated with the current thread that created it. Normally, if another thread attempts to perform an operation using that instance, an error is returned. This is used to ensure that other threads cannot interfere with an operation being performed by the owner thread. In some cases, it may be desirable for one thread in an application to create an instance of the class, establish a connection and then pass that instance to another worker thread. The **AttachThread** method can be used to change the ownership of the class instance to the new worker thread.

This method should be called by the new thread immediately after it has been created, and if the new thread does not release the handle itself, the ownership of the handle should be restored by the original thread. Under no circumstances should **AttachThread** be used to forcibly destroy an instance of a class allocated by another thread while a blocking operation is in progress. To cancel a blocking operation, use the **Cancel** method and then delete the class instance after the blocking function exits and control is returned to the current thread.

See Also

RshClient Class | SocketTools Namespace

RshClient.Cancel Method

Cancel the current blocking client operation.

[Visual Basic]

```
Public Sub Cancel()
```

[C#]

```
public void Cancel();
```

Remarks

When the **Cancel** method is called, the blocking client operation will not immediately fail. An internal flag is set which causes the blocking operation to exit with an error. This means that the application cannot cancel an operation and immediately perform some other blocking function. Instead it must allow the calling stack to unwind, returning back to the blocking operation before making any further function calls.

See Also

RshClient Class | SocketTools Namespace

RshClient.Disconnect Method

Terminate the connection with a remote host.

[Visual Basic]

```
Public Sub Disconnect()
```

[C#]

```
public void Disconnect();
```

Remarks

The **Disconnect** method terminates the connection with the remote host and releases the client handle allocated by the class. Note that the socket is not immediately released when the connection is terminated and will enter a wait state for two minutes. After the time wait period has elapsed, the client will be released by the operating system. This is a normal safety mechanism to handle any packets that may arrive after the connection has been closed.

See Also

RshClient Class | SocketTools Namespace

RshClient.Dispose Method

Releases all resources used by RshClient.

Overload List

Releases all resources used by RshClient.

```
public void Dispose();
```

Releases the unmanaged resources allocated by the RshClient class and optionally releases the managed resources.

```
protected virtual void Dispose(bool);
```

See Also

RshClient Class | SocketTools Namespace

RshClient.Dispose Method ()

Releases all resources used by RshClient.

[Visual Basic]

```
NotOverridable Overloads Public Sub Dispose() _
    Implements IDisposable.Dispose
```

[C#]

```
public void Dispose();
```

Implements

IDisposable.Dispose

Remarks

The **Dispose** method terminates any active connection and explicitly releases the resources allocated for this instance of the class. In some cases, better performance can be achieved if the programmer explicitly releases resources when they are no longer being used. The **Dispose** method provides explicit control over these resources.

Unlike the **Uninitialize** method, once the **Dispose** method has been called, that instance of the class cannot be re-initialized and you should not attempt to access class properties or invoke any methods. Note that this method can be called even if other references to the object are active.

See Also

RshClient Class | SocketTools Namespace | RshClient.Dispose Overload List

RshClient.Dispose Method (Boolean)

Releases the unmanaged resources allocated by the RshClient class and optionally releases the managed resources.

[Visual Basic]

```
Overridable Overloads Protected Sub Dispose( _
   ByVal disposing As Boolean _
)
```

[C#]

```
protected virtual void Dispose(
   bool disposing
);
```

Parameters

disposing

A boolean value which should be specified as **true** to release both managed and unmanaged resources; **false** to release only unmanaged resources.

Remarks

The **Dispose** method terminates any active connection and explicitly releases the resources allocated for this instance of the class. In some cases, better performance can be achieved if the programmer explicitly releases resources when they are no longer being used. The **Dispose** method provides explicit control over these resources.

Unlike the **Uninitialize** method, once the **Dispose** method has been called, that instance of the class cannot be re-initialized and you should not attempt to access class properties or invoke any methods. Note that this method can be called even if other references to the object are active.

You should call **Dispose** in your derived class when you are finished using the derived class. The **Dispose** method leaves the derived class in an unusable state. After calling **Dispose**, you must release all references to the derived class and the **RshClient** class so the memory they were occupying can be reclaimed by garbage collection.

See Also

RshClient Class | SocketTools Namespace | RshClient.Dispose Overload List

RshClient.Execute Method

Execute the specified command on the remote host.

Overload List

Execute the specified command on the remote host.

public bool Execute();

Execute the specified command on the remote host.

public bool Execute(string);

Execute the specified command on the remote host.

public bool Execute(string,int,string);

Execute the specified command on the remote host.

public bool Execute(string,int,string,string,string);

Execute the specified command on the remote host.

public bool Execute(string,int,string,string,string,int);

Execute the specified command on the remote host.

public bool Execute(string,int,string,string,string,int,RemoteOptions);

Execute the specified command on the remote host.

public bool Execute(string,string);

Execute the specified command on the remote host.

public bool Execute(string,string,string);

Execute the specified command on the remote host.

public bool Execute(string,string,string,string);

See Also

RshClient Class | SocketTools Namespace

RshClient.Execute Method (String, Int32, String)

Execute the specified command on the remote host.

[Visual Basic]

```
Overloads Public Function Execute( _
   ByVal hostName As String, _
   ByVal hostPort As Integer, _
   ByVal command As String _
) As Boolean
```

[C#]

```
public bool Execute(
   string hostName,
   int hostPort,
   string command
);
```

Parameters

hostName

A string which specifies the name of the server to connect to. The string may either be an IP address or a fully qualified domain name.

hostPort

An integer value which specifies the port number to connect to. This method may be used to either connect to the rexec service or the rshell service, and which service is selected depends on the port number provided. One of the following values should be used:

Port	Description
rshPortExec	A connection is established with the server using port 512, the rexec service. This service requires that the client provide a username and password to execute the specified command.
rshPortShell	A connection is established with the server using port 514, the rshell service. This service uses host equivalence to authenticate the user. With host equivalence, the remote server considers the client to be equivalent to itself, and as long as the specified user exists on the remote host, the client is permitted to execute commands on behalf of the user without requiring a password. Host equivalence is configured by the server administrator.

command

An string which specifies the command to be executed on the server.

Return Value

A boolean value which specifies if the connection has been established. If the socket is in blocking mode, a return value of **true** indicates that the connection has completed and the application may send and receive data from the remote host. If the client is in non-blocking mode, a return value of **true** indicates that the socket has been successfully created and the connection is in progress.

When a non-blocking connection has completed, the OnConnect event will be fired. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

Remarks

The **Execute** method executes the specified command on a remote host. Output from the command may be read using the **Read** method. Input can be supplied to the program using the **Write** method. To search for a specific sequence of bytes in the output returned by the server, use the **Search** method.

The value of the **UserName** and **Password** properties specify the username and password that will be used to authenticate the client session. The value of the **Timeout** property specifies the timeout period. The value of the **Options** property specifies the options that will be used when establishing the connection.

See Also

RshClient Class | SocketTools Namespace | RshClient.Execute Overload List

RshClient.Execute Method (String, Int32, String, String, String)

Execute the specified command on the remote host.

[Visual Basic]

```
Overloads Public Function Execute( _
   ByVal hostName As String, _
   ByVal hostPort As Integer, _
   ByVal userName As String, _
   ByVal userPassword As String, _
   ByVal command As String _
) As Boolean
```

[C#]

```
public bool Execute(
   string hostName,
   int hostPort,
   string userName,
   string userPassword,
   string command
);
```

Parameters

hostName

A string which specifies the name of the server to connect to. The string may either be an IP address or a fully qualified domain name.

hostPort

An integer value which specifies the port number to connect to. This method may be used to either connect to the rexec service or the rshell service, and which service is selected depends on the port number provided. One of the following values should be used:

Port	Description
rshPortExec	A connection is established with the server using port 512, the rexec service. This service requires that the client provide a username and password to execute the specified command.
rshPortShell	A connection is established with the server using port 514, the rshell service. This service uses host equivalence to authenticate the user. With host equivalence, the remote server considers the client to be equivalent to itself, and as long as the specified user exists on the remote host, the client is permitted to execute commands on behalf of the user without requiring a password. Host equivalence is configured by the server administrator.

userName

A string which specifies the username which used to authenticate the client session.

userPassword

A string which specifies the password to be used to authenticate the user. A password is only used if the client is connecting to the rexec service. The rshell service uses host equivalence to authenticate the user and this argument will be ignored.

command

An string which specifies the command to be executed on the server.

Return Value

A boolean value which specifies if the connection has been established. If the socket is in blocking mode, a return value of **true** indicates that the connection has completed and the application may send and receive data from the remote host. If the client is in non-blocking mode, a return value of **true** indicates that the socket has been successfully created and the connection is in progress.

When a non-blocking connection has completed, the OnConnect event will be fired. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

Remarks

The **Execute** method executes the specified command on a remote host. Output from the command may be read using the **Read** method. Input can be supplied to the program using the **Write** method. To search for a specific sequence of bytes in the output returned by the server, use the **Search** method.

The value of the **Timeout** property specifies the timeout period. The value of the **Options** property specifies the options that will be used when establishing the connection.

RshClient Class | SocketTools Namespace | RshClient.Execute Overload List

RshClient.Execute Method (String, Int32, String, String, String, Int32)

Execute the specified command on the remote host.

```
[Visual Basic]
Overloads Public Function Execute( _
   ByVal hostName As String, _
   ByVal hostPort As Integer, _
   ByVal userName As String, _
   ByVal userPassword As String, _
   ByVal command As String, _
   ByVal timeout As Integer _
) As Boolean
```

```
[C#]
public bool Execute(
   string hostName,
   int hostPort,
   string userName,
   string userPassword,
   string command,
   int timeout
);
```

Parameters

hostName

A string which specifies the name of the server to connect to. The string may either be an IP address or a fully qualified domain name.

hostPort

An integer value which specifies the port number to connect to. This method may be used to either connect to the rexec service or the rshell service, and which service is selected depends on the port number provided. One of the following values should be used:

Port	Description
rshPortExec	A connection is established with the server using port 512, the rexec service. This service requires that the client provide a username and password to execute the specified command.
rshPortShell	A connection is established with the server using port 514, the rshell service. This service uses host equivalence to authenticate the user. With host equivalence, the remote server considers the client to be equivalent to itself, and as long as the specified user exists on the remote host, the client is permitted to execute commands on behalf of the user without requiring a password. Host equivalence is configured by the server administrator.

userName

A string which specifies the username which used to authenticate the client session.

userPassword

A string which specifies the password to be used to authenticate the user. A password is only used if the client is connecting to the rexec service. The rshell service uses host equivalence to authenticate the user and this argument will be ignored.

command

An string which specifies the command to be executed on the server.

timeout

An integer value that specifies the number of seconds that the method will wait for the connection to complete before failing the operation and returning to the caller. This value is only meaningful for blocking connections.

Return Value

A boolean value which specifies if the connection has been established. If the socket is in blocking mode, a return value of **true** indicates that the connection has completed and the application may send and receive data from the remote host. If the client is in non-blocking mode, a return value of **true** indicates that the socket has been successfully created and the connection is in progress.

When a non-blocking connection has completed, the OnConnect event will be fired. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

Remarks

The **Execute** method executes the specified command on a remote host. Output from the command may be read using the **Read** method. Input can be supplied to the program using the **Write** method. To search for a specific sequence of bytes in the output returned by the server, use the **Search** method.

The value of the **Options** property specifies the options that will be used when establishing the connection.

RshClient Class | SocketTools Namespace | RshClient.Execute Overload List

RshClient.Execute Method (String, Int32, String, String, String, Int32, RemoteOptions)

Execute the specified command on the remote host.

[Visual Basic]

```
Overloads Public Function Execute( _
   ByVal hostName As String, _
   ByVal hostPort As Integer, _
   ByVal userName As String, _
   ByVal userPassword As String, _
   ByVal command As String, _
   ByVal timeout As Integer, _
   ByVal options As RemoteOptions _
) As Boolean
```

[C#]

```
public bool Execute(
   string hostName,
   int hostPort,
   string userName,
   string userPassword,
   string command,
   int timeout,
   RemoteOptions options
);
```

Parameters

hostName

A string which specifies the name of the server to connect to. The string may either be an IP address or a fully qualified domain name.

hostPort

An integer value which specifies the port number to connect to. This method may be used to either connect to the rexec service or the rshell service, and which service is selected depends on the port number provided. One of the following values should be used:

Port	Description
rshPortExec	A connection is established with the server using port 512, the rexec service. This service requires that the client provide a username and password to execute the specified command.
rshPortShell	A connection is established with the server using port 514, the rshell service. This service uses host equivalence to authenticate the user. With host equivalence, the remote server considers the client to be equivalent to itself, and as long as the specified user exists on the remote host, the client is permitted to execute commands on behalf of the user without requiring a password. Host equivalence is configured by the server administrator.

userName

A string which specifies the username which used to authenticate the client session.

userPassword

A string which specifies the password to be used to authenticate the user. A password is only used if the client is connecting to the rexec service. The rshell service uses host equivalence to authenticate the user and this argument will be ignored.

command

An string which specifies the command to be executed on the server.

timeout

An integer value that specifies the number of seconds that the method will wait for the connection to complete before failing the operation and returning to the caller. This value is only meaningful for blocking connections.

options

One or more of the RemoteOptions enumeration flags.

Return Value

A boolean value which specifies if the connection has been established. If the socket is in blocking mode, a return value of **true** indicates that the connection has completed and the application may send and receive data from the remote host. If the client is in non-blocking mode, a return value of **true** indicates that the socket has been successfully created and the connection is in progress.

When a non-blocking connection has completed, the OnConnect event will be fired. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

Remarks

The **Execute** method executes the specified command on a remote host. Output from the command may be read using the **Read** method. Input can be supplied to the program using the **Write** method. To search for a specific sequence of bytes in the output returned by the server, use the **Search** method.

See Also

RshClient.Execute Method (String, String)

Execute the specified command on the remote host.

[Visual Basic]

```
Overloads Public Function Execute( _
   ByVal hostName As String, _
   ByVal command As String _
) As Boolean
```

[C#]

```
public bool Execute(
   string hostName,
   string command
);
```

Parameters

hostName

A string which specifies the name of the server to connect to. The string may either be an IP address or a fully qualified domain name.

command

An string which specifies the command to be executed on the server.

Return Value

A boolean value which specifies if the connection has been established. If the socket is in blocking mode, a return value of **true** indicates that the connection has completed and the application may send and receive data from the remote host. If the client is in non-blocking mode, a return value of **true** indicates that the socket has been successfully created and the connection is in progress.

When a non-blocking connection has completed, the OnConnect event will be fired. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

Remarks

The **Execute** method executes the specified command on a remote host. Output from the command may be read using the **Read** method. Input can be supplied to the program using the **Write** method. To search for a specific sequence of bytes in the output returned by the server, use the **Search** method.

The value of the **RemotePort** property specifies the port number. The value of the **UserName** and **Password** properties specify the username and password that will be used to authenticate the client session. The value of the **Command** property specifies the command that will be executed. The value of the **Timeout** property specifies the timeout period. The value of the **Options** property specifies the options that will be used when establishing the connection.

) As Boolean
```

[C#]

```
public bool Execute(
   string hostName,
   string userName,
   string userPassword,
   string command
);
```

Parameters

hostName

A string which specifies the name of the server to connect to. The string may either be an IP address or a fully qualified domain name.

userName

A string which specifies the username which used to authenticate the client session.

userPassword

A string which specifies the password to be used to authenticate the user. A password is only used if the client is connecting to the rexec service. The rshell service uses host equivalence to authenticate the user and this argument will be ignored.

command

An string which specifies the command to be executed on the server.

Return Value

A boolean value which specifies if the connection has been established. If the socket is in blocking mode, a return value of **true** indicates that the connection has completed and the application may send and receive data from the remote host. If the client is in non-blocking mode, a return value of **true** indicates that the socket has been successfully created and the connection is in progress.

When a non-blocking connection has completed, the OnConnect event will be fired. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

Remarks

RshClient.Finalize Method

Destroys an instance of the class, releasing the resources allocated for the session and unloading the networking library.

[Visual Basic]

```
Overrides Protected Sub Finalize()
```

[C#]

```
protected override void Finalize();
```

See Also

RshClient Class | SocketTools Namespace

RshClient.Initialize Method

Initialize an instance of the RshClient class.

Overload List

Initialize an instance of the RshClient class.

public bool Initialize();

Initialize an instance of the RshClient class.

public bool Initialize(string);

See Also

RshClient Class | SocketTools Namespace | Uninitialize Method

RshClient.Initialize Method ()

Initialize an instance of the RshClient class.

[Visual Basic]

```
Overloads Public Function Initialize() As Boolean
```

[C#]

```
public bool Initialize();
```

Return Value

A boolean value which specifies if the class was initialized successfully.

Remarks

The Initialize method can be used to explicitly initialize an instance of the RshClient class, loading the networking library and allocating resources for the current thread. Typically it is not necessary to explicitly call this method because the instance of the class is initialized by the class constructor. However, if the **Uninitialize** method is called, the class must be re-initialized before any other methods are called.

See Also

RshClient Class | SocketTools Namespace | RshClient.Initialize Overload List | Uninitialize Method

RshClient.Initialize Method (String)

Initialize an instance of the RshClient class.

[Visual Basic]

```
Overloads Public Function Initialize( _
   ByVal licenseKey As String _
) As Boolean
```

[C#]

```
public bool Initialize(
   string licenseKey
);
```

Return Value

A boolean value which specifies if the class was initialized successfully.

Remarks

The Initialize method can be used to explicitly initialize an instance of the RshClient class, loading the networking library and allocating resources for the current thread. Typically an application would define the license key as a custom attribute, however this method can be used to initialize the class directly.

The runtime license key for your copy of SocketTools can be generated using the License Manager utility that is included with the product. Note that if you have installed an evaluation license, you will not have a runtime license key and cannot redistribute any applications which use the RshClient class.

Example

The following example shows how to use the Initialize method to initialize an instance of the class. This example assumes that the license key string has been defined in code.

```
SocketTools.RshClient rshClient = new SocketTools.RshClient();

if (rshClient.Initialize(strLicenseKey) == false)
{
    MessageBox.Show(rshClient.LastErrorString, "Error",
                    MessageBoxButtons.OK, MessageBoxIcon.Exclamation);
    return;
}
```

```
Dim rshClient As New SocketTools.RshClient

If rshClient.Initialize(strLicenseKey) = False Then
    MsgBox(rshClient.LastErrorString, vbIconExclamation)
    Exit Sub
End If
```

RshClient.Login Method

Establish an interactive terminal session for the specified user.

Overload List

Establish an interactive terminal session for the specified user.

public bool Login(string);

Establish an interactive terminal session for the specified user.

public bool Login(string,int);

Establish an interactive terminal session for the specified user.

public bool Login(string,int,string);

Establish an interactive terminal session for the specified user.

public bool Login(string,int,string,int);

Establish an interactive terminal session for the specified user.

public bool Login(string,int,string,string,int);

Establish an interactive terminal session for the specified user.

public bool Login(string,int,string,string,int,RemoteOptions);

Establish an interactive terminal session for the specified user.

public bool Login(string,string);

See Also

RshClient Class | SocketTools Namespace

RshClient.Login Method (String)

Establish an interactive terminal session for the specified user.

[Visual Basic]

```
Overloads Public Function Login( _
   ByVal hostName As String _
) As Boolean
```

[C#]

```
public bool Login(
   string hostName
);
```

Parameters

hostName

A string which specifies the name of the server to connect to. The string may either be an IP address or a fully qualified domain name.

Return Value

A boolean value which specifies if the connection has been established. If the socket is in blocking mode, a return value of **true** indicates that the connection has completed and the application may send and receive data from the remote host. If the client is in non-blocking mode, a return value of **true** indicates that the socket has been successfully created and the connection is in progress.

When a non-blocking connection has completed, the OnConnect event will be fired. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

Remarks

The **Login** method logs the specified user in on the remote host. Note that no password is provided to the remote host. This is because the remote login service uses ***user equivalence***. If the client system is recognized by the remote host as being equivalent, the login will proceed directly. If the client system is not recognized, the server will prompt the user for a password. For more information about user equivalence and the remote login service, refer to your server's operating system documentation.

Output from the command may be read using the **Read** method. Input can be supplied to the program using the **Write** method. To search for a specific sequence of bytes in the output returned by the server, use the **Search** method.

RshClient.Login Method (String, Int32)

Establish an interactive terminal session for the specified user.

[Visual Basic]
```
Overloads Public Function Login( _
   ByVal hostName As String, _
   ByVal hostPort As Integer _
) As Boolean
```

[C#]
```
public bool Login(
   string hostName,
   int hostPort
);
```

Parameters

hostName
A string which specifies the name of the server to connect to. The string may either be an IP address or a fully qualified domain name.

hostPort
An integer value which specifies the port number to connect to. The default port for this service is **rshPortLogin**.

Return Value

A boolean value which specifies if the connection has been established. If the socket is in blocking mode, a return value of **true** indicates that the connection has completed and the application may send and receive data from the remote host. If the client is in non-blocking mode, a return value of **true** indicates that the socket has been successfully created and the connection is in progress.

When a non-blocking connection has completed, the OnConnect event will be fired. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

Remarks

The **Login** method logs the specified user in on the remote host. Note that no password is provided to the remote host. This is because the remote login service uses ***user equivalence***. If the client system is recognized by the remote host as being equivalent, the login will proceed directly. If the client system is not recognized, the server will prompt the user for a password. For more information about user equivalence and the remote login service, refer to your server's operating system documentation.

Output from the command may be read using the **Read** method. Input can be supplied to the program using the **Write** method. To search for a specific sequence of bytes in the output returned by the server, use the **Search** method.

RshClient.Read Method (Byte[])

Read data from the server and store it in a byte array.

[Visual Basic]
```
Overloads Public Function Read( _
   ByVal buffer As Byte() _
) As Integer
```

[C#]
```
public int Read(
   byte[] buffer
);
```

Parameters

buffer

A byte array that the data will be stored in.

Return Value

An integer value which specifies the number of bytes actually read from the server. A return value of zero specifies that the remote host has closed the connection and there is no more data available to be read. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Read** method returns data that has been read from the server, up to the size of the byte array passed to the method. If no data is available to be read, an error will be generated if the client is in non-blocking mode. If the client is in blocking mode, the program will stop until data is received from the server or the connection is closed.

See Also

RshClient Class | SocketTools Namespace | RshClient.Read Overload List

RshClient.Read Method (Byte[], Int32)

Read data from the server and store it in a byte array.

[Visual Basic]

```
Overloads Public Function Read( _
   ByVal buffer As Byte(), _
   ByVal length As Integer _
) As Integer
```

[C#]

```
public int Read(
   byte[] buffer,
   int length
);
```

Parameters

buffer

A byte array that the data will be stored in.

length

An integer value which specifies the maximum number of bytes of data to read. This value cannot be larger than the size of the buffer specified by the caller.

Return Value

An integer value which specifies the number of bytes actually read from the server. A return value of zero specifies that the remote host has closed the connection and there is no more data available to be read. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Read** method returns data that has been read from the server, up to the number of bytes specified. If no data is available to be read, an error will be generated if the client is in non-blocking mode. If the client is in blocking mode, the program will stop until data is received from the server or the connection is closed.

See Also

RshClient Class | SocketTools Namespace | RshClient.Read Overload List

RshClient.Read Method (String)

Read data from the server and store it in a string.

[Visual Basic]

```
Overloads Public Function Read( _
   ByRef buffer As String _
) As Integer
```

[C#]

```
public int Read(
   ref string buffer
);
```

Parameters

buffer

A string that will contain the data read from the client.

Return Value

An integer value which specifies the number of bytes actually read from the server. A return value of zero specifies that the remote host has closed the connection and there is no more data available to be read. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Read** method returns data that has been read from the server, up to a maximum of 4096 bytes. If no data is available to be read, an error will be generated if the client is in non-blocking mode. If the client is in blocking mode, the program will stop until data is received from the server or the connection is closed.

This method should only be used if the remote host is sending data that consists of printable characters. Binary data should be read using the method that accepts a byte array as the buffer parameter.

See Also

RshClient Class | SocketTools Namespace | RshClient.Read Overload List

RshClient.Read Method (String, Int32)

Read data from the server and store it in a string.

[Visual Basic]

```
Overloads Public Function Read( _
   ByRef buffer As String, _
   ByVal length As Integer _
) As Integer
```

[C#]

```
public int Read(
   ref string buffer,
   int length
);
```

Parameters

buffer

A string that will contain the data read from the client.

length

An integer value which specifies the maximum number of bytes of data to read.

Return Value

An integer value which specifies the number of bytes actually read from the server. A return value of zero specifies that the remote host has closed the connection and there is no more data available to be read. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Read** method returns data that has been read from the server, up to the number of bytes specified. If no data is available to be read, an error will be generated if the client is in non-blocking mode. If the client is in blocking mode, the program will stop until data is received from the server or the connection is closed.

This method should only be used if the remote host is sending data that consists of printable characters. Binary data should be read using the method that accepts a byte array as the buffer parameter.

RshClient Class | SocketTools Namespace | RshClient.Read Overload List

RshClient.Reset Method

Reset the internal state of the object, resetting all properties to their default values.

[Visual Basic]

```
Public Sub Reset()
```

[C#]

```
public void Reset();
```

Remarks

The **Reset** method returns the object to its default state. If a socket has been allocated, it will be released and any active connections will be terminated. All properties will be reset to their default values.

RshClient Class | SocketTools Namespace

RshClient.Search Method

Search for a specific character sequence in the data stream.

Overload List

Search for a specific character sequence in the data stream.

public bool Search(string);

Search for a specific character sequence in the data stream.

public bool Search(string,byte[],ref int);

Search for a specific character sequence in the data stream.

public bool Search(string,ref string);

See Also

RshClient Class | SocketTools Namespace

RshClient.Search Method (String)

Search for a specific character sequence in the data stream.

[Visual Basic]

```
Overloads Public Function Search( _
   ByVal value As String _
) As Boolean
```

[C#]

```
public bool Search(
   string value
);
```

Parameters

value

A string argument which specifies the sequence of characters to search for in the data stream. When this sequence of characters is found, the method will return.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **Search** method searches for a character sequence in the data stream and stops reading when it is found. This is useful when the client wants to automate responses to the server, such as executing a command and processing the output. The method will discard any data received up to and including the specified character sequence.

See Also

RshClient Class | SocketTools Namespace | RshClient.Search Overload List

RshClient.Search Method (String, Byte[], Int32)

Search for a specific character sequence in the data stream.

[Visual Basic]

```
Overloads Public Function Search( _
   ByVal value As String, _
   ByVal buffer As Byte(), _
   ByRef length As Integer _
) As Boolean
```

[C#]

```
public bool Search(
   string value,
   byte[] buffer,
   ref int length
);
```

Parameters

value

A string argument which specifies the sequence of characters to search for in the data stream. When this sequence of characters is found, the method will return.

buffer

An byte array that will contain the output sent by the server, up to and including the search string character sequence.

length

An integer value passed by reference which should be initialized to the maximum number of bytes of data to store in the buffer. When the method returns, this value will be updated with the actual number of bytes stored in the buffer.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **Search** method searches for a character sequence in the data stream and stops reading when it is found. This is useful when the client wants to automate responses to the server, such as executing a command and processing the output. The method collects the output from the server and stores it in a buffer provided by the caller. When the method returns, the buffer will contain everything sent by the server up to and including the search string.

See Also

RshClient Class | SocketTools Namespace | RshClient.Search Overload List

RshClient.Search Method (String, String)

Search for a specific character sequence in the data stream.

```
[Visual Basic]
Overloads Public Function Search( _
   ByVal value As String, _
   ByRef buffer As String _
) As Boolean
```

```
[C#]
public bool Search(
   string value,
   ref string buffer
);
```

Parameters

value

A string argument which specifies the sequence of characters to search for in the data stream. When this sequence of characters is found, the method will return.

buffer

An string that will contain the output sent by the server, up to and including the search string character sequence.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **Search** method searches for a character sequence in the data stream and stops reading when it is found. This is useful when the client wants to automate responses to the server, such as executing a command and processing the output. The method collects the output from the server and stores it in a buffer provided by the caller. When the method returns, the buffer will contain everything sent by the server up to and including the search string.

RshClient Class | SocketTools Namespace | RshClient.Search Overload List

RshClient.Uninitialize Method

Uninitialize the class library and release any resources allocated for the current thread.

[Visual Basic]

```
Public Sub Uninitialize()
```

[C#]

```
public void Uninitialize();
```

Remarks

The **Uninitialize** method terminates any active connection, releases resources allocated for the current thread and unloads the networking library. After this method has been called, no further client operations may be performed until the class instance has been re-initialized.

If the **Initialize** method is explicitly called by the application, it should be matched by a call to the **Uninitialize** method when that instance of the class is no longer needed.

RshClient Class | SocketTools Namespace | Initialize Method

RshClient.Write Method

Write one or more bytes of data to the server.

Overload List

Write one or more bytes of data to the server.

public int Write(byte[]);

Write one or more bytes of data to the server.

public int Write(byte[],int);

Write a character to the server.

public int Write(char);

Write one or more characters to the server.

public int Write(char,int);

Write a string of characters to the server.

public int Write(string);

Write a string of characters to the server.

public int Write(string,int);

See Also

RshClient Class | SocketTools Namespace

RshClient.Write Method (Byte[])

Write one or more bytes of data to the server.

[Visual Basic]

```
Overloads Public Function Write( _
   ByVal buffer As Byte() _
) As Integer
```

[C#]

```
public int Write(
   byte[] buffer
);
```

Parameters

buffer

A byte array that contains the data to be written to the server.

Return Value

An integer value which specifies the number of bytes actually written to the server. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Write** method sends one or more bytes of data to the server. If there is enough room in the client's internal send buffer to accommodate all of the data, it is copied to the send buffer and control immediately returns to the caller. If amount of data exceeds the available buffer space and the client is in blocking mode, then the method will block until the data can be sent. If the client is in non-blocking mode and the send buffer is full, an error will occur.

RshClient.Write Method (Byte[], Int32)

Write one or more bytes of data to the server.

[Visual Basic]

```
Overloads Public Function Write( _
   ByVal buffer As Byte(), _
   ByVal length As Integer _
) As Integer
```

[C#]

```
public int Write(
   byte[] buffer,
   int length
);
```

Parameters

buffer

A byte array that contains the data to be written to the server.

length

An integer value which specifies the maximum number of bytes of data to write. This value cannot be larger than the size of the buffer specified by the caller.

Return Value

An integer value which specifies the number of bytes actually written to the server. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Write** method sends one or more bytes of data to the server. If there is enough room in the client's internal send buffer to accommodate all of the data, it is copied to the send buffer and control immediately returns to the caller. If amount of data exceeds the available buffer space and the client is in blocking mode, then the method will block until the data can be sent. If the client is in non-blocking mode and the send buffer is full, an error will occur.

See Also

RshClient Class | SocketTools Namespace | RshClient.Write Overload List

RshClient.Write Method (Char)

Write a character to the server.

[Visual Basic]

```
Overloads Public Function Write( _
   ByVal key As Char _
) As Integer
```

[C#]

```
public int Write(
   char key
);
```

Parameters

key

A character which will be written to the server.

Return Value

An integer value which specifies the number of characters actually written to the server. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Write** method sends one character to the server. If the client is in non-blocking mode and the send buffer is full, an error will occur.

See Also

RshClient Class | SocketTools Namespace | RshClient.Write Overload List

RshClient.Write Method (Char, Int32)

Write one or more characters to the server.

[Visual Basic]

```
Overloads Public Function Write( _
   ByVal key As Char, _
   ByVal repeat As Integer _
) As Integer
```

[C#]

```
public int Write(
   char key,
   int repeat
);
```

Parameters

key
A character which will be written to the server.

repeat
The number of characters that will be written to the server.

Return Value

An integer value which specifies the number of characters actually written to the server. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Write** method sends one or more characters to the server. If there is enough room in the client's internal send buffer to accommodate all of the data, it is copied to the send buffer and control immediately returns to the caller. If amount of data exceeds the available buffer space and the client is in blocking mode, then the method will block until the data can be sent. If the client is in non-blocking mode and the send buffer is full, an error will occur.

See Also

RshClient Class | SocketTools Namespace | RshClient.Write Overload List

RshClient.Write Method (String)

Write a string of characters to the server.

[Visual Basic]

```
Overloads Public Function Write( _
   ByVal buffer As String _
) As Integer
```

[C#]

```
public int Write(
   string buffer
);
```

Parameters

buffer

A string which contains the data to be written to the server.

Return Value

An integer value which specifies the number of characters actually written to the server. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Write** method sends a string of characters to the server. If there is enough room in the client's internal send buffer to accommodate all of the data, it is copied to the send buffer and control immediately returns to the caller. If amount of data exceeds the available buffer space and the client is in blocking mode, then the method will block until the data can be sent. If the client is in non-blocking mode and the send buffer is full, an error will occur.

The string will be converted to an array of bytes before being written to the socket. By default, the character encoding used will be for the current locale. Depending on the contents of the string, the number of bytes written may be different than the string length specified. This is because the conversion from Unicode to a byte array may result in a multi-byte character sequence.

RshClient.Write Method (String, Int32)

Write a string of characters to the server.

[Visual Basic]

```
Overloads Public Function Write( _
   ByVal buffer As String, _
   ByVal length As Integer _
) As Integer
```

[C#]

```
public int Write(
   string buffer,
   int length
);
```

Parameters

buffer

A string which contains the data to be written to the server.

length

An integer value which specifies the maximum number of characters to write. This value cannot be larger than the length of the string specified by the caller.

Return Value

An integer value which specifies the number of characters actually written to the server. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Write** method sends a string of characters to the server. If there is enough room in the client's internal send buffer to accommodate all of the data, it is copied to the send buffer and control immediately returns to the caller. If amount of data exceeds the available buffer space and the client is in blocking mode, then the method will block until the data can be sent. If the client is in non-blocking mode and the send buffer is full, an error will occur.

The string will be converted to an array of bytes before being written to the socket. By default, the character encoding used will be for the current locale. Depending on the contents of the string, the number of bytes written may be different than the string length specified. This is because the conversion from Unicode to a byte array may result in a multi-byte character sequence.

RshClient Events

The events of the **RshClient** class are listed below. For a complete list of **RshClient** class members, see the RshClient Members topic.

Public Instance Events

⚡ OnCancel	Occurs when a blocking client operation is canceled.
⚡ OnConnect	Occurs when a connection is established with the remote host.
⚡ OnDisconnect	Occurs when the remote host disconnects from the local system.
⚡ OnError	Occurs when an client operation fails.
⚡ OnRead	Occurs when data is available to be read from the client.
⚡ OnTimeout	Occurs when a blocking operation fails to complete before the timeout period elapses.
⚡ OnWrite	Occurs when data can be written to the client.

See Also

RshClient Class | SocketTools Namespace

RshClient.OnCancel Event

Occurs when a blocking client operation is canceled.

[Visual Basic]
```
Public Event OnCancel As EventHandler
```

[C#]
```
public event EventHandler OnCancel;
```

Remarks

The **OnCancel** event is generated when a blocking client operation, such as sending or receiving data, is canceled with the **Cancel** method. To assist in determining which operation was canceled, check the value of the **Status** property.

See Also

RshClient Class | SocketTools Namespace

RshClient.OnConnect Event

Occurs when a connection is established with the remote host.

[Visual Basic]

```
Public Event OnConnect As EventHandler
```

[C#]

```
public event EventHandler OnConnect;
```

Remarks

The **OnConnect** event occurs when a connection is made with a remote host as a result of a **Connect** method call. When the **Connect** method is called and the **Blocking** property is set to **false**, a socket is created but the connection is not actually established until after this event occurs. Between the time connection process is started and this event fires, no operation may be performed on the client other than calling the **Disconnect** method.

This event is only generated if the client is in non-blocking mode.

See Also

RshClient Class | SocketTools Namespace

RshClient.OnDisconnect Event

Occurs when the remote host disconnects from the local system.

[Visual Basic]
```
Public Event OnDisconnect As EventHandler
```

[C#]
```
public event EventHandler OnDisconnect;
```

Remarks

The **OnDisconnect** event occurs when the remote host closes its connection, terminating the client session with the application. Because there may still be data in the client receive buffers, you should continue to read data from the client until the **Read** method returns a value of 0. Once all of the data has been read, you should call the **Disconnect** method to close the local socket and release the resources allocated for the client.

This event is only generated if the client is in non-blocking mode.

See Also

RshClient Class | SocketTools Namespace

RshClient.OnError Event

Occurs when an client operation fails.

[Visual Basic]

```
Public Event OnError As OnErrorEventHandler
```

[C#]

```
public event OnErrorEventHandler OnError;
```

Event Data

The event handler receives an argument of type RshClient.ErrorEventArgs containing data related to this event. The following **RshClient.ErrorEventArgs** properties provide information specific to this event.

Property	Description
Description	Gets a value which describes the last error that has occurred.
Error	Gets a value which specifies the last error that has occurred.

Remarks

The **OnError** event occurs when a client operation fails.

See Also

RshClient Class | SocketTools Namespace

RshClient.ErrorEventArgs Class

Provides data for the OnError event.

For a list of all members of this type, see RshClient.ErrorEventArgs Members.

System.Object
  System.EventArgs
    SocketTools.RshClient.ErrorEventArgs

[Visual Basic]
```
Public Class RshClient.ErrorEventArgs
    Inherits EventArgs
```

[C#]
```
public class RshClient.ErrorEventArgs : EventArgs
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

ErrorEventArgs specifies the numeric error code and a description of the error that has occurred.

An OnError event occurs when a method fails.

Requirements

Namespace: SocketTools

Assembly: SocketTools.RshClient (in SocketTools.RshClient.dll)

RshClient.ErrorEventArgs Members

RshClient.ErrorEventArgs overview

Public Instance Constructors

RshClient.ErrorEventArgs Constructor	Initializes a new instance of the RshClient.ErrorEventArgs class.

Public Instance Properties

Description	Gets a value which describes the last error that has occurred.
Error	Gets a value which specifies the last error that has occurred.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString (inherited from Object)	Returns a String that represents the current Object.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

RshClient.ErrorEventArgs Class | SocketTools Namespace

RshClient.ErrorEventArgs Constructor

Initializes a new instance of the RshClient.ErrorEventArgs class.

[Visual Basic]

```
Public Sub New()
```

[C#]

```
public RshClient.ErrorEventArgs();
```

See Also

RshClient.ErrorEventArgs Class | SocketTools Namespace

RshClient.ErrorEventArgs Properties

The properties of the **RshClient.ErrorEventArgs** class are listed below. For a complete list of **RshClient.ErrorEventArgs** class members, see the RshClient.ErrorEventArgs Members topic.

Public Instance Properties

Description	Gets a value which describes the last error that has occurred.
Error	Gets a value which specifies the last error that has occurred.

See Also

RshClient.ErrorEventArgs Class | SocketTools Namespace

RshClient.ErrorEventArgs.Description Property

Gets a value which describes the last error that has occurred.

[Visual Basic]

```
Public ReadOnly Property Description As String
```

[C#]

```
public string Description {get;}
```

Property Value

A string which describes the last error that has occurred.

See Also

RshClient.ErrorEventArgs Class | SocketTools Namespace | Error Property

RshClient.ErrorEventArgs.Error Property

Gets a value which specifies the last error that has occurred.

[Visual Basic]

```
Public ReadOnly Property Error As ErrorCode
```

[C#]

```
public RshClient.ErrorCode Error {get;}
```

Property Value

ErrorCode enumeration which specifies the error.

See Also

RshClient.ErrorEventArgs Class | SocketTools Namespace | Description Property

RshClient.OnRead Event

Occurs when data is available to be read from the client.

[Visual Basic]

```
Public Event OnRead As EventHandler
```

[C#]

```
public event EventHandler OnRead;
```

Remarks

The **OnRead** event occurs when data is available to be read from the client. This event is level-triggered, which means that once this event fires, it will not occur again until some data has been read from the client. This design prevents an application from being flooded with event notifications. It is recommended that your application read all of the available data from the server and store it in a local buffer for processing. See the example below.

This event is only generated if the client is in non-blocking mode.

Example

```
Private Sub Socket_OnRead(ByVal sender As Object, ByVal e As System.EventArgs)
Handles Socket.OnRead
    Dim strBuffer As String
    Dim nRead As Integer

    Do
        ' Read up to m_nBufferSize bytes of data from the server
        nRead = Socket.Read(strBuffer, m_nBufferSize)

        If nRead > 0 Then
            ' Append the data to an internal buffer for processing
            m_dataBuffer = m_dataBuffer + strBuffer
        End If
    Loop Until nRead < 1

    ProcessData()
End Sub
```

See Also

RshClient Class | SocketTools Namespace

RshClient.OnTimeout Event

Occurs when a blocking operation fails to complete before the timeout period elapses.

[Visual Basic]
```
Public Event OnTimeout As EventHandler
```

[C#]
```
public event EventHandler OnTimeout;
```

Remarks

The **OnTimeout** event occurs when a blocking operation, such as sending or receiving data on the client, fails to complete before the specified timeout period elapses. The timeout period for a blocking operation can be adjusted by setting the **Timeout** property.

This event is only generated if the client is in blocking mode.

See Also

RshClient Class | SocketTools Namespace

RshClient.OnWrite Event

Occurs when data can be written to the client.

[Visual Basic]

```
Public Event OnWrite As EventHandler
```

[C#]

```
public event EventHandler OnWrite;
```

Remarks

The **OnWrite** event occurs when the application can write data to the client. This event will typically occur when a connection is first established with the remote host, and after the **Write** method has failed because there was insufficient memory available in the client send buffers. In the second case, when some of the buffered data has been successfully sent to the remote host and there is space available in the send buffers, this event is used to signal the application that it may attempt to send more data.

This event is only generated if the client is in non-blocking mode.

See Also

RshClient Class | SocketTools Namespace

RshClient.ErrorCode Enumeration

Specifies the error codes returned by the RshClient class.

[Visual Basic]

```
Public Enum RshClient.ErrorCode
```

[C#]

```
public enum RshClient.ErrorCode
```

Remarks

The RshClient class uses the **ErrorCode** enumeration to specify what error has occurred when a method fails. The current error code may be determined by checking the value of the **LastError** property.

Note that the last error code is only meaningful if the previous operation has failed.

Members

Member Name	Description
errorNone	No error.
errorNotHandleOwner	Handle not owned by the current thread.
errorFileNotFound	The specified file or directory does not exist.
errorFileNotCreated	The specified file could not be created.
errorOperationCanceled	The blocking operation has been canceled.
errorInvalidFileType	The specified file is a block or character device, not a regular file.
errorInvalidDevice	The specified file type is invalid or not a regular file.
errorTooManyParameters	The maximum number of function parameters has been exceeded.
errorInvalidFileName	The specified file name contains invalid characters or is too long.
errorInvalidFileHandle	Invalid file handle passed to function.
errorFileReadFailed	Unable to read data from the specified file.
errorFileWriteFailed	Unable to write data to the specified file.
errorOutOfMemory	Out of memory.
errorAccessDenied	Access denied.
errorInvalidParameter	Invalid argument passed to function.
errorClipboardUnavailable	The system clipboard is currently unavailable.
errorClipboardEmpty	The system clipboard is empty or does not contain any text data.
errorFileEmpty	The specified file does not contain any data.
errorFileExists	The specified file already exists.

errorEndOfFile	End of file.
errorDeviceNotFound	The specified device could not be found.
errorDirectoryNotFound	The specified directory could not be found.
errorInvalidbuffer	Invalid memory address passed to function.
errorBufferTooSmall	The specified buffer is not large enough to contain the data.
errorNoHandles	No more handles are available to this process.
errorOperationWouldBlock	The specified operation would block the current thread.
errorOperationInProgress	A blocking operation is currently in progress.
errorAlreadyInProgress	The specified operation is already in progress.
errorInvalidHandle	Invalid handle passed to function.
errorInvalidAddress	Invalid network address specified.
errorInvalidSize	Datagram is too large to fit in specified buffer.
errorInvalidProtocol	Invalid network protocol specified.
errorProtocolNotAvailable	The specified network protocol is not available.
errorProtocolNotSupported	The specified protocol is not supported.
errorSocketNotSupported	The specified socket type is not supported.
errorInvalidOption	The specified option is invalid.
errorProtocolFamily	Specified protocol family is not supported.
errorProtocolAddress	The specified address is invalid for this protocol family.
errorAddressInUse	The specified address is in use by another process.
errorAddressUnavailable	The specified address cannot be assigned.
errorNetworkUnavailable	The networking subsystem is unavailable.
errorNetworkUnreachable	The specified network is unreachable.
errorNetworkReset	Network dropped connection on remote reset.
errorConnectionAborted	Connection was aborted due to timeout or other failure.
errorConnectionReset	Connection was reset by remote network.
errorOutOfBuffers	No buffer space is available.
errorAlreadyConnected	Connection already established with remote host.
errorNotConnected	No connection established with remote host.
errorConnectionShutdown	Unable to send or receive data after connection shutdown.
errorOperationTimeout	The specified operation has timed out.
errorConnectionRefused	The connection has been refused by the remote host.

errorHostUnavailable	The specified host is unavailable.
errorHostUnreachable	Remote host is unreachable.
errorTooManyProcesses	Too many processes are using the networking subsystem.
errorTooManyThreads	Too many threads have been created by the current process.
errorTooManySessions	Too many client sessions have been created by the current process.
errorInternalFailure	An unexpected internal error has occurred.
errorNetworkNotReady	Network subsystem is not ready for communication.
errorInvalidVersion	This version of the operating system is not supported.
errorNetworkNotInitialized	The networking subsystem has not been initialized.
errorRemoteShutdown	The remote host has initiated a graceful shutdown sequence.
errorInvalidHostName	The specified hostname is invalid or could not be resolved.
errorHostNameNotFound	The specified hostname could not be found.
errorHostNameRefused	Unable to resolve hostname, request refused.
errorHostNameNotResolved	Unable to resolve hostname, no address for specified host.
errorInvalidLicense	The license for this product is invalid.
errorProductNotLicensed	This product is not licensed to perform this operation.
errorNotImplemented	This function has not been implemented on this platform.
errorUnknownLocalhost	Unable to determine local host name.
errorInvalidHostAddress	Invalid host address specified.
errorInvalidServicePort	Invalid service port number specified.
errorInvalidServiceName	Invalid or unknown service name specified.
errorInvalidEventId	Invalid event identifier specified.
errorOperationNotBlocking	No blocking operation in progress on this socket.
errorSecurityNotInitialized	Unable to initialize security interface for this process.
errorSecurityContext	Unable to establish security context for this session.
errorSecurityCredentials	Unable to open certificate store or establish security credentials.
errorSecurityCertificate	Unable to validate the certificate chain for this

	session.
errorSecurityDecryption	Unable to decrypt data stream.
errorSecurityEncryption	Unable to encrypt data stream.
errorOperationNotSupported	The specified operation is not supported.
errorInvalidProtocolVersion	Invalid application protocol version specified.
errorNoServerResponse	No data returned from server.
errorInvalidServerResponse	Invalid data returned from server.
errorUnexpectedServerResponse	Unexpected response code returned from server.
errorServerTransactionFailed	Server transaction failed.
errorServiceUnavailable	The service is currently unavailable.
errorServiceNotReady	The service is not ready, try again later.
errorServerResyncFailed	Unable to resynchronize with server.
errorInvalidProxyType	Invalid proxy server type specified.
errorProxyRequired	Resource must be accessed through specified proxy.
errorInvalidProxyLogin	Unable to login to proxy server using specified credentials.
errorProxyResyncFailed	Unable to resynchronize with proxy server.
errorInvalidCommand	Invalid command specified.
errorInvalidCommandParameter	Invalid command parameter specified.
errorInvalidCommandSequence	Invalid command sequence specified.
errorCommandNotImplemented	Specified command not implemented on this server.
errorCommandNotAuthorized	Specified command not authorized for the current user.
errorCommandAborted	Specified command was aborted by the remote host.
errorOptionNotSupported	The specified option is not supported on this server.
errorRequestNotCompleted	The current client request has not been completed.
errorInvalidUserName	The specified username is invalid.
errorInvalidPassword	The specified password is invalid.
errorInvalidAccount	The specified account name is invalid.
errorAccountRequired	Account name has not been specified.
errorInvalidAuthenticationType	Invalid authentication protocol specified.
errorAuthenticationRequired	User authentication is required.
errorProxyAuthenticationRequired	Proxy authentication required.

errorAlreadyAuthenticated	User has already been authenticated.
errorAuthenticationFailed	Unable to authenticate the specified user.
errorNetworkAdapter	Unable to determine network adapter configuration.
errorInvalidRecordType	Invalid record type specified.
errorInvalidRecordName	Invalid record name specified.
errorInvalidRecordData	Invalid record data specified.
errorConnectionOpen	Data connection already established.
errorConnectionClosed	Server closed data connection.
errorConnectionPassive	Data connection is passive.
errorConnectionFailed	Unable to open data connection to server.
errorInvalidSecurityLevel	Data connection cannot be opened with this security setting.
errorCachedTLSRequired	Data connection requires cached TLS session.
errorDataReadOnly	Data connection is read-only.
errorDataWriteOnly	Data connection is write-only.
errorEndOfData	End of data.
errorRemoteFileUnavailable	Remote file is unavailable.
errorInsufficientStorage	Insufficient storage on server.
errorStorageallocation	File exceeded storage allocation on server.
errorDirectoryExists	The specified directory already exists.
errorDirectoryEmpty	No files returned by the server for the specified directory.
errorEndOfDirectory	End of directory listing.
errorUnknownDirectoryFormat	Unknown directory format.
errorInvalidResource	Invalid resource name specified.
errorResourceRedirected	The specified resource has been redirected.
errorResourceRestricted	Access to this resource has been restricted.
errorResourceNotModified	The specified resource has not been modified.
errorResourceNotFound	The specified resource cannot be found.
errorResourceConflict	Request could not be completed due to the current state of the resource.
errorResourceRemoved	The specified resource has been permanently removed from this server.
errorContentLengthRequired	Request must include the content length.
errorRequestPrecondition	Request could not be completed due to server precondition.
errorUnsupportedMediaType	Request specified an unsupported media type.

errorInvalidContentRange	Content range specified for this resource is invalid.
errorInvalidMessagePart	Message is not multipart or an invalid message part was specified.
errorInvalidMessageHeader	The specified message header is invalid or has not been defined.
errorInvalidMessageBoundary	The multipart message boundary has not been defined.
errorNoFileAttachment	The current message part does not contain a file attachment.
errorUnknownFileType	The specified file type could not be determined.
errorDataNotEncoded	The specified data block could not be encoded.
errorDataNotDecoded	The specified data block could not be decoded.
errorFileNotEncoded	The specified file could not be encoded.
errorFileNotDecoded	The specified file could not be decoded.
errorNoMessageText	No message text.
errorInvalidCharacterSet	Invalid character set specified.
errorInvalidEncodingType	Invalid encoding type specified.
errorInvalidMessageNumber	Invalid message number specified.
errorNoReturnAddress	No valid return address specified.
errorNoValidRecipients	No valid recipients specified.
errorInvalidRecipient	The specified recipient address is invalid.
errorRelayNotAuthorized	The specified domain is invalid or server will not relay messages.
errorMailboxUnavailable	Specified mailbox is currently unavailable.
errorMailboxReadOnly	The selected mailbox cannot be modified.
errorMailboxNotSelected	No mailbox has been selected.
errorInvalidMailbox	Specified mailbox is invalid.
errorInvalidDomain	The specified domain name is invalid or not recognized.
errorInvalidSender	The specified sender address is invalid or not recognized.
errorMessageNotDelivered	Message not delivered to any of the specified recipients.
errorEndOfMessageData	No more message data available to be read
errorInvalidmessageSize	The specified message size is invalid.
errorMessageNotCreated	The message could not be created in the specified mailbox.
errorNoMoreMailboxes	No more mailboxes exist on this server.

errorInvalidEmulationType	The specified terminal emulation type is invalid.
errorInvalidFontHandle	The specified font handle is invalid.
errorInvalidFontName	The specified font name is invalid or unavailable.
errorInvalidPacketSize	The specified packet size is invalid.
errorInvalidPacketData	The specified packet data is invalid.
errorInvalidPacketId	The unique packet identifier is invalid.
errorPacketTTLExpired	The specified packet time-to-live period has expired.
errorInvalidNewsGroup	Invalid newsgroup specified.
errorNoNewsgroupSelected	No newsgroup selected.
errorEmptyNewsgroup	No articles in specified newsgroup.
errorInvalidArticle	Invalid article number specified.
errorNoArticleSelected	No article selected in the current newsgroup.
errorFirstArticle	First article in current newsgroup.
errorLastArticle	Last article in current newsgroup.
errorArticleExists	Unable to transfer article, article already exists.
errorArticleRejected	Unable to transfer article, article rejected.
errorArticleTransferFailed	Article transfer failed.
errorArticlePostingDenied	Posting is not permitted on this server.
errorArticlePostingFailed	Unable to post article on this server.
errorInvalidDateFormat	The specified date format is not recognized.
errorFeatureNotSupported	The specified feature is not supported on this server.
errorInvalidFormHandle	The specified form handle is invalid or a form has not been created.
errorInvalidFormAction	The specified form action is invalid or has not been specified.
errorInvalidFormMethod	The specified form method is invalid or not supported.
errorInvalidFormType	The specified form type is invalid or not supported.
errorInvalidFormField	The specified form field name is invalid or does not exist.
errorEmptyForm	The specified form does not contain any field values.
errorMaximumConnections	The maximum number of client connections exceeded.
errorThreadCreationFailed	Unable to create a new thread for the current process.
errorInvalidThreadHandle	The specified thread handle is no longer valid.

errorThreadTerminated	The specified thread has been terminated.
errorThreadDeadlock	The operation would result in the current thread becoming deadlocked.
errorInvalidClientMoniker	The specified moniker is not associated with any client session.
errorClientMonikerExists	The specified moniker has been assigned to another client session.
errorServerInactive	The specified server is not listening for client connections.
errorServerSuspended	The specified server is suspended and not accepting client connections.
errorNoMessageStore	No message store has been specified.
errorMessageStoreChanged	The message store has changed since it was last accessed.
errorMessageNotFound	No message was found that matches the specified criteria.
errorMessageDeleted	The specified message has been deleted.
errorFileChecksumMismatch	The local and remote file checksums do not match.
errorFileSizeMismatch	The local and remote file sizes do not match.
errorInvalidFeedUrl	The news feed URL is invalid or specifies an unsupported protocol.
errorInvalidFeedFormat	The internal format of the news feed is invalid.
errorInvalidFeedVersion	This version of the news feed is not supported.
errorChannelEmpty	There are no valid items found in this news feed.
errorInvalidItemNumber	The specified channel item identifier is invalid.
errorItemNotFound	The specified channel item could not be found.
errorItemEmpty	The specified channel item does not contain any data.
errorInvalidItemProperty	The specified item property name is invalid.
errorItemPropertyNotFound	The specified item property has not been defined.
errorInvalidChannelTitle	The channel title is invalid or has not been defined.
errorInvalidChannelLink	The channel hyperlink is invalid or has not been defined.
errorInvalidChannelDescription	The channel description is invalid or has not been defined.
errorInvalidItemText	The description for an item is invalid or has not been defined.
errorInvalidItemLink	The hyperlink for an item is invalid or has not been defined.

errorInvalidServiceType	The specified service type is invalid.
errorServiceSuspended	Access to the specified service has been suspended.
errorServiceRestricted	Access to the specified service has been restricted.
errorInvalidProviderName	The specified provider name is invalid or unknown.
errorInvalidPhoneNumber	The specified phone number is invalid or not supported in this region.
errorGatewayNotFound	A message gateway cannot be found for the specified provider.
errorMessageTooLong	The message exceeds the maximum number of characters permitted.
errorInvalidProviderData	The request returned invalid or incomplete service provider data.
errorInvalidGatewayData	The request returned invalid or incomplete message gateway data.
errorMultipleProviders	The request has returned multiple service providers.
errorProviderNotFound	The specified service provider could not be found.
errorInvalidMessageService	The specified message is not supported with this service type.
errorInvalidMessageFormat	The specified message format is invalid.
errorInvalidConfiguration	The specified configuration options are invalid.
errorServerActive	The requested action is not permitted while the server is active.
errorServerPortBound	Unable to obtain exclusive use of the specified local port.
errorInvalidClientSession	The specified client identifier is invalid for this session.
errorClientNotIdentified	The specified client has not provided user credentials.
errorInvalidClientState	The requested action cannot be performed at this time.
errorInvalidResultCode	The specified result code is not valid for this protocol
errorCommandRequired	The specified command is required and cannot be disabled.
errorCommandDisabled	The specified command has been disabled.
errorCommandSequence	The command cannot be processed at this time.
errorCommandCompleted	The previous command has completed.
errorInvalidProgramName	The specified program name is invalid or unrecognized.

errorInvalidRequestHeader	The request header contains one or more invalid values.
errorInvalidVirtualHost	The specified virtual host name is invalid.
errorVirtualHostNotFound	The specified virtual host does not exist.
errorTooManyVirtualHosts	Too many virtual hosts created for this server.
errorInvalidVirtualPath	The specified virtual path name is invalid.
errorVirtualPathNotFound	The specified virtual path does not exist.
errorTooManyVirtualPaths	Too many virtual paths created for this server.
errorInvalidTask	The asynchronous task identifier is invalid.
errorTaskActive	The asynchronous task has not finished.
errorTaskQueued	The asynchronous task has been queued.
errorTaskSuspended	The asynchronous task has been suspended.
errorTaskFinished	The asynchronous task has finished.

Requirements

Namespace: SocketTools

Assembly: SocketTools.RshClient (in SocketTools.RshClient.dll)

SocketTools Namespace | LastError Property | LastErrorString Property | OnError Event

RshClient.TraceOptions Enumeration

Specifies the logging options that the RshClient class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]

```
<Flags>
Public Enum RshClient.TraceOptions
```

[C#]

```
[Flags]
public enum RshClient.TraceOptions
```

Remarks

The RshClient class uses the **TraceOptions** enumeration to specify what kind of debugging information is written to the trace logfile. These options are only meaningful when trace logging is enabled by setting the **Trace** property to **true**.

Members

Member Name	Description	Value
traceDefault	The default trace logging option. This is the same as specifying the **traceInfo** option.	0
traceInfo	All network function calls are written to the trace file. This is the default value.	0
traceError	Only those network function calls which fail are recorded in the trace file.	1
traceWarning	Only those network function calls which fail, or return values which indicate a warning, are recorded in the trace file.	2
traceHexDump	All network function calls are written to the trace file, plus all the data that is sent or received is displayed, in both ASCII and hexadecimal format.	4
traceProcess	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for multithreaded applications that are using worker threads.	4096

Requirements

Namespace: SocketTools

Assembly: SocketTools.RshClient (in SocketTools.RshClient.dll)

See Also

SocketTools Namespace

RshClient.RemoteStatus Enumeration

Specifies the status values that may be returned by the RshClient class.

[Visual Basic]

```
Public Enum RshClient.RemoteStatus
```

[C#]

```
public enum RshClient.RemoteStatus
```

Remarks

The RshClient class uses the **RemoteStatus** enumeration to identify the current status of the client.

Members

Member Name	Description
statusUnused	A client session has not been created. Attempts to perform any network operations, such as sending or receiving data, will generate an error.
statusIdle	A client session has been created, but is not currently in use. A blocking socket operation can be executed at this point.
statusConnect	The client is in the process of establishing a connection with a remote host.
statusRead	The client is in the process of receiving data from a remote host.
statusWrite	The client is in the process of sending data to a remote host.
statusDisconnect	The client session is being closed and subsequent attempts to access the client will result in an error.

Requirements

Namespace: SocketTools

Assembly: SocketTools.RshClient (in SocketTools.RshClient.dll)

SocketTools Namespace

RshClient.RemoteOptions Enumeration

Specifies the options that the RshClient class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]

```
<Flags>
Public Enum RshClient.RemoteOptions
```

[C#]

```
[Flags]
public enum RshClient.RemoteOptions
```

Remarks

The RshClient class uses the **RemoteOptions** enumeration to specify one or more options to be used when establishing a connection with a remote host. Multiple options may be specified if necessary.

Members

Member Name	Description	Value
optionNone	No option specified.	0
optionDefault	The default connection option. This is the same as specifying **optionNone**.	0
optionReservedPort	This option specifies that a reserved port should be used to establish the connection. Reserved ports are those port numbers which are less than 1024. This option should be specified when connecting on the **rshPortShell** port.	1
optionFreeThread	This option specifies that class methods may be called from any thread, and not only the thread that established the connection. Using this option disables certain internal safety checks that are made by the class and may result in unexpected behavior unless you ensure that access to the class instance is synchronized across multiple threads.	524288

Requirements

Namespace: SocketTools

Assembly: SocketTools.RshClient (in SocketTools.RshClient.dll)

SocketTools Namespace

RshClient.OnErrorEventHandler Delegate

Represents the method that will handle the OnError event.

[Visual Basic]

```
Public Delegate Sub RshClient.OnErrorEventHandler( _
   ByVal sender As Object, _
   ByVal e As ErrorEventArgs _
)
```

[C#]

```
public delegate void RshClient.OnErrorEventHandler(
      object sender,
      ErrorEventArgs e
   );
```

Parameters

sender

The source of the event.

e

An ErrorEventArgs that contains the event data.

Remarks

When you create an **OnErrorEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnErrorEventHandler** delegate declaration.

Requirements

Namespace: SocketTools

Assembly: SocketTools.RshClient (in SocketTools.RshClient.dll)

See Also

SocketTools Namespace

RshClient.RuntimeLicenseAttribute Class

Attribute that defines the runtime license key for the class.

For a list of all members of this type, see RshClient.RuntimeLicenseAttribute Members.

System.Object
  System.Attribute
    SocketTools.RshClient.RuntimeLicenseAttribute

[Visual Basic]

```
<AttributeUsage(ValidOn:=AttributeTargets.Assembly, AllowMultiple:=False,
   Inherited:=True)>
Public Class RshClient.RuntimeLicenseAttribute
    Inherits Attribute
```

[C#]

```
[AttributeUsage(ValidOn=AttributeTargets.Assembly, AllowMultiple=False,
   Inherited=True)]
public class RshClient.RuntimeLicenseAttribute : Attribute
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

The RuntimeLicense attribute is used to define the runtime license key that will be used when an instance of the class is created. This attribute is defined in the assembly information module for the language, such as AssemblyInfo.cs when programming C#. The runtime license key must be defined if you wish to redistribute your application.

The runtime license key for your copy of SocketTools can be generated using the License Manager utility that is included with the product. Note that if you have installed an evaluation license, you will not have a runtime license key and cannot redistribute any applications which use the RshClient class.

Example

```
<Assembly: SocketTools.RshClient.RuntimeLicense("abcdefghijklmnop")>
```

```
[assembly: SocketTools.RshClient.RuntimeLicense("abcdefghijklmnop")]
```

Requirements

Namespace: SocketTools

Assembly: SocketTools.RshClient (in SocketTools.RshClient.dll)

RshClient.RuntimeLicenseAttribute Members

RshClient.RuntimeLicenseAttribute overview

Public Instance Constructors

RshClient.RuntimeLicenseAttribute Constructor	Constructor for the RuntimeLicense attribute which defines the runtime license key.

Public Instance Properties

LicenseKey	Returns the value of the runtime license key.
TypeId (inherited from Attribute)	When implemented in a derived class, gets a unique identifier for this Attribute.

Public Instance Methods

Equals (inherited from Attribute)	
GetHashCode (inherited from Attribute)	Returns the hash code for this instance.
GetType (inherited from Object)	Gets the Type of the current instance.
IsDefaultAttribute (inherited from Attribute)	When overridden in a derived class, returns an indication whether the value of this instance is the default value for the derived class.
Match (inherited from Attribute)	When overridden in a derived class, returns a value indicating whether this instance equals a specified object.
ToString (inherited from Object)	Returns a String that represents the current Object.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

RshClient.RuntimeLicenseAttribute Class | SocketTools Namespace

RshClient.RuntimeLicenseAttribute Constructor

Constructor for the RuntimeLicense attribute which defines the runtime license key.

[Visual Basic]

```
Public Sub New( _
   ByVal licenseKey As String _
)
```

[C#]

```
public RshClient.RuntimeLicenseAttribute(
   string licenseKey
);
```

Parameters

licenseKey

A string argument which specifies the runtime license key which will be used to initialize the class library.

Remarks

The runtime license key for your copy of SocketTools can be generated using the License Manager utility that is included with the product. Note that if you have installed an evaluation license, you will not have a runtime license key and cannot redistribute any applications which use the RshClient class.

See Also

RshClient.RuntimeLicenseAttribute Class | SocketTools Namespace

RshClient.RuntimeLicenseAttribute Properties

The properties of the **RshClient.RuntimeLicenseAttribute** class are listed below. For a complete list of **RshClient.RuntimeLicenseAttribute** class members, see the RshClient.RuntimeLicenseAttribute Members topic.

Public Instance Properties

LicenseKey	Returns the value of the runtime license key.
TypeId (inherited from Attribute)	When implemented in a derived class, gets a unique identifier for this Attribute.

See Also

RshClient.RuntimeLicenseAttribute Class | SocketTools Namespace

RshClient.RuntimeLicenseAttribute.LicenseKey Property

Returns the value of the runtime license key.

[Visual Basic]

```
Public Property LicenseKey As String
```

[C#]

```
public string LicenseKey {get; set;}
```

Property Value

A string which contains the runtime license key.

See Also

RshClient.RuntimeLicenseAttribute Class | SocketTools Namespace

RshClientException Class

The exception that is thrown when a client error occurs.

For a list of all members of this type, see RshClientException Members.

System.Object
  System.Exception
    System.ApplicationException
      SocketTools.RshClientException

[Visual Basic]
```
Public Class RshClientException
    Inherits ApplicationException
```

[C#]
```
public class RshClientException : ApplicationException
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

A RshClientException is thrown by the RshClient class when an error occurs.

The default constructor for the RshClientException class sets the **ErrorCode** property to the last client error that occurred.

Requirements

Namespace: SocketTools

Assembly: SocketTools.RshClient (in SocketTools.RshClient.dll)

See Also

RshClientException Members | SocketTools Namespace

RshClientException Members

RshClientException overview

Public Instance Constructors

RshClientException	Overloaded. Initializes a new instance of the RshClientException class.

Public Instance Properties

ErrorCode	Gets a value which specifies the error that caused the exception.
HelpLink (inherited from Exception)	Gets or sets a link to the help file associated with this exception.
InnerException (inherited from Exception)	Gets the Exception instance that caused the current exception.
Message	Gets a value which describes the error that caused the exception.
Number	Gets a value which specifies the numeric value of the error that caused the exception.
Source (inherited from Exception)	Gets or sets the name of the application or the object that causes the error.
StackTrace (inherited from Exception)	Gets a string representation of the frames on the call stack at the time the current exception was thrown.
TargetSite (inherited from Exception)	Gets the method that throws the current exception.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetBaseException (inherited from Exception)	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetObjectData (inherited from Exception)	When overridden in a derived class, sets the SerializationInfo with information about the exception.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString	Creates and returns a string representation of the current exception.

Protected Instance Properties

HResult (inherited from Exception)	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

RshClientException Class | SocketTools Namespace

RshClientException Constructor

Initializes a new instance of the RshClientException class with the last network error code.

Overload List

Initializes a new instance of the RshClientException class with the last network error code.

public RshClientException();

Initializes a new instance of the RshClientException class with a specified error number.

public RshClientException(int);

Initializes a new instance of the RshClientException class with a specified error message.

public RshClientException(string);

Initializes a new instance of the RshClientException class with a specified error message and a reference to the inner exception that is the cause of this exception.

public RshClientException(string,Exception);

See Also

RshClientException Class | SocketTools Namespace

RshClientException Constructor ()

Initializes a new instance of the RshClientException class with the last network error code.

[Visual Basic]

```
Overloads Public Sub New()
```

[C#]

```
public RshClientException();
```

Remarks

The ctor constructor sets the **ErrorCode** property to the last client error that occurred. For more information about the errors that may occur, refer to the RshClient.ErrorCode enumeration.

See Also

RshClientException Class | SocketTools Namespace | RshClientException Constructor Overload List

RshClientException Constructor (String)

Initializes a new instance of the RshClientException class with a specified error message.

[Visual Basic]
```
Overloads Public Sub New( _
   ByVal message As String _
)
```

[C#]
```
public RshClientException(
   string message
);
```

Parameters

message
The error message that explains the reason for the exception.

Remarks

The content of the ***message*** parameter is intended to be understood by humans. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

See Also

RshClientException Class | SocketTools Namespace | RshClientException Constructor Overload List

RshClientException Constructor (String, Exception)

Initializes a new instance of the RshClientException class with a specified error message and a reference to the inner exception that is the cause of this exception.

[Visual Basic]

```
Overloads Public Sub New( _
   ByVal message As String, _
   ByVal innerException As Exception _
)
```

[C#]

```
public RshClientException(
   string message,
   Exception innerException
);
```

Parameters

message

The error message that explains the reason for the exception.

innerException

The exception that is the cause of the current exception. If the ***innerException*** parameter is not a null reference, the current exception is raised in a **catch** block that handles the inner exception.

Remarks

The content of the message parameter is intended to be understood by humans. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

An exception that is thrown as a direct result of a previous exception should include a reference to the previous exception in the **InnerException** property. The **InnerException** property returns the same value that is passed into the constructor, or a null reference if the **InnerException** property does not supply the inner exception value to the constructor.

See Also

RshClientException Class | SocketTools Namespace | RshClientException Constructor Overload List

RshClientException Constructor (Int32)

Initializes a new instance of the RshClientException class with a specified error number.

```
[Visual Basic]
Overloads Public Sub New( _
   ByVal code As Integer _
)
```

```
[C#]
public RshClientException(
   int code
);
```

Parameters

code

An integer value which specifies an error code.

Remarks

This constructor sets the **ErrorCode** property to the specified error code. For more information about the errors that may occur, refer to the RshClient.ErrorCode enumeration.

See Also

RshClientException Class | SocketTools Namespace | RshClientException Constructor Overload List

RshClientException Properties

The properties of the **RshClientException** class are listed below. For a complete list of **RshClientException** class members, see the RshClientException Members topic.

Public Instance Properties

ErrorCode	Gets a value which specifies the error that caused the exception.
HelpLink (inherited from Exception)	Gets or sets a link to the help file associated with this exception.
InnerException (inherited from Exception)	Gets the Exception instance that caused the current exception.
Message	Gets a value which describes the error that caused the exception.
Number	Gets a value which specifies the numeric value of the error that caused the exception.
Source (inherited from Exception)	Gets or sets the name of the application or the object that causes the error.
StackTrace (inherited from Exception)	Gets a string representation of the frames on the call stack at the time the current exception was thrown.
TargetSite (inherited from Exception)	Gets the method that throws the current exception.

Protected Instance Properties

HResult (inherited from Exception)	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception.

See Also

RshClientException Class | SocketTools Namespace

RshClientException.ErrorCode Property

Gets a value which specifies the error that caused the exception.

[Visual Basic]

```
Public ReadOnly Property ErrorCode As ErrorCode
```

[C#]

```
public RshClient.ErrorCode ErrorCode {get;}
```

Property Value

Returns a RshClient.ErrorCode enumeration value which specifies the error code.

Remarks

The **ErrorCode** property returns the error code that specifies the cause of the exception.

The default constructor for the RshClientException class sets the error code to the last network error that occurred. For more information about the errors that may occur, refer to the RshClient.ErrorCode enumeration.

See Also

RshClientException Class | SocketTools Namespace

RshClientException.Message Property

Gets a value which describes the error that caused the exception.

[Visual Basic]

```
Overrides Public ReadOnly Property Message As String
```

[C#]

```
public override string Message {get;}
```

Property Value

A string which describes the error that caused the exception.

Remarks

The **Message** property returns a string which describes the error that caused the exception.

See Also

RshClientException Class | SocketTools Namespace

RshClientException.Number Property

Gets a value which specifies the numeric value of the error that caused the exception.

[Visual Basic]

```
Public ReadOnly Property Number As Integer
```

[C#]

```
public int Number {get;}
```

Property Value

An integer value that specifies the error that caused the exception.

Remarks

The **Number** property returns an integer value which specifies the numeric value of the error that caused the exception. This value is the same as the values returned by the Windows Sockets API. For more information about socket error codes, see the Windows Socket Version 2 API error code documentation in MSDN.

RshClientException Class | SocketTools Namespace

RshClientException Methods

The methods of the **RshClientException** class are listed below. For a complete list of **RshClientException** class members, see the RshClientException Members topic.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetBaseException (inherited from Exception)	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetObjectData (inherited from Exception)	When overridden in a derived class, sets the SerializationInfo with information about the exception.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString	Creates and returns a string representation of the current exception.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

RshClientException Class | SocketTools Namespace

RshClientException.ToString Method

Creates and returns a string representation of the current exception.

[Visual Basic]
```
Overrides Public Function ToString() As String
```

[C#]
```
public override string ToString();
```

Return Value

A string representation of the current exception.

Remarks

The **ToString** method returns a representation of the current exception that is intended to be understood by humans. Where the exception contains culture-sensitive data, the string representation returned by **ToString** is required to take into account the current system culture. Although there are no exact requirements for the format of the returned string, it should attempt to reflect the value of the object as perceived by the user.

This implementation of **ToString** obtains the numeric error code value and a description of the error that caused the current exception. If there is no error message or it is an empty string, then no error message is returned.

This method overrides **ApplicationException.ToString**.

RshClientException Class | SocketTools Namespace

SmtpClient Class

Implements the Simple Mail Transfer Protocol.

For a list of all members of this type, see SmtpClient Members.

System.Object
  SocketTools.SmtpClient

[Visual Basic]
```
Public Class SmtpClient
    Implements IDisposable
```

[C#]
```
public class SmtpClient : IDisposable
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

The Simple Mail Transfer Protocol (SMTP) enables applications to deliver email messages to one or more recipients. The class provides an interface for addressing and delivering messages, and extended features such as user authentication and delivery status notification. There is no requirement to have a specific email application installed or certain types of servers installed on the local system. The class can be used to deliver mail through a wide variety of systems, from standard UNIX based mail servers to Windows systems running Exchange or Lotus Notes and Domino.

Using this class, messages can be delivered directly to the recipient, or they can be routed through a relay server, such as an Internet Service Provider's mail system. The SocketTools.MailMessage class can be integrated with this class in order to provide an extremely simple, yet flexible interface for composing and delivering messages.

This class supports secure connections using the standard TLS protocols. Both implicit and explicit TLS connections can be established, enabling the class to work with a wide variety of servers.

Requirements

Namespace: SocketTools

Assembly: SocketTools.SmtpClient (in SocketTools.SmtpClient.dll)

SmtpClient Members | SocketTools Namespace

SmtpClient Members

SmtpClient overview

Public Static (Shared) Fields

smtpPortDefault	A constant value which specifies the default port number.
smtpPortSecure	A constant value which specifies the default port number for a secure connection.
smtpTimeout	A constant value which specifies the default timeout period.

Public Instance Constructors

SmtpClient Constructor	Initializes a new instance of the SmtpClient class.

Public Instance Fields

Recipient	Gets and sets the recipients specified for the current message.

Public Instance Properties

Authentication	Gets and sets the method used to authenticate the user.
AutoResolve	Gets and sets a value that determines if host names and addresses are automatically resolved.
BearerToken	Gets and sets the bearer token used with OAuth 2.0 authentication.
Blocking	Gets and sets a value which indicates if the client is in blocking mode.
CertificateExpires	Get a value that specifies the date that the security certificate expires.
CertificateIssued	Get a value that specifies the date that the security certificate was issued.
CertificateIssuer	Get a value that provides information about the organization that issued the certificate.
CertificateName	Gets and sets a value that specifies the name of the client certificate.
CertificatePassword	Gets and sets the password associated with the client certificate.
CertificateStatus	Gets a value which indicates the status of the security certificate returned by the remote host.
CertificateStore	Gets and sets a value that specifies the name of the local certificate store.
CertificateSubject	Gets a value that provides information about the

	organization that the server certificate was issued to.
CertificateUser	Gets and sets the user that owns the client certificate.
CipherStrength	Gets a value that indicates the length of the key used by the encryption algorithm for a secure connection.
Extended	Gets and sets a value that specifies if extended SMTP options should be enabled.
Handle	Gets a value that specifies the client handle allocated for the current session.
HashStrength	Gets a value which specifies the length of the message digest that was selected for a secure connection.
HostAddress	Gets and sets a value which specifies the Internet address used to establish a connection.
HostName	Gets and sets a value which specifies the host name used to establish a connection.
IsBlocked	Gets a value which indicates if the current thread is performing a blocking client operation.
IsConnected	Gets a value which indicates if a connection to the remote host has been established.
IsInitialized	Gets a value which indicates if the current instance of the class has been initialized successfully.
IsReadable	Gets a value which indicates if there is data available to be read from the socket connection to the server.
IsWritable	Gets a value which indicates if data can be written to the client without blocking.
LastError	Gets and sets a value which specifies the last error that has occurred.
LastErrorString	Gets a value which describes the last error that has occurred.
LocalAddress	Gets the local Internet address that the client is bound to.
LocalDomain	Gets and sets the local domain name.
Localize	Gets a value that specifies if the date and time are localized.
LocalName	Gets a value which specifies the host name for the local system.
LocalPort	Gets the local port number the client is bound to.
Options	Gets and sets a value which specifies one or more client options.

Password	Gets and sets the password used to authenticate the client.
Recipients	Gets the number of current message recipients.
RemotePort	Gets and sets a value which specifies the remote port number.
RemoteService	Gets and sets a value which specifies the remote service.
ResultCode	Gets a value which specifies the last result code returned by the server.
ResultString	Gets a string value which describes the result of the previous command.
ReturnReceipt	Enables and disables delivery status notification.
Secure	Gets and sets a value which specifies if a secure connection is established.
SecureCipher	Gets a value that specifies the encryption algorithm used for a secure connection.
SecureHash	Gets a value that specifies the message digest algorithm used for a secure connection.
SecureKeyExchange	Gets a value that specifies the key exchange algorithm used for a secure connection.
SecureProtocol	Gets and sets a value which specifies the protocol used for a secure connection.
Sender	Gets and sets the sender email address.
Status	Gets a value which specifies the current status of the client.
ThreadModel	Gets and sets a value which specifies the threading model for the class instance.
ThrowError	Gets and sets a value which specifies if method calls should throw exceptions when an error occurs.
Timeout	Gets and sets a value which specifies a timeout period in seconds.
TimeZone	Gets and sets the current timezone offset in seconds.
Trace	Gets and sets a value which indicates if network function logging is enabled.
TraceFile	Gets and sets a value which specifies the name of the logfile.
TraceFlags	Gets and sets a value which specifies the client function tracing flags.
UserName	Gets and sets the username used to authenticate the client session.

Version	Gets a value which returns the current version of the SmtpClient class library.

Public Instance Methods

AddRecipient	Add an address to the recipient list for the current message.
AppendMessage	Overloaded. Append text to the current message being composed.
AttachThread	Attach an instance of the class to the current thread
Authenticate	Overloaded. Authenticate the client session with a username and password.
Cancel	Cancel the current blocking client operation.
CloseMessage	Closes the current message.
Command	Overloaded. Send a custom command to the server.
Connect	Overloaded. Establish a connection with a remote host.
CreateMessage	Overloaded. Begin the composition of a new message to be delivered.
Disconnect	Terminate the connection with a remote host.
Dispose	Overloaded. Releases all resources used by SmtpClient.
Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
ExpandAddress	Expand the specified email address.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from Object)	Gets the Type of the current instance.
Initialize	Overloaded. Initialize an instance of the SmtpClient class.
Reset	Reset the internal state of the object, resetting all properties to their default values.
SendMessage	Overloaded. Submit the specified message to the mail server for delivery.
ToString (inherited from Object)	Returns a String that represents the current Object.
Uninitialize	Uninitialize the class library and release any resources allocated for the current thread.
VerifyAddress	Verify the specified email address.
Write	Overloaded. Write one or more bytes of data to the server.

Public Instance Events

OnCancel	Occurs when a blocking client operation is canceled.
OnCommand	Occurs when the client sends a command to the remote host and receives a reply indicating the result of that command.
OnConnect	Occurs when a connection is established with the remote host.
OnDisconnect	Occurs when the remote host disconnects from the local system.
OnError	Occurs when an client operation fails.
OnProgress	Occurs as a data stream is being read or written to the client.
OnTimeout	Occurs when a blocking operation fails to complete before the timeout period elapses.

Protected Instance Methods

Dispose	Overloaded. Releases the unmanaged resources allocated by the SmtpClient class and optionally releases the managed resources.
Finalize	Destroys an instance of the class, releasing the resources allocated for the session and unloading the networking library.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

SmtpClient Class | SocketTools Namespace

SmtpClient Constructor

Initializes a new instance of the SmtpClient class.

[Visual Basic]

```
Public Sub New()
```

[C#]

```
public SmtpClient();
```

See Also

SmtpClient Class | SocketTools Namespace

SmtpClient Fields

The fields of the **SmtpClient** class are listed below. For a complete list of **SmtpClient** class members, see the SmtpClient Members topic.

Public Static (Shared) Fields

smtpPortDefault	A constant value which specifies the default port number.
smtpPortSecure	A constant value which specifies the default port number for a secure connection.
smtpTimeout	A constant value which specifies the default timeout period.

Public Instance Fields

Recipient	Gets and sets the recipients specified for the current message.

See Also

SmtpClient Class | SocketTools Namespace

SmtpClient.Recipient Field

Gets and sets the recipients specified for the current message.

[Visual Basic]
```
Public ReadOnly Recipient As RecipientArray
```

[C#]
```
public readonly RecipientArray Recipient;
```

Remarks

The **Recipient** array is used to enumerate the recipient addresses that have been specified for the current message. The list of message recipients managed using this property is used by the **SendMessage** method when delivering the message. This array is zero based, meaning that the first index value is zero. The total number of recipients specified in the message can be determined by checking the value of the **Recipients** property.

SmtpClient Class | SocketTools Namespace

SmtpClient Properties

The properties of the **SmtpClient** class are listed below. For a complete list of **SmtpClient** class members, see the SmtpClient Members topic.

Public Instance Properties

Authentication	Gets and sets the method used to authenticate the user.
AutoResolve	Gets and sets a value that determines if host names and addresses are automatically resolved.
BearerToken	Gets and sets the bearer token used with OAuth 2.0 authentication.
Blocking	Gets and sets a value which indicates if the client is in blocking mode.
CertificateExpires	Get a value that specifies the date that the security certificate expires.
CertificateIssued	Get a value that specifies the date that the security certificate was issued.
CertificateIssuer	Get a value that provides information about the organization that issued the certificate.
CertificateName	Gets and sets a value that specifies the name of the client certificate.
CertificatePassword	Gets and sets the password associated with the client certificate.
CertificateStatus	Gets a value which indicates the status of the security certificate returned by the remote host.
CertificateStore	Gets and sets a value that specifies the name of the local certificate store.
CertificateSubject	Gets a value that provides information about the organization that the server certificate was issued to.
CertificateUser	Gets and sets the user that owns the client certificate.
CipherStrength	Gets a value that indicates the length of the key used by the encryption algorithm for a secure connection.
Extended	Gets and sets a value that specifies if extended SMTP options should be enabled.
Handle	Gets a value that specifies the client handle allocated for the current session.
HashStrength	Gets a value which specifies the length of the message digest that was selected for a secure connection.

HostAddress	Gets and sets a value which specifies the Internet address used to establish a connection.
HostName	Gets and sets a value which specifies the host name used to establish a connection.
IsBlocked	Gets a value which indicates if the current thread is performing a blocking client operation.
IsConnected	Gets a value which indicates if a connection to the remote host has been established.
IsInitialized	Gets a value which indicates if the current instance of the class has been initialized successfully.
IsReadable	Gets a value which indicates if there is data available to be read from the socket connection to the server.
IsWritable	Gets a value which indicates if data can be written to the client without blocking.
LastError	Gets and sets a value which specifies the last error that has occurred.
LastErrorString	Gets a value which describes the last error that has occurred.
LocalAddress	Gets the local Internet address that the client is bound to.
LocalDomain	Gets and sets the local domain name.
Localize	Gets a value that specifies if the date and time are localized.
LocalName	Gets a value which specifies the host name for the local system.
LocalPort	Gets the local port number the client is bound to.
Options	Gets and sets a value which specifies one or more client options.
Password	Gets and sets the password used to authenticate the client.
Recipients	Gets the number of current message recipients.
RemotePort	Gets and sets a value which specifies the remote port number.
RemoteService	Gets and sets a value which specifies the remote service.
ResultCode	Gets a value which specifies the last result code returned by the server.
ResultString	Gets a string value which describes the result of the previous command.
ReturnReceipt	Enables and disables delivery status notification.
Secure	Gets and sets a value which specifies if a secure

	connection is established.
SecureCipher	Gets a value that specifies the encryption algorithm used for a secure connection.
SecureHash	Gets a value that specifies the message digest algorithm used for a secure connection.
SecureKeyExchange	Gets a value that specifies the key exchange algorithm used for a secure connection.
SecureProtocol	Gets and sets a value which specifies the protocol used for a secure connection.
Sender	Gets and sets the sender email address.
Status	Gets a value which specifies the current status of the client.
ThreadModel	Gets and sets a value which specifies the threading model for the class instance.
ThrowError	Gets and sets a value which specifies if method calls should throw exceptions when an error occurs.
Timeout	Gets and sets a value which specifies a timeout period in seconds.
TimeZone	Gets and sets the current timezone offset in seconds.
Trace	Gets and sets a value which indicates if network function logging is enabled.
TraceFile	Gets and sets a value which specifies the name of the logfile.
TraceFlags	Gets and sets a value which specifies the client function tracing flags.
UserName	Gets and sets the username used to authenticate the client session.
Version	Gets a value which returns the current version of the SmtpClient class library.

See Also

SmtpClient Class | SocketTools Namespace

SmtpClient.Authentication Property

Gets and sets the method used to authenticate the user.

[Visual Basic]

```
Public Property Authentication As SmtpAuthentication
```

[C#]

```
public SmtpClient.SmtpAuthentication Authentication {get; set;}
```

Property Value

A SmtpAuthentication enumeration value which specifies the authentication method.

Remarks

The **authXOAuth2** and **authBearer** authentication methods are similar, but they are not interchangeable. Both use an OAuth 2.0 bearer token to authenticate the client session, but they differ in how the token is presented to the server. It is currently preferable to use the XOAUTH2 method because it is more widely available and some service providers do not yet support the OAUTHBEARER method.

See Also

SmtpClient Class | SocketTools Namespace | BearerToken Poperty | Password Property | UserName Property

SmtpClient.AutoResolve Property

Gets and sets a value that determines if host names and addresses are automatically resolved.

[Visual Basic]

```
Public Property AutoResolve As Boolean
```

[C#]

```
public bool AutoResolve {get; set;}
```

Property Value

Returns **true** if host names are automatically resolved to Internet addresses. The default value is **false**.

Remarks

Setting the **AutoResolve** property determines if the class automatically resolves host names and addresses specified by the **HostName** and **HostAddress** properties. If set to **true**, setting the **HostName** property will cause the class to automatically determine the corresponding IP address and update the **HostAddress** property accordingly. Likewise, setting the **HostAddress** property will cause the class to determine the host name and update the **HostName** property. Setting this property to **false** prevents the class from resolving host names until a connection attempt is made.

It is important to note that setting the **HostName** or **HostAddress** property may cause the current thread to block, sometimes for several seconds, until the name or address is resolved. To prevent this behavior, set this property value to **false**.

See Also

SmtpClient Class | SocketTools Namespace

SmtpClient.BearerToken Property

Gets and sets the bearer token used with OAuth 2.0 authentication.

[Visual Basic]
```
Public Property BearerToken As String
```

[C#]
```
public string BearerToken {get; set;}
```

Property Value

Returns a string which contains the bearer token. Assigning a value to this property sets the curent authentication type to use OAuth 2.0 authentication and updates the bearer token.

Remarks

Assigning a value to the **BearerToken** property will automatically change the current authentication method to use OAuth 2.0 if necessary.

You should only use an OAuth 2.0 authentication method if you understand the process of how to request the access token. Obtaining a bearer token requires registering your application with the mail service provider (e.g.: Microsoft or Google), getting a unique client ID associated with your application and then requesting the bearer token using the appropriate scope for the service. Obtaining the initial token will typically involve interactive confirmation on the part of the user, requiring they grant permission to your application to access their mail account.

Your application should not store the bearer token for later use. They usually have a relatively short lifespan, typically about an hour, and are designed to be used with the current client session. You should specify offline access as part of the OAuth 2.0 scope, and store the refresh token provided by the service. The refresh token has a much onger validity period and can be used to obtain a new access token when needed.

If the current authentication method does not use OAuth 2.0, this property will return an empty string and you should use the **Password** property to obtain the current user password.

See Also

SmtpClient Class | SocketTools Namespace | Authentication Property | Password Property | UserName Property

SmtpClient.Blocking Property

Gets and sets a value which indicates if the client is in blocking mode.

[Visual Basic]

```
Public Property Blocking As Boolean
```

[C#]

```
public bool Blocking {get; set;}
```

Property Value

Returns **true** if the client is in blocking mode; otherwise it returns **false**. The default value is **true**.

Remarks

Setting the **Blocking** property determines if client operations complete synchronously or asynchronously. If set to **true**, then each client operation (such as sending or receiving data) will return when the operation has completed or timed-out. If set to **false**, client operations will return immediately. If the operation would result in the client blocking (such as attempting to read data when no data has been sent by the remote host), an error is generated.

It is important to note that certain events, such as **OnConnect OnDisconnect** are only fired if the client is in non-blocking mode.

See Also

SmtpClient Class | SocketTools Namespace

SmtpClient.CertificateExpires Property

Get a value that specifies the date that the security certificate expires.

[Visual Basic]

```
Public ReadOnly Property CertificateExpires As String
```

[C#]

```
public string CertificateExpires {get;}
```

Property Value

A string which specifies a date using the local date and time format.

Remarks

The **CertificateExpires** property returns a string that specifies the date and time that the security certificate expires. This property will return an empty string if a secure connection has not been established with the remote host.

See Also

SmtpClient Class | SocketTools Namespace

SmtpClient.CertificateIssued Property

Get a value that specifies the date that the security certificate was issued.

[Visual Basic]

```
Public ReadOnly Property CertificateIssued As String
```

[C#]

```
public string CertificateIssued {get;}
```

Property Value

A string which specifies a date using the local date and time format.

Remarks

The **CertificateIssued** property returns a string that specifies the date and time that the security certificate was issued. This property will return an empty string if a secure connection has not been established with the remote host.

See Also

SmtpClient Class | SocketTools Namespace

SmtpClient.CertificateIssuer Property

Get a value that provides information about the organization that issued the certificate.

[Visual Basic]

```
Public ReadOnly Property CertificateIssuer As String
```

[C#]

```
public string CertificateIssuer {get;}
```

Property Value

A string that contains a comma separated list of name value pairs.

Remarks

The **CertificateIssuer** property returns a string that contains information about the organization that issued the server certificate. The string value is a comma separated list of tagged name and value pairs. In the nomenclature of the X.500 standard, each of these pairs are called a relative distinguished name (RDN), and when concatenated together, forms the issuer's distinguished name (DN). For example:

```
C=US, O="RSA Data Security, Inc.", OU=Secure Server Certification Authority
```

To obtain a specific value, such as the name of the issuer or the issuer's country, the application must parse the string returned by this property. Some of the common tokens used in the distinguished name are:

Token	Description
C	The ISO standard two character country code.
S	The name of the state or province.
L	The name of the city or locality.
O	The name of the company or organization.
OU	The name of the department or organizational unit
CN	The common name; with X.509 certificates, this is the domain name of the site the certificate was issued for.

This property will return an empty string if a secure connection has not been established with the remote host.

See Also

SmtpClient Class | SocketTools Namespace

SmtpClient.CertificateName Property

Gets and sets a value that specifies the name of the client certificate.

[Visual Basic]

```
Public Property CertificateName As String
```

[C#]

```
public string CertificateName {get; set;}
```

Property Value

A string which specifies the certificate name.

Remarks

The **CertificateName** property is used to specify the name of a client certificate to use when establishing a secure connection. It is only required that you set this property value if the server requires a client certificate for authentication. If this property is not set, a client certificate will not be provided to the server. If a certificate name is specified, the certificate must have a private key associated with it, otherwise the connection attempt will fail because the control will be unable to create a security context for the session.

When the certificate store is searched for a matching certificate, it will first search for any certificate with a friendly name that matches the property value. If no valid certificate is found, it will then search for a certificate with a matching common name.

Certificates may be installed and viewed on the local system using the Certificate Manager that is included with the Windows operating system. For more information, refer to the documentation for the Microsoft Management Console.

See Also

SmtpClient Class | SocketTools Namespace | CertificateStore Property | Secure Property

SmtpClient.CertificateStatus Property

Gets a value which indicates the status of the security certificate returned by the remote host.

[Visual Basic]

```
Public ReadOnly Property CertificateStatus As SecurityCertificate
```

[C#]

```
public SmtpClient.SecurityCertificate CertificateStatus {get;}
```

Property Value

A SecurityCertificate enumeration value which specifies the status of the certificate.

Remarks

The **CertificateStatus** property is used to determine the status of the security certificate returned by the remote host when a secure connection has been established. This property value should be checked after the connection to the server has completed, but prior to beginning a transaction.

Note that if the certificate cannot be validated, the secure connection will not be automatically terminated. It is the responsibility of your application to determine the best course of action to take if the certificate is invalid. Even if the security certificate cannot be validated, the data exchanged with the remote host will still be encrypted.

See Also

SmtpClient Class | SocketTools Namespace

SmtpClient.CertificateStore Property

Gets and sets a value that specifies the name of the local certificate store.

[Visual Basic]

```
Public Property CertificateStore As String
```

[C#]

```
public string CertificateStore {get; set;}
```

Property Value

A string which specifies the certificate store name. The default value is the current user's personal certificate store.

Remarks

The **CertificateStore** property is used to specify the name of the certificate store which contains the security certificate to use when establishing a secure connection. The certificate may either be stored in the registry or in a file. If the certificate is stored in the registry, then this property should be set to one of the following predefined values:

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as VeriSign and Thawte act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. If a certificate store is not specified, this is the default value that is used.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as VeriSign and Thawte are installed as part of the operating system and periodically updated by Microsoft.

In most cases the client certificate will be installed in the user's personal certificate store, and therefore it is not necessary to set this property value because that is the default location that will be used to search for the certificate. This property is only used if the **CertificateName** property is also set to a valid certificate name.

If you are using a local certificate store, with the certificate and private key stored in the registry, you can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU" for the current user, or "HKLM" for the local machine. For example, a certificate store name of "HKLM:MY" would specify the personal certificate store for the local machine, rather than the current user. If neither prefix is specified, it will default to the certificate store for the current user.

This property may also be used to specify a file that contains the client certificate. In this case, the property should specify the full path to the file and must contain both the certificate and private key in PKCS12

format. If the file is protected by a password, the **CertificatePassword** property must also be set to specify the password.

See Also

SmtpClient Class | SocketTools Namespace | CertificatePassword Property | Secure Property

SmtpClient.CertificateSubject Property

Gets a value that provides information about the organization that the server certificate was issued to.

[Visual Basic]
```
Public ReadOnly Property CertificateSubject As String
```

[C#]
```
public string CertificateSubject {get;}
```

Property Value

A string that contains a comma separated list of name value pairs.

Remarks

The **CertificateSubject** property returns a string that contains information about the organization that the server certificate was issued to. The string value is a comma separated list of tagged name and value pairs. In the nomenclature of the X.500 standard, each of these pairs are called a relative distinguished name (RDN), and when concatenated together, forms the issuer's distinguished name (DN). For example:

```
C=US, O="RSA Data Security, Inc.", OU=Secure Server Certification Authority
```

To obtain a specific value, such as the name of the issuer or the issuer's country, the application must parse the string returned by this property. Some of the common tokens used in the distinguished name are:

Token	Description
C	The ISO standard two character country code.
S	The name of the state or province.
L	The name of the city or locality.
O	The name of the company or organization.
OU	The name of the department or organizational unit
CN	The common name; with X.509 certificates, this is the domain name of the site the certificate was issued for.

This property will return an empty string if a secure connection has not been established with the remote host.

See Also

SmtpClient Class | SocketTools Namespace

SmtpClient.CipherStrength Property

Gets a value that indicates the length of the key used by the encryption algorithm for a secure connection.

[Visual Basic]

```
Public ReadOnly Property CipherStrength As Integer
```

[C#]

```
public int CipherStrength {get;}
```

Property Value

An integer value which specifies the encryption key length if a secure connection has been established; otherwise a value of 0 is returned.

Remarks

The **CipherStrength** property returns the number of bits in the key used to encrypt the secure data stream. Common values returned by this property are 128 and 256. A key length of 40 or 56 bits is considered insecure and subject to brute force attacks. 128-bit and 256-bit keys are considered secure. If this property returns a value of 0, this means that a secure connection has not been established with the remote host.

See Also

SmtpClient Class | SocketTools Namespace

SmtpClient.Handle Property

Gets a value that specifies the client handle allocated for the current session.

[Visual Basic]

```
Public ReadOnly Property Handle As Integer
```

[C#]

```
public int Handle {get;}
```

Property Value

An integer which represents a client handle. If there is no active connection, a value of -1 is returned.

Remarks

The **Handle** property specifies the numeric descriptor of the current client session.

See Also

SmtpClient Class | SocketTools Namespace

SmtpClient.HashStrength Property

Gets a value which specifies the length of the message digest that was selected for a secure connection.

[Visual Basic]

```
Public ReadOnly Property HashStrength As Integer
```

[C#]

```
public int HashStrength {get;}
```

Property Value

An integer value which specifies the length of the message digest if a secure connection has been established; otherwise a value of 0 is returned.

Remarks

The **HashStrength** property returns the number of bits used in the message digest (hash) that was selected. Common values returned by this property are 128 and 160. If this property returns a value of 0, this means that a secure connection has not been established with the remote host.

See Also

SmtpClient Class | SocketTools Namespace

SmtpClient.HostAddress Property

Gets and sets a value which specifies the Internet address used to establish a connection.

[Visual Basic]
```
Public Property HostAddress As String
```

[C#]
```
public string HostAddress {get; set;}
```

Property Value

A string which specifies an Internet address.

Remarks

The **HostAddress** property can be used to set the Internet address for a remote system that you wish to communicate with. If the **AutoResolve** property is set to **true** and the address is assigned to a valid host name, the **HostName** property will be updated with that value.

See Also

SmtpClient Class | SocketTools Namespace

SmtpClient.HostName Property

Gets and sets a value which specifies the host name used to establish a connection.

[Visual Basic]
```
Public Property HostName As String
```

[C#]
```
public string HostName {get; set;}
```

Property Value

A string which specifies a host name.

Remarks

The **HostName** property can be used to set the host name for a remote system that you wish to communicate with. If the **AutoResolve** property is set to **true** and the name can be resolved to a valid Internet address, the **HostAddress** property will be updated with that value.

See Also

SmtpClient Class | SocketTools Namespace

SmtpClient.IsBlocked Property

Gets a value which indicates if the current thread is performing a blocking client operation.

[Visual Basic]

```
Public ReadOnly Property IsBlocked As Boolean
```

[C#]

```
public bool IsBlocked {get;}
```

Property Value

Returns **true** if the current thread is blocking, otherwise returns **false**.

Remarks

The **IsBlocked** property returns **true** if the current thread is blocked performing an operation. Because the Windows Sockets API only permits one blocking operation per thread of execution, this property should be checked before starting any blocking operation in response to an event.

If the **IsBlocked** property returns **false**, this means there are no blocking operations on the current thread at that time. However, this does not guarantee that the next client operation will not fail. An application should always check the return value from a client operation and check the value of the **LastError** property if an error occurs.

Note that this property will return **true** if there is any blocking operation being performed by the current thread, regardless of whether this specific instance of the class is responsible for the blocking operation or not.

See Also

SmtpClient Class | SocketTools Namespace

SmtpClient.IsConnected Property

Gets a value which indicates if a connection to the remote host has been established.

[Visual Basic]

```
Public ReadOnly Property IsConnected As Boolean
```

[C#]

```
public bool IsConnected {get;}
```

Property Value

Returns **true** if the connection has been established; otherwise returns **false**.

Remarks

The **IsConnected** property can only be used to indicate if there is still a logical connection to the remote host. It cannot be used to detect abnormal conditions such as the remote host aborting the connection, the physical network connection being lost or other critical errors.

See Also

SmtpClient Class | SocketTools Namespace

SmtpClient.IsInitialized Property

Gets a value which indicates if the current instance of the class has been initialized successfully.

[Visual Basic]
```
Public ReadOnly Property IsInitialized As Boolean
```

[C#]
```
public bool IsInitialized {get;}
```

Property Value

Returns **true** if the class instance has been initialized; otherwise returns **false**.

Remarks

The **IsInitialized** property is used to determine if the current instance of the class has been initialized properly. Normally this is done automatically by the class constructor, however there are circumstances where the class may not be able to initialize itself.

The most common reasons that a class instance may not initialize correctly is that no runtime license key has been defined in the assembly or the license key provided is invalid. It may also indicate a problem with the system configuration or user access rights, such as not being able to load the required networking libraries or not being able to access the system registry.

See Also

SmtpClient Class | SocketTools Namespace

SmtpClient.IsReadable Property

Gets a value which indicates if there is data available to be read from the socket connection to the server.

[Visual Basic]

```
Public ReadOnly Property IsReadable As Boolean
```

[C#]

```
public bool IsReadable {get;}
```

Property Value

Returns **true** if there is data available to be read; otherwise returns **false**.

Remarks

The **IsReadable** property returns **true** if data can be read from the client without blocking. For non-blocking sessions, this property can be checked before the application attempts to read the client. Note that even if this property does return **true** indicating that there is data available to be read, applications should always check the return value from the **Read** method.

See Also

SmtpClient Class | SocketTools Namespace

SmtpClient.IsWritable Property

Gets a value which indicates if data can be written to the client without blocking.

[Visual Basic]

```
Public ReadOnly Property IsWritable As Boolean
```

[C#]

```
public bool IsWritable {get;}
```

Property Value

Returns **true** if data can be written to the client; otherwise returns **false**.

Remarks

The **IsWritable** property returns **true** if data can be written to the client without blocking. For non-blocking sessions, this property can be checked before the application attempts to write data to the client. Note that even if this property does return **true** indicating that data can be written to the client, applications should always check the return value from the **Write** method.

See Also

SmtpClient Class | SocketTools Namespace

SmtpClient.LastError Property

Gets and sets a value which specifies the last error that has occurred.

[Visual Basic]

```
Public Property LastError As ErrorCode
```

[C#]

```
public SmtpClient.ErrorCode LastError {get; set;}
```

Property Value

Returns an ErrorCode enumeration value which specifies the last error code.

Remarks

The **LastError** property returns the error code associated with the last error that occurred for the current instance of the class. It is important to note that this value only has meaning if the previous method indicates that an error has actually occurred.

It is possible to explicitly clear the last error code by assigning the property to the value **ErrorCode.errorNone**.

The error code value can be cast to an integer value for display purposes if required. For a description of the error that can be displayed using a message box or some other similar mechanism, get the value of the **LastErrorString** property.

See Also

SmtpClient Class | SocketTools Namespace

SmtpClient.LastErrorString Property

Gets a value which describes the last error that has occurred.

[Visual Basic]

```
Public ReadOnly Property LastErrorString As String
```

[C#]

```
public string LastErrorString {get;}
```

Property Value

A string which describes the last error that has occurred.

Remarks

The **LastErrorString** property can be used to obtain a description of the last error that occurred for the current instance of the class. It is important to note that this value only has meaning if the previous method indicates that an error has actually occurred.

See Also

SmtpClient Class | SocketTools Namespace

SmtpClient.LocalAddress Property

Gets the local Internet address that the client is bound to.

[Visual Basic]

```
Public ReadOnly Property LocalAddress As String
```

[C#]

```
public string LocalAddress {get;}
```

Property Value

A string which specifies an Internet address.

Remarks

The **LocalAddress** property returns the local Internet address that the client is bound to when a connection is established with a remote host. This property may return either an IPv4 or IPv6 formatted address, depending on the type of connection that was established.

See Also

SmtpClient Class | SocketTools Namespace

SmtpClient.LocalDomain Property

Gets and sets the local domain name.

[Visual Basic]

```
Public Property LocalDomain As String
```

[C#]

```
public string LocalDomain {get; set;}
```

Property Value

A string which specifies the local domain name.

Remarks

The **LocalDomain** returns the local domain name used when the client identifies itself to the mail server. If this property is an empty string, then the control will attempt to automatically determine the appropriate domain name to use based on the system configuration. Setting this property will cause the control to use that value when identifying itself to the server.

This property should only be set if it is absolutely necessary. In most cases, it is preferable to leave this property undefined and allow the control to automatically determine the correct domain name to use. Setting an invalid domain name may cause the mail server to reject the connection.

See Also

SmtpClient Class | SocketTools Namespace

SmtpClient.Localize Property

Gets a value that specifies if the date and time are localized.

[Visual Basic]

```
Public Property Localize As Boolean
```

[C#]

```
public bool Localize {get; set;}
```

Property Value

A boolean value which specifies if the date and time is localized.

Remarks

Setting the **Localize** property controls how date and time values are localized. If the property is set to **true**, then the date and time will be adjusted to the current timezone. If the property is set to **false**, the date and time are specified as UTC (Coordinated Universal Time) values.

See Also

SmtpClient Class | SocketTools Namespace

SmtpClient.LocalName Property

Gets a value which specifies the host name for the local system.

[Visual Basic]

```
Public ReadOnly Property LocalName As String
```

[C#]

```
public string LocalName {get;}
```

Property Value

A string which specifies the local host name.

Remarks

The **LocalName** property returns the fully-qualified host name assigned to the local system. If the system has not been configured with an Internet domain name, then this property will return the NetBIOS name assigned to the local system.

See Also

SmtpClient Class | SocketTools Namespace

SmtpClient.LocalPort Property

Gets the local port number the client is bound to.

[Visual Basic]

```
Public ReadOnly Property LocalPort As Integer
```

[C#]

```
public int LocalPort {get;}
```

Property Value

An integer value which specifies a port number. The default value is 0.

Remarks

The **LocalPort** property is used to identify the local port number that the client is bound to to when a connection is established with a remote host.

See Also

SmtpClient Class | SocketTools Namespace

SmtpClient.Options Property

Gets and sets a value which specifies one or more client options.

[Visual Basic]

```
Public Property Options As SmtpOptions
```

[C#]

```
public SmtpClient.SmtpOptions Options {get; set;}
```

Property Value

Returns one or more SmtpOptions enumeration flags which specify the options for the client. The default value for this property is **smtpOptionNone**.

Remarks

The **Options** property specifies one or more default options options which are used when establishing a connection using the **Connect** method.

See Also

SmtpClient Class | SocketTools Namespace

SmtpClient.Password Property

Gets and sets the password used to authenticate the client.

[Visual Basic]

```
Public Property Password As String
```

[C#]

```
public string Password {get; set;}
```

Property Value

A string which specifies the password.

Remarks

The **Password** property specifies the password used to authenticate the client session. This property is used as the default value for the **Authenticate** method if no password is specified as an argument.

Refer to the **Authentication** property for more information on the available authentication methods. If you are using the OAuth 2.0 authentication method, this property should not be set to the user's password. Instead, you should set the **BearerToken** property to the OAuth 2.0 bearer token issued by the mail service provider. Note that these access tokens can be much larger than your typical password and are only valid for a limited period of time.

You can use the **Password** property to specify an OAuth 2.0 bearer token. However, it is recommended that you use the **BearerToken** property instead of assigning it to this property. It will ensure compatibility with future versions of the class and make it clear in your code you are using an OAuth 2.0 bearer token and not a password. If the **Authentication** property specifies one of the OAuth 2.0 authentication methods, this property will return the bearer token.

See Also

SmtpClient Class | SocketTools Namespace | Authentication Property | BearerToken Property | UserName Property | Authenticate Method

SmtpClient.Recipients Property

Gets the number of current message recipients.

[Visual Basic]

```
Public ReadOnly Property Recipients As Integer
```

[C#]

```
public int Recipients {get;}
```

Property Value

An integer which specifies the number of recipients.

Remarks

The **Recipients** property specifies the number of recipient addresses which have been specified using the **Recipient** property array. The maximum number of recipients for a message varies by server, but is typically limited to approximately 100 addresses.

See Also

SmtpClient Class | SocketTools Namespace

SmtpClient.RemotePort Property

Gets and sets a value which specifies the remote port number.

[Visual Basic]

```
Public Property RemotePort As Integer
```

[C#]

```
public int RemotePort {get; set;}
```

Property Value

An integer value which specifies a port number.

Remarks

The **RemotePort** property is used to set the port number that will be used to establish a connection with a remote host. If the port number specifies a well-known port, the **RemoteService** property will be updated with that name.

See Also

SmtpClient Class | SocketTools Namespace

SmtpClient.ResultCode Property

Gets a value which specifies the last result code returned by the server.

[Visual Basic]
```
Public ReadOnly Property ResultCode As Integer
```

[C#]
```
public int ResultCode {get;}
```

Property Value

An integer value which specifies the last result code returned by the server.

Remarks

Result codes are three-digit numeric values returned by the remote server and may be broken down into the following ranges:

ResultCode	Description
100-199	Positive preliminary result. This indicates that the requested action is being initiated, and the client should expect another reply from the server before proceeding.
200-299	Positive completion result. This indicates that the server has successfully completed the requested action.
300-399	Positive intermediate result. This indicates that the requested action cannot complete until additional information is provided to the server.
400-499	Transient negative completion result. This indicates that the requested action did not take place, but the error condition is temporary and may be attempted again.
500-599	Permanent negative completion result. This indicates that the requested action did not take place.

It is important to note that while some result codes have become standardized, not all servers respond to commands using the same result codes. For example, one server may respond with a result code of 221 to indicate success, while another may respond with a value of 235. It is recommended that applications check for ranges of values to determine if a command was successful, not a specific value.

See Also

SmtpClient Class | SocketTools Namespace

SmtpClient.ResultString Property

Gets a string value which describes the result of the previous command.

[Visual Basic]
```
Public ReadOnly Property ResultString As String
```

[C#]
```
public string ResultString {get;}
```

Property Value

A string which describes the result of the previous command executed on the server.

Remarks

The **ResultString** property returns the result string from the last action taken by the client. This string is generated by the remote server, and typically is used to describe the result code. For example, if an error is indicated by the result code, the result string may describe the condition that caused the error.

See Also

SmtpClient Class | SocketTools Namespace

SmtpClient.ReturnReceipt Property

Enables and disables delivery status notification.

[Visual Basic]

```
Public Property ReturnReceipt As Boolean
```

[C#]

```
public bool ReturnReceipt {get; set;}
```

Property Value

A boolean value which specifies if delivery status notification has been enabled.

Remarks

The **ReturnReceipt** property enables or disables delivery status notification (DSN) by the mail server. If the property is set to True, a mail message will be automatically returned to the sender indicating if the message was delivered successfully, unsuccessfully or delayed by the mail server. If the property is set to False, no delivery status information is sent back to the sender.

Note that delivery status notification is not available on all servers. It is also important to note that a message indicating that delivery was successful does not mean that the message was actually read by the recipient, only that it was delivered to their mailbox.

See Also

SmtpClient Class | SocketTools Namespace

SmtpClient.Secure Property

Gets and sets a value which specifies if a secure connection is established.

[Visual Basic]

```
Public Property Secure As Boolean
```

[C#]

```
public bool Secure {get; set;}
```

Property Value

Returns **true** if a secure connection is established; otherwise returns **false**. The default value is **false**.

Remarks

The **Secure** property determines if a secure connection is established with the remote host. The default value for this property is **false**, which specifies that a standard connection to the server is used. To establish a secure connection, the application should set this property value to **true** prior to calling the **Connect** method. Once the connection has been established, the client may exchange data with the server as with standard connections.

It is strongly recommended that any application that sets this property **true** use error handling to trap an errors that may occur. If the control is unable to initialize the security libraries, or otherwise cannot create a secure session for the client, an exception may be generated when this property value is set.

See Also

SmtpClient Class | SocketTools Namespace

SmtpClient.SecureCipher Property

Gets a value that specifies the encryption algorithm used for a secure connection.

[Visual Basic]

```
Public ReadOnly Property SecureCipher As SecureCipherAlgorithm
```

[C#]

```
public SmtpClient.SecureCipherAlgorithm SecureCipher {get;}
```

Property Value

A SecureCipherAlgorithm enumeration value which identifies the algorithm.

Remarks

The **SecureCipher** property returns a value which identifies the algorithm used to encrypt the data stream. If a secure connection has not been established, this property will return a value of **cipherNone**.

See Also

SmtpClient Class | SocketTools Namespace

SmtpClient.SecureHash Property

Gets a value that specifies the message digest algorithm used for a secure connection.

[Visual Basic]
```
Public ReadOnly Property SecureHash As SecureHashAlgorithm
```

[C#]
```
public SmtpClient.SecureHashAlgorithm SecureHash {get;}
```

Property Value

A SecureHashAlgorithm enumeration value which identifies the algorithm.

Remarks

The **SecureHash** property returns a value which identifies the message digest (hash) algorithm that was selected when a secure connection was established. If a secure connection has not been established, this property will return a value of **hashNone**.

See Also

SmtpClient Class | SocketTools Namespace

SmtpClient.SecureKeyExchange Property

Gets a value that specifies the key exchange algorithm used for a secure connection.

[Visual Basic]

```
Public ReadOnly Property SecureKeyExchange As SecureKeyAlgorithm
```

[C#]

```
public SmtpClient.SecureKeyAlgorithm SecureKeyExchange {get;}
```

Property Value

A SecureKeyAlgorithm enumeration value which identifies the algorithm.

Remarks

The **SecureKeyExchange** property returns a value which identifies the key exchange algorithm that was selected when a secure connection was established. If a secure connection has not been established, this property will return a value of **keyExchangeNone**.

See Also

SmtpClient Class | SocketTools Namespace

SmtpClient.SecureProtocol Property

Gets and sets a value which specifies the protocol used for a secure connection.

[Visual Basic]
```
Public Property SecureProtocol As SecurityProtocols
```

[C#]
```
public SmtpClient.SecurityProtocols SecureProtocol {get; set;}
```

Property Value

A SecurityProtocols enumeration value which identifies the protocol to be used when establishing a secure connection.

Remarks

The **SecureProtocol** property can be used to specify the security protocol to be used when establishing a secure connection with a server or accepting a secure connection from a client. By default, the class will attempt to use either SSL v3 or TLS v1 to establish the connection, with the appropriate protocol automatically selected based on the capabilities of the remote host. It is recommended that you only change this property value if you fully understand the implications of doing so. Assigning a value to this property will override the default protocol and force the class to attempt to use only the protocol specified.

Multiple security protocols may be specified by combining them using a bitwise **or** operator. After a connection has been established, this property will identify the protocol that was selected. Attempting to set this property after a connection has been established will result in an exception being thrown. This property should only be set after setting the **Secure** property to **true** and before calling the **Accept** or **Connect** methods.

In some cases, a server may only accept a secure connection if the TLS v1 protocol is specified. If the security protocol is not compatible with the server, then the connection will fail with an error indicating that the control is unable to establish a security context for the session. In this case, try assigning the property to **protocolTLS1** and attempt the connection again.

See Also

SmtpClient Class | SocketTools Namespace

SmtpClient.Sender Property

Gets and sets the sender email address.

[Visual Basic]
```
Public Property Sender As String
```

[C#]
```
public string Sender {get; set;}
```

Property Value

A string which specifies the sender email address.

Remarks

The **Sender** property is used to specify the default address for the user who is sending the email message. This property should specify a valid email address in the standard Internet format. Typically this is the same address as specified in the From header field for the message, but it is not required that they be the same value.

See Also

SmtpClient Class | SocketTools Namespace

SmtpClient.Status Property

Gets a value which specifies the current status of the client.

[Visual Basic]

```
Public ReadOnly Property Status As SmtpStatus
```

[C#]

```
public SmtpClient.SmtpStatus Status {get;}
```

Property Value

A SmtpStatus enumeration value which specifies the current client status.

Remarks

The **Status** property returns the current status of the client. This property can be used to check on blocking connections to determine if the client is interacting with the remote host before taking some action.

See Also

SmtpClient Class | SocketTools Namespace

SmtpClient.ThreadModel Property

Gets and sets a value which specifies the threading model for the class instance.

[Visual Basic]
```
Public Property ThreadModel As ThreadingModel
```

[C#]
```
public SmtpClient.ThreadingModel ThreadModel {get; set;}
```

Property Value

Returns one or more ThreadingModel enumeration value which specifies the threading model for the client. The default value for this property is **modelSingleThread**.

Remarks

The **ThreadModel** property specifies the threading model that is used by the class instance when a connection is established. The default value for this property is **modelSingleThread**, which specifies that only the thread that established the connection should be permitted to invoke methods. It is important to note that this threading model does not limit the application to a single thread of execution. When a session is established using the **Connect** method, that session is attached to the thread that created it. From that point on, until the session is terminated, only the owner may invoke methods in that instance of the class. The ownership of the class instance may be transferred from one thread to another using the **AttachThread** method.

Setting this property to **modelFreeThread** disables certain internal safety checks that are performed by the class and may result in unexpected behavior unless you ensure that access to the class instance is synchronized across multiple threads. The application must ensure that no two threads will attempt to invoke a blocking method at the same time. In other words, if one thread invokes a method, the application must ensure that another thread will not attempt to invoke any other method at the same time using the same instance of the class.

Changing the value of this property will not affect an active client session. The threading model must be specified prior to invoking the **Connect** method.

See Also

SmtpClient Class | SocketTools Namespace | AttachThread Method | ThreadingModel Enumeration | ThreadModel Attribute

SmtpClient.ThrowError Property

Gets and sets a value which specifies if method calls should throw exceptions when an error occurs.

[Visual Basic]
```
Public Property ThrowError As Boolean
```

[C#]
```
public bool ThrowError {get; set;}
```

Property Value

Returns **true** if method calls will generate exceptions when an error occurs; otherwise returns **false**. The default value is **false**.

Remarks

Error handling for when calling class methods can be done in either of two different styles, according to the value of this property.

If the **ThrowError** property is set to **false**, the application should check the return value of any method that is used, and report errors based upon the documented value of the return code. It is the responsibility of the application to interpret the error code, if it is desired to explain the error in addition to reporting it. This is the default behavior.

If the **ThrowError** property is set to **true**, then exceptions will be generated whenever a method call fails. The program must be written to catch these exceptions and take the appropriate action when an error occurs. Failure to handle an exception will cause the program to terminate abnormally.

Note that if an error occurs while a property is being read or modified, an exception will be raised regardless of the value of the **ThrowError** property.

See Also

SmtpClient Class | SocketTools Namespace

SmtpClient.Timeout Property

Gets and sets a value which specifies a timeout period in seconds.

[Visual Basic]

```
Public Property Timeout As Integer
```

[C#]

```
public int Timeout {get; set;}
```

Property Value

An integer value which specifies a timeout period in seconds.

Remarks

Setting the **Timeout** property specifies the number of seconds until a blocking operation fails and returns an error.

The timeout period is only used when the client is in blocking mode. Although this property can be changed when the client is in non-blocking mode, the value will be ignored until the client is returned to blocking mode.

For most applications it is recommended the timeout period be set between 10 and 20 seconds.

See Also

SmtpClient Class | SocketTools Namespace

SmtpClient.TimeZone Property

Gets and sets the current timezone offset in seconds.

[Visual Basic]

```
Public Property TimeZone As Integer
```

[C#]

```
public int TimeZone {get; set;}
```

Property Value

An integer value which specifies the current timezone offset in seconds.

Remarks

The **TimeZone** property returns the current offset from UTC in seconds. Setting the property changes the current timezone offset to the specified value. The value of this property is initially determined by the date and time settings on the local system.

This property value is used in conjunction with the **Localize** property to control how date and time localization is handled.

See Also

SmtpClient Class | SocketTools Namespace

SmtpClient.Trace Property

Gets and sets a value which indicates if network function logging is enabled.

[Visual Basic]

```
Public Property Trace As Boolean
```

[C#]

```
public bool Trace {get; set;}
```

Property Value

Returns **true** if network function tracing is enabled; otherwise returns **false**. The default value is **false**.

Remarks

The **Trace** property is used to enable (or disable) the tracing of network function calls. When enabled, each function call is logged to a file, including the function parameters, return value and error code if applicable. This facility can be enabled and disabled at run time, and the trace log file can be specified by setting the **TraceFile** property. All function calls that are being logged are appended to the trace file, if it exists. If no trace file exists when tracing is enabled, the trace file is created.

The tracing facility is available in all of the SocketTools networking classes and is enabled or disabled for an entire process. This means that once trace logging is enabled for a given component, all of the function calls made by the process using any of the SocketTools classes will be logged. For example, if you have an application using both the File Transfer Protocol and Post Office Protocol classes, and you set the **Trace** property to **true**, function calls made by both classes will be logged. Additionally, enabling a trace is cumulative, and tracing is not stopped until it is disabled for all classes used by the process.

If trace logging is not enabled, there is no negative impact on performance or throughput. Once enabled, application performance can degrade, especially in those situations in which multiple processes are being traced or the logfile is fairly large. Since logfiles can grow very quickly, even with modest applications, it is recommended that you delete the file when it is no longer needed.

When redistributing your application, make sure that you include the **SocketTools10.TraceLog.dll** module with your installation. If this library is not present, then no trace output will be generated and the value of the **Trace** property will be ignored. Only those function calls made by the SocketTools networking classes will be logged. Calls made directly to the Windows Sockets API, or calls made by other classes, will not be logged.

See Also

SmtpClient Class | SocketTools Namespace

SmtpClient.TraceFile Property

Gets and sets a value which specifies the name of the logfile.

[Visual Basic]

```
Public Property TraceFile As String
```

[C#]

```
public string TraceFile {get; set;}
```

Property Value

A string which specifies the name of the file.

Remarks

The **TraceFile** property is used to specify the name of the trace file that is created when network function tracing is enabled. If this property is set to an empty string (the default value), then a file named **SocketTools.log** is created in the system's temporary directory. If no temporary directory exists, then the file is created in the current working directory.

If the file exists, the trace output is appended to the file, otherwise the file is created. Since network function tracing is enabled per-process, the trace file is shared by all instances of the class being used. If multiple class instances have tracing enabled, the **TraceFile** property should be set to the same value for each instance. Since trace files can grow very quickly, even with modest applications, it is recommended that you delete the file when it is no longer needed.

The trace file has the following format:

```
 MyApp INF: WSAAsyncSelect(46, 0xcc4, 0x7e9, 0x27) returned 0 MyApp WRN:
connect(46, 192.0.0.1:1234, 16) returned -1 [10035] MyApp ERR: accept(46,
NULL, 0x0) returned -1 [10038]
```

The first column contains the name of the process that is being traced. The second column identifies if the trace record is reporting information, a warning, or an error. What follows is the name of the function being called, the arguments passed to the function and the function's return value. If a warning or error is reported, the error code is appended to the record (the value is placed inside brackets).

If parameters are passed as integer values, they are recorded in decimal. If the parameter or return value is a pointer (a memory address), it is recorded as a hexadecimal value preceded with "0x". A special type of pointer, called a null pointer, is recorded as NULL. Those functions which expect socket addresses are displayed in the following format:

```
aa.bb.cc.dd:nnnn
```

The first four numbers separated by periods represent the IP address, and the number following the colon represents the port number in host byte order. Note that in the second line of the above example, the control is attempting to connect to a system with the IP address 192.0.0.1 on port 1234.

Note that if the specified file cannot be created, or the user does not have permission to modify an existing file, the error is silently ignored and no trace output will be generated.

See Also

SmtpClient Class | SocketTools Namespace

SmtpClient.TraceFlags Property

Gets and sets a value which specifies the client function tracing flags.

[Visual Basic]

```
Public Property TraceFlags As TraceOptions
```

[C#]

```
public SmtpClient.TraceOptions TraceFlags {get; set;}
```

Property Value

A TraceOptions enumeration which specifies the amount of detail written to the trace logfile.

Remarks

The **TraceFlags** property is used to specify the type of information written to the trace file when network function tracing is enabled.

Because network function tracing is enabled per-process, the trace flags are shared by all instances of the class being used. If multiple class instances have tracing enabled, the **TraceFlags** property should be set to the same value for each instance. Changing the trace flags for any one instance of the class will affect the logging performed for all SocketTools classes used by the application.

Warnings are generated when a non-fatal error is returned by a network function. For example, if data is being written and the error **errorOperationWouldBlock** occurs, a warning is generated because the application simply needs to attempt to write the data at a later time.

SmtpClient Class | SocketTools Namespace

SmtpClient.UserName Property

Gets and sets the username used to authenticate the client session.

[Visual Basic]

```
Public Property UserName As String
```

[C#]

```
public string UserName {get; set;}
```

Property Value

A string which specifies the username.

Remarks

If a username is not specified when the **Connect** method is called, the value of this property will be used as the default username when establishing a connection with the server.

See Also

SmtpClient Class | SocketTools Namespace

SmtpClient.Version Property

Gets a value which returns the current version of the SmtpClient class library.

[Visual Basic]

```
Public ReadOnly Property Version As String
```

[C#]

```
public string Version {get;}
```

Property Value

A string which specifies the version of the class library.

Remarks

The **Version** property returns a string which identifies the current version and build of the SmtpClient class library. This value can be used by an application for validation and debugging purposes.

SmtpClient Class | SocketTools Namespace

SmtpClient Methods

The methods of the **SmtpClient** class are listed below. For a complete list of **SmtpClient** class members, see the SmtpClient Members topic.

Public Instance Methods

AddRecipient	Add an address to the recipient list for the current message.
AppendMessage	Overloaded. Append text to the current message being composed.
AttachThread	Attach an instance of the class to the current thread
Authenticate	Overloaded. Authenticate the client session with a username and password.
Cancel	Cancel the current blocking client operation.
CloseMessage	Closes the current message.
Command	Overloaded. Send a custom command to the server.
Connect	Overloaded. Establish a connection with a remote host.
CreateMessage	Overloaded. Begin the composition of a new message to be delivered.
Disconnect	Terminate the connection with a remote host.
Dispose	Overloaded. Releases all resources used by SmtpClient.
Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
ExpandAddress	Expand the specified email address.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from Object)	Gets the Type of the current instance.
Initialize	Overloaded. Initialize an instance of the SmtpClient class.
Reset	Reset the internal state of the object, resetting all properties to their default values.
SendMessage	Overloaded. Submit the specified message to the mail server for delivery.
ToString (inherited from Object)	Returns a String that represents the current Object.
Uninitialize	Uninitialize the class library and release any resources allocated for the current thread.

VerifyAddress	Verify the specified email address.
Write	Overloaded. Write one or more bytes of data to the server.

Protected Instance Methods

Dispose	Overloaded. Releases the unmanaged resources allocated by the SmtpClient class and optionally releases the managed resources.
Finalize	Destroys an instance of the class, releasing the resources allocated for the session and unloading the networking library.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

SmtpClient.Authenticate Method

Authenticate the client session.

Overload List

Authenticate the client session.

public bool Authenticate();

Authenticate the client session with a username and password.

public bool Authenticate(string,string);

See Also

SmtpClient Class | SocketTools Namespace | Authentication Property | BearerToken Property | Extended Property | Password Property | UserName Property

SmtpClient.Authenticate Method ()

Authenticate the client session.

[Visual Basic]
```
Overloads Public Function Authenticate() As Boolean
```

[C#]
```
public bool Authenticate();
```

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **Authenticate** method is used to authenticate the current client session to the mail server, ensuring that only valid users may deliver messages through the server. This method uses the LOGIN authentication mechanism by default and you can specify an alternate authentication method by setting the the **Authentication** property.

Authentication requires the server to support the AUTH extended SMTP command and the **Extended** property must be set to True prior to establishing the connection. If the server does not support the specified type of authentication, an error will be returned.

The value of the **UserName** property is used to specify the username and the value of the **Password** property is used to specify the password. If OAuth 2.0 is being used for authentication, the value of the **BearerToken** property will be provided to the server.

If you with to use OAuth 2.0 for authentication, set the **Authentication** property to the desired authentication type and the **BearerToken** property to the value of the bearer token prior to calling this method. The connection must be secure, and the server must advertise its support for OAuth 2.0 or the authentication attempt will fail. This method will not attempt to automatically refresh an expired token.

If you provide a user name and password to the **Connect** method, or you set the **UserName** property and either the **Password** or **BearerToken** property prior to calling the **Connect** method, authentication will be automatically attempted at the time the connection is made. This method is only required if you do not provde user credentials when the connection is established and wish to authenticate the client session at a later time.

See Also

SmtpClient Class | SocketTools Namespace | SmtpClient.Authenticate Overload List | Authentication Property | BearerToken Property | Extended Property | Password Property | UserName Property

SmtpClient.Authenticate Method (String, String)

Authenticate the client session with a username and password.

[Visual Basic]

```
Overloads Public Function Authenticate( _
   ByVal userName As String, _
   ByVal userPassword As String _
) As Boolean
```

[C#]

```
public bool Authenticate(
   string userName,
   string userPassword
);
```

Parameters

userName

A string which specifies the username used to authenticate the client session.

userPassword

A string which specifies the password which will be used to authenticate the client session with the remote host. Not all mail servers require the client to authenticate the session. If you are using OAuth 2.0 authentication, this parameter specifies the bearer token provided by the mail service.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **Authenticate** method is used to authenticate the current client session to the mail server, ensuring that only valid users may deliver messages through the server. This method uses the LOGIN authentication mechanism by default and you can specify an alternate authentication method by setting the the **Authentication** property.

Authentication requires the server to support the AUTH extended SMTP command and the **Extended** property must be set to True prior to establishing the connection. If the server does not support the specified type of authentication, an error will be returned.

If you with to use OAuth 2.0 for authentication, set the **Authentication** property to the desired authentication type prior to calling this method. The connection must be secure, and the server must advertise its support for OAuth 2.0 or the authentication attempt will fail. This method will not attempt to automatically refresh an expired token.

If you provide a user name and password to the **Connect** method, or you set the **UserName** property and either the **Password** or **BearerToken** property prior to calling the **Connect** method, authentication will be automatically attempted at the time the connection is made. This method is only required if you do not provde user credentials when the connection is established and wish to authenticate the client session at a later time.

See Also

SmtpClient.AddRecipient Method

Add an address to the recipient list for the current message.

[Visual Basic]

```
Public Function AddRecipient( _
   ByVal address As String _
) As Boolean
```

[C#]

```
public bool AddRecipient(
   string address
);
```

Parameters

address

A string which specifies the recipient address.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **AddRecipient** method adds the specified address to the recipient list for the current message. This method should be called after the message transaction has begun with a call to the **CreateMessage** method. Most servers impose a limit of approximately 100 recipient addresses that will be accepted for a single message.

Note that this method does not update the **Recipient** property, which maintains an internal list of recipient addresses used by the **SendMessage** method. This method should only be used in conjunction with the **CreateMessage** method.

See Also

SmtpClient Class | SocketTools Namespace

SmtpClient.AppendMessage Method

Append text to the current message being composed.

Overload List

Append text to the current message being composed.

public bool AppendMessage(byte[],int);

Append text to the current message being composed.

public bool AppendMessage(string);

See Also

SmtpClient Class | SocketTools Namespace

SmtpClient.AppendMessage Method (Byte[], Int32)

Append text to the current message being composed.

[Visual Basic]
```
Overloads Public Function AppendMessage( _
   ByVal buffer As Byte(), _
   ByVal length As Integer _
) As Boolean
```

[C#]
```
public bool AppendMessage(
   byte[] buffer,
   int length
);
```

Parameters

buffer

A byte array which specifies the data to be appended to the message.

length

An integer value which specifies the maximum number of bytes of data to append to the message. This value cannot be larger than the size of the buffer specified by the caller

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **AppendMessage** method appends the specified text to the current message. This method will cause the current thread to block until the article transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

This method is useful for composing a message where the application needs to dynamically create the header, followed by a large amount of text. The message contents should be text, with each line terminated with a carriage return and linefeed character. Not all mail servers support sending 8-bit characters, so the message contents may need to be encoded if it uses anything other than standard US ASCII. To append binary data, it should be encoded using either the uucode or base64 (MIME) algorithms. It is recommended that you use the **SocketTools.MailMessage** class to manage file attachments and other complex message types.

See Also

SmtpClient Class | SocketTools Namespace | SmtpClient.AppendMessage Overload List

SmtpClient.AppendMessage Method (String)

Append text to the current message being composed.

[Visual Basic]
```
Overloads Public Function AppendMessage( _
   ByVal buffer As String _
) As Boolean
```

[C#]
```
public bool AppendMessage(
   string buffer
);
```

Parameters

buffer
A byte array which specifies the data to be appended to the message.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **AppendMessage** method appends the specified text to the current message. This method will cause the current thread to block until the article transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

SmtpClient Class | SocketTools Namespace | SmtpClient.AppendMessage Overload List

SmtpClient.AttachThread Method

Attach an instance of the class to the current thread

[Visual Basic]
```
Public Function AttachThread() As Boolean
```

[C#]
```
public bool AttachThread();
```

Return Value

A boolean value which specifies if the client could be attached to the current thread. If this method returns **false**, the client could not be attached to the thread and the application should check the value of the LastError property to determine the cause of the failure.

Remarks

When an instance of the class is created it is associated with the current thread that created it. Normally, if another thread attempts to perform an operation using that instance, an error is returned. This is used to ensure that other threads cannot interfere with an operation being performed by the owner thread. In some cases, it may be desirable for one thread in an application to create an instance of the class, establish a connection and then pass that instance to another worker thread. The **AttachThread** method can be used to change the ownership of the class instance to the new worker thread.

This method should be called by the new thread immediately after it has been created, and if the new thread does not release the handle itself, the ownership of the handle should be restored by the original thread. Under no circumstances should **AttachThread** be used to forcibly destroy an instance of a class allocated by another thread while a blocking operation is in progress. To cancel a blocking operation, use the **Cancel** method and then delete the class instance after the blocking function exits and control is returned to the current thread.

See Also

SmtpClient Class | SocketTools Namespace

SmtpClient.Cancel Method

Cancel the current blocking client operation.

[Visual Basic]
```
Public Sub Cancel()
```

[C#]
```
public void Cancel();
```

Remarks

When the **Cancel** method is called, the blocking client operation will not immediately fail. An internal flag is set which causes the blocking operation to exit with an error. This means that the application cannot cancel an operation and immediately perform some other blocking function. Instead it must allow the calling stack to unwind, returning back to the blocking operation before making any further function calls.

See Also

SmtpClient Class | SocketTools Namespace

SmtpClient.CloseMessage Method

Closes the current message.

[Visual Basic]
```
Public Function CloseMessage() As Boolean
```

[C#]
```
public bool CloseMessage();
```

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **CloseArticle** method closes the current message that has been created and submits it to the mail server for delivery.

See Also

SmtpClient Class | SocketTools Namespace

SmtpClient.Command Method

Send a custom command to the server.

Overload List

Send a custom command to the server.

public bool Command(string);

Send a custom command to the server.

public bool Command(string,string);

See Also

SmtpClient Class | SocketTools Namespace

SmtpClient.Command Method (String)

Send a custom command to the server.

[Visual Basic]

```
Overloads Public Function Command( _
   ByVal command As String _
) As Boolean
```

[C#]

```
public bool Command(
   string command
);
```

Parameters

command

A string which specifies the command to send. Valid commands vary based on the Internet protocol and the type of server that the client is connected to. Consult the protocol standard and/or the technical reference documentation for the server to determine what commands may be issued by a client application.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **Command** method sends a command to the remote host and processes the result code sent back in response to that command. This method can be used to send custom commands to a server to take advantage of features or capabilities that may not be supported internally by the class library.

To determine the specific status code returned by the server, check the value of the **ResultCode** property after the method returns.

See Also

SmtpClient Class | SocketTools Namespace | SmtpClient.Command Overload List

SmtpClient.Command Method (String, String)

Send a custom command to the server.

[Visual Basic]
```
Overloads Public Function Command( _
   ByVal command As String, _
   ByVal parameters As String _
) As Boolean
```

[C#]
```
public bool Command(
   string command,
   string parameters
);
```

Parameters

command

A string which specifies the command to send. Valid commands vary based on the Internet protocol and the type of server that the client is connected to. Consult the protocol standard and/or the technical reference documentation for the server to determine what commands may be issued by a client application.

parameters

An string which specifies one or more parameters to be sent along with the command. If more than one parameter is required, they must be separated by a single space character. Consult the protocol standard and/or technical reference documentation for the server to determine what parameters should be provided when issuing a specific command.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **Command** method sends a command to the remote host and processes the result code sent back in response to that command. This method can be used to send custom commands to a server to take advantage of features or capabilities that may not be supported internally by the class library.

To determine the specific status code returned by the server, check the value of the **ResultCode** property after the method returns.

SmtpClient.Connect Method

Establish a connection with a remote host.

Overload List

Establish a connection with a remote host.

public bool Connect();

Establish a connection with a remote host.

public bool Connect(string);

Establish a connection with a remote host.

public bool Connect(string,int);

Establish a connection with a remote host.

public bool Connect(string,int,int);

Establish a connection with a remote host.

public bool Connect(string,int,int,SmtpOptions);

Establish a connection with a remote host.

public bool Connect(string,int,string,string);

Establish a connection with a remote host.

public bool Connect(string,int,string,string,int);

Establish a connection with a remote host.

public bool Connect(string,int,string,string,int,SmtpOptions);

Establish a connection with a remote host.

public bool Connect(string,string,string);

See Also

SmtpClient Class | SocketTools Namespace | Authentication Property | BearerToken Property | HostName Property | Options Property | Password Property | UserName Property

SmtpClient.Connect Method ()

Establish a connection with a remote host.

[Visual Basic]
```
Overloads Public Function Connect() As Boolean
```

[C#]
```
public bool Connect();
```

Return Value

A boolean value which specifies if the connection has been established. If the client is in blocking mode, a return value of **true** indicates that the connection has completed and the application may send and receive data from the remote host. If the client is in non-blocking mode, a return value of **true** indicates that the client has successfully created a socket and the connection is in progress.

When a non-blocking connection has completed, the OnConnect event will be fired. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

Remarks

This method establishes a connection using assigned property values.

The value of the **HostName** or **HostAddress** property will be used to determine the host name or address to connect to.

The value of the **RemotePort** property will be used to determine the port number to connect to.

The value of the **UserName** property specifies the username that will be used to authenticate the session.

The value of the **Password** property specifies the password that will be used to authenticate the session.

The value of the **Timeout** property will be used to specify the timeout period.

The value of the **Options** property will be used to specify the default options for the connection.

SmtpClient.Connect Method (String)

Establish a connection with a remote host.

[Visual Basic]

```
Overloads Public Function Connect( _
   ByVal hostName As String _
) As Boolean
```

[C#]

```
public bool Connect(
   string hostName
);
```

Parameters

hostName

A string which specifies the remote host to establish a connection with. This may specify a host name or an Internet address in dot-notation.

Return Value

A boolean value which specifies if the connection has been established. If the client is in blocking mode, a return value of **true** indicates that the connection has completed and the application may send and receive data from the remote host. If the client is in non-blocking mode, a return value of **true** indicates that the client has successfully created a socket and the connection is in progress.

When a non-blocking connection has completed, the OnConnect event will be fired. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

Remarks

This method establishes a connection using assigned property values.

The value of the **RemotePort** property will be used to determine the port number to connect to.

The value of the **UserName** property specifies the username that will be used to authenticate the session.

The value of the **Password** property specifies the password that will be used to authenticate the session.

The value of the **Timeout** property will be used to specify the timeout period.

The value of the **Options** property will be used to specify the default options for the connection.

SmtpClient.Connect Method (String, Int32)

Establish a connection with a remote host.

[Visual Basic]

```
Overloads Public Function Connect( _
   ByVal hostName As String, _
   ByVal hostPort As Integer _
) As Boolean
```

[C#]

```
public bool Connect(
   string hostName,
   int hostPort
);
```

Parameters

hostName

A string which specifies the remote host to establish a connection with. This may specify a host name or an Internet address in dot-notation.

hostPort

An integer which specifies the port number for the connection. This value must be greater than zero and the maximum valid port number is 65535.

Return Value

A boolean value which specifies if the connection has been established. If the client is in blocking mode, a return value of **true** indicates that the connection has completed and the application may send and receive data from the remote host. If the client is in non-blocking mode, a return value of **true** indicates that the client has successfully created a socket and the connection is in progress.

When a non-blocking connection has completed, the OnConnect event will be fired. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

Remarks

This method establishes a connection using assigned property values.

The value of the **UserName** property specifies the username that will be used to authenticate the session.

The value of the **Password** property specifies the password that will be used to authenticate the session.

The value of the **Timeout** property will be used to specify the timeout period.

The value of the **Options** property will be used to specify the default options for the connection.

SmtpClient.Connect Method (String, Int32, Int32)

Establish a connection with a remote host.

[Visual Basic]

```
Overloads Public Function Connect( _
   ByVal hostName As String, _
   ByVal hostPort As Integer, _
   ByVal timeout As Integer _
) As Boolean
```

[C#]

```
public bool Connect(
   string hostName,
   int hostPort,
   int timeout
);
```

Parameters

hostName

A string which specifies the remote host to establish a connection with. This may specify a host name or an Internet address in dot-notation.

hostPort

An integer which specifies the port number for the connection. This value must be greater than zero and the maximum valid port number is 65535.

timeout

An integer value that specifies the number of seconds that the method will wait for the connection to complete before failing the operation and returning to the caller. This value is only meaningful for blocking connections.

Return Value

A boolean value which specifies if the connection has been established. If the client is in blocking mode, a return value of **true** indicates that the connection has completed and the application may send and receive data from the remote host. If the client is in non-blocking mode, a return value of **true** indicates that the client has successfully created a socket and the connection is in progress.

When a non-blocking connection has completed, the OnConnect event will be fired. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

Remarks

This method establishes a connection using assigned property values.

The value of the **UserName** property specifies the username that will be used to authenticate the session.

The value of the **Password** property specifies the password that will be used to authenticate the session.

The value of the **Options** property will be used to specify the default options for the connection.

SmtpClient.Connect Method (String, Int32, Int32, SmtpOptions)

Establish a connection with a remote host.

[Visual Basic]
```
Overloads Public Function Connect( _
   ByVal hostName As String, _
   ByVal hostPort As Integer, _
   ByVal timeout As Integer, _
   ByVal options As SmtpOptions _
) As Boolean
```

[C#]
```
public bool Connect(
   string hostName,
   int hostPort,
   int timeout,
   SmtpOptions options
);
```

Parameters

hostName
A string which specifies the remote host to establish a connection with. This may specify a host name or an Internet address in dot-notation.

hostPort
An integer which specifies the port number for the connection. This value must be greater than zero and the maximum valid port number is 65535.

timeout
An integer value that specifies the number of seconds that the method will wait for the connection to complete before failing the operation and returning to the caller. This value is only meaningful for blocking connections.

options
One or more of the SmtpOptions enumeration flags.

Return Value

A boolean value which specifies if the connection has been established. If the client is in blocking mode, a return value of **true** indicates that the connection has completed and the application may send and receive data from the remote host. If the client is in non-blocking mode, a return value of **true** indicates that the client has successfully created a socket and the connection is in progress.

When a non-blocking connection has completed, the OnConnect event will be fired. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

SmtpClient Class | SocketTools Namespace | SmtpClient.Connect Overload List | Authentication Property | BearerToken Property | HostName Property | Options Property | Password Property | UserName Property

SmtpClient.Connect Method (String, Int32, String, String)

Establish a connection with a remote host.

[Visual Basic]
```
Overloads Public Function Connect( _
   ByVal hostName As String, _
   ByVal hostPort As Integer, _
   ByVal userName As String, _
   ByVal userPassword As String _
) As Boolean
```

[C#]
```
public bool Connect(
   string hostName,
   int hostPort,
   string userName,
   string userPassword
);
```

Parameters

hostName

A string which specifies the remote host to establish a connection with. This may specify a host name or an Internet address in dot-notation.

hostPort

An integer which specifies the port number for the connection. This value must be greater than zero and the maximum valid port number is 65535.

userName

A string which specifies the username which will be used to authenticate the client session with the remote host. Not all mail servers require the client to authenticate the session.

userPassword

A string which specifies the password which will be used to authenticate the client session with the remote host. Not all mail servers require the client to authenticate the session. If you are using OAuth 2.0 authentication, this parameter specifies the bearer token provided by the mail service.

Return Value

A boolean value which specifies if the connection has been established. If the client is in blocking mode, a return value of **true** indicates that the connection has completed and the application may send and receive data from the remote host. If the client is in non-blocking mode, a return value of **true** indicates that the client has successfully created a socket and the connection is in progress.

When a non-blocking connection has completed, the OnConnect event will be fired. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

Remarks

This method establishes a connection using assigned property values.

The value of the **Timeout** property will be used to specify the timeout period.

The value of the **Options** property will be used to specify the default options for the connection.

An integer value that specifies the number of seconds that the method will wait for the connection to complete before failing the operation and returning to the caller. This value is only meaningful for blocking connections.

Return Value

A boolean value which specifies if the connection has been established. If the client is in blocking mode, a return value of **true** indicates that the connection has completed and the application may send and receive data from the remote host. If the client is in non-blocking mode, a return value of **true** indicates that the client has successfully created a socket and the connection is in progress.

When a non-blocking connection has completed, the OnConnect event will be fired. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

SmtpClient Class | SocketTools Namespace | SmtpClient.Connect Overload List | Authentication Property | BearerToken Property | HostName Property | Options Property | Password Property | UserName Property

SmtpClient.Connect Method (String, Int32, String, String, Int32, SmtpOptions)

Establish a connection with a remote host.

[Visual Basic]

```
Overloads Public Function Connect( _
   ByVal hostName As String, _
   ByVal hostPort As Integer, _
   ByVal userName As String, _
   ByVal userPassword As String, _
   ByVal timeout As Integer, _
   ByVal options As SmtpOptions _
) As Boolean
```

[C#]

```
public bool Connect(
   string hostName,
   int hostPort,
   string userName,
   string userPassword,
   int timeout,
   SmtpOptions options
);
```

Parameters

hostName

A string which specifies the remote host to establish a connection with. This may specify a host name or an Internet address in dot-notation.

hostPort

An integer which specifies the port number for the connection. This value must be greater than zero and the maximum valid port number is 65535.

userName

A string which specifies the username which will be used to authenticate the client session with the remote host. Not all mail servers require the client to authenticate the session.

userPassword

A string which specifies the password which will be used to authenticate the client session with the remote host. Not all mail servers require the client to authenticate the session. If you are using OAuth 2.0 authentication, this parameter specifies the bearer token provided by the mail service.

timeout

An integer value that specifies the number of seconds that the method will wait for the connection to complete before failing the operation and returning to the caller. This value is only meaningful for blocking connections.

options

One or more of the SmtpOptions enumeration flags.

Return Value

A boolean value which specifies if the connection has been established. If the client is in blocking mode, a return value of **true** indicates that the connection has completed and the application may send and receive data from the remote host. If the client is in non-blocking mode, a return value of **true** indicates that the client has successfully created a socket and the connection is in progress.

When a non-blocking connection has completed, the OnConnect event will be fired. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

SmtpClient Class | SocketTools Namespace | SmtpClient.Connect Overload List | Authentication Property | BearerToken Property | HostName Property | Options Property | Password Property | UserName Property

SmtpClient.Connect Method (String, String, String)

Establish a connection with a remote host.

[Visual Basic]

```
Overloads Public Function Connect( _
   ByVal hostName As String, _
   ByVal userName As String, _
   ByVal userPassword As String _
) As Boolean
```

[C#]

```
public bool Connect(
   string hostName,
   string userName,
   string userPassword
);
```

Parameters

hostName

A string which specifies the remote host to establish a connection with. This may specify a host name or an Internet address in dot-notation.

userName

A string which specifies the username which will be used to authenticate the client session with the remote host. Not all mail servers require the client to authenticate the session.

userPassword

A string which specifies the password which will be used to authenticate the client session with the remote host. Not all mail servers require the client to authenticate the session. If you are using OAuth 2.0 authentication, this parameter specifies the bearer token provided by the mail service.

Return Value

A boolean value which specifies if the connection has been established. If the client is in blocking mode, a return value of **true** indicates that the connection has completed and the application may send and receive data from the remote host. If the client is in non-blocking mode, a return value of **true** indicates that the client has successfully created a socket and the connection is in progress.

When a non-blocking connection has completed, the OnConnect event will be fired. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

Remarks

This method establishes a connection using assigned property values.

The value of the **RemotePort** property will be used to determine the port number to connect to.

The value of the **Timeout** property will be used to specify the timeout period.

The value of the **Options** property will be used to specify the default options for the connection.

SmtpClient.CreateMessage Method

Begin the composition of a new message to be delivered.

Overload List

Begin the composition of a new message to be delivered.

public bool CreateMessage(string);

Begin the composition of a new message to be delivered.

public bool CreateMessage(string,int);

See Also

SmtpClient Class | SocketTools Namespace

SmtpClient.CreateMessage Method (String)

Begin the composition of a new message to be delivered.

```
[Visual Basic]
Overloads Public Function CreateMessage( _
   ByVal messageSender As String _
) As Boolean
```

```
[C#]
public bool CreateMessage(
   string messageSender
);
```

Parameters

messageSender

A string which specifies the email address of the user sending the message. This typically corresponds to the address in the From header of the message, but it is not required that they be the same.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **CreateMessage** method begins the composition of a new message to be submitted to the mail server for delivery. There are several steps that must be followed when dynamically composing a message using the **CreateMessage** method:

1. Call the **CreateMessage** method to begin the message composition. The sender email address should generally be the same address as the one used in the "From" header field in the message.
2. Call the **AddRecipient** method for each recipient of the message. These addresses are typically specified in the "To" and "Cc" header fields in the message. Additional addresses may also be be provided which are not specified in the email message itself. This is how one or more blind carbon copies of a message is delivered. Most servers have a limit on the total number of recipients that may be specified for a single message. This limit is usually around 100 addresses.
3. Call the **Write** method to write the contents of the message to the data stream. The application may also choose to use the **AppendMessage** method to write out a large amount of message data.
4. Call the **CloseMessage** method to close the message and submit it to the mail server for delivery.

For applications that do not need to dynamically compose the message and already have the message contents stored in a file or memory buffer, the **SendMessage** method is the preferred method of submitting a message for delivery

See Also

SmtpClient Class | SocketTools Namespace | SmtpClient.CreateMessage Overload List

SmtpClient.CreateMessage Method (String, Int32)

Begin the composition of a new message to be delivered.

[Visual Basic]

```
Overloads Public Function CreateMessage( _
   ByVal messageSender As String, _
   ByVal messageSize As Integer _
) As Boolean
```

[C#]

```
public bool CreateMessage(
   string messageSender,
   int messageSize
);
```

Parameters

messageSender

A string which specifies the email address of the user sending the message. This typically corresponds to the address in the From header of the message, but it is not required that they be the same.

messageSize

An integer which specifies the size of the message in bytes. If the size of the message is unknown, this argument should be omitted or passed as value of zero. This argument is ignored if the server does not support extended features. If the message size is larger than what the server will accept, this method will fail. Most Internet Service Providers impose a limit on the size of an email message, typically between 5 and 10 megabytes.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **CreateMessage** method begins the composition of a new message to be submitted to the mail server for delivery. There are several steps that must be followed when dynamically composing a message using the **CreateMessage** method:

1. Call the **CreateMessage** method to begin the message composition. The sender email address should generally be the same address as the one used in the "From" header field in the message.
2. Call the **AddRecipient** method for each recipient of the message. These addresses are typically specified in the "To" and "Cc" header fields in the message. Additional addresses may also be be provided which are not specified in the email message itself. This is how one or more blind carbon copies of a message is delivered. Most servers have a limit on the total number of recipients that may be specified for a single message. This limit is usually around 100 addresses.
3. Call the **Write** method to write the contents of the message to the data stream. The application may also choose to use the **AppendMessage** method to write out a large amount of message data.
4. Call the **CloseMessage** method to close the message and submit it to the

mail server for delivery.

For applications that do not need to dynamically compose the message and already have the message contents stored in a file or memory buffer, the **SendMessage** method is the preferred method of submitting a message for delivery

SmtpClient Class | SocketTools Namespace | SmtpClient.CreateMessage Overload List

SmtpClient.Disconnect Method

Terminate the connection with a remote host.

[Visual Basic]

```
Public Sub Disconnect()
```

[C#]

```
public void Disconnect();
```

Remarks

The **Disconnect** method terminates the connection with the remote host and releases the client handle allocated by the class. Note that the socket is not immediately released when the connection is terminated and will enter a wait state for two minutes. After the time wait period has elapsed, the client will be released by the operating system. This is a normal safety mechanism to handle any packets that may arrive after the connection has been closed.

SmtpClient Class | SocketTools Namespace

SmtpClient.Dispose Method

Releases all resources used by SmtpClient.

Overload List

Releases all resources used by SmtpClient.

public void Dispose();

Releases the unmanaged resources allocated by the SmtpClient class and optionally releases the managed resources.

protected virtual void Dispose(bool);

See Also

SmtpClient Class | SocketTools Namespace

SmtpClient.Dispose Method ()

Releases all resources used by SmtpClient.

[Visual Basic]

```
NotOverridable Overloads Public Sub Dispose() _
    Implements IDisposable.Dispose
```

[C#]

```
public void Dispose();
```

Implements

IDisposable.Dispose

Remarks

The **Dispose** method terminates any active connection and explicitly releases the resources allocated for this instance of the class. In some cases, better performance can be achieved if the programmer explicitly releases resources when they are no longer being used. The **Dispose** method provides explicit control over these resources.

Unlike the **Uninitialize** method, once the **Dispose** method has been called, that instance of the class cannot be re-initialized and you should not attempt to access class properties or invoke any methods. Note that this method can be called even if other references to the object are active.

See Also

SmtpClient Class | SocketTools Namespace | SmtpClient.Dispose Overload List

SmtpClient.Dispose Method (Boolean)

Releases the unmanaged resources allocated by the SmtpClient class and optionally releases the managed resources.

[Visual Basic]

```
Overridable Overloads Protected Sub Dispose( _
   ByVal disposing As Boolean _
)
```

[C#]

```
protected virtual void Dispose(
   bool disposing
);
```

Parameters

disposing

A boolean value which should be specified as **true** to release both managed and unmanaged resources; **false** to release only unmanaged resources.

Remarks

The **Dispose** method terminates any active connection and explicitly releases the resources allocated for this instance of the class. In some cases, better performance can be achieved if the programmer explicitly releases resources when they are no longer being used. The **Dispose** method provides explicit control over these resources.

Unlike the **Uninitialize** method, once the **Dispose** method has been called, that instance of the class cannot be re-initialized and you should not attempt to access class properties or invoke any methods. Note that this method can be called even if other references to the object are active.

You should call **Dispose** in your derived class when you are finished using the derived class. The **Dispose** method leaves the derived class in an unusable state. After calling **Dispose**, you must release all references to the derived class and the **SmtpClient** class so the memory they were occupying can be reclaimed by garbage collection.

SmtpClient Class | SocketTools Namespace | SmtpClient.Dispose Overload List

SmtpClient.ExpandAddress Method

Expand the specified email address.

[Visual Basic]

```
Public Function ExpandAddress( _
   ByVal address As String, _
   ByRef expandedAddress As String _
) As Boolean
```

[C#]

```
public bool ExpandAddress(
   string address,
   ref string expandedAddress
);
```

Parameters

address

A string which specifies the address to expand.

expandedAddress

A string passed by reference which will contain the list of expanded addresses when the method returns.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **ExpandAddress** method requests that the server expand the specified email address. Typically this is used to expand aliases which refer to a mailing list, returning all of the members of that list. A server may not support this command, or may restrict its usage. An application should not depend on the ability to expand addresses.

SmtpClient Class | SocketTools Namespace

SmtpClient.Initialize Method

Initialize an instance of the SmtpClient class.

Overload List

Initialize an instance of the SmtpClient class.

public bool Initialize();

Initialize an instance of the SmtpClient class.

public bool Initialize(string);

See Also

SmtpClient Class | SocketTools Namespace | Uninitialize Method

SmtpClient.Initialize Method ()

Initialize an instance of the SmtpClient class.

[Visual Basic]
```
Overloads Public Function Initialize() As Boolean
```

[C#]
```
public bool Initialize();
```

Return Value

A boolean value which specifies if the class was initialized successfully.

Remarks

The Initialize method can be used to explicitly initialize an instance of the SmtpClient class, loading the networking library and allocating resources for the current thread. Typically it is not necessary to explicitly call this method because the instance of the class is initialized by the class constructor. However, if the **Uninitialize** method is called, the class must be re-initialized before any other methods are called.

See Also

SmtpClient Class | SocketTools Namespace | SmtpClient.Initialize Overload List | Uninitialize Method

SmtpClient.Initialize Method (String)

Initialize an instance of the SmtpClient class.

[Visual Basic]

```
Overloads Public Function Initialize( _
   ByVal licenseKey As String _
) As Boolean
```

[C#]

```
public bool Initialize(
   string licenseKey
);
```

Return Value

A boolean value which specifies if the class was initialized successfully.

Remarks

The Initialize method can be used to explicitly initialize an instance of the SmtpClient class, loading the networking library and allocating resources for the current thread. Typically an application would define the license key as a custom attribute, however this method can be used to initialize the class directly.

The runtime license key for your copy of SocketTools can be generated using the License Manager utility that is included with the product. Note that if you have installed an evaluation license, you will not have a runtime license key and cannot redistribute any applications which use the SmtpClient class.

Example

The following example shows how to use the Initialize method to initialize an instance of the class. This example assumes that the license key string has been defined in code.

```
SocketTools.SmtpClient smtpClient = new SocketTools.SmtpClient();

if (smtpClient.Initialize(strLicenseKey) == false)
{
    MessageBox.Show(smtpClient.LastErrorString, "Error",
                    MessageBoxButtons.OK, MessageBoxIcon.Exclamation);
    return;
}
```

```
Dim smtpClient As New SocketTools.SmtpClient

If smtpClient.Initialize(strLicenseKey) = False Then
    MsgBox(smtpClient.LastErrorString, vbIconExclamation)
    Exit Sub
End If
```

See Also

SmtpClient Class | SocketTools Namespace | SmtpClient.Initialize Overload List | RuntimeLicenseAttribute Class | Uninitialize Method

SmtpClient.Reset Method

Reset the internal state of the object, resetting all properties to their default values.

[Visual Basic]

```
Public Sub Reset()
```

[C#]

```
public void Reset();
```

Remarks

The **Reset** method returns the object to its default state. If a socket has been allocated, it will be released and any active connections will be terminated. All properties will be reset to their default values.

SmtpClient.SendMessage Method

Submit the specified message to the mail server for delivery.

Overload List

Submit the specified message to the mail server for delivery.

public bool SendMessage(byte[],int);

Submit the specified message to the mail server for delivery.

public bool SendMessage(string);

Submit the specified message to the mail server for delivery.

public bool SendMessage(string,string,byte[],int);

Submit the specified message to the mail server for delivery.

public bool SendMessage(string,string,string);

See Also

SmtpClient Class | SocketTools Namespace

SmtpClient.SendMessage Method (Byte[], Int32)

Submit the specified message to the mail server for delivery.

[Visual Basic]

```
Overloads Public Function SendMessage( _
   ByVal buffer As Byte(), _
   ByVal length As Integer _
) As Boolean
```

[C#]

```
public bool SendMessage(
   byte[] buffer,
   int length
);
```

Parameters

buffer

A byte array that contains the message to be delivered to the specified recipients. The message must be text and conform to the basic structure defined in RFC 822. There must be one or more headers separated by a blank line, followed by the body of the message. Each line of text must be terminated by a carriage return and linefeed character sequence. Note that more complex multipart MIME messages may also be used, but it is recommended that you use the **SocketTools.MailMessage** class to compose them.

length

An integer value which specifies the number of bytes of data in the specified buffer. This value cannot be larger than the size of the buffer provided by the caller.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **SendMessage** method enables an application to send a formatted email message using the current mail server. This provides a convenient one-step method of addressing and sending a message, and is designed to easily integrate with the **SocketTools.MailMessage** class.

This method will cause the current thread to block until the message transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

The value of the **Sender** property will be used to specify the address of the user sending the message. The addresses assigned to the **Recipient** array will be used to specify the message recipients.

See Also

SmtpClient.SendMessage Method (String, String, Byte[], Int32)

Submit the specified message to the mail server for delivery.

[Visual Basic]

```
Overloads Public Function SendMessage( _
   ByVal senderAddress As String, _
   ByVal recipientAddress As String, _
   ByVal buffer As Byte(), _
   ByVal length As Integer _
) As Boolean
```

[C#]

```
public bool SendMessage(
   string senderAddress,
   string recipientAddress,
   byte[] buffer,
   int length
);
```

Parameters

senderAddress
A string argument which specifies the email address of the person sending the message. This typically corresponds to the address in the From header of the message, but it is not required that they be the same.

recipientAddress
A string argument which specifies the email address of the person or persons to receive the message. Multiple addresses may be specified by separating each address with a comma. It should be noted that this protocol is only concerned with the delivery of a message and not its contents. Header fields in the message are not parsed to automatically determine the recipients. This argument should be a concatenation of all recipients, including carbon copies and blind carbon copies, with each address separated with a comma.

buffer
A byte array that contains the message to be delivered to the specified recipients. The message must be text and conform to the basic structure defined in RFC 822. There must be one or more headers separated by a blank line, followed by the body of the message. Each line of text must be terminated by a carriage return and linefeed character sequence. Note that more complex multipart MIME messages may also be used, but it is recommended that you use the **SocketTools.MailMessage** class to compose them.

length
An integer value which specifies the number of bytes of data in the specified buffer. This value cannot be larger than the size of the buffer provided by the caller.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **SendMessage** method enables an application to send a formatted email message using the current mail server. This provides a convenient one-step method of addressing and sending a message, and is designed to easily integrate with the **SocketTools.MailMessage** class.

This method will cause the current thread to block until the message transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

SmtpClient.SendMessage Method (String, String, String)

Submit the specified message to the mail server for delivery.

[Visual Basic]

```
Overloads Public Function SendMessage( _
   ByVal senderAddress As String, _
   ByVal recipientAddress As String, _
   ByVal buffer As String _
) As Boolean
```

[C#]

```
public bool SendMessage(
   string senderAddress,
   string recipientAddress,
   string buffer
);
```

Parameters

senderAddress

A string argument which specifies the email address of the person sending the message. This typically corresponds to the address in the From header of the message, but it is not required that they be the same.

recipientAddress

A string argument which specifies the email address of the person or persons to receive the message. Multiple addresses may be specified by separating each address with a comma. It should be noted that this protocol is only concerned with the delivery of a message and not its contents. Header fields in the message are not parsed to automatically determine the recipients. This argument should be a concatenation of all recipients, including carbon copies and blind carbon copies, with each address separated with a comma.

buffer

A string that contains the message to be delivered to the specified recipients. The message must be text and conform to the basic structure defined in RFC 822. There must be one or more headers separated by a blank line, followed by the body of the message. Each line of text must be terminated by a carriage return and linefeed character sequence. Note that more complex multipart MIME messages may also be used, but it is recommended that you use the **SocketTools.MailMessage** class to compose them.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **SendMessage** method enables an application to send a formatted email message using the current mail server. This provides a convenient one-step method of addressing and sending a message, and is designed to easily integrate with the **SocketTools.MailMessage** class.

This method will cause the current thread to block until the message transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

SmtpClient Class | SocketTools Namespace | SmtpClient.SendMessage Overload List

SmtpClient.Uninitialize Method

Uninitialize the class library and release any resources allocated for the current thread.

[Visual Basic]

```
Public Sub Uninitialize()
```

[C#]

```
public void Uninitialize();
```

Remarks

The **Uninitialize** method terminates any active connection, releases resources allocated for the current thread and unloads the networking library. After this method has been called, no further client operations may be performed until the class instance has been re-initialized.

If the **Initialize** method is explicitly called by the application, it should be matched by a call to the **Uninitialize** method when that instance of the class is no longer needed.

See Also

SmtpClient Class | SocketTools Namespace | Initialize Method

SmtpClient.VerifyAddress Method

Verify the specified email address.

```
[Visual Basic]
Public Function VerifyAddress( _
   ByVal address As String, _
   ByRef verifiedAddress As String _
) As Boolean
```

```
[C#]
public bool VerifyAddress(
   string address,
   ref string verifiedAddress
);
```

Parameters

address
A string which specifies the address to verify.

verifiedAddress
A string passed by reference which will contain the verified address when the method returns.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **VerifyAddress** method requests that the server verify the specified email address. Typically this is used to verify that a recipient address is valid, and return a fully qualified email address for that recipient. A server may not support this command, or may restrict its usage. An application should not depend on the ability to verify addresses.

SmtpClient.Write Method

Write one or more bytes of data to the server.

Overload List

Write one or more bytes of data to the server.

public int Write(byte[]);

Write one or more bytes of data to the server.

public int Write(byte[],int);

Write a string of characters to the server.

public int Write(string);

Write a string of characters to the server.

public int Write(string,int);

See Also

SmtpClient Class | SocketTools Namespace

SmtpClient.Write Method (Byte[])

Write one or more bytes of data to the server.

[Visual Basic]

```
Overloads Public Function Write( _
   ByVal buffer As Byte() _
) As Integer
```

[C#]

```
public int Write(
   byte[] buffer
);
```

Parameters

buffer
A byte array that contains the data to be written to the server.

Return Value

An integer value which specifies the number of bytes actually written to the server. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Write** method sends one or more bytes of data to the server. If there is enough room in the client's internal send buffer to accommodate all of the data, it is copied to the send buffer and control immediately returns to the caller. If amount of data exceeds the available buffer space and the client is in blocking mode, then the method will block until the data can be sent. If the client is in non-blocking mode and the send buffer is full, an error will occur.

If the **Write** method is used to send the message contents to the server, the application must first call the **CreateMessage** method to specify the sender and the length of the message, followed by one or more calls to the **AddRecipient** method to specify each recipient of the message. When all of the message text has been submitted to the server, the application must call the **CloseMessage** method.

The message text is filtered by the **Write** method, and it will automatically normalize end-of-line character sequences to ensure the message meets the protocol requirements. The message itself must be in a standard RFC 822 or multi-part MIME message format, or the server may reject the message. Binary data, such as file attachments, should always be encoded. The **SocketTools.MailMessage** class can be used to compose and export a message in the correct format, which can then be submitted to the server.

It is recommended that most applications use the **SendMessage** method, which submits the message in a single method call.

See Also

SmtpClient Class | SocketTools Namespace | SmtpClient.Write Overload List

SmtpClient.Write Method (Byte[], Int32)

Write one or more bytes of data to the server.

```
[Visual Basic]
Overloads Public Function Write( _
   ByVal buffer As Byte(), _
   ByVal length As Integer _
) As Integer
```

```
[C#]
public int Write(
   byte[] buffer,
   int length
);
```

Parameters

buffer

A byte array that contains the data to be written to the server.

length

An integer value which specifies the maximum number of bytes of data to write. This value cannot be larger than the size of the buffer specified by the caller.

Return Value

An integer value which specifies the number of bytes actually written to the server. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Write** method sends one or more bytes of data to the server. If there is enough room in the client's internal send buffer to accommodate all of the data, it is copied to the send buffer and control immediately returns to the caller. If amount of data exceeds the available buffer space and the client is in blocking mode, then the method will block until the data can be sent. If the client is in non-blocking mode and the send buffer is full, an error will occur.

If the **Write** method is used to send the message contents to the server, the application must first call the **CreateMessage** method to specify the sender and the length of the message, followed by one or more calls to the **AddRecipient** method to specify each recipient of the message. When all of the message text has been submitted to the server, the application must call the **CloseMessage** method.

The message text is filtered by the **Write** method, and it will automatically normalize end-of-line character sequences to ensure the message meets the protocol requirements. The message itself must be in a standard RFC 822 or multi-part MIME message format, or the server may reject the message. Binary data, such as file attachments, should always be encoded. The **SocketTools.MailMessage** class can be used to compose and export a message in the correct format, which can then be submitted to the server.

It is recommended that most applications use the **SendMessage** method, which submits the message in a single method call.

SmtpClient.Write Method (String)

Write a string of characters to the server.

[Visual Basic]

```
Overloads Public Function Write( _
   ByVal buffer As String _
) As Integer
```

[C#]

```
public int Write(
   string buffer
);
```

Parameters

buffer

A string which contains the data to be written to the server.

Return Value

An integer value which specifies the number of characters actually written to the server. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Write** method sends a string of characters to the server. If there is enough room in the client's internal send buffer to accommodate all of the data, it is copied to the send buffer and control immediately returns to the caller. If amount of data exceeds the available buffer space and the client is in blocking mode, then the method will block until the data can be sent. If the client is in non-blocking mode and the send buffer is full, an error will occur.

If the **Write** method is used to send the message contents to the server, the application must first call the **CreateMessage** method to specify the sender and the length of the message, followed by one or more calls to the **AddRecipient** method to specify each recipient of the message. When all of the message text has been submitted to the server, the application must call the **CloseMessage** method.

The message text is filtered by the **Write** method, and it will automatically normalize end-of-line character sequences to ensure the message meets the protocol requirements. The message itself must be in a standard RFC 822 or multi-part MIME message format, or the server may reject the message. Binary data, such as file attachments, should always be encoded. The **SocketTools.MailMessage** class can be used to compose and export a message in the correct format, which can then be submitted to the server.

It is recommended that most applications use the **SendMessage** method, which submits the message in a single method call.

SmtpClient.Write Method (String, Int32)

Write a string of characters to the server.

[Visual Basic]

```
Overloads Public Function Write( _
   ByVal buffer As String, _
   ByVal length As Integer _
) As Integer
```

[C#]

```
public int Write(
   string buffer,
   int length
);
```

Parameters

buffer
A string which contains the data to be written to the server.

length
An integer value which specifies the maximum number of characters to write. This value cannot be larger than the length of the string specified by the caller.

Return Value

An integer value which specifies the number of characters actually written to the server. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Write** method sends a string of characters to the server. If there is enough room in the client's internal send buffer to accommodate all of the data, it is copied to the send buffer and control immediately returns to the caller. If amount of data exceeds the available buffer space and the client is in blocking mode, then the method will block until the data can be sent. If the client is in non-blocking mode and the send buffer is full, an error will occur.

If the **Write** method is used to send the message contents to the server, the application must first call the **CreateMessage** method to specify the sender and the length of the message, followed by one or more calls to the **AddRecipient** method to specify each recipient of the message. When all of the message text has been submitted to the server, the application must call the **CloseMessage** method.

The message text is filtered by the **Write** method, and it will automatically normalize end-of-line character sequences to ensure the message meets the protocol requirements. The message itself must be in a standard RFC 822 or multi-part MIME message format, or the server may reject the message. Binary data, such as file attachments, should always be encoded. The **SocketTools.MailMessage** class can be used to compose and export a message in the correct format, which can then be submitted to the server.

It is recommended that most applications use the **SendMessage** method, which submits the message in a single method call.

SmtpClient Events

The events of the **SmtpClient** class are listed below. For a complete list of **SmtpClient** class members, see the SmtpClient Members topic.

Public Instance Events

⚡ OnCancel	Occurs when a blocking client operation is canceled.
⚡ OnCommand	Occurs when the client sends a command to the remote host and receives a reply indicating the result of that command.
⚡ OnConnect	Occurs when a connection is established with the remote host.
⚡ OnDisconnect	Occurs when the remote host disconnects from the local system.
⚡ OnError	Occurs when an client operation fails.
⚡ OnProgress	Occurs as a data stream is being read or written to the client.
⚡ OnTimeout	Occurs when a blocking operation fails to complete before the timeout period elapses.

See Also

SmtpClient Class | SocketTools Namespace

SmtpClient.OnCancel Event

Occurs when a blocking client operation is canceled.

[Visual Basic]

```
Public Event OnCancel As EventHandler
```

[C#]

```
public event EventHandler OnCancel;
```

Remarks

The **OnCancel** event is generated when a blocking client operation, such as sending or receiving data, is canceled with the **Cancel** method. To assist in determining which operation was canceled, check the value of the **Status** property.

See Also

SmtpClient Class | SocketTools Namespace

SmtpClient.OnCommand Event

Occurs when the client sends a command to the remote host and receives a reply indicating the result of that command.

[Visual Basic]
```
Public Event OnCommand As OnCommandEventHandler
```

[C#]
```
public event OnCommandEventHandler OnCommand;
```

Event Data

The event handler receives an argument of type SmtpClient.CommandEventArgs containing data related to this event. The following **SmtpClient.CommandEventArgs** properties provide information specific to this event.

Property	Description
ResultCode	Gets a value which specifies the last result code returned by the server.
ResultString	Gets a string value which describes the result of the previous command.

Remarks

The **OnCommand** event is generated when the client receives a reply from the server after some action has been taken.

See Also

SmtpClient Class | SocketTools Namespace

SmtpClient.CommandEventArgs Class

Provides data for the OnCommand event.

For a list of all members of this type, see SmtpClient.CommandEventArgs Members.

System.Object
  System.EventArgs
    SocketTools.SmtpClient.CommandEventArgs

[Visual Basic]
```
Public Class SmtpClient.CommandEventArgs
    Inherits EventArgs
```

[C#]
```
public class SmtpClient.CommandEventArgs : EventArgs
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

CommandEventArgs specifies the result code and result string for the last command executed by the server.

The OnCommand event occurs whenever a command is executed on the server.

Requirements

Namespace: SocketTools

Assembly: SocketTools.SmtpClient (in SocketTools.SmtpClient.dll)

SmtpClient.CommandEventArgs Members

SmtpClient.CommandEventArgs overview

Public Instance Constructors

SmtpClient.CommandEventArgs Constructor	Initializes a new instance of the SmtpClient.CommandEventArgs class.

Public Instance Properties

ResultCode	Gets a value which specifies the last result code returned by the server.
ResultString	Gets a string value which describes the result of the previous command.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString (inherited from Object)	Returns a String that represents the current Object.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

SmtpClient.CommandEventArgs Class | SocketTools Namespace

SmtpClient.CommandEventArgs Constructor

Initializes a new instance of the SmtpClient.CommandEventArgs class.

[Visual Basic]

```
Public Sub New()
```

[C#]

```
public SmtpClient.CommandEventArgs();
```

See Also

SmtpClient.CommandEventArgs Class | SocketTools Namespace

SmtpClient.CommandEventArgs Properties

The properties of the **SmtpClient.CommandEventArgs** class are listed below. For a complete list of **SmtpClient.CommandEventArgs** class members, see the SmtpClient.CommandEventArgs Members topic.

Public Instance Properties

ResultCode	Gets a value which specifies the last result code returned by the server.
ResultString	Gets a string value which describes the result of the previous command.

See Also

SmtpClient.CommandEventArgs Class | SocketTools Namespace

SmtpClient.CommandEventArgs.ResultCode Property

Gets a value which specifies the last result code returned by the server.

[Visual Basic]

```
Public ReadOnly Property ResultCode As Integer
```

[C#]

```
public int ResultCode {get;}
```

Property Value

An integer value which specifies the last result code returned by the server.

Remarks

This property should be checked after the **Command** method is used to execute a command on the server to determine if the operation was successful. Result codes are three-digit numeric values returned by the remote server and may be broken down into the following ranges:

ResultCode	Description
100-199	Positive preliminary result. This indicates that the requested action is being initiated, and the client should expect another reply from the server before proceeding.
200-299	Positive completion result. This indicates that the server has successfully completed the requested action.
300-399	Positive intermediate result. This indicates that the requested action cannot complete until additional information is provided to the server.
400-499	Transient negative completion result. This indicates that the requested action did not take place, but the error condition is temporary and may be attempted again.
500-599	Permanent negative completion result. This indicates that the requested action did not take place.

It is important to note that while some result codes have become standardized, not all servers respond to commands using the same result codes. For example, one server may respond with a result code of 221 to indicate success, while another may respond with a value of 235. It is recommended that applications check for ranges of values to determine if a command was successful, not a specific value.

See Also

SmtpClient.CommandEventArgs Class | SocketTools Namespace

SmtpClient.CommandEventArgs.ResultString Property

Gets a string value which describes the result of the previous command.

[Visual Basic]

```
Public ReadOnly Property ResultString As String
```

[C#]

```
public string ResultString {get;}
```

Property Value

A string which describes the result of the previous command executed on the server.

Remarks

This string is generated by the remote server, and typically is used to describe the result code. For example, if an error is indicated by the result code, the result string may describe the condition that caused the error.

See Also

SmtpClient.CommandEventArgs Class | SocketTools Namespace

SmtpClient.OnConnect Event

Occurs when a connection is established with the remote host.

[Visual Basic]

```
Public Event OnConnect As EventHandler
```

[C#]

```
public event EventHandler OnConnect;
```

Remarks

The **OnConnect** event occurs when a connection is made with a remote host as a result of a **Connect** method call. When the **Connect** method is called and the **Blocking** property is set to **false**, a socket is created but the connection is not actually established until after this event occurs. Between the time connection process is started and this event fires, no operation may be performed on the client other than calling the **Disconnect** method.

This event is only generated if the client is in non-blocking mode.

See Also

SmtpClient Class | SocketTools Namespace

SmtpClient.OnDisconnect Event

Occurs when the remote host disconnects from the local system.

[Visual Basic]

```
Public Event OnDisconnect As EventHandler
```

[C#]

```
public event EventHandler OnDisconnect;
```

Remarks

The **OnDisconnect** event occurs when the remote host closes its connection, terminating the client session with the application. Because there may still be data in the client receive buffers, you should continue to read data from the client until the **Read** method returns a value of 0. Once all of the data has been read, you should call the **Disconnect** method to close the local socket and release the resources allocated for the client.

This event is only generated if the client is in non-blocking mode.

See Also

SmtpClient Class | SocketTools Namespace

SmtpClient.OnError Event

Occurs when an client operation fails.

[Visual Basic]

```
Public Event OnError As OnErrorEventHandler
```

[C#]

```
public event OnErrorEventHandler OnError;
```

Event Data

The event handler receives an argument of type SmtpClient.ErrorEventArgs containing data related to this event. The following **SmtpClient.ErrorEventArgs** properties provide information specific to this event.

Property	Description
Description	Gets a value which describes the last error that has occurred.
Error	Gets a value which specifies the last error that has occurred.

Remarks

The **OnError** event occurs when a client operation fails.

See Also

SmtpClient Class | SocketTools Namespace

SmtpClient.ErrorEventArgs Class

Provides data for the OnError event.

For a list of all members of this type, see SmtpClient.ErrorEventArgs Members.

System.Object
  System.EventArgs
    SocketTools.SmtpClient.ErrorEventArgs

[Visual Basic]

```
Public Class SmtpClient.ErrorEventArgs
    Inherits EventArgs
```

[C#]

```
public class SmtpClient.ErrorEventArgs : EventArgs
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

ErrorEventArgs specifies the numeric error code and a description of the error that has occurred.

An OnError event occurs when a method fails.

Requirements

Namespace: SocketTools

Assembly: SocketTools.SmtpClient (in SocketTools.SmtpClient.dll)

SmtpClient.ErrorEventArgs Properties

The properties of the **SmtpClient.ErrorEventArgs** class are listed below. For a complete list of **SmtpClient.ErrorEventArgs** class members, see the SmtpClient.ErrorEventArgs Members topic.

Public Instance Properties

Description	Gets a value which describes the last error that has occurred.
Error	Gets a value which specifies the last error that has occurred.

See Also

SmtpClient.ErrorEventArgs Class | SocketTools Namespace

SmtpClient.ErrorEventArgs.Description Property

Gets a value which describes the last error that has occurred.

[Visual Basic]

```
Public ReadOnly Property Description As String
```

[C#]

```
public string Description {get;}
```

Property Value

A string which describes the last error that has occurred.

See Also

SmtpClient.ErrorEventArgs Class | SocketTools Namespace | Error Property

SmtpClient.ErrorEventArgs.Error Property

Gets a value which specifies the last error that has occurred.

[Visual Basic]

```
Public ReadOnly Property Error As ErrorCode
```

[C#]

```
public SmtpClient.ErrorCode Error {get;}
```

Property Value

ErrorCode enumeration which specifies the error.

See Also

SmtpClient.OnProgress Event

Occurs as a data stream is being read or written to the client.

[Visual Basic]

```
Public Event OnProgress As OnProgressEventHandler
```

[C#]

```
public event OnProgressEventHandler OnProgress;
```

Event Data

The event handler receives an argument of type SmtpClient.ProgressEventArgs containing data related to this event. The following **SmtpClient.ProgressEventArgs** properties provide information specific to this event.

Property	Description
BytesCopied	Gets a value which specifies the number of bytes of data that has been read or written.
BytesTotal	Gets a value which specifies the total number of bytes in the data stream.
Percent	Gets a value which specifies the percentage of data that has been read or written.

Remarks

The **OnProgress** event occurs as a data stream is being read or written to the client. If large amounts of data are being read or written, this event can be used to update a progress bar or other user-interface component to provide the user with some visual feedback on the progress of the operation.

See Also

For a list of all members of this type, see SmtpClient.ProgressEventArgs Members.

System.Object
  System.EventArgs
    SocketTools.SmtpClient.ProgressEventArgs

[Visual Basic]
```
Public Class SmtpClient.ProgressEventArgs
    Inherits EventArgs
```

[C#]
```
public class SmtpClient.ProgressEventArgs : EventArgs
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

ProgressEventArgs specifies the number of bytes copied from the data stream, the total number of bytes in the data stream and a completion percentage.

The OnProgress event occurs as a data stream is being read or written to the client.

Requirements

Namespace: SocketTools

Assembly: SocketTools.SmtpClient (in SocketTools.SmtpClient.dll)

SmtpClient.ProgressEventArgs Properties

The properties of the **SmtpClient.ProgressEventArgs** class are listed below. For a complete list of **SmtpClient.ProgressEventArgs** class members, see the SmtpClient.ProgressEventArgs Members topic.

Public Instance Properties

BytesCopied	Gets a value which specifies the number of bytes of data that has been read or written.
BytesTotal	Gets a value which specifies the total number of bytes in the data stream.
Percent	Gets a value which specifies the percentage of data that has been read or written.

See Also

SmtpClient.ProgressEventArgs Class | SocketTools Namespace

SmtpClient.ProgressEventArgs.BytesCopied Property

Gets a value which specifies the number of bytes of data that has been read or written.

[Visual Basic]

```
Public ReadOnly Property BytesCopied As Integer
```

[C#]

```
public int BytesCopied {get;}
```

Property Value

An integer value which specifies the number of bytes of data.

Remarks

The **BytesCopied** property specifies the number of bytes that have been read from the client and stored in the local stream buffer, or written from the stream buffer to the client.

See Also

SmtpClient.ProgressEventArgs Class | SocketTools Namespace | BytesTotal Property | Percent Property

SmtpClient.ProgressEventArgs.BytesTotal Property

Gets a value which specifies the total number of bytes in the data stream.

[Visual Basic]
```
Public ReadOnly Property BytesTotal As Integer
```

[C#]
```
public int BytesTotal {get;}
```

Property Value

An integer value which specifies the number of bytes of data.

Remarks

The **BytesTotal** property specifies the total amount of data being read from the client and stored in the data stream, or written from the data stream to the client. If the amount of data was unknown or unspecified at the time the method call was made, then this value will always be the same as the **BytesCopied** property.

See Also

SmtpClient.ProgressEventArgs Class | SocketTools Namespace | BytesCopied Property | Percent Property

SmtpClient.ProgressEventArgs.Percent Property

Gets a value which specifies the percentage of data that has been read or written.

[Visual Basic]

```
Public ReadOnly Property Percent As Integer
```

[C#]

```
public int Percent {get;}
```

Property Value

An integer value which specifies a percentage.

Remarks

The **Percent** property specifies the percentage of data that has been transmitted, expressed as an integer value between 0 and 100, inclusive. If the maximum size of the data stream was not specified by the caller, this value will always be 100.

See Also

SmtpClient.ProgressEventArgs Class | SocketTools Namespace | BytesCopied Property | BytesTotal Property

SmtpClient.OnTimeout Event

Occurs when a blocking operation fails to complete before the timeout period elapses.

[Visual Basic]

```
Public Event OnTimeout As EventHandler
```

[C#]

```
public event EventHandler OnTimeout;
```

Remarks

The **OnTimeout** event occurs when a blocking operation, such as sending or receiving data on the client, fails to complete before the specified timeout period elapses. The timeout period for a blocking operation can be adjusted by setting the **Timeout** property.

This event is only generated if the client is in blocking mode.

See Also

SmtpClient Class | SocketTools Namespace

SmtpClient.ErrorCode Enumeration

Specifies the error codes returned by the SmtpClient class.

[Visual Basic]

```
Public Enum SmtpClient.ErrorCode
```

[C#]

```
public enum SmtpClient.ErrorCode
```

Remarks

The SmtpClient class uses the **ErrorCode** enumeration to specify what error has occurred when a method fails. The current error code may be determined by checking the value of the **LastError** property.

Note that the last error code is only meaningful if the previous operation has failed.

Members

Member Name	Description
errorNone	No error.
errorNotHandleOwner	Handle not owned by the current thread.
errorFileNotFound	The specified file or directory does not exist.
errorFileNotCreated	The specified file could not be created.
errorOperationCanceled	The blocking operation has been canceled.
errorInvalidFileType	The specified file is a block or character device, not a regular file.
errorInvalidDevice	The specified file type is invalid or not a regular file.
errorTooManyParameters	The maximum number of function parameters has been exceeded.
errorInvalidFileName	The specified file name contains invalid characters or is too long.
errorInvalidFileHandle	Invalid file handle passed to function.
errorFileReadFailed	Unable to read data from the specified file.
errorFileWriteFailed	Unable to write data to the specified file.
errorOutOfMemory	Out of memory.
errorAccessDenied	Access denied.
errorInvalidParameter	Invalid argument passed to function.
errorClipboardUnavailable	The system clipboard is currently unavailable.
errorClipboardEmpty	The system clipboard is empty or does not contain any text data.
errorFileEmpty	The specified file does not contain any data.
errorFileExists	The specified file already exists.

errorEndOfFile	End of file.
errorDeviceNotFound	The specified device could not be found.
errorDirectoryNotFound	The specified directory could not be found.
errorInvalidbuffer	Invalid memory address passed to function.
errorBufferTooSmall	The specified buffer is not large enough to contain the data.
errorNoHandles	No more handles are available to this process.
errorOperationWouldBlock	The specified operation would block the current thread.
errorOperationInProgress	A blocking operation is currently in progress.
errorAlreadyInProgress	The specified operation is already in progress.
errorInvalidHandle	Invalid handle passed to function.
errorInvalidAddress	Invalid network address specified.
errorInvalidSize	Datagram is too large to fit in specified buffer.
errorInvalidProtocol	Invalid network protocol specified.
errorProtocolNotAvailable	The specified network protocol is not available.
errorProtocolNotSupported	The specified protocol is not supported.
errorSocketNotSupported	The specified socket type is not supported.
errorInvalidOption	The specified option is invalid.
errorProtocolFamily	Specified protocol family is not supported.
errorProtocolAddress	The specified address is invalid for this protocol family.
errorAddressInUse	The specified address is in use by another process.
errorAddressUnavailable	The specified address cannot be assigned.
errorNetworkUnavailable	The networking subsystem is unavailable.
errorNetworkUnreachable	The specified network is unreachable.
errorNetworkReset	Network dropped connection on remote reset.
errorConnectionAborted	Connection was aborted due to timeout or other failure.
errorConnectionReset	Connection was reset by remote network.
errorOutOfBuffers	No buffer space is available.
errorAlreadyConnected	Connection already established with remote host.
errorNotConnected	No connection established with remote host.
errorConnectionShutdown	Unable to send or receive data after connection shutdown.
errorOperationTimeout	The specified operation has timed out.
errorConnectionRefused	The connection has been refused by the remote host.

errorHostUnavailable	The specified host is unavailable.
errorHostUnreachable	Remote host is unreachable.
errorTooManyProcesses	Too many processes are using the networking subsystem.
errorTooManyThreads	Too many threads have been created by the current process.
errorTooManySessions	Too many client sessions have been created by the current process.
errorInternalFailure	An unexpected internal error has occurred.
errorNetworkNotReady	Network subsystem is not ready for communication.
errorInvalidVersion	This version of the operating system is not supported.
errorNetworkNotInitialized	The networking subsystem has not been initialized.
errorRemoteShutdown	The remote host has initiated a graceful shutdown sequence.
errorInvalidHostName	The specified hostname is invalid or could not be resolved.
errorHostNameNotFound	The specified hostname could not be found.
errorHostNameRefused	Unable to resolve hostname, request refused.
errorHostNameNotResolved	Unable to resolve hostname, no address for specified host.
errorInvalidLicense	The license for this product is invalid.
errorProductNotLicensed	This product is not licensed to perform this operation.
errorNotImplemented	This function has not been implemented on this platform.
errorUnknownLocalhost	Unable to determine local host name.
errorInvalidHostAddress	Invalid host address specified.
errorInvalidServicePort	Invalid service port number specified.
errorInvalidServiceName	Invalid or unknown service name specified.
errorInvalidEventId	Invalid event identifier specified.
errorOperationNotBlocking	No blocking operation in progress on this socket.
errorSecurityNotInitialized	Unable to initialize security interface for this process.
errorSecurityContext	Unable to establish security context for this session.
errorSecurityCredentials	Unable to open certificate store or establish security credentials.
errorSecurityCertificate	Unable to validate the certificate chain for this

	session.
errorSecurityDecryption	Unable to decrypt data stream.
errorSecurityEncryption	Unable to encrypt data stream.
errorOperationNotSupported	The specified operation is not supported.
errorInvalidProtocolVersion	Invalid application protocol version specified.
errorNoServerResponse	No data returned from server.
errorInvalidServerResponse	Invalid data returned from server.
errorUnexpectedServerResponse	Unexpected response code returned from server.
errorServerTransactionFailed	Server transaction failed.
errorServiceUnavailable	The service is currently unavailable.
errorServiceNotReady	The service is not ready, try again later.
errorServerResyncFailed	Unable to resynchronize with server.
errorInvalidProxyType	Invalid proxy server type specified.
errorProxyRequired	Resource must be accessed through specified proxy.
errorInvalidProxyLogin	Unable to login to proxy server using specified credentials.
errorProxyResyncFailed	Unable to resynchronize with proxy server.
errorInvalidCommand	Invalid command specified.
errorInvalidCommandParameter	Invalid command parameter specified.
errorInvalidCommandSequence	Invalid command sequence specified.
errorCommandNotImplemented	Specified command not implemented on this server.
errorCommandNotAuthorized	Specified command not authorized for the current user.
errorCommandAborted	Specified command was aborted by the remote host.
errorOptionNotSupported	The specified option is not supported on this server.
errorRequestNotCompleted	The current client request has not been completed.
errorInvalidUserName	The specified username is invalid.
errorInvalidPassword	The specified password is invalid.
errorInvalidAccount	The specified account name is invalid.
errorAccountRequired	Account name has not been specified.
errorInvalidAuthenticationType	Invalid authentication protocol specified.
errorAuthenticationRequired	User authentication is required.
errorProxyAuthenticationRequired	Proxy authentication required.

errorAlreadyAuthenticated	User has already been authenticated.
errorAuthenticationFailed	Unable to authenticate the specified user.
errorNetworkAdapter	Unable to determine network adapter configuration.
errorInvalidRecordType	Invalid record type specified.
errorInvalidRecordName	Invalid record name specified.
errorInvalidRecordData	Invalid record data specified.
errorConnectionOpen	Data connection already established.
errorConnectionClosed	Server closed data connection.
errorConnectionPassive	Data connection is passive.
errorConnectionFailed	Unable to open data connection to server.
errorInvalidSecurityLevel	Data connection cannot be opened with this security setting.
errorCachedTLSRequired	Data connection requires cached TLS session.
errorDataReadOnly	Data connection is read-only.
errorDataWriteOnly	Data connection is write-only.
errorEndOfData	End of data.
errorRemoteFileUnavailable	Remote file is unavailable.
errorInsufficientStorage	Insufficient storage on server.
errorStorageallocation	File exceeded storage allocation on server.
errorDirectoryExists	The specified directory already exists.
errorDirectoryEmpty	No files returned by the server for the specified directory.
errorEndOfDirectory	End of directory listing.
errorUnknownDirectoryFormat	Unknown directory format.
errorInvalidResource	Invalid resource name specified.
errorResourceRedirected	The specified resource has been redirected.
errorResourceRestricted	Access to this resource has been restricted.
errorResourceNotModified	The specified resource has not been modified.
errorResourceNotFound	The specified resource cannot be found.
errorResourceConflict	Request could not be completed due to the current state of the resource.
errorResourceRemoved	The specified resource has been permanently removed from this server.
errorContentLengthRequired	Request must include the content length.
errorRequestPrecondition	Request could not be completed due to server precondition.
errorUnsupportedMediaType	Request specified an unsupported media type.

errorInvalidContentRange	Content range specified for this resource is invalid.
errorInvalidMessagePart	Message is not multipart or an invalid message part was specified.
errorInvalidMessageHeader	The specified message header is invalid or has not been defined.
errorInvalidMessageBoundary	The multipart message boundary has not been defined.
errorNoFileAttachment	The current message part does not contain a file attachment.
errorUnknownFileType	The specified file type could not be determined.
errorDataNotEncoded	The specified data block could not be encoded.
errorDataNotDecoded	The specified data block could not be decoded.
errorFileNotEncoded	The specified file could not be encoded.
errorFileNotDecoded	The specified file could not be decoded.
errorNoMessageText	No message text.
errorInvalidCharacterSet	Invalid character set specified.
errorInvalidEncodingType	Invalid encoding type specified.
errorInvalidMessageNumber	Invalid message number specified.
errorNoReturnAddress	No valid return address specified.
errorNoValidRecipients	No valid recipients specified.
errorInvalidRecipient	The specified recipient address is invalid.
errorRelayNotAuthorized	The specified domain is invalid or server will not relay messages.
errorMailboxUnavailable	Specified mailbox is currently unavailable.
errorMailboxReadOnly	The selected mailbox cannot be modified.
errorMailboxNotSelected	No mailbox has been selected.
errorInvalidMailbox	Specified mailbox is invalid.
errorInvalidDomain	The specified domain name is invalid or not recognized.
errorInvalidSender	The specified sender address is invalid or not recognized.
errorMessageNotDelivered	Message not delivered to any of the specified recipients.
errorEndOfMessageData	No more message data available to be read
errorInvalidmessageSize	The specified message size is invalid.
errorMessageNotCreated	The message could not be created in the specified mailbox.
errorNoMoreMailboxes	No more mailboxes exist on this server.

errorInvalidEmulationType	The specified terminal emulation type is invalid.
errorInvalidFontHandle	The specified font handle is invalid.
errorInvalidFontName	The specified font name is invalid or unavailable.
errorInvalidPacketSize	The specified packet size is invalid.
errorInvalidPacketData	The specified packet data is invalid.
errorInvalidPacketId	The unique packet identifier is invalid.
errorPacketTTLExpired	The specified packet time-to-live period has expired.
errorInvalidNewsGroup	Invalid newsgroup specified.
errorNoNewsgroupSelected	No newsgroup selected.
errorEmptyNewsgroup	No articles in specified newsgroup.
errorInvalidArticle	Invalid article number specified.
errorNoArticleSelected	No article selected in the current newsgroup.
errorFirstArticle	First article in current newsgroup.
errorLastArticle	Last article in current newsgroup.
errorArticleExists	Unable to transfer article, article already exists.
errorArticleRejected	Unable to transfer article, article rejected.
errorArticleTransferFailed	Article transfer failed.
errorArticlePostingDenied	Posting is not permitted on this server.
errorArticlePostingFailed	Unable to post article on this server.
errorInvalidDateFormat	The specified date format is not recognized.
errorFeatureNotSupported	The specified feature is not supported on this server.
errorInvalidFormHandle	The specified form handle is invalid or a form has not been created.
errorInvalidFormAction	The specified form action is invalid or has not been specified.
errorInvalidFormMethod	The specified form method is invalid or not supported.
errorInvalidFormType	The specified form type is invalid or not supported.
errorInvalidFormField	The specified form field name is invalid or does not exist.
errorEmptyForm	The specified form does not contain any field values.
errorMaximumConnections	The maximum number of client connections exceeded.
errorThreadCreationFailed	Unable to create a new thread for the current process.
errorInvalidThreadHandle	The specified thread handle is no longer valid.

errorThreadTerminated	The specified thread has been terminated.
errorThreadDeadlock	The operation would result in the current thread becoming deadlocked.
errorInvalidClientMoniker	The specified moniker is not associated with any client session.
errorClientMonikerExists	The specified moniker has been assigned to another client session.
errorServerInactive	The specified server is not listening for client connections.
errorServerSuspended	The specified server is suspended and not accepting client connections.
errorNoMessageStore	No message store has been specified.
errorMessageStoreChanged	The message store has changed since it was last accessed.
errorMessageNotFound	No message was found that matches the specified criteria.
errorMessageDeleted	The specified message has been deleted.
errorFileChecksumMismatch	The local and remote file checksums do not match.
errorFileSizeMismatch	The local and remote file sizes do not match.
errorInvalidFeedUrl	The news feed URL is invalid or specifies an unsupported protocol.
errorInvalidFeedFormat	The internal format of the news feed is invalid.
errorInvalidFeedVersion	This version of the news feed is not supported.
errorChannelEmpty	There are no valid items found in this news feed.
errorInvalidItemNumber	The specified channel item identifier is invalid.
errorItemNotFound	The specified channel item could not be found.
errorItemEmpty	The specified channel item does not contain any data.
errorInvalidItemProperty	The specified item property name is invalid.
errorItemPropertyNotFound	The specified item property has not been defined.
errorInvalidChannelTitle	The channel title is invalid or has not been defined.
errorInvalidChannelLink	The channel hyperlink is invalid or has not been defined.
errorInvalidChannelDescription	The channel description is invalid or has not been defined.
errorInvalidItemText	The description for an item is invalid or has not been defined.
errorInvalidItemLink	The hyperlink for an item is invalid or has not been defined.

errorInvalidServiceType	The specified service type is invalid.
errorServiceSuspended	Access to the specified service has been suspended.
errorServiceRestricted	Access to the specified service has been restricted.
errorInvalidProviderName	The specified provider name is invalid or unknown.
errorInvalidPhoneNumber	The specified phone number is invalid or not supported in this region.
errorGatewayNotFound	A message gateway cannot be found for the specified provider.
errorMessageTooLong	The message exceeds the maximum number of characters permitted.
errorInvalidProviderData	The request returned invalid or incomplete service provider data.
errorInvalidGatewayData	The request returned invalid or incomplete message gateway data.
errorMultipleProviders	The request has returned multiple service providers.
errorProviderNotFound	The specified service provider could not be found.
errorInvalidMessageService	The specified message is not supported with this service type.
errorInvalidMessageFormat	The specified message format is invalid.
errorInvalidConfiguration	The specified configuration options are invalid.
errorServerActive	The requested action is not permitted while the server is active.
errorServerPortBound	Unable to obtain exclusive use of the specified local port.
errorInvalidClientSession	The specified client identifier is invalid for this session.
errorClientNotIdentified	The specified client has not provided user credentials.
errorInvalidClientState	The requested action cannot be performed at this time.
errorInvalidResultCode	The specified result code is not valid for this protocol
errorCommandRequired	The specified command is required and cannot be disabled.
errorCommandDisabled	The specified command has been disabled.
errorCommandSequence	The command cannot be processed at this time.
errorCommandCompleted	The previous command has completed.
errorInvalidProgramName	The specified program name is invalid or unrecognized.

errorInvalidRequestHeader	The request header contains one or more invalid values.
errorInvalidVirtualHost	The specified virtual host name is invalid.
errorVirtualHostNotFound	The specified virtual host does not exist.
errorTooManyVirtualHosts	Too many virtual hosts created for this server.
errorInvalidVirtualPath	The specified virtual path name is invalid.
errorVirtualPathNotFound	The specified virtual path does not exist.
errorTooManyVirtualPaths	Too many virtual paths created for this server.
errorInvalidTask	The asynchronous task identifier is invalid.
errorTaskActive	The asynchronous task has not finished.
errorTaskQueued	The asynchronous task has been queued.
errorTaskSuspended	The asynchronous task has been suspended.
errorTaskFinished	The asynchronous task has finished.

SmtpClient.SecureCipherAlgorithm Enumeration

Specifies the encryption algorithms that the SmtpClient class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]

```
<Flags>
Public Enum SmtpClient.SecureCipherAlgorithm
```

[C#]

```
[Flags]
public enum SmtpClient.SecureCipherAlgorithm
```

Remarks

The SmtpClient class uses the **SecureCipherAlgorithm** enumeration to identify which encryption algorithm was selected when a secure connection was established with the remote host.

Members

Member Name	Description	Value
cipherNone	No cipher has been selected. A secure connection has not been established with the remote host.	0
cipherRC2	The RC2 block cipher was selected. This is a variable key length cipher which supports keys between 40- and 128-bits in length, in 8-bit increments.	1
cipherRC4	The RC4 stream cipher was selected. This is a variable key length cipher which supports keys between 40- and 128-bits in length, in 8-bit increments.	2
cipherRC5	The RC5 block cipher was selected. This is a variable key length cipher which supports keys up to 2040 bits, in 8-bit increments.	4
cipherDES	The DES (Data Encryption Standard) block cipher was selected. This is a fixed key length cipher using 56-bit keys.	8
cipherDES3	The Triple DES block cipher was selected. This cipher encrypts the data three times using different keys, effectively using a 168-bit key length.	16
cipherDESX	A variant of the DES block cipher which XORs an extra 64-bits of the key before and after the plaintext has been encrypted, increasing the key size to 184 bits.	32
cipherAES	The Advanced Encryption Standard	64

	cipher (also known as the Rijndael cipher) is a fixed block size cipher which use a key size of 128, 192 or 256 bits. This cipher is supported on Windows XP SP3 SP3 and later versions of the operating system.	
cipherSkipjack	The Skipjack block cipher was selected. This is a fixed key length cipher, using 80-bit keys.	128

SmtpClient.SecureHashAlgorithm Enumeration

Specifies the hash algorithms that the SmtpClient class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

```
[Visual Basic]
<Flags>
Public Enum SmtpClient.SecureHashAlgorithm
```

```
[C#]
[Flags]
public enum SmtpClient.SecureHashAlgorithm
```

Remarks

The SmtpClient class uses the **SecureHashAlgorithm** enumeration to identify the message digest (hash) algorithm that was selected when a secure connection was established with the remote host.

Members

Member Name	Description	Value
hashNone	No hash algorithm has been selected. This is not a secure connection with the server.	0
hashMD5	The MD5 algorithm was selected. This algorithm produces a 128-bit message digest. This algorithm is no longer considered to be cryptographically secure.	1
hashSHA	The SHA-1 algorithm was selected. This algorithm produces a 160-bit message digest. This algorithm is no longer considered to be cryptographically secure.	2
hashSHA256	The SHA-256 algorithm was selected. This algorithm produces a 256-bit message digest.	4
hashSHA384	The SHA-384 algorithm was selected. This algorithm produces a 384-bit message digest.	8
hashSHA512	The SHA-512 algorithm was selected. This algorithm produces a 512-bit message digest.	16

SmtpClient.SecureKeyAlgorithm Enumeration

Specifies the key exchange algorithms that the SmtpClient class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]
```
<Flags>
Public Enum SmtpClient.SecureKeyAlgorithm
```

[C#]
```
[Flags]
public enum SmtpClient.SecureKeyAlgorithm
```

Remarks

The SmtpClient class uses the **SecureKeyAlgorithm** enumeration to identify the key exchange algorithm that was selected when a secure connection was established with the remote host.

Members

Member Name	Description	Value
keyExchangeNone	No key exchange algorithm has been selected. This is not a secure connection with the server.	0
keyExchangeRSA	The RSA public key exchange algorithm has been selected.	1
keyExchangeKEA	The KEA public key exchange algorithm has been selected. This is an improved version of the Diffie-Hellman public key algorithm.	2
keyExchangeDH	The Diffie-Hellman public key exchange algorithm has been selected.	4
keyExchangeECDH	The Elliptic Curve Diffie-Hellman key exchange algorithm was selected. This is a variant of the Diffie-Hellman algorithm which uses elliptic curve cryptography. This key exchange algorithm is only supported on Windows XP SP3 SP3 and later versions of the operating system.	8

SmtpClient.SecurityCertificate Enumeration

Specifies the security certificate status values that may be returned by the SmtpClient class.

[Visual Basic]

```
Public Enum SmtpClient.SecurityCertificate
```

[C#]

```
public enum SmtpClient.SecurityCertificate
```

Remarks

The SmtpClient class uses the **SecurityCertificate** enumeration to identify the current status of the certificate that was provided by the remote host when a secure connection was established.

Members

Member Name	Description
certificateNone	No certificate information is available. A secure connection was not established with the server.
certificateValid	The certificate is valid.
certificateNoMatch	The certificate is valid, however the domain name specified in the certificate does not match the domain name of the remote host. The application can examine the **CertificateSubject** property to determine the site the certificate was issued to.
certificateExpired	The certificate has expired and is no longer valid. The application can examine the **CertificateExpires** property to determine when the certificate expired.
certificateRevoked	The certificate has been revoked and is no longer valid. It is recommended that the application immediately terminate the connection if this status is returned.
certificateUntrusted	The certificate has not been issued by a trusted authority, or the certificate is not trusted on the local host. It is recommended that the application immediately terminate the connection if this status is returned.
certificateInvalid	The certificate is invalid. This typically indicates that the internal structure of the certificate is damaged. It is recommended that the application immediately terminate the connection if this status is returned.

SocketTools Namespace

SmtpClient.SecurityProtocols Enumeration

Specifies the security protocols that the SmtpClient class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]
```
<Flags>
Public Enum SmtpClient.SecurityProtocols
```

[C#]
```
[Flags]
public enum SmtpClient.SecurityProtocols
```

Remarks

The SmtpClient class uses the **SecurityProtocols** enumeration to specify one or more security protocols to be used when establishing a connection with a remote host. Multiple protocols may be specified if necessary and the actual protocol used will be negotiated with the remote host. It is recommended that most applications use **protocolDefault** when creating a secure connection.

Members

Member Name	Description	Value
protocolNone	No security protocol will be used, a secure connection will not be established.	0
protocolSSL2	The SSL 2.0 protocol has been selected. This protocol has been deprecated and is no longer widely used. It is not recommended that this protocol be used when establishing secure connections.	1
protocolSSL3	The SSL 3.0 protocol has been selected. This protocol has been deprecated and is no longer widely used. It is not recommended that this protocol be used when establishing secure connections. In most cases, this protocol is only selected if TLS is not supported by the server.	2
protocolTLS10	The TLS 1.0 protocol has been selected. This version of the protocol is commonly used by older servers and is the only version of TLS supported on Windows platforms prior to Windows 7 SP1 and Windows Server 2008 R2.	4
protocolTLS11	The TLS 1.1 protocol has been selected. This version of TLS is supported on Windows 7 SP1 and Windows Server 2008 R2 and later versions of the	8

	operating system.	
protocolTLS12	The TLS 1.2 protocol has been selected. This is the default version of the protocol and is supported on Windows 7 SP1 and Windows Server 2008 R2 and later versions of Windows. It is recommended that you use this version of TLS.	16
protocolSSL	Any version of the Secure Sockets Layer (SSL) protocol should be used. The actual protocol version used will be negotiated with the remote host.	3
protocolTLS	Any version of the the Transport Layer Security (TLS) protocol should be used. The actual protocol version used will be negotiated with the remote host, with with preference for TLS 1.2.	28
protocolTLS1	Version 1.0, 1.1 or 1.2 of the the Transport Layer Security (TLS) protocol should be used. The actual protocol version used will be negotiated with the remote host, with preference for TLS 1.2.	28
protocolDefault	The default selection of security protocols will be used when establishing a connection. The TLS 1.2, 1.1 and 1.0 protocols will be negotiated with the host, in that order of preference. This option will always request the latest version of the preferred security protocols and is the recommended value.	16
protocolUnknown	An unknown or unsupported security protocol has been specified. This value indicates an error condition.	4096

Requirements

Namespace: SocketTools

Assembly: SocketTools.SmtpClient (in SocketTools.SmtpClient.dll)

SocketTools Namespace

SmtpClient.SmtpOptions Enumeration

Specifies the options that the SmtpClient class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]

```
<Flags>
Public Enum SmtpClient.SmtpOptions
```

[C#]

```
[Flags]
public enum SmtpClient.SmtpOptions
```

Remarks

The SmtpClient class uses the **SmtpOptions** enumeration to specify one or more options to be used when establishing a connection with a remote host. Multiple options may be specified if necessary.

Members

Member Name	Description	Value
optionNone	No option specified.	0
optionDefault	The default connection option. This is the same as specifying **optionExtended**.	1
optionExtended	Extended SMTP commands should be used if possible. This option enables features such as authentication and delivery status notification. If this option is not specified, the class will not attempt to use any extended features.	1
optionTunnel	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established. This option also forces all connections to be outbound and enables the firewall compatibility features in the client.	1024
optionTrustedSite	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using either the SSL or TLS protocols.	2048
optionSecure	This option specifies the client should	4096

	attempt to establish a secure connection with the server. The server must support secure connections using either the SSL or TLS protocol.	
optionExplicitSSL	This option specifies the client should attempt to establish a secure explicit SSL session. The initial connection to the server is not encrypted, and the client will attempt to negotiate a secure connection by sending the STARTTLS command to the server. Some servers may require this option when connecting to the server on ports other than the default secure port of 465.	4096
optionImplicitSSL	This option specifies the client should attempt to establish a secure implicit SSL session. The SSL handshake is initiated immediately after the connection to the server has been established.	8192
optionSecureFallback	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will permit connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.	32768
optionPreferIPv6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.	262144
optionFreeThread	This option specifies that class methods may be called from any thread, and not only the thread that established the connection. Using this option disables certain internal safety checks that are made by the class and may result in unexpected behavior unless you ensure that access to the class instance is synchronized across multiple threads.	524288

Requirements

Namespace: SocketTools

Assembly: SocketTools.SmtpClient (in SocketTools.SmtpClient.dll)

SocketTools Namespace

SmtpClient.SmtpStatus Enumeration

Specifies the status values that may be returned by the SmtpClient class.

[Visual Basic]
```
Public Enum SmtpClient.SmtpStatus
```

[C#]
```
public enum SmtpClient.SmtpStatus
```

Remarks

The SmtpClient class uses the **SmtpStatus** enumeration to identify the current status of the client.

Members

Member Name	Description
statusUnused	A client session has not been created. Attempts to perform any network operations, such as sending or receiving data, will generate an error.
statusIdle	A client session has been created, but is not currently in use. A blocking socket operation can be executed at this point.
statusConnect	The client is in the process of establishing a connection with a remote host.
statusRead	The client is in the process of receiving data from a remote host.
statusWrite	The client is in the process of sending data to a remote host.
statusDisconnect	The client session is being closed and subsequent attempts to access the client will result in an error.

Requirements

Namespace: SocketTools

Assembly: SocketTools.SmtpClient (in SocketTools.SmtpClient.dll)

SmtpClient.TraceOptions Enumeration

Specifies the logging options that the SmtpClient class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

```
[Visual Basic]
<Flags>
Public Enum SmtpClient.TraceOptions
```

```
[C#]
[Flags]
public enum SmtpClient.TraceOptions
```

Remarks

The SmtpClient class uses the **TraceOptions** enumeration to specify what kind of debugging information is written to the trace logfile. These options are only meaningful when trace logging is enabled by setting the **Trace** property to **true**.

Members

Member Name	Description	Value
traceDefault	The default trace logging option. This is the same as specifying the **traceInfo** option.	0
traceInfo	All network function calls are written to the trace file. This is the default value.	0
traceError	Only those network function calls which fail are recorded in the trace file.	1
traceWarning	Only those network function calls which fail, or return values which indicate a warning, are recorded in the trace file.	2
traceHexDump	All network function calls are written to the trace file, plus all the data that is sent or received is displayed, in both ASCII and hexadecimal format.	4
traceProcess	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for multithreaded applications that are using worker threads.	4096

SmtpClient.OnCommandEventHandler Delegate

Represents the method that will handle the OnCommand event.

[Visual Basic]

```
Public Delegate Sub SmtpClient.OnCommandEventHandler( _
   ByVal sender As Object, _
   ByVal e As CommandEventArgs _
)
```

[C#]

```
public delegate void SmtpClient.OnCommandEventHandler(
      object sender,
      CommandEventArgs e
   );
```

Parameters

sender

The source of the event.

e

A CommandEventArgs object that contains the event data.

Remarks

When you create an **OnCommandEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnCommandEventHandler** delegate declaration.

Requirements

Namespace: SocketTools

Assembly: SocketTools.SmtpClient (in SocketTools.SmtpClient.dll)

SocketTools Namespace

SmtpClient.OnErrorEventHandler Delegate

Represents the method that will handle the OnError event.

```
[Visual Basic]
Public Delegate Sub SmtpClient.OnErrorEventHandler( _
   ByVal sender As Object, _
   ByVal e As ErrorEventArgs _
)
```

```
[C#]
public delegate void SmtpClient.OnErrorEventHandler(
      object sender,
      ErrorEventArgs e
   );
```

Parameters

sender
The source of the event.

e
An ErrorEventArgs that contains the event data.

Remarks

When you create an **OnErrorEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnErrorEventHandler** delegate declaration.

Requirements

Namespace: SocketTools

Assembly: SocketTools.SmtpClient (in SocketTools.SmtpClient.dll)

SocketTools Namespace

SmtpClient.OnProgressEventHandler Delegate

Represents the method that will handle the OnProgress event.

[Visual Basic]

```
Public Delegate Sub SmtpClient.OnProgressEventHandler( _
   ByVal sender As Object, _
   ByVal e As ProgressEventArgs _
)
```

[C#]

```
public delegate void SmtpClient.OnProgressEventHandler(
      object sender,
      ProgressEventArgs e
   );
```

Parameters

sender

The source of the event.

e

A ProgressEventArgs that contains the event data.

Remarks

When you create an **OnProgressEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnProgressEventHandler** delegate declaration.

SocketTools Namespace

SmtpClient.RuntimeLicenseAttribute Class

Attribute that defines the runtime license key for the class.

For a list of all members of this type, see SmtpClient.RuntimeLicenseAttribute Members.

System.Object
  System.Attribute
    SocketTools.SmtpClient.RuntimeLicenseAttribute

[Visual Basic]

```
<AttributeUsage(ValidOn:=AttributeTargets.Assembly, AllowMultiple:=False,
   Inherited:=True)>
Public Class SmtpClient.RuntimeLicenseAttribute
    Inherits Attribute
```

[C#]

```
[AttributeUsage(ValidOn=AttributeTargets.Assembly, AllowMultiple=False,
   Inherited=True)]
public class SmtpClient.RuntimeLicenseAttribute : Attribute
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

The RuntimeLicense attribute is used to define the runtime license key that will be used when an instance of the class is created. This attribute is defined in the assembly information module for the language, such as AssemblyInfo.cs when programming C#. The runtime license key must be defined if you wish to redistribute your application.

The runtime license key for your copy of SocketTools can be generated using the License Manager utility that is included with the product. Note that if you have installed an evaluation license, you will not have a runtime license key and cannot redistribute any applications which use the SmtpClient class.

Example

```
<Assembly: SocketTools.SmtpClient.RuntimeLicense("abcdefghijklmnop")>
```

```
[assembly: SocketTools.SmtpClient.RuntimeLicense("abcdefghijklmnop")]
```

Requirements

Namespace: SocketTools

Assembly: SocketTools.SmtpClient (in SocketTools.SmtpClient.dll)

SmtpClient.RuntimeLicenseAttribute Members | SocketTools Namespace

SmtpClient.RuntimeLicenseAttribute Members

SmtpClient.RuntimeLicenseAttribute overview

Public Instance Constructors

SmtpClient.RuntimeLicenseAttribute Constructor	Constructor for the RuntimeLicense attribute which defines the runtime license key.

Public Instance Properties

LicenseKey	Returns the value of the runtime license key.
TypeId (inherited from Attribute)	When implemented in a derived class, gets a unique identifier for this Attribute.

Public Instance Methods

Equals (inherited from Attribute)	
GetHashCode (inherited from Attribute)	Returns the hash code for this instance.
GetType (inherited from Object)	Gets the Type of the current instance.
IsDefaultAttribute (inherited from Attribute)	When overridden in a derived class, returns an indication whether the value of this instance is the default value for the derived class.
Match (inherited from Attribute)	When overridden in a derived class, returns a value indicating whether this instance equals a specified object.
ToString (inherited from Object)	Returns a String that represents the current Object.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

SmtpClient.RuntimeLicenseAttribute Class | SocketTools Namespace

SmtpClient.RuntimeLicenseAttribute Constructor

Constructor for the RuntimeLicense attribute which defines the runtime license key.

[Visual Basic]

```
Public Sub New( _
   ByVal licenseKey As String _
)
```

[C#]

```
public SmtpClient.RuntimeLicenseAttribute(
   string licenseKey
);
```

Parameters

licenseKey

A string argument which specifies the runtime license key which will be used to initialize the class library.

Remarks

The runtime license key for your copy of SocketTools can be generated using the License Manager utility that is included with the product. Note that if you have installed an evaluation license, you will not have a runtime license key and cannot redistribute any applications which use the SmtpClient class.

See Also

SmtpClient.RuntimeLicenseAttribute Class | SocketTools Namespace

SmtpClient.RuntimeLicenseAttribute Properties

The properties of the **SmtpClient.RuntimeLicenseAttribute** class are listed below. For a complete list of **SmtpClient.RuntimeLicenseAttribute** class members, see the SmtpClient.RuntimeLicenseAttribute Members topic.

Public Instance Properties

LicenseKey	Returns the value of the runtime license key.
TypeId (inherited from Attribute)	When implemented in a derived class, gets a unique identifier for this Attribute.

See Also

SmtpClient.RuntimeLicenseAttribute Class | SocketTools Namespace

SmtpClient.RuntimeLicenseAttribute.LicenseKey Property

Returns the value of the runtime license key.

[Visual Basic]

```
Public Property LicenseKey As String
```

[C#]

```
public string LicenseKey {get; set;}
```

Property Value

A string which contains the runtime license key.

See Also

SmtpClient.RuntimeLicenseAttribute Class | SocketTools Namespace

SmtpClientException Class

The exception that is thrown when a client error occurs.

For a list of all members of this type, see SmtpClientException Members.

System.Object
  System.Exception
    System.ApplicationException
      SocketTools.SmtpClientException

[Visual Basic]

```
Public Class SmtpClientException
    Inherits ApplicationException
```

[C#]

```
public class SmtpClientException : ApplicationException
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

A SmtpClientException is thrown by the SmtpClient class when an error occurs.

The default constructor for the SmtpClientException class sets the **ErrorCode** property to the last client error that occurred.

Requirements

Namespace: SocketTools

Assembly: SocketTools.SmtpClient (in SocketTools.SmtpClient.dll)

See Also

SmtpClientException Members | SocketTools Namespace

SmtpClientException Members

SmtpClientException overview

Public Instance Constructors

SmtpClientException	Overloaded. Initializes a new instance of the SmtpClientException class.

Public Instance Properties

ErrorCode	Gets a value which specifies the error that caused the exception.
HelpLink (inherited from Exception)	Gets or sets a link to the help file associated with this exception.
InnerException (inherited from Exception)	Gets the Exception instance that caused the current exception.
Message	Gets a value which describes the error that caused the exception.
Number	Gets a value which specifies the numeric value of the error that caused the exception.
Source (inherited from Exception)	Gets or sets the name of the application or the object that causes the error.
StackTrace (inherited from Exception)	Gets a string representation of the frames on the call stack at the time the current exception was thrown.
TargetSite (inherited from Exception)	Gets the method that throws the current exception.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetBaseException (inherited from Exception)	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetObjectData (inherited from Exception)	When overridden in a derived class, sets the SerializationInfo with information about the exception.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString	Creates and returns a string representation of the current exception.

Protected Instance Properties

HResult (inherited from Exception)	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

SmtpClientException Class | SocketTools Namespace

SmtpClientException Constructor

Initializes a new instance of the SmtpClientException class with the last network error code.

Overload List

Initializes a new instance of the SmtpClientException class with the last network error code.

public SmtpClientException();

Initializes a new instance of the SmtpClientException class with a specified error number.

public SmtpClientException(int);

Initializes a new instance of the SmtpClientException class with a specified error message.

public SmtpClientException(string);

Initializes a new instance of the SmtpClientException class with a specified error message and a reference to the inner exception that is the cause of this exception.

public SmtpClientException(string,Exception);

See Also

SmtpClientException Class | SocketTools Namespace

SmtpClientException Constructor ()

Initializes a new instance of the SmtpClientException class with the last network error code.

[Visual Basic]

```
Overloads Public Sub New()
```

[C#]

```
public SmtpClientException();
```

Remarks

The ctor constructor sets the **ErrorCode** property to the last client error that occurred. For more information about the errors that may occur, refer to the SmtpClient.ErrorCode enumeration.

See Also

SmtpClientException Class | SocketTools Namespace | SmtpClientException Constructor Overload List

SmtpClientException Constructor (String)

Initializes a new instance of the SmtpClientException class with a specified error message.

[Visual Basic]

```
Overloads Public Sub New( _
   ByVal message As String _
)
```

[C#]

```
public SmtpClientException(
   string message
);
```

Parameters

message

The error message that explains the reason for the exception.

Remarks

The content of the ***message*** parameter is intended to be understood by humans. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

See Also

SmtpClientException Class | SocketTools Namespace | SmtpClientException Constructor Overload List

SmtpClientException Constructor (String, Exception)

Initializes a new instance of the SmtpClientException class with a specified error message and a reference to the inner exception that is the cause of this exception.

[Visual Basic]

```
Overloads Public Sub New( _
   ByVal message As String, _
   ByVal innerException As Exception _
)
```

[C#]

```
public SmtpClientException(
   string message,
   Exception innerException
);
```

Parameters

message
The error message that explains the reason for the exception.

innerException
The exception that is the cause of the current exception. If the ***innerException*** parameter is not a null reference, the current exception is raised in a **catch** block that handles the inner exception.

Remarks

The content of the message parameter is intended to be understood by humans. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

An exception that is thrown as a direct result of a previous exception should include a reference to the previous exception in the **InnerException** property. The **InnerException** property returns the same value that is passed into the constructor, or a null reference if the **InnerException** property does not supply the inner exception value to the constructor.

See Also

SmtpClientException Class | SocketTools Namespace | SmtpClientException Constructor Overload List

SmtpClientException Constructor (Int32)

Initializes a new instance of the SmtpClientException class with a specified error number.

[Visual Basic]

```
Overloads Public Sub New( _
   ByVal code As Integer _
)
```

[C#]

```
public SmtpClientException(
   int code
);
```

Parameters

code

An integer value which specifies an error code.

Remarks

This constructor sets the **ErrorCode** property to the specified error code. For more information about the errors that may occur, refer to the SmtpClient.ErrorCode enumeration.

See Also

SmtpClientException Class | SocketTools Namespace | SmtpClientException Constructor Overload List

SmtpClientException Properties

The properties of the **SmtpClientException** class are listed below. For a complete list of **SmtpClientException** class members, see the SmtpClientException Members topic.

Public Instance Properties

ErrorCode	Gets a value which specifies the error that caused the exception.
HelpLink (inherited from Exception)	Gets or sets a link to the help file associated with this exception.
InnerException (inherited from Exception)	Gets the Exception instance that caused the current exception.
Message	Gets a value which describes the error that caused the exception.
Number	Gets a value which specifies the numeric value of the error that caused the exception.
Source (inherited from Exception)	Gets or sets the name of the application or the object that causes the error.
StackTrace (inherited from Exception)	Gets a string representation of the frames on the call stack at the time the current exception was thrown.
TargetSite (inherited from Exception)	Gets the method that throws the current exception.

Protected Instance Properties

HResult (inherited from Exception)	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception.

See Also

SmtpClientException Class | SocketTools Namespace

SmtpClientException.ErrorCode Property

Gets a value which specifies the error that caused the exception.

[Visual Basic]

```
Public ReadOnly Property ErrorCode As ErrorCode
```

[C#]

```
public SmtpClient.ErrorCode ErrorCode {get;}
```

Property Value

Returns a SmtpClient.ErrorCode enumeration value which specifies the error code.

Remarks

The **ErrorCode** property returns the error code that specifies the cause of the exception.

The default constructor for the SmtpClientException class sets the error code to the last network error that occurred. For more information about the errors that may occur, refer to the SmtpClient.ErrorCode enumeration.

See Also

SmtpClientException Class | SocketTools Namespace

SmtpClientException.Message Property

Gets a value which describes the error that caused the exception.

[Visual Basic]

```
Overrides Public ReadOnly Property Message As String
```

[C#]

```
public override string Message {get;}
```

Property Value

A string which describes the error that caused the exception.

Remarks

The **Message** property returns a string which describes the error that caused the exception.

See Also

SmtpClientException Class | SocketTools Namespace

SmtpClientException.Number Property

Gets a value which specifies the numeric value of the error that caused the exception.

[Visual Basic]

```
Public ReadOnly Property Number As Integer
```

[C#]

```
public int Number {get;}
```

Property Value

An integer value that specifies the error that caused the exception.

Remarks

The **Number** property returns an integer value which specifies the numeric value of the error that caused the exception. This value is the same as the values returned by the Windows Sockets API. For more information about socket error codes, see the Windows Socket Version 2 API error code documentation in MSDN.

See Also

SmtpClientException Class | SocketTools Namespace

SmtpClientException Methods

The methods of the **SmtpClientException** class are listed below. For a complete list of **SmtpClientException** class members, see the SmtpClientException Members topic.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetBaseException (inherited from Exception)	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetObjectData (inherited from Exception)	When overridden in a derived class, sets the SerializationInfo with information about the exception.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString	Creates and returns a string representation of the current exception.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

SmtpClientException Class | SocketTools Namespace

SmtpClientException.ToString Method

Creates and returns a string representation of the current exception.

[Visual Basic]

```
Overrides Public Function ToString() As String
```

[C#]

```
public override string ToString();
```

Return Value

A string representation of the current exception.

Remarks

The **ToString** method returns a representation of the current exception that is intended to be understood by humans. Where the exception contains culture-sensitive data, the string representation returned by **ToString** is required to take into account the current system culture. Although there are no exact requirements for the format of the returned string, it should attempt to reflect the value of the object as perceived by the user.

This implementation of **ToString** obtains the numeric error code value and a description of the error that caused the current exception. If there is no error message or it is an empty string, then no error message is returned.

This method overrides **ApplicationException.ToString**.

See Also

SmtpClientException Class | SocketTools Namespace

SocketWrench Class

A general purpose TCP/IP networking class for developing client and server applications.

For a list of all members of this type, see SocketWrench Members.

System.Object
  SocketTools.SocketWrench

[Visual Basic]

```
Public Class SocketWrench
    Implements IDisposable
```

[C#]

```
public class SocketWrench : IDisposable
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

At the core of each of the SocketTools networking classes is the Windows Sockets API. This provides a low level interface for sending and receiving data over the Internet or a local intranet using the Transmission Control Protocol (TCP) and/or User Datagram Protocol (UDP). The SocketWrench class provides a simpler interface to the Windows Sockets API, without sacrificing features or functionality. Using SocketWrench, you can easily create client and server applications while avoiding many of the mundane tasks and common problems that programmers face when developing Internet applications.

This class supports secure connections using the standard SSL and TLS protocols and can also be used to create secure, custom server programs. Both implicit and explicit SSL connections are supported, enabling the class to work with a wide variety of client and server applications without requiring that you use third-party classes or understand Microsoft's cryptography classes.

Requirements

Namespace: SocketTools

Assembly: SocketTools.SocketWrench (in SocketTools.SocketWrench.dll)

SocketWrench Members

SocketWrench overview

Public Instance Constructors

SocketWrench Constructor	Initializes a new instance of the SocketWrench class.

Public Instance Fields

AdapterAddress	Returns the IP address associated with the specified network adapter.
HostAlias	Returns the aliases for a given host name.

Public Instance Properties

AdapterCount	Get the number of available local and remote network adapters.
AddressFamily	Gets and sets a value that determines which version of the Internet Protocol will be used.
AtMark	Get a value that indicates if the next receive will return urgent data.
AutoResolve	Gets and sets a value that determines if host names and addresses are automatically resolved.
Backlog	Gets and sets a value that indicates the number of connections that may be queued for a listening socket.
Blocking	Gets and sets a value which indicates if the socket is in blocking mode.
Broadcast	Gets and sets a value which indicates if datagrams will be broadcast over the local network.
ByteOrder	Gets and sets a value which indicates how integer data is read and written to the socket.
CertificateExpires	Get a value that specifies the date that the security certificate expires.
CertificateIssued	Get a value that specifies the date that the security certificate was issued.
CertificateIssuer	Get a value that provides information about the organization that issued the certificate.
CertificateName	Gets and sets a value that specifies the name of the security certificate.
CertificatePassword	Gets and sets the password associated with the security certificate.
CertificateStatus	Gets a value which indicates the status of the security certificate returned by the remote host.

CertificateStore	Gets and sets a value that specifies the name of the local certificate store.
CertificateSubject	Gets a value that provides information about the organization that the server certificate was issued to.
CertificateUser	Gets and sets the user that owns the security certificate.
CipherStrength	Gets a value that indicates the length of the key used by the encryption algorithm for a secure connection.
CodePage	Gets and sets the code page used when reading and writing text.
ExternalAddress	Gets a value that specifies the external Internet address for the local system.
Handle	Gets a value that specifies the socket handle allocated for the current session.
HashStrength	Gets a value which specifies the length of the message digest that was selected for a secure connection.
HostAddress	Gets and sets a value which specifies the Internet address used to establish a connection.
HostFile	Gets and sets a value that specifies the name of a host file used to resolve host names and addresses.
HostName	Gets and sets a value which specifies the host name used to establish a connection.
InLine	Gets and sets a value that indicates if urgent data is received in-line with non-urgent data.
IsBlocked	Gets a value which indicates if the current thread is performing a blocking socket operation.
IsClosed	Gets a value which indicates if the connection to the remote host has been closed.
IsConnected	Gets a value which indicates if a connection to the remote host has been established.
IsInitialized	Gets a value which indicates if the current instance of the class has been initialized successfully.
IsListening	Gets a value which indicates if the socket is listening for client connections.
IsReadable	Gets a value which indicates if there is data available to be read from the socket.
IsWritable	Gets a value which indicates if data can be written to the socket without blocking.
KeepAlive	Gets and sets a value which indicates if keep-alive

	packets are sent on a connected socket.
LastError	Gets and sets a value which specifies the last error that has occurred.
LastErrorString	Gets a value which describes the last error that has occurred.
Linger	Gets and sets a value which specifies the number of seconds to wait for the socket to disconnect from the remote host.
LocalAddress	Gets and sets the local Internet address that the socket will be bound to.
LocalName	Gets a value which specifies the host name for the local system.
LocalPort	Gets and sets a value which specifies the local port number the socket will be bound to.
LocalService	Gets and sets a value which specifies the local service the socket will be bound to.
NoDelay	Gets and sets a value which specifies if the Nagle algorithm should be enabled or disabled.
Options	Gets and sets a value which specifies one or more socket options.
PeerAddress	Gets a value that specifies the Internet address of the remote host.
PeerName	Gets a value that specifies the name of the remote host.
PeerPort	Gets a value that specifies the port number used by the remote host.
PhysicalAddress	Gets a value which specifies the MAC address for the local system's network adapter.
Protocol	Gets and sets a value which specifies the socket protocol.
RemotePort	Gets and sets a value which specifies the remote port number.
RemoteService	Gets and sets a value which specifies the remote service.
ReservedPort	Gets and sets a value which indicates if a reserved port number was used.
ReuseAddress	Gets and sets a value which indicates if a socket address can be reused.
Route	Gets and sets a value which indicates if packets should be routed.
Secure	Gets and sets a value which specifies if a secure connection is established.

SecureCipher	Gets a value that specifies the encryption algorithm used for a secure connection.
SecureHash	Gets a value that specifies the message digest algorithm used for a secure connection.
SecureKeyExchange	Gets a value that specifies the key exchange algorithm used for a secure connection.
SecureProtocol	Gets and sets a value which specifies the protocol used for a secure connection.
Status	Gets a value which specifies the current status of the socket.
ThreadModel	Gets and sets a value which specifies the threading model for the class instance.
ThrowError	Gets and sets a value which specifies if method calls should throw exceptions when an error occurs.
Timeout	Gets and sets a value which specifies a timeout period in seconds.
Trace	Gets and sets a value which indicates if network function logging is enabled.
TraceFile	Gets and sets a value which specifies the name of the network function tracing logfile.
TraceFlags	Gets and sets a value which specifies the network function tracing flags.
Urgent	Gets and sets a value which specifies if urgent data will be read or written.
Version	Gets a value which returns the current version of the SocketWrench class library.

Public Instance Methods

Abort	Abort the connection with a remote host.
Accept	Overloaded. Accepts a client connection on a listening socket, specifying a timeout period and one or more socket options.
AttachThread	Attach an instance of the class to the current thread
Bind	Overloaded. Bind the socket to the specified local address and port number.
Cancel	Cancel the current blocking socket operation.
Connect	Overloaded. Establish a connection with a remote host.
Disconnect	Terminate the connection with a remote host.
Dispose	Overloaded. Releases all resources used by SocketWrench.

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from Object)	Gets the Type of the current instance.
Initialize	Overloaded. Initialize an instance of the SocketWrench class.
Listen	Overloaded. Listen for incoming client connections, specifying the local network address, port number and connection backlog.
Peek	Overloaded. Read data from the socket and store it in a byte array, but do not remove the data from the socket buffers.
Read	Overloaded. Read data from the socket and store it in a byte array.
ReadFrom	Overloaded. Read data from the socket and store it in a byte array.
ReadLine	Overloaded. Read up to a line of data from the socket and return it in a string buffer.
ReadStream	Overloaded. Read a data stream from the socket and store it in the specified byte array.
Reject	Rejects a connection request from a remote host.
Reset	Reset the internal state of the object, resetting all properties to their default values.
Resolve	Resolves a host name to a host IP address.
Shutdown	Overloaded. Disable sending or receiving data on the socket.
StoreStream	Overloaded. Reads a data stream from the socket and stores it in the specified file.
ToString (inherited from Object)	Returns a String that represents the current Object.
Uninitialize	Uninitialize the class library and release any resources allocated for the current thread.
Write	Overloaded. Write one or more bytes of data to the socket.
WriteLine	Overloaded. Send a line of text to the remote host, terminated by a carriage-return and linefeed.
WriteStream	Overloaded. Write a stream of bytes to the socket.
WriteTo	Overloaded. Write one or more bytes of data to the socket.

Public Instance Events

OnAccept	Occurs when a remote host attempts to establish a connection with the local system.
OnCancel	Occurs when a blocking socket operation is canceled.
OnConnect	Occurs when a connection is established with the remote host.
OnDisconnect	Occurs when the remote host disconnects from the local system.
OnError	Occurs when an socket operation fails.
OnProgress	Occurs as a data stream is being read or written to the socket.
OnRead	Occurs when data is available to be read from the socket.
OnTimeout	Occurs when a blocking operation fails to complete before the timeout period elapses.
OnWrite	Occurs when data can be written to the socket.

Protected Instance Methods

Dispose	Overloaded. Releases the unmanaged resources allocated by the SocketWrench class and optionally releases the managed resources.
Finalize	Destroys an instance of the class, releasing the resources allocated for the session and unloading the networking library.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

SocketWrench Class | SocketTools Namespace

SocketWrench Constructor

Initializes a new instance of the SocketWrench class.

[Visual Basic]
```
Public Sub New()
```

[C#]
```
public SocketWrench();
```

Example

The following example demonstrates creating an instance of the **SocketWrench** class object and resolving a hostname into an Internet address using the Resolve method.

```
Dim Socket As SocketTools.SocketWrench
Dim strHostName As String
Dim strHostAddress As String

Socket = New SocketTools.SocketWrench
strHostName = TextBox1.Text.Trim()

If Socket.Resolve(strHostName, strHostAddress) Then
    StatusBar1.Text = "The Internet address for " + strHostName + " is " +
strHostAddress
Else
    StatusBar1.Text = "The Internet address for " + strHostName + " could not be
resolved"
End If
```

See Also

SocketWrench Class | SocketTools Namespace

SocketWrench Fields

The fields of the **SocketWrench** class are listed below. For a complete list of **SocketWrench** class members, see the SocketWrench Members topic.

Public Instance Fields

AdapterAddress	Returns the IP address associated with the specified network adapter.
HostAlias	Returns the aliases for a given host name.

See Also

SocketWrench Class | SocketTools Namespace

SocketWrench.AdapterAddress Field

Returns the IP address associated with the specified network adapter.

[Visual Basic]

```
Public ReadOnly AdapterAddress As AdapterAddressArray
```

[C#]

```
public readonly AdapterAddressArray AdapterAddress;
```

Remarks

The **AdapterAddress** array returns the IP addresses that are associated with the local network or remote dial-up network adapters configured on the system. The **AdapterCount** property can be used to determine the number of adapters that are available.

Multihomed systems with more than one local network adapter, or a combination of local and dial-up adapters will not be listed in a specific order. An application should not make the assumption that the first address returned by **AdapterAddress** always refers to a local network adapter.

Note that it is possible that the **AdapterCount** property will return 0, and **AdapterAddress** will return an empty string. This indicates that the system does not have a physical network adapter with an assigned IP address, and there are no dial-up networking connections currently active. If a dial-up networking connection is established at some later point, the **AdapterCount** property will change to 1, and the **AdapterAddress** property will return the IP address allocated for that connection.

See Also

SocketWrench Class | SocketTools Namespace | AdapterAddressArray Class | AdapterCount Property

SocketWrench.HostAlias Field

Returns the aliases for a given host name.

[Visual Basic]

```
Public ReadOnly HostAlias As HostAliasArray
```

[C#]

```
public readonly HostAliasArray HostAlias;
```

Remarks

The **HostAlias** array returns the aliases assigned to the host specified by the **HostAddress** or **HostName** properties. If the host address or name can be resolved, the first element in the **HostAlias** array always refers to the host's fully qualified domain name.

The end of the alias list is indicated when the property returns an empty string. The array is zero based, meaning that the first index value is zero.

Example

```
Dim nIndex As Integer

ListBox1.Items.Clear()
Socket.HostName = strHostName

For nIndex = 0 To Socket.HostAliases - 1
    ListBox1.Items.Add(Socket.HostAlias(nIndex))
Next
```

SocketWrench Properties

The properties of the **SocketWrench** class are listed below. For a complete list of **SocketWrench** class members, see the SocketWrench Members topic.

Public Instance Properties

AdapterCount	Get the number of available local and remote network adapters.
AddressFamily	Gets and sets a value that determines which version of the Internet Protocol will be used.
AtMark	Get a value that indicates if the next receive will return urgent data.
AutoResolve	Gets and sets a value that determines if host names and addresses are automatically resolved.
Backlog	Gets and sets a value that indicates the number of connections that may be queued for a listening socket.
Blocking	Gets and sets a value which indicates if the socket is in blocking mode.
Broadcast	Gets and sets a value which indicates if datagrams will be broadcast over the local network.
ByteOrder	Gets and sets a value which indicates how integer data is read and written to the socket.
CertificateExpires	Get a value that specifies the date that the security certificate expires.
CertificateIssued	Get a value that specifies the date that the security certificate was issued.
CertificateIssuer	Get a value that provides information about the organization that issued the certificate.
CertificateName	Gets and sets a value that specifies the name of the security certificate.
CertificatePassword	Gets and sets the password associated with the security certificate.
CertificateStatus	Gets a value which indicates the status of the security certificate returned by the remote host.
CertificateStore	Gets and sets a value that specifies the name of the local certificate store.
CertificateSubject	Gets a value that provides information about the organization that the server certificate was issued to.
CertificateUser	Gets and sets the user that owns the security certificate.
CipherStrength	Gets a value that indicates the length of the key

	used by the encryption algorithm for a secure connection.
CodePage	Gets and sets the code page used when reading and writing text.
ExternalAddress	Gets a value that specifies the external Internet address for the local system.
Handle	Gets a value that specifies the socket handle allocated for the current session.
HashStrength	Gets a value which specifies the length of the message digest that was selected for a secure connection.
HostAddress	Gets and sets a value which specifies the Internet address used to establish a connection.
HostFile	Gets and sets a value that specifies the name of a host file used to resolve host names and addresses.
HostName	Gets and sets a value which specifies the host name used to establish a connection.
InLine	Gets and sets a value that indicates if urgent data is received in-line with non-urgent data.
IsBlocked	Gets a value which indicates if the current thread is performing a blocking socket operation.
IsClosed	Gets a value which indicates if the connection to the remote host has been closed.
IsConnected	Gets a value which indicates if a connection to the remote host has been established.
IsInitialized	Gets a value which indicates if the current instance of the class has been initialized successfully.
IsListening	Gets a value which indicates if the socket is listening for client connections.
IsReadable	Gets a value which indicates if there is data available to be read from the socket.
IsWritable	Gets a value which indicates if data can be written to the socket without blocking.
KeepAlive	Gets and sets a value which indicates if keep-alive packets are sent on a connected socket.
LastError	Gets and sets a value which specifies the last error that has occurred.
LastErrorString	Gets a value which describes the last error that has occurred.
Linger	Gets and sets a value which specifies the number of seconds to wait for the socket to disconnect from the remote host.

LocalAddress	Gets and sets the local Internet address that the socket will be bound to.
LocalName	Gets a value which specifies the host name for the local system.
LocalPort	Gets and sets a value which specifies the local port number the socket will be bound to.
LocalService	Gets and sets a value which specifies the local service the socket will be bound to.
NoDelay	Gets and sets a value which specifies if the Nagle algorithm should be enabled or disabled.
Options	Gets and sets a value which specifies one or more socket options.
PeerAddress	Gets a value that specifies the Internet address of the remote host.
PeerName	Gets a value that specifies the name of the remote host.
PeerPort	Gets a value that specifies the port number used by the remote host.
PhysicalAddress	Gets a value which specifies the MAC address for the local system's network adapter.
Protocol	Gets and sets a value which specifies the socket protocol.
RemotePort	Gets and sets a value which specifies the remote port number.
RemoteService	Gets and sets a value which specifies the remote service.
ReservedPort	Gets and sets a value which indicates if a reserved port number was used.
ReuseAddress	Gets and sets a value which indicates if a socket address can be reused.
Route	Gets and sets a value which indicates if packets should be routed.
Secure	Gets and sets a value which specifies if a secure connection is established.
SecureCipher	Gets a value that specifies the encryption algorithm used for a secure connection.
SecureHash	Gets a value that specifies the message digest algorithm used for a secure connection.
SecureKeyExchange	Gets a value that specifies the key exchange algorithm used for a secure connection.
SecureProtocol	Gets and sets a value which specifies the protocol used for a secure connection.

Status	Gets a value which specifies the current status of the socket.
ThreadModel	Gets and sets a value which specifies the threading model for the class instance.
ThrowError	Gets and sets a value which specifies if method calls should throw exceptions when an error occurs.
Timeout	Gets and sets a value which specifies a timeout period in seconds.
Trace	Gets and sets a value which indicates if network function logging is enabled.
TraceFile	Gets and sets a value which specifies the name of the network function tracing logfile.
TraceFlags	Gets and sets a value which specifies the network function tracing flags.
Urgent	Gets and sets a value which specifies if urgent data will be read or written.
Version	Gets a value which returns the current version of the SocketWrench class library.

See Also

SocketWrench Class | SocketTools Namespace

SocketWrench.AdapterCount Property

Get the number of available local and remote network adapters.

[Visual Basic]

```
Public ReadOnly Property AdapterCount As Integer
```

[C#]

```
public int AdapterCount {get;}
```

Property Value

Returns the number of available local and remote network adapters.

Remarks

The **AdapterCount** property returns the number of local and remote dial-up networking adapters available on the local system. This value can be used in conjunction with the **AdapterAddress** array to enumerate the IP addresses assigned to the various network adapters.

Note that it is possible that the **AdapterCount** property will return 0, and **AdapterAddress** will return an empty string. This indicates that the system does not have a physical network adapter with an assigned IP address, and there are no dial-up networking connections currently active. If a dial-up networking connection is established at some later point, the **AdapterCount** property will change to 1, and the **AdapterAddress** property will return the IP address allocated for that connection.

See Also

SocketWrench Class | SocketTools Namespace | AdapterAddress Field

SocketWrench.AtMark Property

Get a value that indicates if the next receive will return urgent data.

[Visual Basic]

```
Public ReadOnly Property AtMark As Boolean
```

[C#]

```
public bool AtMark {get;}
```

Property Value

Returns **true** if the next read on the socket will return urgent data.

Remarks

This property can only be used if the **Protocol** property is set to **SocketProtocol.socketStream** and the **InLine** property has been set to **true**.

See Also

SocketWrench Class | SocketTools Namespace

SocketWrench.AutoResolve Property

Gets and sets a value that determines if host names and addresses are automatically resolved.

[Visual Basic]

```
Public Property AutoResolve As Boolean
```

[C#]

```
public bool AutoResolve {get; set;}
```

Property Value

Returns **true** if host names are automatically resolved to Internet addresses. The default value is **false**.

Remarks

Setting the **AutoResolve** property determines if the class automatically resolves host names and addresses specified by the **HostName** and **HostAddress** properties. If set to **true**, setting the **HostName** property will cause the class to automatically determine the corresponding IP address and update the **HostAddress** property accordingly. Likewise, setting the **HostAddress** property will cause the class to determine the host name and update the **HostName** property. Setting this property to **false** prevents the class from resolving host names until a connection attempt is made.

It is important to note that setting the **HostName** or **HostAddress** property may cause the current thread to block, sometimes for several seconds, until the name or address is resolved. To prevent this behavior, set this property value to **false**.

See Also

SocketWrench Class | SocketTools Namespace

SocketWrench.Backlog Property

Gets and sets a value that indicates the number of connections that may be queued for a listening socket.

[Visual Basic]

```
Public Property Backlog As Integer
```

[C#]

```
public int Backlog {get; set;}
```

Property Value

Returns an integer value that specifies the size of the backlog queue. The default value is 5.

Remarks

The **Backlog** property specifies the maximum size of the queue used to manage pending connections to the service. If the property is set to value which exceeds the maximum size for the underlying service provider, it will be silently adjusted to the nearest legal value. There is no standard way to determine what the maximum backlog value is.

This property must be set to the desired value before the **Listen** method is called, if the **Listen** method is used with default parameters.

See Also

SocketWrench Class | SocketTools Namespace

SocketWrench.Blocking Property

Gets and sets a value which indicates if the socket is in blocking mode.

[Visual Basic]
```
Public Property Blocking As Boolean
```

[C#]
```
public bool Blocking {get; set;}
```

Property Value

Returns **true** if the socket is in blocking mode; otherwise it returns **false**. The default value is **true**.

Remarks

Setting the **Blocking** property determines if socket operations complete synchronously or asynchronously. If set to **true**, then each socket operation (such as sending or receiving data) will return when the operation has completed or timed-out. If set to **false**, socket operations will return immediately. If the operation would result in the socket blocking (such as attempting to read data when no data has been sent by the remote host), an error is generated.

It is important to note that certain events, such as **OnDisconnect, OnRead** and **OnWrite** are only fired if the socket is in non-blocking mode.

See Also

SocketWrench Class | SocketTools Namespace

SocketWrench.Broadcast Property

Gets and sets a value which indicates if datagrams will be broadcast over the local network.

[Visual Basic]
```
Public Property Broadcast As Boolean
```

[C#]
```
public bool Broadcast {get; set;}
```

Property Value

Returns **true** if datagrams will be broadcast; otherwise returns **false**. The default value is **false**.

Remarks

If the **Broadcast** property is set to a value of **true**, the datagram written to the socket will be broadcast to all systems on the network. Use of this property is restricted to the UDP protocol and the value is ignored for TCP connections.

See Also

SocketWrench Class | SocketTools Namespace

SocketWrench.ByteOrder Property

Gets and sets a value which indicates how integer data is read and written to the socket.

[Visual Basic]

```
Public Property ByteOrder As SocketByteOrder
```

[C#]

```
public SocketWrench.SocketByteOrder ByteOrder {get; set;}
```

Property Value

A SocketByteOrder enumeration value which specifies the byte order. The default is **byteOrderNative**.

Remarks

The **ByteOrder** property is used to specify how integer data is written to and read from the socket. The default value for this property is **byteOrderNative**, which specifies that integers should be written in the native byte order for the local machine. A value of **byteOrderNetwork** indicates that integers should be written in network byte order.

When applications write integer values on a socket (instead of string representations of those values), they should typically be converted to network byte order before they are sent. Likewise, when an integer value is read, it should then be converted from the network byte order back to the byte order used by the local machine. The native byte order, also called the host byte order, should only be used if it can be assured that both the sender and the receiver are running on an identical or compatible machine architectures (for example, if both systems are Intel-based).

See Also

SocketWrench Class | SocketTools Namespace

SocketWrench.CertificateExpires Property

Get a value that specifies the date that the security certificate expires.

[Visual Basic]

```
Public ReadOnly Property CertificateExpires As String
```

[C#]

```
public string CertificateExpires {get;}
```

Property Value

A string which specifies a date using the local date and time format.

Remarks

The **CertificateExpires** property returns a string that specifies the date and time that the security certificate expires. This property will return an empty string if a secure connection has not been established with the remote host.

See Also

SocketWrench Class | SocketTools Namespace

SocketWrench.CertificateIssued Property

Get a value that specifies the date that the security certificate was issued.

[Visual Basic]

```
Public ReadOnly Property CertificateIssued As String
```

[C#]

```
public string CertificateIssued {get;}
```

Property Value

A string which specifies a date using the local date and time format.

Remarks

The **CertificateIssued** property returns a string that specifies the date and time that the security certificate was issued. This property will return an empty string if a secure connection has not been established with the remote host.

See Also

SocketWrench Class | SocketTools Namespace

SocketWrench.CertificateIssuer Property

Get a value that provides information about the organization that issued the certificate.

[Visual Basic]

```
Public ReadOnly Property CertificateIssuer As String
```

[C#]

```
public string CertificateIssuer {get;}
```

Property Value

A string that contains a comma separated list of name value pairs.

Remarks

The **CertificateIssuer** property returns a string that contains information about the organization that issued the server certificate. The string value is a comma separated list of tagged name and value pairs. In the nomenclature of the X.500 standard, each of these pairs are called a relative distinguished name (RDN), and when concatenated together, forms the issuer's distinguished name (DN). For example:

```
C=US, O="RSA Data Security, Inc.", OU=Secure Server Certification Authority
```

To obtain a specific value, such as the name of the issuer or the issuer's country, the application must parse the string returned by this property. Some of the common tokens used in the distinguished name are:

Token	Description
C	The ISO standard two character country code.
S	The name of the state or province.
L	The name of the city or locality.
O	The name of the company or organization.
OU	The name of the department or organizational unit
CN	The common name; with X.509 certificates, this is the domain name of the site the certificate was issued for.

This property will return an empty string if a secure connection has not been established with the remote host.

See Also

SocketWrench Class | SocketTools Namespace

SocketWrench.CertificateName Property

Gets and sets a value that specifies the name of the security certificate.

[Visual Basic]
```
Public Property CertificateName As String
```

[C#]
```
public string CertificateName {get; set;}
```

Property Value

A string which specifies the certificate name.

Remarks

The **CertificateName** property sets the common name or friendly name of the certificate that should be used when establishing a secure client connection or accepting a secure connection from a remote host. This property is used in conjunction with the **CertificateStore** property to identify the client or server certificate.

For client applications, it is only required that you set this property value if the server requires a client certificate for authentication. If this property is not set, a client certificate will not be provided to the server. The certificate must be designated as a client certificate and have a private key associated with it, otherwise the connection attempt will fail.

For server applications, it is required that you specify a certificate name if security has been enabled by setting the **Secure** property to true. The certificate must be designated as a server certificate and have a private key associated with it, otherwise incoming client connections cannot be accepted.

When the certificate store is searched for a matching certificate, it will first search for any certificate with a friendly name that matches the property value. If no valid certificate is found, it will then search for a certificate with a matching common name.

Certificates may be installed and viewed on the local system using the Certificate Manager that is included with the Windows operating system. For more information, refer to the documentation for the Microsoft Management Console.

See Also

SocketWrench Class | SocketTools Namespace | CertificateStore Property | Secure Property

SocketWrench.CertificateStatus Property

Gets a value which indicates the status of the security certificate returned by the remote host.

[Visual Basic]

```
Public ReadOnly Property CertificateStatus As SecurityCertificate
```

[C#]

```
public SocketWrench.SecurityCertificate CertificateStatus {get;}
```

Property Value

A SecurityCertificate enumeration value which specifies the status of the certificate.

Remarks

The **CertificateStatus** property is used to determine the status of the security certificate returned by the remote host when a secure connection has been established. This property value should be checked after the connection to the server has completed, but prior to beginning a transaction.

Note that if the certificate cannot be validated, the secure connection will not be automatically terminated. It is the responsibility of your application to determine the best course of action to take if the certificate is invalid. Even if the security certificate cannot be validated, the data exchanged with the remote host will still be encrypted.

See Also

SocketWrench Class | SocketTools Namespace

SocketWrench.CertificateStore Property

Gets and sets a value that specifies the name of the local certificate store.

```
[Visual Basic]
Public Property CertificateStore As String
```

```
[C#]
public string CertificateStore {get; set;}
```

Property Value

A string which specifies the certificate store name. The default value is the current user's personal certificate store.

Remarks

The **CertificateStore** property is used to specify the name of the certificate store which contains the security certificate to use when establishing a secure connection. The certificate may either be stored in the registry or in a file. If the certificate is stored in the registry, then this property should be set to one of the following predefined values:

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as VeriSign and Thawte act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. If a certificate store is not specified, this is the default value that is used.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as VeriSign and Thawte are installed as part of the operating system and periodically updated by Microsoft.

In most cases the client certificate will be installed in the user's personal certificate store, and therefore it is not necessary to set this property value because that is the default location that will be used to search for the certificate. This property is only used if the **CertificateName** property is also set to a valid certificate name.

If you are using a local certificate store, with the certificate and private key stored in the registry, you can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU" for the current user, or "HKLM" for the local machine. For example, a certificate store name of "HKLM:MY" would specify the personal certificate store for the local machine, rather than the current user. If neither prefix is specified, it will default to the certificate store for the current user.

This property may also be used to specify a file that contains the client certificate. In this case, the property should specify the full path to the file and must contain both the certificate and private key in PKCS12

format. If the file is protected by a password, the **CertificatePassword** property must also be set to specify the password.

See Also

SocketWrench Class | SocketTools Namespace | CertificatePassword Property | Secure Property

SocketWrench.CertificateSubject Property

Gets a value that provides information about the organization that the server certificate was issued to.

[Visual Basic]
```
Public ReadOnly Property CertificateSubject As String
```

[C#]
```
public string CertificateSubject {get;}
```

Property Value

A string that contains a comma separated list of name value pairs.

Remarks

The **CertificateSubject** property returns a string that contains information about the organization that the server certificate was issued to. The string value is a comma separated list of tagged name and value pairs. In the nomenclature of the X.500 standard, each of these pairs are called a relative distinguished name (RDN), and when concatenated together, forms the issuer's distinguished name (DN). For example:

```
C=US, O="RSA Data Security, Inc.", OU=Secure Server Certification Authority
```

To obtain a specific value, such as the name of the issuer or the issuer's country, the application must parse the string returned by this property. Some of the common tokens used in the distinguished name are:

Token	Description
C	The ISO standard two character country code.
S	The name of the state or province.
L	The name of the city or locality.
O	The name of the company or organization.
OU	The name of the department or organizational unit
CN	The common name; with X.509 certificates, this is the domain name of the site the certificate was issued for.

This property will return an empty string if a secure connection has not been established with the remote host.

See Also

SocketWrench Class | SocketTools Namespace

SocketWrench.CipherStrength Property

Gets a value that indicates the length of the key used by the encryption algorithm for a secure connection.

[Visual Basic]
```
Public ReadOnly Property CipherStrength As Integer
```

[C#]
```
public int CipherStrength {get;}
```

Property Value

An integer value which specifies the encryption key length if a secure connection has been established; otherwise a value of 0 is returned.

Remarks

The **CipherStrength** property returns the number of bits in the key used to encrypt the secure data stream. Common values returned by this property are 128 and 256. A key length of 40 or 56 bits is considered insecure and subject to brute force attacks. 128-bit and 256-bit keys are considered secure. If this property returns a value of 0, this means that a secure connection has not been established with the remote host.

See Also

SocketWrench Class | SocketTools Namespace

SocketWrench.CodePage Property

Gets and sets the code page used when reading and writing text.

[Visual Basic]
```
Public Property CodePage As Integer
```

[C#]
```
public int CodePage {get; set;}
```

Property Value

An integer value which specifies the current code page. A value of zero specifies the default code page for the current locale should be used. To preserve the original Unicode text, you can use code page 65001 which specifies UTF-8 character encoding.

Remarks

All data which is exchanged over a socket is sent and received as 8-bit bytes, typically referred to as "octets" in networking terminology. However, strings in .NET are Unicode where each character is represented by 16 bits. To send and receive data using strings, these Unicode strings are converted to a stream of bytes.

By default, strings are converted to an array of bytes using the code page for the current locale, mapping the 16-bit Unicode characters to bytes. Similarly, when reading data from the socket into a string buffer, the stream of bytes received from the remote host are converted to Unicode before they are returned to your application.

If you are exchanging text with another system and it appears to corrupted or characters are being replaced with question marks or other symbols, it is likely the system is sending text which is using a different character encoding. Most services use UTF-8 encoding to represent non-ASCII characters and selecting the UTF-8 code page will typically resolve the issue.

Strings are only guaranteed to be safe when sending and receiving text. Using a string data type is not recommended when reading or writing binary data to a socket. If possible, you should always use a byte array as the buffer parameter for the Read and Write methods whenever you are exchanging binary data.

For backwards compatibility, this class defaults to using the code page for the current locale. This property value directly corresponds to Windows code page identifiers, and will accept any valid code page supported by the .NET Framework. Setting this property to an invalid code page will generate an exception.

See Also

SocketWrench Class | SocketTools Namespace

SocketWrench.ExternalAddress Property

Gets a value that specifies the external Internet address for the local system.

[Visual Basic]

```
Public ReadOnly Property ExternalAddress As String
```

[C#]

```
public string ExternalAddress {get;}
```

Property Value

A string which specifies an Internet address using dotted notation.

Remarks

The **ExternalAddress** property returns the IP address assigned to the router that connects the local host to the Internet. This is typically used by an application executing on a system in a local network that uses a router which performs Network Address Translation (NAT). In that network configuration, the **LocalAddress** property will only return the IP address for the local system on the LAN side of the network unless a connection has already been established to a remote host. The **ExternalAddress** property can be used to determine the IP address assigned to the router on the Internet side of the connection and can be particularly useful for servers running on a system behind a NAT router.

Using this property requires that you have an active connection to the Internet; checking the value of this property on a system that uses dial-up networking may cause the operating system to automatically connect to the Internet service provider. The class may be unable to determine the external IP address for the local host for a number of reasons, particularly if the system is behind a firewall or uses a proxy server that restricts access to external sites on the Internet. If the external address for the local host cannot be determined, the property will return an empty string.

If the class is able to obtain a valid external address for the local host, that address will be cached for sixty minutes. Because dial-up connections typically have different IP addresses assigned to them each time the system is connected to the Internet, it is recommended that this property only be used in conjunction with broadband connections using a NAT router.

It is important to note that checking this property value may cause the current thread to block until the external IP address can be resolved and should never be used in conjunction with non-blocking (asynchronous) socket connections. If you need to check this property value in an application which uses asynchronous sockets, it is recommended that you create a new thread and access the property from within that thread.

See Also

SocketWrench Class | SocketTools Namespace

SocketWrench.Handle Property

Gets a value that specifies the socket handle allocated for the current session.

[Visual Basic]

```
Public ReadOnly Property Handle As Integer
```

[C#]

```
public int Handle {get;}
```

Property Value

An integer which represents a socket handle. If there is no active connection, a value of -1 is returned.

Remarks

The **Handle** property specifies the socket descriptor of the listening socket. To accept the connection, a new instance of the SocketWrench class should be created, passing this value to the **Accept** method in the new class instance.

See Also

SocketWrench Class | SocketTools Namespace

SocketWrench.HashStrength Property

Gets a value which specifies the length of the message digest that was selected for a secure connection.

[Visual Basic]

```
Public ReadOnly Property HashStrength As Integer
```

[C#]

```
public int HashStrength {get;}
```

Property Value

An integer value which specifies the length of the message digest if a secure connection has been established; otherwise a value of 0 is returned.

Remarks

The **HashStrength** property returns the number of bits used in the message digest (hash) that was selected. Common values returned by this property are 128 and 160. If this property returns a value of 0, this means that a secure connection has not been established with the remote host.

See Also

SocketWrench Class | SocketTools Namespace

SocketWrench.HostAddress Property

Gets and sets a value which specifies the Internet address used to establish a connection.

[Visual Basic]

```
Public Property HostAddress As String
```

[C#]

```
public string HostAddress {get; set;}
```

Property Value

A string which specifies an Internet address using dotted notation.

Remarks

The **HostAddress** property can be used to set the Internet address for a remote system that you wish to communicate with. If the **AutoResolve** property is set to **true** and the address is assigned to a valid host name, the **HostName** property will be updated with that value.

See Also

SocketWrench Class | SocketTools Namespace

SocketWrench.HostFile Property

Gets and sets a value that specifies the name of a host file used to resolve host names and addresses.

[Visual Basic]
```
Public Property HostFile As String
```

[C#]
```
public string HostFile {get; set;}
```

Property Value

A string which specifies a file name.

Remarks

The **HostFile** property is used to specify the name of an alternate file for resolving hostnames and IP addresses. The host file is used as a database that maps an IP address to one or more hostnames, and is used when setting the **HostName** or **HostAddress** properties and establishing a connection with a remote host. The file is a plain text file, with each line in the file specifying a record, and each field separated by spaces or tabs. The format of the file must be as follows:

```
ipaddress hostname [hostalias ...]
```

For example, one typical entry maps the name "localhost" to the local loopback IP address. This would be entered as:

```
127.0.0.1 localhost
```

The hash character (#) may be used to specify a comment in the file, and all characters after it are ignored up to the end of the line. Blank lines are ignored, as are any lines which do not follow the required format.

Setting this property loads the file into memory allocated for the current thread. If the contents of the file have changed after the function has been called, those changes will not be reflected when resolving hostnames or addresses. To reload the host file from disk, set the property again with the same file name. To remove the alternate host file from memory, specify an empty string as the file name.

If a host file has been specified, it is processed before the default host file when resolving a hostname into an IP address, or an IP address into a hostname. If the host name or address is not found, or no host file has been specified, a nameserver lookup is performed.

Because the alternate host file is cached for the current thread, setting this property will affect all instances of the class in the same thread. For example, if a project has created three instances of the class, setting the HostFile property will affect all three instances, not just the instance that set the property. To determine if an alternate host file has been cached, check the property value. If the property returns an empty string, no alternate host file has been cached.

See Also

SocketWrench Class | SocketTools Namespace

SocketWrench.HostName Property

Gets and sets a value which specifies the host name used to establish a connection.

[Visual Basic]
```
Public Property HostName As String
```

[C#]
```
public string HostName {get; set;}
```

Property Value

A string which specifies a host name.

Remarks

The **HostName** property can be used to set the host name for a remote system that you wish to communicate with. If the **AutoResolve** property is set to **true** and the name can be resolved to a valid Internet address, the **HostAddress** property will be updated with that value.

See Also

SocketWrench Class | SocketTools Namespace

SocketWrench.InLine Property

Gets and sets a value that indicates if urgent data is received in-line with non-urgent data.

[Visual Basic]

```
Public Property InLine As Boolean
```

[C#]

```
public bool InLine {get; set;}
```

Property Value

Returns **true** if urgent data will be received in-line; otherwise returns **false**. The default value is **false**.

Remarks

The **InLine** property controls how urgent (out-of-band) data is handled when reading data from the socket. If set to a value of **true**, urgent data is placed in the data stream along with non-urgent data. To determine if the data that is being read is urgent, the **AtMark** property can be read.

See Also

SocketWrench Class | SocketTools Namespace

SocketWrench.IsBlocked Property

Gets a value which indicates if the current thread is performing a blocking socket operation.

[Visual Basic]

```
Public ReadOnly Property IsBlocked As Boolean
```

[C#]

```
public bool IsBlocked {get;}
```

Property Value

Returns **true** if the current thread is blocking, otherwise returns **false**.

Remarks

The **IsBlocked** property returns **true** if the current thread is blocked performing an operation. Because the Windows Sockets API only permits one blocking operation per thread of execution, this property should be checked before starting any blocking operation in response to an event.

If the **IsBlocked** property returns **false**, this means there are no blocking operations on the current thread at that time. However, this does not guarantee that the next socket operation will not fail. An application should always check the return value from a socket operation and check the value of the **LastError** property if an error occurs.

Note that this property will return **true** if there is any blocking operation being performed by the current thread, regardless of whether this specific instance of the class is responsible for the blocking operation or not.

See Also

SocketWrench Class | SocketTools Namespace

SocketWrench.IsClosed Property

Gets a value which indicates if the connection to the remote host has been closed.

[Visual Basic]

```
Public ReadOnly Property IsClosed As Boolean
```

[C#]

```
public bool IsClosed {get;}
```

Property Value

Returns **true** if the connection has been closed; otherwise returns **false**.

See Also

SocketWrench Class | SocketTools Namespace

SocketWrench.IsConnected Property

Gets a value which indicates if a connection to the remote host has been established.

[Visual Basic]

```
Public ReadOnly Property IsConnected As Boolean
```

[C#]

```
public bool IsConnected {get;}
```

Property Value

Returns **true** if the connection has been established; otherwise returns **false**.

Remarks

The **IsConnected** property can only be used to indicate if there is still a logical connection to the remote host. It cannot be used to detect abnormal conditions such as the remote host aborting the connection, the physical network connection being lost or other critical errors.

See Also

SocketWrench Class | SocketTools Namespace

SocketWrench.IsInitialized Property

Gets a value which indicates if the current instance of the class has been initialized successfully.

[Visual Basic]
```
Public ReadOnly Property IsInitialized As Boolean
```

[C#]
```
public bool IsInitialized {get;}
```

Property Value

Returns **true** if the class instance has been initialized; otherwise returns **false**.

Remarks

The **IsInitialized** property is used to determine if the current instance of the class has been initialized properly. Normally this is done automatically by the class constructor, however there are circumstances where the class may not be able to initialize itself.

The most common reasons that a class instance may not initialize correctly is that no runtime license key has been defined in the assembly or the license key provided is invalid. It may also indicate a problem with the system configuration or user access rights, such as not being able to load the required networking libraries or not being able to access the system registry.

See Also

SocketWrench Class | SocketTools Namespace

SocketWrench.IsListening Property

Gets a value which indicates if the socket is listening for client connections.

[Visual Basic]

```
Public ReadOnly Property IsListening As Boolean
```

[C#]

```
public bool IsListening {get;}
```

Property Value

Returns **true** if the socket is listening for client connections; otherwise returns **false**.

Remarks

The **IsListening** property will return **true** if the socket was created using the **Listen** method and it is currently accepting incoming client connections. In all other situations, this property will return **false**.

See Also

SocketWrench Class | SocketTools Namespace

SocketWrench.IsReadable Property

Gets a value which indicates if there is data available to be read from the socket.

[Visual Basic]

```
Public ReadOnly Property IsReadable As Boolean
```

[C#]

```
public bool IsReadable {get;}
```

Property Value

Returns **true** if there is data available to be read; otherwise returns **false**.

Remarks

The **IsReadable** property returns **true** if data can be read from the socket without blocking. For non-blocking sockets, this property can be checked before the application attempts to read the socket. Note that even if this property does return **true** indicating that there is data available to be read, applications should always check the return value from the **Read** method.

See Also

SocketWrench Class | SocketTools Namespace

SocketWrench.IsWritable Property

Gets a value which indicates if data can be written to the socket without blocking.

[Visual Basic]

```
Public ReadOnly Property IsWritable As Boolean
```

[C#]

```
public bool IsWritable {get;}
```

Property Value

Returns **true** if data can be written to the socket; otherwise returns **false**.

Remarks

The **IsWritable** property returns **true** if data can be written to the socket without blocking. For non-blocking sockets, this property can be checked before the application attempts to write data to the socket. Note that even if this property does return **true** indicating that data can be written to the socket, applications should always check the return value from the **Write** method.

See Also

SocketWrench Class | SocketTools Namespace

SocketWrench.KeepAlive Property

Gets and sets a value which indicates if keep-alive packets are sent on a connected socket.

[Visual Basic]
```
Public Property KeepAlive As Boolean
```

[C#]
```
public bool KeepAlive {get; set;}
```

Property Value

Returns **true** if keep-alive packets are sent when the connection is idle, otherwise returns **false**. The default value is **false**.

Remarks

Setting the **KeepAlive** property to a value of **true** specifies that special packets are to be sent to the remote system when no data is being exchanged to ensure the connection remains active. This property can only be set for sockets that were created with the **Protocol** property set to a value of **SocketProtocol.protocolStream**.

If this property is set to **true**, keep-alive packets will start being generated five seconds after the socket has become idle with no data being sent or received. Enabling this option can be used by applications to detect when a physical network connection has been lost. However, it is recommended that most applications query the remote host directly to determine if the connection is still active. This is typically accomplished by sending specific commands to the server to query its status, or checking the elapsed time since the last response from the server.

See Also

SocketWrench Class | SocketTools Namespace

SocketWrench.LastError Property

Gets and sets a value which specifies the last error that has occurred.

[Visual Basic]

```
Public Property LastError As ErrorCode
```

[C#]

```
public SocketWrench.ErrorCode LastError {get; set;}
```

Property Value

Returns an ErrorCode enumeration value which specifies the last error code.

Remarks

The **LastError** property returns the error code associated with the last error that occurred for the current instance of the class. It is important to note that this value only has meaning if the previous method indicates that an error has actually occurred.

It is possible to explicitly clear the last error code by assigning the property to the value **ErrorCode.errorNone**.

The error code value can be cast to an integer value for display purposes if required. For a description of the error that can be displayed using a message box or some other similar mechanism, get the value of the **LastErrorString** property.

See Also

SocketWrench Class | SocketTools Namespace

SocketWrench.LastErrorString Property

Gets a value which describes the last error that has occurred.

[Visual Basic]

```
Public ReadOnly Property LastErrorString As String
```

[C#]

```
public string LastErrorString {get;}
```

Property Value

A string which describes the last error that has occurred.

Remarks

The **LastErrorString** property can be used to obtain a description of the last error that occurred for the current instance of the class. It is important to note that this value only has meaning if the previous method indicates that an error has actually occurred.

See Also

SocketWrench Class | SocketTools Namespace

SocketWrench.Linger Property

Gets and sets a value which specifies the number of seconds to wait for the socket to disconnect from the remote host.

[Visual Basic]

```
Public Property Linger As Integer
```

[C#]

```
public int Linger {get; set;}
```

Property Value

An integer value which specifies a number of seconds. The default value is 0.

Remarks

Setting the **Linger** property to a value greater than zero indicates that the **Disconnect** method should wait up to the specified number of seconds for any data on the socket to be written before it is closed. A value of zero indicates that the socket should be closed immediately (but gracefully, without data loss).

See Also

SocketWrench Class | SocketTools Namespace

SocketWrench.LocalAddress Property

Gets and sets the local Internet address that the socket will be bound to.

[Visual Basic]

```
Public Property LocalAddress As String
```

[C#]

```
public string LocalAddress {get; set;}
```

Property Value

A string which specifies an Internet address in dotted notation.

Remarks

The **LocalAddress** property is used to specify the local Internet address that the socket will be bound to when a connection is established with a remote host. By default this property is not assigned a value, which specifies that the socket should be bound to any appropriate network interface on the local system.

See Also

SocketWrench Class | SocketTools Namespace

SocketWrench.LocalName Property

Gets a value which specifies the host name for the local system.

[Visual Basic]

```
Public ReadOnly Property LocalName As String
```

[C#]

```
public string LocalName {get;}
```

Property Value

A string which specifies the local host name.

Remarks

The **LocalName** property returns the fully-qualified host name assigned to the local system. If the system has not been configured with an Internet domain name, then this property will return the NetBIOS name assigned to the local system.

See Also

SocketWrench Class | SocketTools Namespace

SocketWrench.LocalPort Property

Gets and sets a value which specifies the local port number the socket will be bound to.

[Visual Basic]

```
Public Property LocalPort As Integer
```

[C#]

```
public int LocalPort {get; set;}
```

Property Value

An integer value which specifies a port number. The default value is 0.

Remarks

The **LocalPort** property is used to specify the local port number that the socket will be bound to when a connection is established with a remote host. By default this property value is 0, which specifies that the socket should be bound to any appropriate port number that is available on the local system. After a connection has been established, this property will return the actual port number that was allocated for the socket.

See Also

SocketWrench Class | SocketTools Namespace

SocketWrench.NoDelay Property

Gets and sets a value which specifies if the Nagle algorithm should be enabled or disabled.

[Visual Basic]

```
Public Property NoDelay As Boolean
```

[C#]

```
public bool NoDelay {get; set;}
```

Property Value

Returns **true** if the Nagle algorithm has been disabled; otherwise it returns **false**. The default value is **false**.

Remarks

The **NoDelay** property is used to enable or disable the Nagle algorithm, which buffers unacknowledged data and insures that a full-size packet can be sent to the remote host. By default this property value is set to **false**, which enables the Nagle algorithm (in other words, the data being written may not actually be sent until it is optimal to do so). Setting this property to **true** disables the Nagle algorithm, maintaining the time delays between the data packets being sent.

This property should be set to **true** only if it is absolutely required and the implications of doing so are understood. Disabling the Nagle algorithm can have a significant negative impact on the performance of your application.

See Also

SocketWrench Class | SocketTools Namespace

SocketWrench.Options Property

Gets and sets a value which specifies one or more socket options.

[Visual Basic]

```
Public Property Options As SocketOptions
```

[C#]

```
public SocketWrench.SocketOptions Options {get; set;}
```

Property Value

Returns one or more SocketOptions enumeration flags which specify the options for the socket. The default value for this property is **socketOptionNone**.

Remarks

The **Options** property specifies one or more default socket options which are used when creating a socket using either the **Accept** or **Connect** methods.

See Also

SocketWrench Class | SocketTools Namespace

SocketWrench.PeerAddress Property

Gets a value that specifies the Internet address of the remote host.

[Visual Basic]

```
Public ReadOnly Property PeerAddress As String
```

[C#]

```
public string PeerAddress {get;}
```

Property Value

A string which specifies an Internet address in dotted notation.

Remarks

The **PeerAddress** property returns the Internet address of the remote system that the local host is connected to. If a datagram socket is being used, this property will return the address of the system which sent the last datagram that was read. If no connection has been established, this property will return an empty string.

If this property is accessed inside an **OnAccept** event handler, it will return the address of the client that is requesting the connection. The application may use this information to determine if it wishes to accept or reject the client connection. If the address is not available to the client at that time, this property will return the address 0.0.0.0.

See Also

SocketWrench Class | SocketTools Namespace

SocketWrench.PeerName Property

Gets a value that specifies the name of the remote host.

[Visual Basic]

```
Public ReadOnly Property PeerName As String
```

[C#]

```
public string PeerName {get;}
```

Property Value

A string which specifies the peer host name.

Remarks

The **PeerName** property returns the name of the remote system that the local host is connected to. If a datagram socket is being used, this property will return the name of the system which sent the last datagram that was read.

Accessing this property may cause the thread to block until the peer address can be resolved to a host name.

See Also

SocketWrench Class | SocketTools Namespace

SocketWrench.PeerPort Property

Gets a value that specifies the port number used by the remote host.

[Visual Basic]

```
Public ReadOnly Property PeerPort As Integer
```

[C#]

```
public int PeerPort {get;}
```

Property Value

An integer value which specifies the peer port number.

Remarks

The **PeerName** property returns the port number of the remote system that the local host is connected to. If a datagram socket is being used, this property will return the port number of the remote host which sent the last datagram that was read.

See Also

SocketWrench Class | SocketTools Namespace

SocketWrench.PhysicalAddress Property

Gets a value which specifies the MAC address for the local system's network adapter.

[Visual Basic]

```
Public ReadOnly Property PhysicalAddress As String
```

[C#]

```
public string PhysicalAddress {get;}
```

Property Value

A string which specifies the network adapter MAC address.

Remarks

The **PhysicalAddress** property returns the Media Access Control (MAC) address for an Ethernet or Token Ring network adapter installed and configured on the local system. Since it is guaranteed that every adapter is assigned a unique address throughout the world, this value can be safely used for identification purposes. It is possible that this property will return an empty string, which indicates that it could not find a network adapter.

If more than one physical network adapter is installed on the system, this property will return the MAC address of the first adapter that it finds.

See Also

SocketWrench Class | SocketTools Namespace

SocketWrench.Protocol Property

Gets and sets a value which specifies the socket protocol.

[Visual Basic]
```
Public Property Protocol As SocketProtocol
```

[C#]
```
public SocketWrench.SocketProtocol Protocol {get; set;}
```

Property Value

Returns a SocketProtocol enumeration value which specifies the socket protocol. The default value is **socketStream**.

Remarks

The **Protocol** property specifies the type of socket that will be created. This property may only be set before the **Connect** method is called; attempting to change this property value after a connection has been established will generate an error.

See Also

SocketWrench Class | SocketTools Namespace

SocketWrench.RemotePort Property

Gets and sets a value which specifies the remote port number.

[Visual Basic]

```
Public Property RemotePort As Integer
```

[C#]

```
public int RemotePort {get; set;}
```

Property Value

An integer value which specifies a port number.

Remarks

The **RemotePort** property is used to set the port number that will be used to establish a connection with a remote host. If the port number specifies a well-known port, the **RemoteService** property will be updated with that name.

See Also

SocketWrench Class | SocketTools Namespace

SocketWrench.ReservedPort Property

Gets and sets a value which indicates if a reserved port number was used.

[Visual Basic]
```
Public Property ReservedPort As Boolean
```

[C#]
```
public bool ReservedPort {get; set;}
```

Property Value

Returns **true** if a reserved port number was used; otherwise returns **false**. The default value is **false**.

Remarks

The **ReservedPort** property determines if a reserved local port number is use when the socket is created (reserved port numbers are in the range of 513 through 1023, inclusive). Some application protocols require that the client bind to a local port number in this range. By setting the **LocalPort** property to 0 and the **ReservedPort** property to **true**, a reserved port number will be used when the socket is created. The default value for this property is **false**, which specifies that a standard port number with a value of 1024 or higher will be bound to the socket unless the **LocalPort** property is explicitly set to a non-zero value. Reserved ports should only be used by those applications that need them to implement a specific protocol.

It is possible that the error **errorAddressInUse** will be returned when attempting to connect using a reserved port number. The value of the **LocalPort** property will specify the reserved port number that could not be used.

See Also

SocketWrench Class | SocketTools Namespace

SocketWrench.ReuseAddress Property

Gets and sets a value which indicates if a socket address can be reused.

[Visual Basic]

```
Public Property ReuseAddress As Boolean
```

[C#]

```
public bool ReuseAddress {get; set;}
```

Property Value

Returns **true** if an address can be reused; otherwise returns **false**. The default value is **true**.

Remarks

The **ReuseAddress** property determines if a socket can be bound to an address and port number that were recently used. If this property is **true**, then addresses can be reused as needed. If the property is **false**, then addresses cannot be reused and an error will be generated if the address was was recently used by another socket.

This property is typically used by server applications. By setting the property to **true**, a server can be stopped and immediately restarted using the same port number; otherwise, the server must wait approximately two minutes before the port can be reused.

If you wish to determine if a local port number is already in use by another application, set this property to **false** and attempt to create a socket using that port number. If another application is already using that port number, an error will be generated indicating that the address is in use and the socket could not be created.

See Also

SocketWrench Class | SocketTools Namespace

SocketWrench.Route Property

Gets and sets a value which indicates if packets should be routed.

[Visual Basic]

```
Public Property Route As Boolean
```

[C#]

```
public bool Route {get; set;}
```

Property Value

Returns **true** if packets should be routed; otherwise returns **false**. The default value is **true**.

Remarks

The **Route** property determines if routing tables should be used when sending data. If the property is set to **false**, then packets will be sent directly to the network interface; if there is a router between the local and remote hosts, the data will be lost. It is not recommended that you change this property value unless it is required by your application and you fully understand the implications of doing so.

See Also

SocketWrench Class | SocketTools Namespace

SocketWrench.Secure Property

Gets and sets a value which specifies if a secure connection is established.

[Visual Basic]
```
Public Property Secure As Boolean
```

[C#]
```
public bool Secure {get; set;}
```

Property Value

Returns **true** if a secure connection is established; otherwise returns **false**. The default value is **false**.

Remarks

The **Secure** property determines if a secure connection is established with the remote host. The default value for this property is **false**, which specifies that a standard connection to the server is used. To establish a secure connection, the application should set this property value to **true** prior to calling the **Accept** or **Connect** methods. Once the connection has been established, the client may exchange data with the server as with standard connections.

It is possible for an application to establish a non-secure connection, and then switch to a secure connection at some later point during the session. Initially set the **Secure** property to **false**, then connect to the server normally. Once the connection has been established, setting the **Secure** property to true will cause the application to negotiate a secure connection with the remote host. If the socket was created using the **Accept** method, the class will block and wait for the client to begin the negotiation. If the socket was created using the **Connect** method, it will immediately begin the negotiation with the server. Note that if a non-blocking (asynchronous) socket is being used, the application must wait to set the **Secure** property to **true** after the **OnConnect** event has fired.

Setting the **Secure** property to **false** during a connection will cause the class to send a shutdown message to the remote host. This may cause the remote host to terminate the connection, however it will not close the socket. It is recommended that applications do not set the **Secure** property to **false** after a secure connection has been established, and instead use the **Disconnect** method to close the connection.

It is strongly recommended that any application that sets this property **true** use error handling to trap an errors that may occur. If the class is unable to initialize the security libraries, or otherwise cannot create a secure session for the client, an error will be generated when this property value is set.

Example

```
Socket.ThrowError = True

Try
    Socket.Secure = True
    Socket.Connect(strHostName, nHostPort, defTimeout)

    Socket.WriteLine("GET " + strFileName + " HTTP/1.0")
    Socket.WriteLine("Host: " + strHostName)
    Socket.WriteLine("Accept: text/*")
    Socket.WriteLine()

    Do
        Socket.ReadLine(strBuffer)
    Loop Until strBuffer.Length = 0

    Socket.ReadStream(strBuffer, True)
```

```
Catch ex As SocketTools.SocketWrenchException
    MsgBox(ex.Message)
End Try

Socket.Disconnect()
```

SocketWrench Class | SocketTools Namespace

SocketWrench.SecureCipher Property

Gets a value that specifies the encryption algorithm used for a secure connection.

[Visual Basic]

```
Public ReadOnly Property SecureCipher As SecureCipherAlgorithm
```

[C#]

```
public SocketWrench.SecureCipherAlgorithm SecureCipher {get;}
```

Property Value

A SecureCipherAlgorithm enumeration value which identifies the algorithm.

Remarks

The **SecureCipher** property returns a value which identifies the algorithm used to encrypt the data stream. If a secure connection has not been established, this property will return a value of **cipherNone**.

See Also

SocketWrench Class | SocketTools Namespace

SocketWrench.SecureHash Property

Gets a value that specifies the message digest algorithm used for a secure connection.

[Visual Basic]

```
Public ReadOnly Property SecureHash As SecureHashAlgorithm
```

[C#]

```
public SocketWrench.SecureHashAlgorithm SecureHash {get;}
```

Property Value

A SecureHashAlgorithm enumeration value which identifies the algorithm.

Remarks

The **SecureHash** property returns a value which identifies the message digest (hash) algorithm that was selected when a secure connection was established. If a secure connection has not been established, this property will return a value of **hashNone**.

See Also

SocketWrench Class | SocketTools Namespace

SocketWrench.SecureKeyExchange Property

Gets a value that specifies the key exchange algorithm used for a secure connection.

[Visual Basic]

```
Public ReadOnly Property SecureKeyExchange As SecureKeyAlgorithm
```

[C#]

```
public SocketWrench.SecureKeyAlgorithm SecureKeyExchange {get;}
```

Property Value

A SecureKeyAlgorithm enumeration value which identifies the algorithm.

Remarks

The **SecureKeyExchange** property returns a value which identifies the key exchange algorithm that was selected when a secure connection was established. If a secure connection has not been established, this property will return a value of **keyExchangeNone**.

See Also

SocketWrench Class | SocketTools Namespace

SocketWrench.SecureProtocol Property

Gets and sets a value which specifies the protocol used for a secure connection.

[Visual Basic]
```
Public Property SecureProtocol As SecurityProtocols
```

[C#]
```
public SocketWrench.SecurityProtocols SecureProtocol {get; set;}
```

Property Value

A SecurityProtocols enumeration value which identifies the protocol to be used when establishing a secure connection.

Remarks

The **SecureProtocol** property can be used to specify the security protocol to be used when establishing a secure connection with a server or accepting a secure connection from a client. By default, the class will attempt to use either SSL v3 or TLS v1 to establish the connection, with the appropriate protocol automatically selected based on the capabilities of the remote host. It is recommended that you only change this property value if you fully understand the implications of doing so. Assigning a value to this property will override the default protocol and force the class to attempt to use only the protocol specified.

Multiple security protocols may be specified by combining them using a bitwise **or** operator. After a connection has been established, this property will identify the protocol that was selected. Attempting to set this property after a connection has been established will result in an exception being thrown. This property should only be set after setting the **Secure** property to **true** and before calling the **Accept** or **Connect** methods.

In some cases, a server may only accept a secure connection if the TLS v1 protocol is specified. If the security protocol is not compatible with the server, then the connection will fail with an error indicating that the class is unable to establish a security context for the session. In this case, try assigning the property to **protocolTLS1** and attempt the connection again.

See Also

SocketWrench Class | SocketTools Namespace

SocketWrench.Status Property

Gets a value which specifies the current status of the socket.

[Visual Basic]

```
Public ReadOnly Property Status As SocketStatus
```

[C#]

```
public SocketWrench.SocketStatus Status {get;}
```

Property Value

A SocketStatus enumeration value which specifies the current socket status.

Remarks

The **Status** property returns the current status of the socket. This property should be checked on blocking sockets to determine if the socket is in use before taking some action.

See Also

SocketWrench Class | SocketTools Namespace

SocketWrench.ThreadModel Property

Gets and sets a value which specifies the threading model for the class instance.

[Visual Basic]

```
Public Property ThreadModel As ThreadingModel
```

[C#]

```
public SocketWrench.ThreadingModel ThreadModel {get; set;}
```

Property Value

Returns one or more ThreadingModel enumeration value which specifies the threading model for the client. The default value for this property is **modelSingleThread**.

Remarks

The **ThreadModel** property specifies the threading model that is used by the class instance when a connection is established. The default value for this property is **modelSingleThread**, which specifies that only the thread that established the connection should be permitted to invoke methods. It is important to note that this threading model does not limit the application to a single thread of execution. When a session is established using the **Connect** method, that session is attached to the thread that created it. From that point on, until the session is terminated, only the owner may invoke methods in that instance of the class. The ownership of the class instance may be transferred from one thread to another using the **AttachThread** method.

Setting this property to **modelFreeThread** disables certain internal safety checks that are performed by the class and may result in unexpected behavior unless you ensure that access to the class instance is synchronized across multiple threads. The application must ensure that no two threads will attempt to invoke a blocking method at the same time. In other words, if one thread invokes a method, the application must ensure that another thread will not attempt to invoke any other method at the same time using the same instance of the class.

Changing the value of this property will not affect an active client session. The threading model must be specified prior to invoking the **Connect** method.

See Also

SocketWrench Class | SocketTools Namespace | AttachThread Method | ThreadingModel Enumeration | ThreadModel Attribute

SocketWrench.ThrowError Property

Gets and sets a value which specifies if method calls should throw exceptions when an error occurs.

[Visual Basic]

```
Public Property ThrowError As Boolean
```

[C#]

```
public bool ThrowError {get; set;}
```

Property Value

Returns **true** if method calls will generate exceptions when an error occurs; otherwise returns **false**. The default value is **false**.

Remarks

Error handling for when calling class methods can be done in either of two different styles, according to the value of this property.

If the **ThrowError** property is set to **false**, the application should check the return value of any method that is used, and report errors based upon the documented value of the return code. It is the responsibility of the application to interpret the error code, if it is desired to explain the error in addition to reporting it. This is the default behavior.

If the **ThrowError** property is set to **true**, then exceptions will be generated whenever a method call fails. The program must be written to catch these exceptions and take the appropriate action when an error occurs. Failure to handle an exception will cause the program to terminate abnormally.

Note that if an error occurs while a property is being read or modified, an exception will be raised regardless of the value of the **ThrowError** property.

See Also

SocketWrench Class | SocketTools Namespace

SocketWrench.Timeout Property

Gets and sets a value which specifies a timeout period in seconds.

[Visual Basic]
```
Public Property Timeout As Integer
```

[C#]
```
public int Timeout {get; set;}
```

Property Value

An integer value which specifies a timeout period in seconds.

Remarks

Setting the **Timeout** property specifies the number of seconds until a blocking socket operation fails and returns an error.

The timeout period is only used when the socket is in blocking mode. Although this property can be changed when the socket is in non-blocking mode, the value will be ignored until the socket is returned to blocking mode.

For most applications it is recommended the timeout period be set between 10 and 20 seconds.

See Also

SocketWrench Class | SocketTools Namespace

SocketWrench.Trace Property

Gets and sets a value which indicates if network function logging is enabled.

[Visual Basic]
```
Public Property Trace As Boolean
```

[C#]
```
public bool Trace {get; set;}
```

Property Value

Returns **true** if network function tracing is enabled; otherwise returns **false**. The default value is **false**.

Remarks

The **Trace** property is used to enable (or disable) the tracing of network function calls. When enabled, each function call is logged to a file, including the function parameters, return value and error code if applicable. This facility can be enabled and disabled at run time, and the trace log file can be specified by setting the **TraceFile** property. All function calls that are being logged are appended to the trace file, if it exists. If no trace file exists when tracing is enabled, the trace file is created.

The tracing facility is available in all of the SocketTools networking classes and is enabled or disabled for an entire process. This means that once trace logging is enabled for a given component, all of the function calls made by the process using any of the SocketTools classes will be logged. For example, if you have an application using both the File Transfer Protocol and Post Office Protocol classes, and you set the **Trace** property to **true**, function calls made by both classes will be logged. Additionally, enabling a trace is cumulative, and tracing is not stopped until it is disabled for all classes used by the process.

If trace logging is not enabled, there is no negative impact on performance or throughput. Once enabled, application performance can degrade, especially in those situations in which multiple processes are being traced or the logfile is fairly large. Since logfiles can grow very quickly, even with modest applications, it is recommended that you delete the file when it is no longer needed.

When redistributing your application, make sure that you include the **SocketTools10.TraceLog.dll** module with your installation. If this library is not present, then no trace output will be generated and the value of the **Trace** property will be ignored. Only those function calls made by the SocketTools networking classes will be logged. Calls made directly to the Windows Sockets API, or calls made by other classes, will not be logged.

See Also

SocketWrench Class | SocketTools Namespace

SocketWrench.TraceFile Property

Gets and sets a value which specifies the name of the network function tracing logfile.

[Visual Basic]

```
Public Property TraceFile As String
```

[C#]

```
public string TraceFile {get; set;}
```

Property Value

A string which specifies the name of the file.

Remarks

The **TraceFile** property is used to specify the name of the trace file that is created when network function tracing is enabled. If this property is set to an empty string (the default value), then a file named **SocketTools.log** is created in the system's temporary directory. If no temporary directory exists, then the file is created in the current working directory.

If the file exists, the trace output is appended to the file, otherwise the file is created. Since network function tracing is enabled per-process, the trace file is shared by all instances of the class being used. If multiple class instances have tracing enabled, the **TraceFile** property should be set to the same value for each instance. Since trace files can grow very quickly, even with modest applications, it is recommended that you delete the file when it is no longer needed.

The trace file has the following format:

```
 MyApp INF: WSAAsyncSelect(46, 0xcc4, 0x7e9, 0x27) returned 0 MyApp WRN:
connect(46, 192.0.0.1:1234, 16) returned -1 [10035] MyApp ERR: accept(46,
NULL, 0x0) returned -1 [10038]
```

The first column contains the name of the process that is being traced. The second column identifies if the trace record is reporting information, a warning, or an error. What follows is the name of the function being called, the arguments passed to the function and the function's return value. If a warning or error is reported, the error code is appended to the record (the value is placed inside brackets).

If parameters are passed as integer values, they are recorded in decimal. If the parameter or return value is a pointer (a memory address), it is recorded as a hexadecimal value preceded with "0x". A special type of pointer, called a null pointer, is recorded as NULL. Those functions which expect socket addresses are displayed in the following format:

```
aa.bb.cc.dd:nnnn
```

The first four numbers separated by periods represent the IP address, and the number following the colon represents the port number in host byte order. Note that in the second line of the above example, the class is attempting to connect to a system with the IP address 192.0.0.1 on port 1234.

Note that if the specified file cannot be created, or the user does not have permission to modify an existing file, the error is silently ignored and no trace output will be generated.

See Also

SocketWrench Class | SocketTools Namespace

SocketWrench.TraceFlags Property

Gets and sets a value which specifies the network function tracing flags.

[Visual Basic]

```
Public Property TraceFlags As TraceOptions
```

[C#]

```
public SocketWrench.TraceOptions TraceFlags {get; set;}
```

Property Value

A TraceOptions enumeration which specifies the amount of detail written to the trace logfile.

Remarks

The **TraceFlags** property is used to specify the type of information written to the trace file when network function tracing is enabled.

Because network function tracing is enabled per-process, the trace flags are shared by all instances of the class being used. If multiple class instances have tracing enabled, the **TraceFlags** property should be set to the same value for each instance. Changing the trace flags for any one instance of the class will affect the logging performed for all SocketTools classes used by the application.

Warnings are generated when a non-fatal error is returned by a network function. For example, if data is being written and the error **errorOperationWouldBlock** occurs, a warning is generated because the application simply needs to attempt to write the data at a later time.

See Also

SocketWrench Class | SocketTools Namespace

SocketWrench.Urgent Property

Gets and sets a value which specifies if urgent data will be read or written.

[Visual Basic]

```
Public Property Urgent As Boolean
```

[C#]

```
public bool Urgent {get; set;}
```

Property Value

Returns **true** if urgent data will be read or written; otherwise returns **false**. The default value is **false**.

Remarks

The **Urgent** property affects how the **Read** and **Write** methods receive and transmit data to the remote host. If set to a value of **true**, urgent (out-of-band) data will be read or written. The property value will automatically be reset to a value of **false** after the data has been read or written.

It is important to note that all systems may support more than one byte of urgent data if the data is not being received in-line. Refer to the **InLine** property for additional information. This property should only be set to **true** if required by the application and the implications of doing so are understood.

SocketWrench Class | SocketTools Namespace

SocketWrench.Version Property

Gets a value which returns the current version of the SocketWrench class library.

[Visual Basic]

```
Public ReadOnly Property Version As String
```

[C#]

```
public string Version {get;}
```

Property Value

A string which specifies the version of the class library.

Remarks

The **Version** property returns a string which identifies the current version and build of the SocketWrench class library. This value can be used by an application for validation and debugging purposes.

See Also

SocketWrench Class | SocketTools Namespace

SocketWrench Methods

The methods of the **SocketWrench** class are listed below. For a complete list of **SocketWrench** class members, see the SocketWrench Members topic.

Public Instance Methods

Abort	Abort the connection with a remote host.
Accept	Overloaded. Accepts a client connection on a listening socket, specifying a timeout period and one or more socket options.
AttachThread	Attach an instance of the class to the current thread
Bind	Overloaded. Bind the socket to the specified local address and port number.
Cancel	Cancel the current blocking socket operation.
Connect	Overloaded. Establish a connection with a remote host.
Disconnect	Terminate the connection with a remote host.
Dispose	Overloaded. Releases all resources used by SocketWrench.
Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from Object)	Gets the Type of the current instance.
Initialize	Overloaded. Initialize an instance of the SocketWrench class.
Listen	Overloaded. Listen for incoming client connections, specifying the local network address, port number and connection backlog.
Peek	Overloaded. Read data from the socket and store it in a byte array, but do not remove the data from the socket buffers.
Read	Overloaded. Read data from the socket and store it in a byte array.
ReadFrom	Overloaded. Read data from the socket and store it in a byte array.
ReadLine	Overloaded. Read up to a line of data from the socket and return it in a string buffer.
ReadStream	Overloaded. Read a data stream from the socket and store it in the specified byte array.

Reject	Rejects a connection request from a remote host.
Reset	Reset the internal state of the object, resetting all properties to their default values.
Resolve	Resolves a host name to a host IP address.
Shutdown	Overloaded. Disable sending or receiving data on the socket.
StoreStream	Overloaded. Reads a data stream from the socket and stores it in the specified file.
ToString (inherited from Object)	Returns a String that represents the current Object.
Uninitialize	Uninitialize the class library and release any resources allocated for the current thread.
Write	Overloaded. Write one or more bytes of data to the socket.
WriteLine	Overloaded. Send a line of text to the remote host, terminated by a carriage-return and linefeed.
WriteStream	Overloaded. Write a stream of bytes to the socket.
WriteTo	Overloaded. Write one or more bytes of data to the socket.

Protected Instance Methods

Dispose	Overloaded. Releases the unmanaged resources allocated by the SocketWrench class and optionally releases the managed resources.
Finalize	Destroys an instance of the class, releasing the resources allocated for the session and unloading the networking library.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

SocketWrench Class | SocketTools Namespace

SocketWrench.Abort Method

Abort the connection with a remote host.

[Visual Basic]

```
Public Sub Abort()
```

[C#]

```
public void Abort();
```

Remarks

The **Abort** method immediately closes the socket, without waiting for any remaining data to be written out. This method should only be used when the connection must be closed immediately. If this method is used, the remote host will see the connection as being terminated abnormally.

It is recommended that applications using the **Disconnect** method unless it is absolutely necessary to terminate the connection and immediately release the socket handle.

SocketWrench.Accept Method

Accepts a client connection on a listening socket.

Overload List

Accepts a client connection on a listening socket.

public bool Accept(int);

Accepts a client connection on a listening socket, specifying one or more socket options.

public bool Accept(int,SocketOptions);

Accepts a client connection on a listening socket, specifying a timeout period and one or more socket options.

public bool Accept(int,int,SocketOptions);

See Also

SocketWrench Class | SocketTools Namespace | Listen Method

SocketWrench.Accept Method (Int32)

Accepts a client connection on a listening socket.

[Visual Basic]

```
Overloads Public Function Accept( _
   ByVal handle As Integer _
) As Boolean
```

[C#]

```
public bool Accept(
   int handle
);
```

Parameters

handle

The socket identifier of a listening socket. If the object that invokes this method is not the listening socket, then the listening socket may continue to listen for incoming connections. If the object of a listening socket invokes this method with its own handle, then it ceases to listen, and no other host can establish a connection with the application.

Return Value

A boolean value which specifies if the client connection has been accepted. If the method returns **true**, the connection has been accepted and the application may send and receive data with the remote host. If this method returns **false**, the connection could not be accepted and the application should check the value of the **LastError** property to determine the cause of the failure.

See Also

SocketWrench Class | SocketTools Namespace | SocketWrench.Accept Overload List | Listen Method

SocketWrench.Accept Method (Int32, SocketOptions)

Accepts a client connection on a listening socket, specifying one or more socket options.

[Visual Basic]

```
Overloads Public Function Accept( _
   ByVal handle As Integer, _
   ByVal options As SocketOptions _
) As Boolean
```

[C#]

```
public bool Accept(
   int handle,
   SocketOptions options
);
```

Parameters

handle

The socket identifier of a listening socket. If the object that invokes this method is not the listening socket, then the listening socket may continue to listen for incoming connections. If the object of a listening socket invokes this method with its own handle, then it ceases to listen, and no other host can establish a connection with the application.

options

One or more of the SocketOptions enumeration flags.

Return Value

A boolean value which specifies if the client connection has been accepted. If the method returns **true**, the connection has been accepted and the application may send and receive data with the remote host. If this method returns **false**, the connection could not be accepted and the application should check the value of the **LastError** property to determine the cause of the failure.

See Also

SocketWrench Class | SocketTools Namespace | SocketWrench.Accept Overload List | Listen Method

SocketWrench.Accept Method (Int32, Int32, SocketOptions)

Accepts a client connection on a listening socket, specifying a timeout period and one or more socket options.

[Visual Basic]

```
Overloads Public Function Accept( _
   ByVal handle As Integer, _
   ByVal timeout As Integer, _
   ByVal options As SocketOptions _
) As Boolean
```

[C#]

```
public bool Accept(
   int handle,
   int timeout,
   SocketOptions options
);
```

Parameters

handle

The socket identifier of a listening socket. If the object that invokes this method is not the listening socket, then the listening socket may continue to listen for incoming connections. If the object of a listening socket invokes this method with its own handle, then it ceases to listen, and no other host can establish a connection with the application.

timeout

Specifies the number of seconds that the method will wait for a client connection to be established on the listening socket. This value only has meaning for a blocking socket.

options

One or more of the SocketOptions enumeration flags.

Return Value

A boolean value which specifies if the client connection has been accepted. If the method returns **true**, the connection has been accepted and the application may send and receive data with the remote host. If this method returns **false**, the connection could not be accepted and the application should check the value of the LastError property to determine the cause of the failure.

See Also

SocketWrench Class | SocketTools Namespace | SocketWrench.Accept Overload List | Listen Method

SocketWrench.AttachThread Method

Attach an instance of the class to the current thread

[Visual Basic]
```
Public Function AttachThread() As Boolean
```

[C#]
```
public bool AttachThread();
```

Return Value

A boolean value which specifies if the socket could be attached to the current thread. If this method returns **false**, the socket could not be attached to the thread and the application should check the value of the LastError property to determine the cause of the failure.

Remarks

When an instance of the class is created it is associated with the current thread that created it. Normally, if another thread attempts to perform an operation using that instance, an error is returned. This is used to ensure that other threads cannot interfere with an operation being performed by the owner thread. In some cases, it may be desirable for one thread in an application to create an instance of the class, establish a connection and then pass that instance to another worker thread. The **AttachThread** method can be used to change the ownership of the class instance to the new worker thread.

This method should be called by the new thread immediately after it has been created, and if the new thread does not release the handle itself, the ownership of the handle should be restored by the original thread. Under no circumstances should **AttachThread** be used to forcibly destroy an instance of a class allocated by another thread while a blocking operation is in progress. To cancel a blocking operation, use the **Cancel** method and then delete the class instance after the blocking function exits and control is returned to the current thread.

See Also

SocketWrench Class | SocketTools Namespace

SocketWrench.Bind Method

Bind the socket to the specified local address and port number.

Overload List

Bind the socket to the specified local address and port number.

public bool Bind(string,int);

Bind the socket to the specified local address and port number.

public bool Bind(string,int,SocketOptions);

Bind the socket to the specified local address and port number.

public bool Bind(string,int,SocketProtocol);

Bind the socket to the specified local address and port number.

public bool Bind(string,int,SocketProtocol,SocketOptions);

See Also

SocketWrench Class | SocketTools Namespace

SocketWrench.Bind Method (String, Int32)

Bind the socket to the specified local address and port number.

[Visual Basic]

```
Overloads Public Function Bind( _
   ByVal localAddress As String, _
   ByVal localPort As Integer _
) As Boolean
```

[C#]

```
public bool Bind(
   string localAddress,
   int localPort
);
```

Parameters

localAddress

A string which specifies the local Internet address that the socket should be bound to. To bind to any valid network interface on the local system, specify the address 0.0.0.0. Applications should only specify a particular address if it is absolutely necessary. In most cases a local address is not required when establishing a client connection.

localPort

An integer value which specifies a local port number that the socket should be bound to. To bind to any available port number, specify a port number of 0. Applications should only specify a particular port number if it is absolutely necessary. The maximum valid port number is 65535.

Return Value

A boolean value which specifies if the socket could be bound to the specified address. If this method returns **false**, the socket could not be bound to the address and the application should check the value of the LastError property to determine the cause of the failure.

Remarks

The **Bind** method is used to specify the local address and port number that a socket will be bound to when it is created. When this method is called with **socketDatagram** as the specified protocol, it will immediately create the datagram socket and bind it to the given address.

When this method is called with **socketStream** as the specified protocol, creation of the socket is deferred until the **Connect** method is called. For stream sockets, this method will set the local address, port number and default options used when the socket is actually created.

See Also

SocketWrench Class | SocketTools Namespace | SocketWrench.Bind Overload List

SocketWrench.Bind Method (String, Int32, SocketOptions)

Bind the socket to the specified local address and port number.

[Visual Basic]

```
Overloads Public Function Bind( _
   ByVal localAddress As String, _
   ByVal localPort As Integer, _
   ByVal options As SocketOptions _
) As Boolean
```

[C#]

```
public bool Bind(
   string localAddress,
   int localPort,
   SocketOptions options
);
```

Parameters

localAddress

A string which specifies the local Internet address that the socket should be bound to. To bind to any valid network interface on the local system, specify the address 0.0.0.0. Applications should only specify a particular address if it is absolutely necessary. In most cases a local address is not required when establishing a client connection.

localPort

An integer value which specifies a local port number that the socket should be bound to. To bind to any available port number, specify a port number of 0. Applications should only specify a particular port number if it is absolutely necessary. The maximum valid port number is 65535.

options

One or more of the SocketOptions enumeration flags.

Return Value

A boolean value which specifies if the socket could be bound to the specified address. If this method returns **false**, the socket could not be bound to the address and the application should check the value of the LastError property to determine the cause of the failure.

Remarks

The **Bind** method is used to specify the local address and port number that a socket will be bound to when it is created. When this method is called with **socketDatagram** as the specified protocol, it will immediately create the datagram socket and bind it to the given address.

When this method is called with **socketStream** as the specified protocol, creation of the socket is deferred until the **Connect** method is called. For stream sockets, this method will set the local address, port number and default options used when the socket is actually created.

See Also

SocketWrench Class | SocketTools Namespace | SocketWrench.Bind Overload List

SocketWrench.Bind Method (String, Int32, SocketProtocol)

Bind the socket to the specified local address and port number.

[Visual Basic]

```
Overloads Public Function Bind( _
   ByVal localAddress As String, _
   ByVal localPort As Integer, _
   ByVal protocol As SocketProtocol _
) As Boolean
```

[C#]

```
public bool Bind(
   string localAddress,
   int localPort,
   SocketProtocol protocol
);
```

Parameters

localAddress

A string which specifies the local Internet address that the socket should be bound to. To bind to any valid network interface on the local system, specify the address 0.0.0.0. Applications should only specify a particular address if it is absolutely necessary. In most cases a local address is not required when establishing a client connection.

localPort

An integer value which specifies a local port number that the socket should be bound to. To bind to any available port number, specify a port number of 0. Applications should only specify a particular port number if it is absolutely necessary. The maximum valid port number is 65535.

protocol

One of the SocketProtocol enumeration values which specify the type of socket to be created.

Return Value

A boolean value which specifies if the socket could be bound to the specified address. If this method returns **false**, the socket could not be bound to the address and the application should check the value of the LastError property to determine the cause of the failure.

Remarks

The **Bind** method is used to specify the local address and port number that a socket will be bound to when it is created. When this method is called with **socketDatagram** as the specified protocol, it will immediately create the datagram socket and bind it to the given address.

When this method is called with **socketStream** as the specified protocol, creation of the socket is deferred until the **Connect** method is called. For stream sockets, this method will set the local address, port number and default options used when the socket is actually created.

See Also

SocketWrench Class | SocketTools Namespace | SocketWrench.Bind Overload List

SocketWrench.Bind Method (String, Int32, SocketProtocol, SocketOptions)

Bind the socket to the specified local address and port number.

[Visual Basic]

```
Overloads Public Function Bind( _
   ByVal localAddress As String, _
   ByVal localPort As Integer, _
   ByVal protocol As SocketProtocol, _
   ByVal options As SocketOptions _
) As Boolean
```

[C#]

```
public bool Bind(
   string localAddress,
   int localPort,
   SocketProtocol protocol,
   SocketOptions options
);
```

Parameters

localAddress

A string which specifies the local Internet address that the socket should be bound to. To bind to any valid network interface on the local system, specify the address 0.0.0.0. Applications should only specify a particular address if it is absolutely necessary. In most cases a local address is not required when establishing a client connection.

localPort

An integer value which specifies a local port number that the socket should be bound to. To bind to any available port number, specify a port number of 0. Applications should only specify a particular port number if it is absolutely necessary. The maximum valid port number is 65535.

protocol

One of the SocketProtocol enumeration values which specify the type of socket to be created.

options

One or more of the SocketOptions enumeration flags.

Return Value

A boolean value which specifies if the socket could be bound to the specified address. If this method returns **false**, the socket could not be bound to the address and the application should check the value of the LastError property to determine the cause of the failure.

Remarks

The **Bind** method is used to specify the local address and port number that a socket will be bound to when it is created. When this method is called with **socketDatagram** as the specified protocol, it will immediately create the datagram socket and bind it to the given address.

When this method is called with **socketStream** as the specified protocol, creation of the socket is deferred until the **Connect** method is called. For stream sockets, this method will set the local address, port number and default options used when the socket is actually created.

See Also

SocketWrench Class | SocketTools Namespace | SocketWrench.Bind Overload List

SocketWrench.Cancel Method

Cancel the current blocking socket operation.

[Visual Basic]

```
Public Sub Cancel()
```

[C#]

```
public void Cancel();
```

Remarks

When the **Cancel** method is called, the blocking socket operation will not immediately fail. An internal flag is set which causes the blocking operation to exit with an error. This means that the application cannot cancel an operation and immediately perform some other blocking function. Instead it must allow the calling stack to unwind, returning back to the blocking operation before making any further function calls.

SocketWrench Class | SocketTools Namespace

SocketWrench.Connect Method

Establish a connection with a remote host.

Overload List

Establish a connection with a remote host.

public bool Connect();

Establish a connection with a remote host.

public bool Connect(string,int);

Establish a connection with a remote host.

public bool Connect(string,int,SocketProtocol,int);

Establish a connection with a remote host.

public bool Connect(string,int,SocketProtocol,int,SocketOptions);

Establish a connection with a remote host.

public bool Connect(string,int,SocketProtocol,int,SocketOptions,string,int);

Establish a connection with a remote host.

public bool Connect(string,int,int);

See Also

SocketWrench Class | SocketTools Namespace

SocketWrench.Connect Method ()

Establish a connection with a remote host.

[Visual Basic]
```
Overloads Public Function Connect() As Boolean
```

[C#]
```
public bool Connect();
```

Return Value

A boolean value which specifies if the connection has been established. If the socket is in blocking mode, a return value of **true** indicates that the connection has completed and the application may send and receive data from the remote host. If the socket is in non-blocking mode, a return value of **true** indicates that the socket has been successfully created and the connection is in progress. When the connection has completed, the OnConnect event will be fired. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

Remarks

This method establishes a connection using assigned property values.

The value of the **HostName** or **HostAddress** property will be used to determine the host name or address to connect to.

The value of the **RemotePort** property will be used to determine the port number to connect to.

The value of the **Protocol** property will specify which protocol is used to establish the connection.

The value of the **Timeout** property will be used to specify the timeout period.

The value of the **Options** property will be used to specify the default options for the connection.

See Also

SocketWrench Class | SocketTools Namespace | SocketWrench.Connect Overload List

SocketWrench.Connect Method (String, Int32)

Establish a connection with a remote host.

[Visual Basic]

```
Overloads Public Function Connect( _
   ByVal hostName As String, _
   ByVal hostPort As Integer _
) As Boolean
```

[C#]

```
public bool Connect(
   string hostName,
   int hostPort
);
```

Parameters

hostName

A string which specifies the remote host to establish a connection with. This may specify a host name or an Internet address in dot-notation.

hostPort

An integer which specifies the port number for the connection. This value must be greater than zero and the maximum valid port number is 65535.

Return Value

A boolean value which specifies if the connection has been established. If the socket is in blocking mode, a return value of **true** indicates that the connection has completed and the application may send and receive data from the remote host. If the socket is in non-blocking mode, a return value of **true** indicates that the socket has been successfully created and the connection is in progress. When the connection has completed, the OnConnect event will be fired. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

Remarks

This method will use the value of the Protocol property to determine which protocol is used to establish the connection. By default, the **socketStream** protocol will be used.

See Also

SocketWrench Class | SocketTools Namespace | SocketWrench.Connect Overload List

SocketWrench.Connect Method (String, Int32, SocketProtocol, Int32)

Establish a connection with a remote host.

[Visual Basic]

```
Overloads Public Function Connect( _
   ByVal hostName As String, _
   ByVal hostPort As Integer, _
   ByVal protocol As SocketProtocol, _
   ByVal timeout As Integer _
) As Boolean
```

[C#]

```
public bool Connect(
   string hostName,
   int hostPort,
   SocketProtocol protocol,
   int timeout
);
```

Parameters

hostName

A string which specifies the remote host to establish a connection with. This may specify a host name or an Internet address in dot-notation.

hostPort

An integer which specifies the port number for the connection. This value must be greater than zero and the maximum valid port number is 65535.

protocol

One of the SocketProtocol enumeration values which specify the type of socket to be created.

timeout

An integer value that specifies the number of seconds that the method will wait for the connection to complete before failing the operation and returning to the caller. This value is only meaningful for blocking sockets.

Return Value

A boolean value which specifies if the connection has been established. If the socket is in blocking mode, a return value of **true** indicates that the connection has completed and the application may send and receive data from the remote host. If the socket is in non-blocking mode, a return value of **true** indicates that the socket has been successfully created and the connection is in progress.

When a non-blocking connection has completed, the OnConnect event will be fired. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

Remarks

When this method is called with **socketDatagram** as the specified protocol, it does not actually establish a connection. Instead, it simply establishes a default destination address and port that is used with subsequent calls to the **Read** and **Write** methods.

See Also

SocketWrench Class | SocketTools Namespace | SocketWrench.Connect Overload List

SocketWrench.Connect Method (String, Int32, SocketProtocol, Int32, SocketOptions)

Establish a connection with a remote host.

[Visual Basic]

```
Overloads Public Function Connect( _
   ByVal hostName As String, _
   ByVal hostPort As Integer, _
   ByVal protocol As SocketProtocol, _
   ByVal timeout As Integer, _
   ByVal options As SocketOptions _
) As Boolean
```

[C#]

```
public bool Connect(
   string hostName,
   int hostPort,
   SocketProtocol protocol,
   int timeout,
   SocketOptions options
);
```

Parameters

hostName
A string which specifies the remote host to establish a connection with. This may specify a host name or an Internet address in dot-notation.

hostPort
An integer which specifies the port number for the connection. This value must be greater than zero and the maximum valid port number is 65535.

protocol
One of the SocketProtocol enumeration values which specify the type of socket to be created.

timeout
An integer value that specifies the number of seconds that the method will wait for the connection to complete before failing the operation and returning to the caller. This value is only meaningful for blocking sockets.

options
One or more of the SocketOptions enumeration flags.

Return Value

A boolean value which specifies if the connection has been established. If the socket is in blocking mode, a return value of **true** indicates that the connection has completed and the application may send and receive data from the remote host. If the socket is in non-blocking mode, a return value of **true** indicates that the socket has been successfully created and the connection is in progress.

When a non-blocking connection has completed, the OnConnect event will be fired. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

Remarks

When this method is called with **socketDatagram** as the specified protocol, it does not actually establish a connection. Instead, it simply establishes a default destination address and port that is used with subsequent calls to the **Read** and **Write** methods.

) As Boolean
```

[C#]

```
public bool Connect(
   string hostName,
   int hostPort,
   SocketProtocol protocol,
   int timeout,
   SocketOptions options,
   string localAddress,
   int localPort
);
```

Parameters

hostName

A string which specifies the remote host to establish a connection with. This may specify a host name or an Internet address in dot-notation.

hostPort

An integer which specifies the port number for the connection. This value must be greater than zero and the maximum valid port number is 65535.

protocol

One of the SocketProtocol enumeration values which specify the type of socket to be created.

timeout

An integer value that specifies the number of seconds that the method will wait for the connection to complete before failing the operation and returning to the caller. This value is only meaningful for blocking sockets.

options

One or more of the SocketOptions enumeration flags.

localAddress

A string which specifies the local Internet address that the socket should be bound to. To bind to any valid network interface on the local system, specify the address 0.0.0.0. Applications should only specify a particular address if it is absolutely necessary. In most cases a local address is not required when establishing a client connection.

localPort

An integer value which specifies a local port number that the socket should be bound to. To bind to any available port number, specify a port number of 0. Applications should only specify a particular port number if it is absolutely necessary. The maximum valid port number is 65535.

Return Value

A boolean value which specifies if the connection has been established. If the socket is in blocking mode, a return value of **true** indicates that the connection has completed and the application may send and receive data from the remote host. If the socket is in non-blocking mode, a return value of **true** indicates that the socket has been successfully created and the connection is in progress.

When a non-blocking connection has completed, the OnConnect event will be fired. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

Remarks

When this method is called with **socketDatagram** as the specified protocol, it does not actually establish a connection. Instead, it simply establishes a default destination address and port that is used with subsequent calls to the Read and Write methods.

SocketWrench Class | SocketTools Namespace | SocketWrench.Connect Overload List

SocketWrench.Connect Method (String, Int32, Int32)

Establish a connection with a remote host.

```
[Visual Basic]
Overloads Public Function Connect( _
   ByVal hostName As String, _
   ByVal hostPort As Integer, _
   ByVal timeout As Integer _
) As Boolean
```

```
[C#]
public bool Connect(
   string hostName,
   int hostPort,
   int timeout
);
```

Parameters

hostName

A string which specifies the remote host to establish a connection with. This may specify a host name or an Internet address in dot-notation.

hostPort

An integer which specifies the port number for the connection. This value must be greater than zero and the maximum valid port number is 65535.

timeout

An integer value that specifies the number of seconds that the method will wait for the connection to complete before failing the operation and returning to the caller. This value is only meaningful for blocking sockets.

Return Value

A boolean value which specifies if the connection has been established. If the socket is in blocking mode, a return value of **true** indicates that the connection has completed and the application may send and receive data from the remote host. If the socket is in non-blocking mode, a return value of **true** indicates that the socket has been successfully created and the connection is in progress.

When a non-blocking connection has completed, the OnConnect event will be fired. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

Remarks

This method will use the value of the Protocol property to determine which protocol is used to establish the connection. By default, the **socketStream** protocol will be used.

See Also

SocketWrench Class | SocketTools Namespace | SocketWrench.Connect Overload List

SocketWrench.Disconnect Method

Terminate the connection with a remote host.

[Visual Basic]

```
Public Sub Disconnect()
```

[C#]

```
public void Disconnect();
```

Remarks

The **Disconnect** method terminates the connection with the remote host and closes the socket handle allocated by the class. Note that the socket is not immediately released when the connection is terminated and will enter a wait state for two minutes. After the time wait period has elapsed, the socket will be released by the operating system. This is a normal safety mechanism to handle any packets that may arrive after the connection has been closed.

To immediately terminate the connection and release the socket, use the **Abort** method.

SocketWrench.Dispose Method ()

Releases all resources used by SocketWrench.

[Visual Basic]

```
NotOverridable Overloads Public Sub Dispose() _
    Implements IDisposable.Dispose
```

[C#]

```
public void Dispose();
```

Implements

IDisposable.Dispose

Remarks

The **Dispose** method terminates any active connection and explicitly releases the resources allocated for this instance of the class. In some cases, better performance can be achieved if the programmer explicitly releases resources when they are no longer being used. The **Dispose** method provides explicit control over these resources.

Unlike the **Uninitialize** method, once the **Dispose** method has been called, that instance of the class cannot be re-initialized and you should not attempt to access class properties or invoke any methods. Note that this method can be called even if other references to the object are active.

See Also

SocketWrench Class | SocketTools Namespace | SocketWrench.Dispose Overload List

SocketWrench.Dispose Method (Boolean)

Releases the unmanaged resources allocated by the SocketWrench class and optionally releases the managed resources.

[Visual Basic]

```
Overridable Overloads Protected Sub Dispose( _
   ByVal disposing As Boolean _
)
```

[C#]

```
protected virtual void Dispose(
   bool disposing
);
```

Parameters

disposing

A boolean value which should be specified as **true** to release both managed and unmanaged resources; **false** to release only unmanaged resources.

Remarks

The **Dispose** method terminates any active connection and explicitly releases the resources allocated for this instance of the class. In some cases, better performance can be achieved if the programmer explicitly releases resources when they are no longer being used. The **Dispose** method provides explicit control over these resources.

Unlike the **Uninitialize** method, once the **Dispose** method has been called, that instance of the class cannot be re-initialized and you should not attempt to access class properties or invoke any methods. Note that this method can be called even if other references to the object are active.

You should call **Dispose** in your derived class when you are finished using the derived class. The **Dispose** method leaves the derived class in an unusable state. After calling **Dispose**, you must release all references to the derived class and the **SocketWrench** class so the memory they were occupying can be reclaimed by garbage collection.

SocketWrench Class | SocketTools Namespace

SocketWrench.Initialize Method

Initialize an instance of the SocketWrench class.

Overload List

Initialize an instance of the SocketWrench class.

public bool Initialize();

Initialize an instance of the SocketWrench class.

public bool Initialize(string);

See Also

SocketWrench Class | SocketTools Namespace | Uninitialize Method

SocketWrench.Initialize Method ()

Initialize an instance of the SocketWrench class.

[Visual Basic]

```
Overloads Public Function Initialize() As Boolean
```

[C#]

```
public bool Initialize();
```

Return Value

A boolean value which specifies if the class was initialized successfully.

Remarks

The Initialize method can be used to explicitly initialize an instance of the SocketWrench class, loading the networking library and allocating resources for the current thread. Typically it is not necessary to explicitly call this method because the instance of the class is initialized by the class constructor. However, if the **Uninitialize** method is called, the class must be re-initialized before any other methods are called.

See Also

SocketWrench Class | SocketTools Namespace | SocketWrench.Initialize Overload List | Uninitialize Method

SocketWrench.Initialize Method (String)

Initialize an instance of the SocketWrench class.

[Visual Basic]

```
Overloads Public Function Initialize( _
   ByVal licenseKey As String _
) As Boolean
```

[C#]

```
public bool Initialize(
   string licenseKey
);
```

Return Value

A boolean value which specifies if the class was initialized successfully.

Remarks

The Initialize method can be used to explicitly initialize an instance of the SocketWrench class, loading the networking library and allocating resources for the current thread. Typically an application would define the license key as a custom attribute, however this method can be used to initialize the class directly.

The runtime license key for your copy of SocketWrench can be generated using the License Manager utility that is included with the product. Note that if you have installed an evaluation license, you will not have a runtime license key and cannot redistribute any applications which use the SocketWrench class.

Example

The following example shows how to use the Initialize method to initialize an instance of the class. This example assumes that the license key string has been defined in code.

```
SocketTools.SocketWrench socket = new SocketTools.SocketWrench();

if (socket.Initialize(strLicenseKey) == false)
{
    MessageBox.Show(socket.LastErrorString, "Error",
                    MessageBoxButtons.OK, MessageBoxIcon.Exclamation);
    return;
}
```

```
Dim Socket As New SocketTools.SocketWrench

If Socket.Initialize(strLicenseKey) = False Then
    MsgBox(Socket.LastErrorString, vbIconExclamation)
    Exit Sub
End If
```

SocketWrench.Listen Method

Listen for incoming client connections.

Overload List

Listen for incoming client connections.

public bool Listen();

Listen for incoming client connections, specifying the local port number.

public bool Listen(int);

Listen for incoming client connections, specifying the local network address and port number.

public bool Listen(string,int);

Listen for incoming client connections, specifying the local network address, port number and connection backlog.

public bool Listen(string,int,int);

See Also

SocketWrench Class | SocketTools Namespace | Blocking Property | LocalAddress Property | LocalPort Property | Accept Method | OnAccept Event

SocketWrench.Listen Method ()

Listen for incoming client connections.

[Visual Basic]

```
Overloads Public Function Listen() As Boolean
```

[C#]

```
public bool Listen();
```

Return Value

A boolean value which specifies if the listening socket could be created successfully. A value of **true** indicates that a listening socket has been created. A value of **false** indicates that a listening socket could not be created using the specified address or port number and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The value of the **LocalAddress** property is used to specify the network address that will be used to listen for client connections. If the property has not been set, or is set to the address 0.0.0.0 then connections will be listened for on any valid network adapter configured on the system.

The value of the **LocalPort** property is used to specify the port number to listen for connections on.

After the listening socket has been created, the application should then call the **Accept** method to wait for a client to establish a connection. If the **Blocking** property is set to **false**, then the **OnAccept** event will fire when a client attempts to establish a connection.

See Also

SocketWrench Class | SocketTools Namespace | SocketWrench.Listen Overload List | Blocking Property | LocalAddress Property | LocalPort Property | Accept Method | OnAccept Event

SocketWrench.Listen Method (Int32)

Listen for incoming client connections, specifying the local port number.

[Visual Basic]

```
Overloads Public Function Listen( _
   ByVal localPort As Integer _
) As Boolean
```

[C#]

```
public bool Listen(
   int localPort
);
```

Parameters

localPort

An integer argument which specifies the port number to listen for connections on. The minimum port value is 1, the maximum port value is 65535.

Return Value

A boolean value which specifies if the listening socket could be created successfully. A value of **true** indicates that a listening socket has been created. A value of **false** indicates that a listening socket could not be created using the specified address or port number and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The value of the **LocalAddress** property is used to specify the network address that will be used to listen for client connections. If the property has not been set, or is set to the address 0.0.0.0 then connections will be listened for on any valid network adapter configured on the system.

After the listening socket has been created, the application should then call the **Accept** method to wait for a client to establish a connection. If the **Blocking** property is set to **false**, then the **OnAccept** event will fire when a client attempts to establish a connection.

SocketWrench.Listen Method (String, Int32)

Listen for incoming client connections, specifying the local network address and port number.

```
[Visual Basic]
Overloads Public Function Listen( _
   ByVal localAddress As String, _
   ByVal localPort As Integer _
) As Boolean
```

```
[C#]
public bool Listen(
   string localAddress,
   int localPort
);
```

Parameters

localAddress

A string argument which specifies the IP address of the network adapter that the class should use when listening for connection requests. If this argument is not specified, the class will bind to any suitable adapter on the local system. An address of 0.0.0.0 specifies that it should listen for connections on any network adapter configured on the system.

localPort

An integer argument which specifies the port number to listen for connections on. The minimum port value is 1, the maximum port value is 65535.

Return Value

A boolean value which specifies if the listening socket could be created successfully. A value of **true** indicates that a listening socket has been created. A value of **false** indicates that a listening socket could not be created using the specified address or port number and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

After the listening socket has been created, the application should then call the **Accept** method to wait for a client to establish a connection. If the **Blocking** property is set to **false**, then the **OnAccept** event will fire when a client attempts to establish a connection.

SocketWrench.Listen Method (String, Int32, Int32)

Listen for incoming client connections, specifying the local network address, port number and connection backlog.

[Visual Basic]

```
Overloads Public Function Listen( _
   ByVal localAddress As String, _
   ByVal localPort As Integer, _
   ByVal backlog As Integer _
) As Boolean
```

[C#]

```
public bool Listen(
   string localAddress,
   int localPort,
   int backlog
);
```

Parameters

localAddress

A string argument which specifies the IP address of the network adapter that the class should use when listening for connection requests. If this argument is not specified, the class will bind to any suitable adapter on the local system. An address of 0.0.0.0 specifies that it should listen for connections on any network adapter configured on the system.

localPort

An integer argument which specifies the port number to listen for connections on. The minimum port value is 1, the maximum port value is 65535.

backlog

An integer argument which specifies the maximum size of the queue used to manage pending connections to the service. If the argument is set to value which exceeds the maximum size for the underlying service provider, it will be silently adjusted to the nearest legal value.

Return Value

A boolean value which specifies if the listening socket could be created successfully. A value of **true** indicates that a listening socket has been created. A value of **false** indicates that a listening socket could not be created using the specified address or port number and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

After the listening socket has been created, the application should then call the **Accept** method to wait for a client to establish a connection. If the **Blocking** property is set to **false**, then the **OnAccept** event will fire when a client attempts to establish a connection.

SocketWrench.Read Method

Read data from the socket and store it in a byte array.

Overload List

Read data from the socket and store it in a byte array.

public int Read(byte[]);

Read data from the socket and store it in a byte array.

public int Read(byte[],int);

Read data from the socket and store it in a string.

public int Read(ref string);

Read data from the socket and store it in a string.

public int Read(ref string,int);

See Also

SocketWrench Class | SocketTools Namespace

SocketWrench.Read Method (Byte[])

Read data from the socket and store it in a byte array.

[Visual Basic]

```
Overloads Public Function Read( _
   ByVal buffer As Byte() _
) As Integer
```

[C#]

```
public int Read(
   byte[] buffer
);
```

Parameters

buffer

A byte array that the data will be stored in.

Return Value

An integer value which specifies the number of bytes actually read from the socket. A return value of zero specifies that the remote host has closed the connection and there is no more data available to be read. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Read** method returns data that has been read from the socket, up to the size of the byte array passed to the method. If no data is available to be read, an error will be generated if the socket is in non-blocking mode. If the socket is in blocking mode, the program will stop until data is received from the server or the connection is closed.

See Also

SocketWrench Class | SocketTools Namespace | SocketWrench.Read Overload List

SocketWrench.Read Method (Byte[], Int32)

Read data from the socket and store it in a byte array.

[Visual Basic]

```
Overloads Public Function Read( _
   ByVal buffer As Byte(), _
   ByVal length As Integer _
) As Integer
```

[C#]

```
public int Read(
   byte[] buffer,
   int length
);
```

Parameters

buffer

A byte array that the data will be stored in.

length

An integer value which specifies the maximum number of bytes of data to read. This value cannot be larger than the size of the buffer specified by the caller.

Return Value

An integer value which specifies the number of bytes actually read from the socket. A return value of zero specifies that the remote host has closed the connection and there is no more data available to be read. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Read** method returns data that has been read from the socket, up to the number of bytes specified. If no data is available to be read, an error will be generated if the socket is in non-blocking mode. If the socket is in blocking mode, the program will stop until data is received from the server or the connection is closed.

See Also

SocketWrench Class | SocketTools Namespace | SocketWrench.Read Overload List

SocketWrench.Read Method (String)

Read data from the socket and store it in a string.

[Visual Basic]

```
Overloads Public Function Read( _
   ByRef buffer As String _
) As Integer
```

[C#]

```
public int Read(
   ref string buffer
);
```

Parameters

buffer

A string that will contain the data read from the socket.

Return Value

An integer value which specifies the number of bytes actually read from the socket. A return value of zero specifies that the remote host has closed the connection and there is no more data available to be read. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Read** method returns data that has been read from the socket, up to a maximum of 8192 bytes. If no data is available to be read, an error will be generated if the socket is in non-blocking mode. If the socket is in blocking mode, the program will stop until data is received from the server or the connection is closed.

This method should only be used if the remote host is sending data that consists of printable characters. Binary data should be read using the method that accepts a byte array as the buffer parameter.

Read data from the socket and store it in a string.

[Visual Basic]

```
Overloads Public Function Read( _
   ByRef buffer As String, _
   ByVal length As Integer _
) As Integer
```

[C#]

```
public int Read(
   ref string buffer,
   int length
);
```

Parameters

buffer

A string that will contain the data read from the socket.

length

An integer value which specifies the maximum number of bytes of data to read.

Return Value

An integer value which specifies the number of bytes actually read from the socket. A return value of zero specifies that the remote host has closed the connection and there is no more data available to be read. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Read** method returns data that has been read from the socket, up to the number of bytes specified. If no data is available to be read, an error will be generated if the socket is in non-blocking mode. If the socket is in blocking mode, the program will stop until data is received from the server or the connection is closed.

This method should only be used if the remote host is sending data that consists of printable characters. Binary data should be read using the method that accepts a byte array as the buffer parameter.

SocketWrench Class | SocketTools Namespace

SocketWrench.ReadFrom Method (Byte[], Int32, String, Int32)

Read data from the socket and store it in a byte array.

[Visual Basic]

```
Overloads Public Function ReadFrom( _
   ByVal buffer As Byte(), _
   ByVal length As Integer, _
   ByRef hostAddress As String, _
   ByRef hostPort As Integer _
) As Integer
```

[C#]

```
public int ReadFrom(
   byte[] buffer,
   int length,
   ref string hostAddress,
   ref int hostPort
);
```

Parameters

buffer

A byte array that the data will be stored in.

length

An integer value which specifies the maximum number of bytes of data to read. This value cannot be larger than the size of the buffer specified by the caller.

hostAddress

A string passed by reference that will contain the remote host Internet address when the method returns. For stream sockets, this will be the same as the address used to establish the connection. For datagram sockets, this will specify the address of host that sent the datagram.

hostPort

An integer passed by reference that will contain the remote host port number when the method returns. For stream sockets, this will be the same as the port number used to establish the connection. For datagram sockets, this will specify the port number used by the host that sent the datagram.

Return Value

An integer value which specifies the number of bytes actually read from the socket. A return value of zero specifies that the remote host has closed the connection and there is no more data available to be read. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **ReadFrom** method returns data that has been read from the socket, up to the number of bytes specified. If no data is available to be read, an error will be generated if the socket is in non-blocking mode. If the socket is in blocking mode, the program will stop until data is received from the server or the connection is closed.

This method is typically used when reading binary data from a datagram socket.

   ByVal buffer As Byte(), _
   ByRef hostAddress As String, _
   ByRef hostPort As Integer _
) As Integer
```

[C#]

```
public int ReadFrom(
   byte[] buffer,
   ref string hostAddress,
   ref int hostPort
);
```

Parameters

buffer

A byte array that the data will be stored in.

hostAddress

A string passed by reference that will contain the remote host Internet address when the method returns. For stream sockets, this will be the same as the address used to establish the connection. For datagram sockets, this will specify the address of host that sent the datagram.

hostPort

An integer passed by reference that will contain the remote host port number when the method returns. For stream sockets, this will be the same as the port number used to establish the connection. For datagram sockets, this will specify the port number used by the host that sent the datagram.

Return Value

An integer value which specifies the number of bytes actually read from the socket. A return value of zero specifies that the remote host has closed the connection and there is no more data available to be read. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **ReadFrom** method returns data that has been read from the socket, up to the number of bytes specified. If no data is available to be read, an error will be generated if the socket is in non-blocking mode. If the socket is in blocking mode, the program will stop until data is received from the server or the connection is closed.

This method is typically used when reading binary data from a datagram socket.

See Also

SocketWrench Class | SocketTools Namespace | SocketWrench.ReadFrom Overload List

SocketWrench.ReadFrom Method (String, Int32, String, Int32)

Read data from the socket and store it in a string.

[Visual Basic]

```
Overloads Public Function ReadFrom( _
   ByRef buffer As String, _
   ByVal length As Integer, _
   ByRef hostAddress As String, _
   ByRef hostPort As Integer _
) As Integer
```

[C#]

```
public int ReadFrom(
   ref string buffer,
   int length,
   ref string hostAddress,
   ref int hostPort
);
```

Parameters

buffer
A string that will contain the data read from the socket.

length
An integer value which specifies the maximum number of bytes of data to read.

hostAddress
A string passed by reference that will contain the remote host Internet address when the method returns. For stream sockets, this will be the same as the address used to establish the connection. For datagram sockets, this will specify the address of host that sent the datagram.

hostPort
An integer passed by reference that will contain the remote host port number when the method returns. For stream sockets, this will be the same as the port number used to establish the connection. For datagram sockets, this will specify the port number used by the host that sent the datagram.

Return Value

An integer value which specifies the number of bytes actually read from the socket. A return value of zero specifies that the remote host has closed the connection and there is no more data available to be read. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **ReadFrom** method returns data that has been read from the socket, up to the number of bytes specified. If no data is available to be read, an error will be generated if the socket is in non-blocking mode. If the socket is in blocking mode, the program will stop until data is received from the server or the connection is closed.

This method should only be used if the remote host is sending data that consists of printable characters. Binary data should be read using the method that accepts a byte array as the buffer parameter.

This method is typically used when reading text data from a datagram socket.

See Also

SocketWrench Class | SocketTools Namespace | SocketWrench.ReadFrom Overload List

SocketWrench.ReadFrom Method (String, String, Int32)

Read data from the socket and store it in a string.

[Visual Basic]

```
Overloads Public Function ReadFrom( _
   ByRef buffer As String, _
   ByRef hostAddress As String, _
   ByRef hostPort As Integer _
) As Integer
```

[C#]

```
public int ReadFrom(
   ref string buffer,
   ref string hostAddress,
   ref int hostPort
);
```

Parameters

buffer
A string that will contain the data read from the socket.

hostAddress
A string passed by reference that will contain the remote host Internet address when the method returns. For stream sockets, this will be the same as the address used to establish the connection. For datagram sockets, this will specify the address of host that sent the datagram.

hostPort
An integer passed by reference that will contain the remote host port number when the method returns. For stream sockets, this will be the same as the port number used to establish the connection. For datagram sockets, this will specify the port number used by the host that sent the datagram.

Return Value

An integer value which specifies the number of bytes actually read from the socket. A return value of zero specifies that the remote host has closed the connection and there is no more data available to be read. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **ReadFrom** method returns data that has been read from the socket, up to the maximum size of a datagram. If no data is available to be read, an error will be generated if the socket is in non-blocking mode. If the socket is in blocking mode, the program will stop until data is received from the server or the connection is closed.

This method should only be used if the remote host is sending data that consists of printable characters. Binary data should be read using the method that accepts a byte array as the buffer parameter.

This method is typically used when reading text data from a datagram socket.

Read up to a line of data from the socket and return it in a string buffer.

Overload List

Read up to a line of data from the socket and return it in a string buffer.

public bool ReadLine(ref string);

Read up to a line of data from the socket and return it in a string buffer.

public bool ReadLine(ref string,int);

See Also

SocketWrench Class | SocketTools Namespace

SocketWrench.ReadLine Method (String)

Read up to a line of data from the socket and return it in a string buffer.

[Visual Basic]
```
Overloads Public Function ReadLine( _
   ByRef buffer As String _
) As Boolean
```

[C#]
```
public bool ReadLine(
   ref string buffer
);
```

Parameters

buffer

A string which will contain the data read from the socket.

Return Value

This method returns a Boolean value which specifies if a line of data has been read. A value of **true** indicates a line of data has been read. If an error occurs or there is no more data available to read, then the method will return **false**. It is possible for data to be returned in the string buffer even if the return value is **false**. Applications should check the length of the string after the method returns to determine if any data was copied into the buffer. For example, if a timeout occurs while the method is waiting for more data to arrive on the socket, it will return zero; however, data may have already been copied into the string buffer prior to the error condition. It is the responsibility of the application to process that data, regardless of the method return value.

Remarks

The **ReadLine** method reads data from the socket up to 8192 bytes in length or until an end-of-line character sequence is encountered. Unlike the **Read** method which reads arbitrary bytes of data, this method is specifically designed to return a single line of text data in a string variable. When an end-of-line character sequence is encountered, the method will stop and return the data up to that point; the string will not contain the carriage-return or linefeed characters.

There are some limitations when using the **ReadLine** method. The method should only be used to read text, never binary data. In particular, it will discard nulls, linefeed and carriage return control characters. This method will force the current thread to block until an end-of-line character sequence is processed, the read operation times out or the remote host closes its end of the socket connection. If the **Blocking** property is set to **false**, calling this method will automatically switch the socket into a blocking mode, read the data and then restore the socket to non-blocking mode. If another socket operation is attempted while **ReadLine** is blocked waiting for data from the remote host, an error will occur. It is recommended that this method only be used with blocking socket connections.

The **Read** and **ReadLine** methods can be intermixed, however be aware that the **Read** method will consume any data that has already been buffered by the **ReadLine** method and this may have unexpected results.

See Also

SocketWrench Class | SocketTools Namespace | SocketWrench.ReadLine Overload List

SocketWrench.ReadLine Method (String, Int32)

Read up to a line of data from the socket and return it in a string buffer.

[Visual Basic]

```
Overloads Public Function ReadLine( _
   ByRef buffer As String, _
   ByVal length As Integer _
) As Boolean
```

[C#]

```
public bool ReadLine(
   ref string buffer,
   int length
);
```

Parameters

buffer

A string which will contain the data read from the socket.

length

An integer value which specifies the maximum number of bytes of data to read.

Return Value

This method returns a Boolean value which specifies if a line of data has been read. A value of **true** indicates a line of data has been read. If an error occurs or there is no more data available to read, then the method will return **false**. It is possible for data to be returned in the string buffer even if the return value is **false**. Applications should check the length of the string after the method returns to determine if any data was copied into the buffer. For example, if a timeout occurs while the method is waiting for more data to arrive on the socket, it will return zero; however, data may have already been copied into the string buffer prior to the error condition. It is the responsibility of the application to process that data, regardless of the method return value.

Remarks

The **ReadLine** method reads data from the socket up to the specified number of bytes or until an end-of-line character sequence is encountered. Unlike the **Read** method which reads arbitrary bytes of data, this method is specifically designed to return a single line of text data in a string variable. When an end-of-line character sequence is encountered, the method will stop and return the data up to that point; the string will not contain the carriage-return or linefeed characters.

There are some limitations when using the **ReadLine** method. The method should only be used to read text, never binary data. In particular, it will discard nulls, linefeed and carriage return control characters. This method will force the current thread to block until an end-of-line character sequence is processed, the read operation times out or the remote host closes its end of the socket connection. If the **Blocking** property is set to **false**, calling this method will automatically switch the socket into a blocking mode, read the data and then restore the socket to non-blocking mode. If another socket operation is attempted while **ReadLine** is blocked waiting for data from the remote host, an error will occur. It is recommended that this method only be used with blocking socket connections.

The **Read** and **ReadLine** methods can be intermixed, however be aware that the **Read** method will consume any data that has already been buffered by the **ReadLine** method and this may have unexpected results.

SocketWrench Class | SocketTools Namespace

SocketWrench.ReadStream Method (Byte[], Int32)

Read a data stream from the socket and store it in the specified byte array.

[Visual Basic]

```
Overloads Public Function ReadStream( _
   ByVal buffer As Byte(), _
   ByRef length As Integer _
) As Boolean
```

[C#]

```
public bool ReadStream(
   byte[] buffer,
   ref int length
);
```

Parameters

buffer

A byte array that the data will be stored in.

length

An integer value passed by reference which specifies the maximum number of bytes of data to read. This value cannot be larger than the size of the buffer specified by the caller. When the method returns, this value will be updated with the actual number of bytes read from the socket.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

This method will force the current thread to block until the operation completes. If this method is called and the **Blocking** property is set to **false**, it will automatically switch the socket into a blocking mode, read the data stream and then restore the socket to non-blocking mode when it has finished. If another socket operation is attempted while **ReadStream** is blocked waiting for data from the remote host, an error will occur. It is recommended that this method only be used with blocking (synchronous) socket connections; if the application needs to establish multiple simultaneous connections, it should create worker threads to manage each connection.

It is possible for data to be returned in the buffer even if the method returns **false**. Applications should also check the value of the ***length*** parameter to determine if any data was copied into the buffer. For example, if a timeout occurs while the method is waiting for more data to arrive on the socket, it will return zero; however, data may have already been copied into the buffer prior to the error condition. It is the responsibility of the application to process that data, regardless of the method return value.

Because **ReadStream** can potentially cause the current thread to block for long periods of time as the data stream is being read, the class will periodically generate **OnProgress** events. An application can use this event to update the user interface as the data is being read. Note that an application should never perform a blocking operation inside the event handler.

SocketWrench Class | SocketTools Namespace | SocketWrench.ReadStream Overload List

SocketWrench.ReadStream Method (Byte[], Int32, Byte[])

Read a data stream from the socket and store it in the specified byte array.

[Visual Basic]

```
Overloads Public Function ReadStream( _
   ByVal buffer As Byte(), _
   ByRef length As Integer, _
   ByVal marker As Byte() _
) As Boolean
```

[C#]

```
public bool ReadStream(
   byte[] buffer,
   ref int length,
   byte[] marker
);
```

Parameters

buffer

A byte array that the data will be stored in.

length

An integer value passed by reference which specifies the maximum number of bytes of data to read. This value cannot be larger than the size of the buffer specified by the caller. When the method returns, this value will be updated with the actual number of bytes read from the socket.

marker

An array of bytes which is used to designate the logical end of the data stream. When this byte sequence is encountered by the method, it will stop reading and return to the caller. The buffer will contain all of the data read from the socket up to and including the end-of-stream marker.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

This method will force the current thread to block until the operation completes. If this method is called and the **Blocking** property is set to **false**, it will automatically switch the socket into a blocking mode, read the data stream and then restore the socket to non-blocking mode when it has finished. If another socket operation is attempted while **ReadStream** is blocked waiting for data from the remote host, an error will occur. It is recommended that this method only be used with blocking (synchronous) socket connections; if the application needs to establish multiple simultaneous connections, it should create worker threads to manage each connection.

It is possible for data to be returned in the buffer even if the method returns **false**. Applications should also check the value of the *length* parameter to determine if any data was copied into the buffer. For example, if a timeout occurs while the method is waiting for more data to arrive on the socket, it will return zero; however, data may have already been copied into the buffer prior to the error condition. It is the responsibility of the application to process that data, regardless of the method return value.

Because **ReadStream** can potentially cause the current thread to block for long periods of time as the data stream is being read, the class will periodically generate **OnProgress** events. An application can use this event to update the user interface as the data is being read. Note that an application should never perform a blocking operation inside the event handler.

SocketWrench Class | SocketTools Namespace | SocketWrench.ReadStream Overload List

SocketWrench.ReadStream Method (String, Boolean)

Read a data stream from the socket and store it in the specified string.

[Visual Basic]

```
Overloads Public Function ReadStream( _
   ByRef buffer As String, _
   ByVal convertText As Boolean _
) As Boolean
```

[C#]

```
public bool ReadStream(
   ref string buffer,
   bool convertText
);
```

Parameters

buffer

A string that will contain the data read from the socket.

convertText

A boolean flag which specifies if the data data stream is considered to be textual and should be modified so that end-of-line character sequences are converted to follow standard Windows conventions. This will ensure that all lines of text are terminated with a carriage-return and linefeed sequence. Because this option modifies the data stream, it should never be used with binary data. Using this option may result in the amount of data returned in the buffer to be larger than the source data. For example, if the source data only terminates a line of text with a single linefeed, this option will have the effect of inserting a carriage-return character before each linefeed.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

This method will force the current thread to block until the operation completes. If this method is called and the **Blocking** property is set to **false**, it will automatically switch the socket into a blocking mode, read the data stream and then restore the socket to non-blocking mode when it has finished. If another socket operation is attempted while **ReadStream** is blocked waiting for data from the remote host, an error will occur. It is recommended that this method only be used with blocking (synchronous) socket connections; if the application needs to establish multiple simultaneous connections, it should create worker threads to manage each connection.

It is possible for data to be returned in the buffer even if the method returns **false**. Applications should also check the length of the string to determine if any data was copied into the buffer. For example, if a timeout occurs while the method is waiting for more data to arrive on the socket, it will return zero; however, data may have already been copied into the buffer prior to the error condition. It is the responsibility of the application to process that data, regardless of the method return value.

Because **ReadStream** can potentially cause the current thread to block for long periods of time as the data stream is being read, the class will periodically generate **OnProgress** events. An application can use this event to update the user interface as the data is being read. Note that an application should never perform a blocking operation inside the event handler.

SocketWrench.ReadStream Method (String, Int32, String, Boolean)

Read a data stream from the socket and store it in the specified string.

[Visual Basic]

```
Overloads Public Function ReadStream( _
   ByRef buffer As String, _
   ByRef length As Integer, _
   ByVal marker As String, _
   ByVal convertText As Boolean _
) As Boolean
```

[C#]

```
public bool ReadStream(
   ref string buffer,
   ref int length,
   string marker,
   bool convertText
);
```

Parameters

buffer
A string that will contain the data read from the socket.

length
An integer value passed by reference which specifies the maximum number of bytes of data to read. This value cannot be larger than the size of the buffer specified by the caller. When the method returns, this value will be updated with the actual number of bytes read from the socket.

marker
A string which is used to designate the logical end of the data stream. When this character sequence is encountered by the method, it will stop reading and return to the caller. The string buffer will contain all of the data read from the socket up to and including the end-of-stream marker.

convertText
A boolean flag which specifies if the data data stream is considered to be textual and should be modified so that end-of-line character sequences are converted to follow standard Windows conventions. This will ensure that all lines of text are terminated with a carriage-return and linefeed sequence. Because this option modifies the data stream, it should never be used with binary data. Using this option may result in the amount of data returned in the buffer to be larger than the source data. For example, if the source data only terminates a line of text with a single linefeed, this option will have the effect of inserting a carriage-return character before each linefeed.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

This method will force the current thread to block until the operation completes. If this method is called and the **Blocking** property is set to **false**, it will automatically switch the socket into a blocking mode, read the data stream and then restore the socket to non-blocking mode when it has finished. If another socket operation is attempted while **ReadStream** is blocked waiting for data from the remote host, an error will occur. It is recommended that this method only be used with blocking (synchronous) socket connections; if the application needs to establish multiple simultaneous connections, it should create worker threads to manage each connection.

It is possible for data to be returned in the buffer even if the method returns **false**. Applications should also check the value of the ***length*** parameter to determine if any data was copied into the buffer. For example, if a timeout occurs while the method is waiting for more data to arrive on the socket, it will return zero; however, data may have already been copied into the buffer prior to the error condition. It is the responsibility of the application to process that data, regardless of the method return value.

Because **ReadStream** can potentially cause the current thread to block for long periods of time as the data stream is being read, the class will periodically generate **OnProgress** events. An application can use this event to update the user interface as the data is being read. Note that an application should never perform a blocking operation inside the event handler.

SocketWrench Class | SocketTools Namespace | SocketWrench.ReadStream Overload List

SocketWrench.Reject Method

Rejects a connection request from a remote host.

[Visual Basic]

```
Public Function Reject() As Boolean
```

[C#]

```
public bool Reject();
```

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **Reject** method rejects a pending client connection and the remote host will see this as the connection being aborted. If there are no pending client connections at the time, this method will immediately return with an error indicating that the operation would cause the thread to block.

SocketWrench Class | SocketTools Namespace

SocketWrench.Reset Method

Reset the internal state of the object, resetting all properties to their default values.

[Visual Basic]

```
Public Sub Reset()
```

[C#]

```
public void Reset();
```

Remarks

The **Reset** method returns the object to its default state. If a socket has been allocated, it will be released and any active connections will be terminated. All properties will be reset to their default values.

SocketWrench Class | SocketTools Namespace

SocketWrench.Resolve Method

Resolves a host name to a host IP address.

[Visual Basic]

```
Public Function Resolve( _
   ByVal hostName As String, _
   ByRef hostAddress As String _
) As Boolean
```

[C#]

```
public bool Resolve(
   string hostName,
   ref string hostAddress
);
```

Parameters

hostName

A string which specifies the host name to be resolved.

hostAddress

A string which will contain the Internet address for the specified host.

Return Value

This method returns a Boolean value. If the host name can be resolved, the return value is **true**. If the host name cannot be resolved, the return value is **false**. To get extended error information, check the value of the **LastError** property.

See Also

SocketWrench Class | SocketTools Namespace

SocketWrench.Shutdown Method

Disable sending data on the socket.

Overload List

Disable sending data on the socket.

public bool Shutdown();

Disable sending or receiving data on the socket.

public bool Shutdown(ShutdownOptions);

See Also

SocketWrench Class | SocketTools Namespace | Disconnect Method

SocketWrench.Shutdown Method ()

Disable sending data on the socket.

[Visual Basic]
```
Overloads Public Function Shutdown() As Boolean
```

[C#]
```
public bool Shutdown();
```

Return Value

A boolean value which specifies if the operation completed successfully. A return value of **false** indicates an error has occurred. To get extended error information, check the value of the **LastError** property.

Remarks

In some asynchronous applications, it may be desirable for a client to inform the server that no further communication is wanted, while allowing the client to read any residual data that may reside in internal buffers on the client side. **Shutdown** accomplishes this because the socket handle is still valid after it has been called, although some or all communication with the remote host has ceased. Note that most applications do not typically need to use this method. To close a socket connection gracefully, you should use the **Disconnect** method.

See Also

SocketWrench Class | SocketTools Namespace | SocketWrench.Shutdown Overload List | Disconnect Method

SocketWrench.Shutdown Method (ShutdownOptions)

Disable sending or receiving data on the socket.

[Visual Basic]

```
Overloads Public Function Shutdown( _
   ByVal options As ShutdownOptions _
) As Boolean
```

[C#]

```
public bool Shutdown(
   ShutdownOptions options
);
```

Parameters

options

One of the ShutdownOptions enumeration values which specifies the operation that will no longer be allowed.

Return Value

A boolean value which specifies if the operation completed successfully. A return value of **false** indicates an error has occurred. To get extended error information, check the value of the **LastError** property.

Remarks

In some asynchronous applications, it may be desirable for a client to inform the server that no further communication is wanted, while allowing the client to read any residual data that may reside in internal buffers on the client side. **Shutdown** accomplishes this because the socket handle is still valid after it has been called, although some or all communication with the remote host has ceased.

Note that most applications do not typically need to use this method. To close a socket connection gracefully, you should use the **Disconnect** method.

SocketWrench Class | SocketTools Namespace

SocketWrench.StoreStream Method (String)

Reads a data stream from the socket and stores it in the specified file.

[Visual Basic]

```
Overloads Public Function StoreStream( _
   ByVal fileName As String _
) As Boolean
```

[C#]

```
public bool StoreStream(
   string fileName
);
```

Parameters

fileName

A string variable that specifies the name of the file that will contain the data read from the socket. If the file does not exist, it will be created. If the file does exist, the contents will be overwritten.

Return Value

A boolean value which specifies if the operation completed successfully. A return value of **false** indicates an error has occurred. To get extended error information, check the value of the **LastError** property.

Remarks

This method will force the current thread to block until the operation completes. If this method is called with the **Blocking** property set to **false**, it will automatically switch the socket into a blocking mode, read the data stream and then restore the socket to non-blocking mode when it has finished. If another socket operation is attempted while **StoreStream** is blocked waiting for data from the remote host, an error will occur. It is recommended that this method only be used with blocking (synchronous) socket connections; if the application needs to establish multiple simultaneous connections, it should create worker threads to manage each connection.

Because **StoreStream** can potentially cause the current thread to block for long periods of time as the data stream is being read, the class instance will periodically generate **OnProgress** events. An application can use this event to update the user interface as the data is being read. Note that an application should never perform a blocking operation inside the event handler.

See Also

SocketWrench Class | SocketTools Namespace | SocketWrench.StoreStream Overload List

SocketWrench.StoreStream Method (String, Int32)

Reads a data stream from the socket and stores it in the specified file.

[Visual Basic]

```
Overloads Public Function StoreStream( _
   ByVal fileName As String, _
   ByRef length As Integer _
) As Boolean
```

[C#]

```
public bool StoreStream(
   string fileName,
   ref int length
);
```

Parameters

fileName

A string variable that specifies the name of the file that will contain the data read from the socket. If the file does not exist, it will be created. If the file does exist, the contents will be overwritten.

length

An integer value which specifies the maximum amount of data to be read from the socket. When the method returns, this variable will be updated with the actual number of bytes read. Note that because this argument is passed by reference and modified by the method, you must provide a variable, not a numeric constant. If the value is initialized to zero, this method will read data from the socket until the remote host disconnects or an error occurs.

Return Value

A boolean value which specifies if the operation completed successfully. A return value of **false** indicates an error has occurred. To get extended error information, check the value of the **LastError** property.

Remarks

This method will force the current thread to block until the operation completes. If this method is called with the **Blocking** property set to **false**, it will automatically switch the socket into a blocking mode, read the data stream and then restore the socket to non-blocking mode when it has finished. If another socket operation is attempted while **StoreStream** is blocked waiting for data from the remote host, an error will occur. It is recommended that this method only be used with blocking (synchronous) socket connections; if the application needs to establish multiple simultaneous connections, it should create worker threads to manage each connection.

Because **StoreStream** can potentially cause the current thread to block for long periods of time as the data stream is being read, the class instance will periodically generate **OnProgress** events. An application can use this event to update the user interface as the data is being read. Note that an application should never perform a blocking operation inside the event handler.

See Also

SocketWrench Class | SocketTools Namespace | SocketWrench.StoreStream Overload List

SocketWrench.StoreStream Method (String, Int32, Boolean)

Reads a data stream from the socket and stores it in the specified file.

[Visual Basic]

```
Overloads Public Function StoreStream( _
   ByVal fileName As String, _
   ByRef length As Integer, _
   ByVal convertText As Boolean _
) As Boolean
```

[C#]

```
public bool StoreStream(
   string fileName,
   ref int length,
   bool convertText
);
```

Parameters

fileName

A string variable that specifies the name of the file that will contain the data read from the socket. If the file does not exist, it will be created. If the file does exist, the contents will be overwritten.

length

An integer value which specifies the maximum amount of data to be read from the socket. When the method returns, this variable will be updated with the actual number of bytes read. Note that because this argument is passed by reference and modified by the method, you must provide a variable, not a numeric constant. If the value is initialized to zero, this method will read data from the socket until the remote host disconnects or an error occurs.

convertText

A boolean flag which specifies if the data data stream is considered to be textual and should be modified so that end-of-line character sequences are converted to follow standard Windows conventions. This will ensure that all lines of text are terminated with a carriage-return and linefeed sequence. Because this option modifies the data stream, it should never be used with binary data. Using this option may result in the amount of data stored in the file to be larger than the source data. For example, if the source data only terminates a line of text with a single linefeed, this option will have the effect of inserting a carriage-return character before each linefeed.

Return Value

A boolean value which specifies if the operation completed successfully. A return value of **false** indicates an error has occurred. To get extended error information, check the value of the **LastError** property.

Remarks

This method will force the current thread to block until the operation completes. If this method is called with the **Blocking** property set to **false**, it will automatically switch the socket into a blocking mode, read the data stream and then restore the socket to non-blocking mode when it has finished. If another socket operation is attempted while **StoreStream** is blocked waiting for data from the remote host, an error will occur. It is recommended that this method only be used with blocking (synchronous) socket connections; if the application needs to establish multiple simultaneous connections, it should create worker threads to manage each connection.

Because **StoreStream** can potentially cause the current thread to block for long periods of time as the data stream is being read, the class instance will periodically generate **OnProgress** events. An application can use this event to update the user interface as the data is being read. Note that an application should never perform a blocking operation inside the event handler.

SocketWrench.StoreStream Method (String, Int32, Int32, SocketStream)

Reads a data stream from the socket and stores it in the specified file.

[Visual Basic]

```
Overloads Public Function StoreStream( _
   ByVal fileName As String, _
   ByRef length As Integer, _
   ByVal offset As Integer, _
   ByVal options As SocketStream _
) As Boolean
```

[C#]

```
public bool StoreStream(
   string fileName,
   ref int length,
   int offset,
   SocketStream options
);
```

Parameters

fileName

A string variable that specifies the name of the file that will contain the data read from the socket. If the file does not exist, it will be created. If the file does exist, the contents will be overwritten.

length

An integer value which specifies the maximum amount of data to be read from the socket. When the method returns, this variable will be updated with the actual number of bytes read. Note that because this argument is passed by reference and modified by the method, you must provide a variable, not a numeric constant. If the value is initialized to zero, this method will read data from the socket until the remote host disconnects or an error occurs.

offset

A numeric value which specifies the byte offset into the file where the method will start storing data read from the socket. Note that all data after this offset will be truncated. If a value of zero is specified, the file will be completely overwritten if it already exists.

options

One of the SocketStream enumeration values which specifies how the data is processed.

Return Value

A boolean value which specifies if the operation completed successfully. A return value of **false** indicates an error has occurred. To get extended error information, check the value of the **LastError** property.

Remarks

This method will force the current thread to block until the operation completes. If this method is called with the **Blocking** property set to **false**, it will automatically switch the socket into a blocking mode, read the data stream and then restore the socket to non-blocking mode when it has finished. If another socket operation is attempted while **StoreStream** is blocked waiting for data from the remote host, an error will occur. It is recommended that this method only be used with blocking (synchronous) socket connections; if the application needs to establish multiple simultaneous connections, it should create worker threads to manage each connection.

Because **StoreStream** can potentially cause the current thread to block for long periods of time as the data stream is being read, the class will periodically generate **OnProgress** events. An application can use this event to update the user interface as the data is being read. Note that an application should never perform a blocking operation inside the event handler.

SocketWrench Class | SocketTools Namespace | SocketWrench.StoreStream Overload List

SocketWrench.StoreStream Method (String, Int32, Int32, Boolean)

Reads a data stream from the socket and stores it in the specified file.

[Visual Basic]

```
Overloads Public Function StoreStream( _
   ByVal fileName As String, _
   ByRef length As Integer, _
   ByVal offset As Integer, _
   ByVal convertText As Boolean _
) As Boolean
```

[C#]

```
public bool StoreStream(
   string fileName,
   ref int length,
   int offset,
   bool convertText
);
```

Parameters

fileName

A string variable that specifies the name of the file that will contain the data read from the socket. If the file does not exist, it will be created. If the file does exist, the contents will be overwritten.

length

An integer value which specifies the maximum amount of data to be read from the socket. When the method returns, this variable will be updated with the actual number of bytes read. Note that because this argument is passed by reference and modified by the method, you must provide a variable, not a numeric constant. If the value is initialized to zero, this method will read data from the socket until the remote host disconnects or an error occurs.

offset

A numeric value which specifies the byte offset into the file where the method will start storing data read from the socket. Note that all data after this offset will be truncated. If a value of zero is specified, the file will be completely overwritten if it already exists.

convertText

A boolean flag which specifies if the data data stream is considered to be textual and should be modified so that end-of-line character sequences are converted to follow standard Windows conventions. This will ensure that all lines of text are terminated with a carriage-return and linefeed sequence. Because this option modifies the data stream, it should never be used with binary data. Using this option may result in the amount of data stored in the file to be larger than the source data. For example, if the source data only terminates a line of text with a single linefeed, this option will have the effect of inserting a carriage-return character before each linefeed.

Return Value

A boolean value which specifies if the operation completed successfully. A return value of **false** indicates an error has occurred. To get extended error information, check the value of the **LastError** property.

Remarks

This method will force the current thread to block until the operation completes. If this method is called with the **Blocking** property set to **false**, it will automatically switch the socket into a blocking mode, read the data stream and then restore the socket to non-blocking mode when it has finished. If another socket operation is attempted while **StoreStream** is blocked waiting for data from the remote host, an error will occur. It is recommended that this method only be used with blocking (synchronous) socket connections; if the application needs to establish multiple simultaneous connections, it should create worker threads to manage each connection.

Because **StoreStream** can potentially cause the current thread to block for long periods of time as the data stream is being read, the class instance will periodically generate **OnProgress** events. An application can use this event to update the user interface as the data is being read. Note that an application should never perform a blocking operation inside the event handler.

SocketWrench Class | SocketTools Namespace | SocketWrench.StoreStream Overload List

SocketWrench.Uninitialize Method

Uninitialize the class library and release any resources allocated for the current thread.

[Visual Basic]

```
Public Sub Uninitialize()
```

[C#]

```
public void Uninitialize();
```

Remarks

The **Uninitialize** method terminates any active connection, releases resources allocated for the current thread and unloads the networking library. After this method has been called, no further socket operations may be performed until the class instance has been re-initialized.

If the **Initialize** method is explicitly called by the application, it should be matched by a call to the **Uninitialize** method when that instance of the class is no longer needed.

SocketWrench.Write Method

Write one or more bytes of data to the socket.

Overload List

Write one or more bytes of data to the socket.

public int Write(byte[]);

Write one or more bytes of data to the socket.

public int Write(byte[],int);

Write a string of characters to the socket.

public int Write(string);

Write a string of characters to the socket.

public int Write(string,int);

See Also

SocketWrench Class | SocketTools Namespace

SocketWrench.Write Method (Byte[])

Write one or more bytes of data to the socket.

[Visual Basic]

```
Overloads Public Function Write( _
   ByVal buffer As Byte() _
) As Integer
```

[C#]

```
public int Write(
   byte[] buffer
);
```

Parameters

buffer

A byte array that contains the data to be written to the socket.

Return Value

An integer value which specifies the number of bytes actually written to the socket. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Write** method sends one or more bytes of data to the remote host. If there is enough room in the socket's internal send buffer to accommodate all of the data, it is copied to the send buffer and control immediately returns to the caller. If amount of data exceeds the available buffer space and the socket is in blocking mode, then the method will block until the data can be sent. If the socket is in non-blocking mode and the send buffer is full, an error will occur.

See Also

SocketWrench Class | SocketTools Namespace | SocketWrench.Write Overload List

SocketWrench.Write Method (Byte[], Int32)

Write one or more bytes of data to the socket.

[Visual Basic]

```
Overloads Public Function Write( _
   ByVal buffer As Byte(), _
   ByVal length As Integer _
) As Integer
```

[C#]

```
public int Write(
   byte[] buffer,
   int length
);
```

Parameters

buffer
A byte array that contains the data to be written to the socket.

length
An integer value which specifies the maximum number of bytes of data to write. This value cannot be larger than the size of the buffer specified by the caller.

Return Value

An integer value which specifies the number of bytes actually written to the socket. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Write** method sends one or more bytes of data to the remote host. If there is enough room in the socket's internal send buffer to accommodate all of the data, it is copied to the send buffer and control immediately returns to the caller. If amount of data exceeds the available buffer space and the socket is in blocking mode, then the method will block until the data can be sent. If the socket is in non-blocking mode and the send buffer is full, an error will occur.

See Also

SocketWrench Class | SocketTools Namespace | SocketWrench.Write Overload List

SocketWrench.Write Method (String)

Write a string of characters to the socket.

[Visual Basic]

```
Overloads Public Function Write( _
   ByVal buffer As String _
) As Integer
```

[C#]

```
public int Write(
   string buffer
);
```

Parameters

buffer

A string which contains the data to be written to the socket.

Return Value

An integer value which specifies the number of characters actually written to the socket. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Write** method sends a string of characters to the remote host. If there is enough room in the socket's internal send buffer to accommodate all of the data, it is copied to the send buffer and control immediately returns to the caller. If amount of data exceeds the available buffer space and the socket is in blocking mode, then the method will block until the data can be sent. If the socket is in non-blocking mode and the send buffer is full, an error will occur.

The string will be converted to an array of bytes before being written to the socket. By default, the character encoding used will be for the current locale. Depending on the contents of the string, the number of bytes written may be different than the string length specified. This is because the conversion from Unicode to a byte array may result in a multi-byte character sequence.

You should never use strings to read and write binary data. Always use byte arrays to ensure that no character conversion is performed.

SocketWrench.Write Method (String, Int32)

Write a string of characters to the socket.

[Visual Basic]

```
Overloads Public Function Write( _
   ByVal buffer As String, _
   ByVal length As Integer _
) As Integer
```

[C#]

```
public int Write(
   string buffer,
   int length
);
```

Parameters

buffer

A string which contains the data to be written to the socket.

length

An integer value which specifies the maximum number of characters to write. This value cannot be larger than the length of the string specified by the caller.

Return Value

An integer value which specifies the number of characters actually written to the socket. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Write** method sends a string of characters to the remote host. If there is enough room in the socket's internal send buffer to accommodate all of the data, it is copied to the send buffer and control immediately returns to the caller. If amount of data exceeds the available buffer space and the socket is in blocking mode, then the method will block until the data can be sent. If the socket is in non-blocking mode and the send buffer is full, an error will occur.

The string will be converted to an array of bytes before being written to the socket. By default, the character encoding used will be for the current locale. Depending on the contents of the string, the number of bytes written may be different than the string length specified. This is because the conversion from Unicode to a byte array may result in a multi-byte character sequence.

You should never use strings to read and write binary data. Always use byte arrays to ensure that no character conversion is performed.

SocketWrench.WriteLine Method

Send an empty line of text to the remote host, terminated by a carriage-return and linefeed.

Overload List

Send an empty line of text to the remote host, terminated by a carriage-return and linefeed.

public bool WriteLine();

Send a line of text to the remote host, terminated by a carriage-return and linefeed.

public bool WriteLine(string);

Send a line of text to the remote host, terminated by a carriage-return and linefeed.

public bool WriteLine(string,ref int);

See Also

SocketWrench Class | SocketTools Namespace

SocketWrench.WriteLine Method ()

Send an empty line of text to the remote host, terminated by a carriage-return and linefeed.

[Visual Basic]

```
Overloads Public Function WriteLine() As Boolean
```

[C#]

```
public bool WriteLine();
```

Return Value

A boolean value which specifies if the operation completed successfully. A return value of **false** indicates an error has occurred. To get extended error information, check the value of the **LastError** property.

Remarks

The **WriteLine** method will send an empty line of text, terminated by a carriage-return and linefeed. Calling this method will force the application to block until the complete line of text has been written, the write operation times out or the remote host aborts the connection. If this method is called with the **Blocking** property set to **false**, it will automatically switch the socket into a blocking mode, send the data and then restore the socket to non-blocking mode. If another socket operation is attempted while the **WriteLine** method is blocked sending data to the remote host, an error will occur. It is recommended that this method only be used with blocking socket connections.

The **Write** and **WriteLine** methods can be safely intermixed.

See Also

SocketWrench Class | SocketTools Namespace | SocketWrench.WriteLine Overload List

SocketWrench.WriteLine Method (String)

Send a line of text to the remote host, terminated by a carriage-return and linefeed.

[Visual Basic]

```
Overloads Public Function WriteLine( _
   ByVal buffer As String _
) As Boolean
```

[C#]

```
public bool WriteLine(
   string buffer
);
```

Parameters

buffer

A string which contains the data that will be sent to the remote host. The data will always be terminated with a carriage-return and linefeed control character sequence. If the string is empty, then a only a carriage-return and linefeed are written to the socket. Note that if the string contains a null character, any data that follows the null character will be discarded.

Return Value

A boolean value which specifies if the operation completed successfully. A return value of **false** indicates an error has occurred. To get extended error information, check the value of the **LastError** property.

Remarks

The **WriteLine** method should only be used to send text, never binary data. In particular, this method will discard any data that follows a null character and will append linefeed and carriage return control characters to the data stream. Calling this method will force the current thread to block until the complete line of text has been written, the write operation times out or the remote host aborts the connection. If this method is called with the **Blocking** property set to **false**, it will automatically switch the socket into a blocking mode, send the data and then restore the socket to non-blocking mode. If another socket operation is attempted while the **WriteLine** method is blocked sending data to the remote host, an error will occur. It is recommended that this method only be used with blocking socket connections.

The **Write** and **WriteLine** methods can be safely intermixed.

```

[C#]

```
public bool WriteLine(
   string buffer,
   ref int length
);
```

Parameters

buffer

A string which contains the data that will be sent to the remote host. The data will always be terminated with a carriage-return and linefeed control character sequence. If the string is empty, then a only a carriage-return and linefeed are written to the socket. Note that if the string contains a null character, any data that follows the null character will be discarded.

length

An integer value which specifies the maximum number of characters to write. This value cannot be larger than the length of the string specified by the caller.

Return Value

A boolean value which specifies if the operation completed successfully. A return value of **false** indicates an error has occurred. To get extended error information, check the value of the **LastError** property.

Remarks

The **WriteLine** method should only be used to send text, never binary data. In particular, this method will discard any data that follows a null character and will append linefeed and carriage return control characters to the data stream. Calling this method will force the current thread to block until the complete line of text has been written, the write operation times out or the remote host aborts the connection. If this method is called with the **Blocking** property set to **false**, it will automatically switch the socket into a blocking mode, send the data and then restore the socket to non-blocking mode. If another socket operation is attempted while the **WriteLine** method is blocked sending data to the remote host, an error will occur. It is recommended that this method only be used with blocking socket connections.

The **Write** and **WriteLine** methods can be safely intermixed.

SocketWrench.WriteStream Method

Write a stream of bytes to the socket.

Overload List

Write a stream of bytes to the socket.

public bool WriteStream(byte[],ref int);

Write a string of characters to the socket.

public bool WriteStream(string,ref int);

See Also

SocketWrench Class | SocketTools Namespace

SocketWrench.WriteStream Method (Byte[], Int32)

Write a stream of bytes to the socket.

[Visual Basic]

```
Overloads Public Function WriteStream( _
   ByVal buffer As Byte(), _
   ByRef length As Integer _
) As Boolean
```

[C#]

```
public bool WriteStream(
   byte[] buffer,
   ref int length
);
```

Parameters

buffer

A byte array that contains the data to be written to the socket.

length

An integer value passed by reference which specifies the maximum number of bytes to write. This value cannot be larger than the size of the buffer specified by the caller. When the method returns, this value will be updated with the actual number of bytes written to the socket.

Return Value

A boolean value which specifies if the operation completed successfully. A return value of **false** indicates an error has occurred. To get extended error information, check the value of the **LastError** property.

Remarks

The **WriteStream** method enables an application to write an arbitrarily large stream of data from a byte array to the socket. Unlike the **Write** method, which may not write all of the data in a single call, the **WriteStream** method will only return when all of the data has been written or an error occurs.

This method will force the current thread to block until the operation completes. If this method is called with the **Blocking** property set to **false**, it will automatically switch the socket into a blocking mode, write the data stream and then restore the socket to non-blocking mode when it has finished. If another socket operation is attempted while **WriteStream** is blocked sending data to the remote host, an error will occur. It is recommended that this method only be used with blocking (synchronous) socket connections; if the application needs to establish multiple simultaneous connections, it should create worker threads to manage each connection.

It is possible that some data will have been written to the socket even if the method returns **false**. Applications should also check the value of the *length* argument to determine if any data was sent. For example, if a timeout occurs while the function is waiting to write more data, it will return zero; however, some data may have already been written to the socket prior to the error condition.

Because **WriteStream** can potentially cause the current thread to block for long periods of time as the data stream is being written, the class instance will periodically generate **OnProgress** events. An application can use this event to update the user interface as the data is being written. Note that an application should never perform a blocking operation inside the event handler.

SocketWrench.WriteTo Method (Byte[], Int32, String, Int32)

Write one or more bytes of data to the socket.

[Visual Basic]

```
Overloads Public Function WriteTo( _
   ByVal buffer As Byte(), _
   ByVal length As Integer, _
   ByVal hostAddress As String, _
   ByVal hostPort As Integer _
) As Integer
```

[C#]

```
public int WriteTo(
   byte[] buffer,
   int length,
   string hostAddress,
   int hostPort
);
```

Parameters

buffer
A byte array that contains the data to be written to the socket.

length
An integer value which specifies the maximum number of bytes of data to write. This value cannot be larger than the size of the buffer specified by the caller.

hostAddress
A string value which specifies the address of the remote host that the data will be sent to. For datagram sockets, this may be any valid Internet address. For stream sockets, this must be the same address that was used to establish the connection.

hostPort
An integer value which specifies the port number of the remote host that the data will be sent to. For datagram sockets, this may be any valid port number. For stream sockets, this must be the same port number that was used to establish the connection.

Return Value

An integer value which specifies the number of bytes actually written to the socket. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **WriteTo** method sends one or more bytes of data to the remote host. If there is enough room in the socket's internal send buffer to accommodate all of the data, it is copied to the send buffer and control immediately returns to the caller. If amount of data exceeds the available buffer space and the socket is in blocking mode, then the method will block until the data can be sent. If the socket is in non-blocking mode and the send buffer is full, an error will occur.

This method is typically used when writing binary data to a datagram socket.

   int length,
   string hostAddress,
   int hostPort
);
```

Parameters

buffer

A string that contains the data to be written to the socket.

length

An integer value which specifies the maximum number of characters to write. This value cannot be larger than the length of the string specified by the caller.

hostAddress

A string value which specifies the address of the remote host that the data will be sent to. For datagram sockets, this may be any valid Internet address. For stream sockets, this must be the same address that was used to establish the connection.

hostPort

An integer value which specifies the port number of the remote host that the data will be sent to. For datagram sockets, this may be any valid port number. For stream sockets, this must be the same port number that was used to establish the connection.

Return Value

An integer value which specifies the number of bytes actually written to the socket. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **WriteTo** method sends a string of characters to the remote host. If there is enough room in the socket's internal send buffer to accommodate all of the data, it is copied to the send buffer and control immediately returns to the caller. If amount of data exceeds the available buffer space and the socket is in blocking mode, then the method will block until the data can be sent. If the socket is in non-blocking mode and the send buffer is full, an error will occur.

This method is typically used when writing text data to a datagram socket.

SocketWrench Class | SocketTools Namespace | SocketWrench.WriteTo Overload List

SocketWrench.WriteTo Method (String, String, Int32)

Write a string of characters to the socket.

[Visual Basic]

```
Overloads Public Function WriteTo( _
   ByVal buffer As String, _
   ByVal hostAddress As String, _
   ByVal hostPort As Integer _
) As Integer
```

[C#]

```
public int WriteTo(
   string buffer,
   string hostAddress,
   int hostPort
);
```

Parameters

buffer
A string that contains the data to be written to the socket.

hostAddress
A string value which specifies the address of the remote host that the data will be sent to. For datagram sockets, this may be any valid Internet address. For stream sockets, this must be the same address that was used to establish the connection.

hostPort
An integer value which specifies the port number of the remote host that the data will be sent to. For datagram sockets, this may be any valid port number. For stream sockets, this must be the same port number that was used to establish the connection.

Return Value

An integer value which specifies the number of bytes actually written to the socket. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **WriteTo** method sends a string of characters to the remote host. If there is enough room in the socket's internal send buffer to accommodate all of the data, it is copied to the send buffer and control immediately returns to the caller. If amount of data exceeds the available buffer space and the socket is in blocking mode, then the method will block until the data can be sent. If the socket is in non-blocking mode and the send buffer is full, an error will occur.

This method is typically used when writing text data to a datagram socket.

SocketWrench Events

The events of the **SocketWrench** class are listed below. For a complete list of **SocketWrench** class members, see the SocketWrench Members topic.

Public Instance Events

⚡ OnAccept	Occurs when a remote host attempts to establish a connection with the local system.
⚡ OnCancel	Occurs when a blocking socket operation is canceled.
⚡ OnConnect	Occurs when a connection is established with the remote host.
⚡ OnDisconnect	Occurs when the remote host disconnects from the local system.
⚡ OnError	Occurs when an socket operation fails.
⚡ OnProgress	Occurs as a data stream is being read or written to the socket.
⚡ OnRead	Occurs when data is available to be read from the socket.
⚡ OnTimeout	Occurs when a blocking operation fails to complete before the timeout period elapses.
⚡ OnWrite	Occurs when data can be written to the socket.

SocketWrench Class | SocketTools Namespace

SocketWrench.OnAccept Event

Occurs when a remote host attempts to establish a connection with the local system.

[Visual Basic]

```
Public Event OnAccept As OnAcceptEventHandler
```

[C#]

```
public event OnAcceptEventHandler OnAccept;
```

Event Data

The event handler receives an argument of type SocketWrench.AcceptEventArgs containing data related to this event. The following **SocketWrench.AcceptEventArgs** property provides information specific to this event.

Property	Description
Handle	Gets a value that specifies the socket handle for the listening server.

Remarks

The **OnAccept** event occurs when a remote host attempts to connect to the local system. A connection is not actually established until it has been accepted by the listening server. To accept the connection, the application must call the **Accept** method.

The **PeerAddress** or **PeerName** properties may be used to determine the Internet address and host name of the remote host that is establishing the connection. Note that this information may not be available until after the **Accept** method is called to accept the connection.

This event is only generated if the socket is in non-blocking mode.

See Also

SocketWrench Class | SocketTools Namespace

SocketWrench.AcceptEventArgs Class

Provides data for the OnAccept event.

For a list of all members of this type, see SocketWrench.AcceptEventArgs Members.

System.Object
  System.EventArgs
    SocketTools.SocketWrench.AcceptEventArgs

[Visual Basic]
```
Public Class SocketWrench.AcceptEventArgs
    Inherits EventArgs
```

[C#]
```
public class SocketWrench.AcceptEventArgs : EventArgs
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

AcceptEventArgs specifies the socket handle for the server that should accept the incoming client connection.

The OnAccept event occurs when a remote host attempts to establish a connection with the local system.

Requirements

Namespace: SocketTools

Assembly: SocketTools.SocketWrench (in SocketTools.SocketWrench.dll)

SocketWrench.AcceptEventArgs overview

Public Instance Constructors

SocketWrench.AcceptEventArgs Constructor	Initializes a new instance of the SocketWrench.AcceptEventArgs class.

Public Instance Properties

Handle	Gets a value that specifies the socket handle for the listening server.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString (inherited from Object)	Returns a String that represents the current Object.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

SocketWrench.AcceptEventArgs Class | SocketTools Namespace

SocketWrench.AcceptEventArgs Constructor

Initializes a new instance of the SocketWrench.AcceptEventArgs class.

[Visual Basic]

```
Public Sub New()
```

[C#]

```
public SocketWrench.AcceptEventArgs();
```

See Also

SocketWrench.AcceptEventArgs Class | SocketTools Namespace

SocketWrench.AcceptEventArgs Properties

The properties of the **SocketWrench.AcceptEventArgs** class are listed below. For a complete list of **SocketWrench.AcceptEventArgs** class members, see the SocketWrench.AcceptEventArgs Members topic.

Public Instance Properties

Handle	Gets a value that specifies the socket handle for the listening server.

See Also

SocketWrench.AcceptEventArgs Class | SocketTools Namespace

SocketWrench.AcceptEventArgs.Handle Property

Gets a value that specifies the socket handle for the listening server.

[Visual Basic]

```
Public ReadOnly Property Handle As Integer
```

[C#]

```
public int Handle {get;}
```

Property Value

An integer value which specifies the server socket handle.

See Also

SocketWrench.AcceptEventArgs Class | SocketTools Namespace

SocketWrench.OnCancel Event

Occurs when a blocking socket operation is canceled.

[Visual Basic]

```
Public Event OnCancel As EventHandler
```

[C#]

```
public event EventHandler OnCancel;
```

Remarks

The **OnCancel** event is generated when a blocking socket operation, such as sending or receiving data, is canceled with the **Cancel** method. To assist in determining which operation was canceled, check the value of the **Status** property.

See Also

SocketWrench Class | SocketTools Namespace

SocketWrench.OnConnect Event

Occurs when a connection is established with the remote host.

[Visual Basic]

```
Public Event OnConnect As EventHandler
```

[C#]

```
public event EventHandler OnConnect;
```

Remarks

The **OnConnect** event occurs when a connection is made with a remote host as a result of a **Connect** method call. When the **Connect** method is called and the **Blocking** property is set to **false**, a socket is created but the connection is not actually established until after this event occurs. Between the time connection process is started and this event fires, no operation may be performed on the socket other than calling the **Disconnect** method.

This event is only generated if the socket is in non-blocking mode.

See Also

SocketWrench Class | SocketTools Namespace

SocketWrench.OnDisconnect Event

Occurs when the remote host disconnects from the local system.

[Visual Basic]

```
Public Event OnDisconnect As EventHandler
```

[C#]

```
public event EventHandler OnDisconnect;
```

Remarks

The **OnDisconnect** event occurs when the remote host closes its socket, terminating its connection with the application. Because there may still be data in the socket receive buffers, you should continue to read data from the socket until the **Read** method returns a value of 0. Once all of the data has been read, you should call the **Disconnect** method to close the local socket and terminate the session.

This event is only generated if the socket is in non-blocking mode.

See Also

SocketWrench Class | SocketTools Namespace

SocketWrench.OnError Event

Occurs when an socket operation fails.

[Visual Basic]

```
Public Event OnError As OnErrorEventHandler
```

[C#]

```
public event OnErrorEventHandler OnError;
```

Event Data

The event handler receives an argument of type SocketWrench.ErrorEventArgs containing data related to this event. The following **SocketWrench.ErrorEventArgs** properties provide information specific to this event.

Property	Description
Description	Gets a value which describes the last error that has occurred.
Error	Gets a value which specifies the last error that has occurred.

Remarks

The **OnError** event occurs when a socket operation fails.

See Also

SocketWrench Class | SocketTools Namespace

SocketWrench.ErrorEventArgs Class

Provides data for the OnError event.

For a list of all members of this type, see SocketWrench.ErrorEventArgs Members.

System.Object
  System.EventArgs
    SocketTools.SocketWrench.ErrorEventArgs

[Visual Basic]
```
Public Class SocketWrench.ErrorEventArgs
    Inherits EventArgs
```

[C#]
```
public class SocketWrench.ErrorEventArgs : EventArgs
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

ErrorEventArgs specifies the numeric error code and a description of the error that has occurred.

An OnError event occurs when a method fails.

Requirements

Namespace: SocketTools

Assembly: SocketTools.SocketWrench (in SocketTools.SocketWrench.dll)

The properties of the **SocketWrench.ErrorEventArgs** class are listed below. For a complete list of **SocketWrench.ErrorEventArgs** class members, see the SocketWrench.ErrorEventArgs Members topic.

Public Instance Properties

Description	Gets a value which describes the last error that has occurred.
Error	Gets a value which specifies the last error that has occurred.

See Also

SocketWrench.ErrorEventArgs Class | SocketTools Namespace

SocketWrench.ErrorEventArgs.Description Property

Gets a value which describes the last error that has occurred.

[Visual Basic]

```
Public ReadOnly Property Description As String
```

[C#]

```
public string Description {get;}
```

Property Value

A string which describes the last error that has occurred.

See Also

SocketWrench.ErrorEventArgs Class | SocketTools Namespace | Error Property

SocketWrench.ErrorEventArgs.Error Property

Gets a value which specifies the last error that has occurred.

[Visual Basic]

```
Public ReadOnly Property Error As ErrorCode
```

[C#]

```
public SocketWrench.ErrorCode Error {get;}
```

Property Value

ErrorCode enumeration which specifies the error.

See Also

SocketWrench.ErrorEventArgs Class | SocketTools Namespace | Description Property

SocketWrench.OnProgress Event

Occurs as a data stream is being read or written to the socket.

[Visual Basic]

```
Public Event OnProgress As OnProgressEventHandler
```

[C#]

```
public event OnProgressEventHandler OnProgress;
```

Event Data

The event handler receives an argument of type SocketWrench.ProgressEventArgs containing data related to this event. The following **SocketWrench.ProgressEventArgs** properties provide information specific to this event.

Property	Description
BytesCopied	Gets a value which specifies the number of bytes of data that has been read or written.
BytesTotal	Gets a value which specifies the total number of bytes in the data stream.
Percent	Gets a value which specifies the percentage of data that has been read or written.

Remarks

The **OnProgress** event occurs as a data stream is being read or written to the socket. If large amounts of data are being read or written, this event can be used to update a progress bar or other user-interface component to provide the user with some visual feedback on the progress of the operation.

This event is only generated when the **ReadStream**, **WriteStream** or **StoreStream** methods are called.

See Also

SocketWrench Class | SocketTools Namespace

SocketWrench.ProgressEventArgs Class

Provides data for the OnProgress event.

For a list of all members of this type, see SocketWrench.ProgressEventArgs Members.

System.Object
  System.EventArgs
    SocketTools.SocketWrench.ProgressEventArgs

[Visual Basic]
```
Public Class SocketWrench.ProgressEventArgs
    Inherits EventArgs
```

[C#]
```
public class SocketWrench.ProgressEventArgs : EventArgs
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

ProgressEventArgs specifies the number of bytes copied from the data stream, the total number of bytes in the data stream and a completion percentage.

The OnProgress event occurs as a data stream is being read or written to the socket. This event only occurs when the **ReadStream**, **WriteStream** or **StoreStream** methods are called.

Requirements

Namespace: SocketTools

Assembly: SocketTools.SocketWrench (in SocketTools.SocketWrench.dll)

SocketWrench.ProgressEventArgs Properties

The properties of the **SocketWrench.ProgressEventArgs** class are listed below. For a complete list of **SocketWrench.ProgressEventArgs** class members, see the SocketWrench.ProgressEventArgs Members topic.

Public Instance Properties

BytesCopied	Gets a value which specifies the number of bytes of data that has been read or written.
BytesTotal	Gets a value which specifies the total number of bytes in the data stream.
Percent	Gets a value which specifies the percentage of data that has been read or written.

See Also

SocketWrench.ProgressEventArgs Class | SocketTools Namespace

SocketWrench.ProgressEventArgs.BytesCopied Property

Gets a value which specifies the number of bytes of data that has been read or written.

[Visual Basic]

```
Public ReadOnly Property BytesCopied As Integer
```

[C#]

```
public int BytesCopied {get;}
```

Property Value

An integer value which specifies the number of bytes of data.

Remarks

The **BytesCopied** property specifies the number of bytes that have been read from the socket and stored in the local stream buffer, or written from the stream buffer to the socket.

See Also

SocketWrench.ProgressEventArgs Class | SocketTools Namespace | BytesTotal Property | Percent Property

SocketWrench.ProgressEventArgs.BytesTotal Property

Gets a value which specifies the total number of bytes in the data stream.

[Visual Basic]

```
Public ReadOnly Property BytesTotal As Integer
```

[C#]

```
public int BytesTotal {get;}
```

Property Value

An integer value which specifies the number of bytes of data.

Remarks

The **BytesTotal** property specifies the total amount of data being read from the socket and stored in the data stream, or written from the data stream to the socket. If the amount of data was unknown or unspecified at the time the method call was made, then this value will always be the same as the **BytesCopied** property.

See Also

SocketWrench.ProgressEventArgs Class | SocketTools Namespace | BytesCopied Property | Percent Property

SocketWrench.ProgressEventArgs.Percent Property

Gets a value which specifies the percentage of data that has been read or written.

[Visual Basic]

```
Public ReadOnly Property Percent As Integer
```

[C#]

```
public int Percent {get;}
```

Property Value

An integer value which specifies a percentage.

Remarks

The **Percent** property specifies the percentage of data that has been transmitted, expressed as an integer value between 0 and 100, inclusive. If the maximum size of the data stream was not specified by the caller, this value will always be 100.

See Also

SocketWrench.ProgressEventArgs Class | SocketTools Namespace | BytesCopied Property | BytesTotal Property

SocketWrench.OnRead Event

Occurs when data is available to be read from the socket.

[Visual Basic]
```
Public Event OnRead As EventHandler
```

[C#]
```
public event EventHandler OnRead;
```

Remarks

The **OnRead** event occurs when data is available to be read from the socket. This event is level-triggered, which means that once this event fires, it will not occur again until some data has been read from the socket. This design prevents an application from being flooded with event notifications. It is recommended that your application read all of the available data from the socket and store it in a local buffer for processing. See the example below.

This event is only generated if the socket is in non-blocking mode.

Example

```
Private Sub Socket_OnRead(ByVal sender As Object, ByVal e As System.EventArgs)
Handles Socket.OnRead
    Dim strBuffer As String
    Dim nRead As Integer

    Do
        ' Read up to m_nBufferSize bytes of data from the socket
        nRead = Socket.Read(strBuffer, m_nBufferSize)

        If nRead > 0 Then
            ' Append the data to an internal buffer for processing
            m_dataBuffer = m_dataBuffer + strBuffer
        End If
    Loop Until nRead < 1

    ProcessData()
End Sub
```

See Also

SocketWrench Class | SocketTools Namespace

SocketWrench.OnTimeout Event

Occurs when a blocking operation fails to complete before the timeout period elapses.

[Visual Basic]

```
Public Event OnTimeout As EventHandler
```

[C#]

```
public event EventHandler OnTimeout;
```

Remarks

The **OnTimeout** event occurs when a blocking operation, such as sending or receiving data on the socket, fails to complete before the specified timeout period elapses. The timeout period for a blocking operation can be adjusted by setting the **Timeout** property.

This event is only generated if the socket is in blocking mode.

See Also

SocketWrench Class | SocketTools Namespace

SocketWrench.OnWrite Event

Occurs when data can be written to the socket.

[Visual Basic]

```
Public Event OnWrite As EventHandler
```

[C#]

```
public event EventHandler OnWrite;
```

Remarks

The **OnWrite** event occurs when the application can write data to the socket. This event will typically occur when a connection is first established with the remote host, and after the **Write** method has failed because there was insufficient memory available in the socket send buffers. In the second case, when some of the buffered data has been successfully sent to the remote host and there is space available in the send buffers, this event is used to signal the application that it may attempt to send more data.

This event is only generated if the socket is in non-blocking mode.

See Also

SocketWrench Class | SocketTools Namespace

SocketWrench.ErrorCode Enumeration

Specifies the error codes returned by the SocketWrench class.

[Visual Basic]

```
Public Enum SocketWrench.ErrorCode
```

[C#]

```
public enum SocketWrench.ErrorCode
```

Remarks

The SocketWrench class uses the **ErrorCode** enumeration to specify what error has occurred when a method fails. The current error code may be determined by checking the value of the **LastError** property.

Note that the last error code is only meaningful if the previous operation has failed.

Members

Member Name	Description
errorNone	No error.
errorNotHandleOwner	Handle not owned by the current thread.
errorFileNotFound	The specified file or directory does not exist.
errorFileNotCreated	The specified file could not be created.
errorOperationCanceled	The blocking operation has been canceled.
errorInvalidFileType	The specified file is a block or character device, not a regular file.
errorInvalidDevice	The specified file type is invalid or not a regular file.
errorTooManyParameters	The maximum number of function parameters has been exceeded.
errorInvalidFileName	The specified file name contains invalid characters or is too long.
errorInvalidFileHandle	Invalid file handle passed to function.
errorFileReadFailed	Unable to read data from the specified file.
errorFileWriteFailed	Unable to write data to the specified file.
errorOutOfMemory	Out of memory.
errorAccessDenied	Access denied.
errorInvalidParameter	Invalid argument passed to function.
errorClipboardUnavailable	The system clipboard is currently unavailable.
errorClipboardEmpty	The system clipboard is empty or does not contain any text data.
errorFileEmpty	The specified file does not contain any data.
errorFileExists	The specified file already exists.

errorEndOfFile	End of file.
errorDeviceNotFound	The specified device could not be found.
errorDirectoryNotFound	The specified directory could not be found.
errorInvalidBuffer	Invalid memory address passed to function.
errorBufferTooSmall	The specified buffer is not large enough to contain the data.
errorNoHandles	No more handles are available to this process.
errorOperationWouldBlock	The specified operation would block the current thread.
errorOperationInProgress	A blocking operation is currently in progress.
errorAlreadyInProgress	The specified operation is already in progress.
errorInvalidHandle	Invalid handle passed to function.
errorInvalidAddress	Invalid network address specified.
errorInvalidSize	Datagram is too large to fit in specified buffer.
errorInvalidProtocol	Invalid network protocol specified.
errorProtocolNotAvailable	The specified network protocol is not available.
errorProtocolNotSupported	The specified protocol is not supported.
errorSocketNotSupported	The specified socket type is not supported.
errorInvalidOption	The specified option is invalid.
errorProtocolFamily	Specified protocol family is not supported.
errorProtocolAddress	The specified address is invalid for this protocol family.
errorAddressInUse	The specified address is in use by another process.
errorAddressUnavailable	The specified address cannot be assigned.
errorNetworkUnavailable	The networking subsystem is unavailable.
errorNetworkUnreachable	The specified network is unreachable.
errorNetworkReset	Network dropped connection on remote reset.
errorConnectionAborted	Connection was aborted due to timeout or other failure.
errorConnectionReset	Connection was reset by remote network.
errorOutOfBuffers	No buffer space is available.
errorAlreadyConnected	Connection already established with remote host.
errorNotConnected	No connection established with remote host.
errorConnectionShutdown	Unable to send or receive data after connection shutdown.
errorOperationTimeout	The specified operation has timed out.
errorConnectionRefused	The connection has been refused by the remote host.

errorHostUnavailable	The specified host is unavailable.
errorHostUnreachable	Remote host is unreachable.
errorTooManyProcesses	Too many processes are using the networking subsystem.
errorTooManyThreads	Too many threads have been created by the current process.
errorTooManySessions	Too many client sessions have been created by the current process.
errorInternalFailure	An unexpected internal error has occurred.
errorNetworkNotReady	Network subsystem is not ready for communication.
errorInvalidVersion	This version of the operating system is not supported.
errorNetworkNotInitialized	The networking subsystem has not been initialized.
errorRemoteShutdown	The remote host has initiated a graceful shutdown sequence.
errorInvalidHostName	The specified hostname is invalid or could not be resolved.
errorHostNameNotFound	The specified hostname could not be found.
errorHostNameRefused	Unable to resolve hostname, request refused.
errorHostNameNotResolved	Unable to resolve hostname, no address for specified host.
errorInvalidLicense	The license for this product is invalid.
errorProductNotLicensed	This product is not licensed to perform this operation.
errorNotImplemented	This function has not been implemented on this platform.
errorUnknownLocalhost	Unable to determine local host name.
errorInvalidHostAddress	Invalid host address specified.
errorInvalidServicePort	Invalid service port number specified.
errorInvalidServiceName	Invalid or unknown service name specified.
errorInvalidEventId	Invalid event identifier specified.
errorOperationNotBlocking	No blocking operation in progress on this socket.
errorSecurityNotInitialized	Unable to initialize security interface for this process.
errorSecurityContext	Unable to establish security context for this session.
errorSecurityCredentials	Unable to open certificate store or establish security credentials.
errorSecurityCertificate	Unable to validate the certificate chain for this

	session.
errorSecurityDecryption	Unable to decrypt data stream.
errorSecurityEncryption	Unable to encrypt data stream.

SocketTools Namespace

SocketWrench.SecureKeyAlgorithm Enumeration

Specifies the key exchange algorithms that the SocketWrench class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]
```
<Flags>
Public Enum SocketWrench.SecureKeyAlgorithm
```

[C#]
```
[Flags]
public enum SocketWrench.SecureKeyAlgorithm
```

Remarks

The SocketWrench class uses the **SecureKeyAlgorithm** enumeration to identify the key exchange algorithm that was selected when a secure connection was established with the remote host.

Members

Member Name	Description	Value
keyExchangeNone	No key exchange algorithm has been selected. This is not a secure connection with the server.	0
keyExchangeRSA	The RSA public key exchange algorithm has been selected.	1
keyExchangeKEA	The KEA public key exchange algorithm has been selected. This is an improved version of the Diffie-Hellman public key algorithm.	2
keyExchangeDH	The Diffie-Hellman public key exchange algorithm has been selected.	4
keyExchangeECDH	The Elliptic Curve Diffie-Hellman key exchange algorithm was selected. This is a variant of the Diffie-Hellman algorithm which uses elliptic curve cryptography. This key exchange algorithm is only supported on Windows XP SP3 SP3 and later versions of the operating system.	8

Requirements

Namespace: SocketTools

Assembly: SocketTools.SocketWrench (in SocketTools.SocketWrench.dll)

SocketTools Namespace

SocketWrench.SecureCipherAlgorithm Enumeration

Specifies the encryption algorithms that the SocketWrench class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]
```
<Flags>
Public Enum SocketWrench.SecureCipherAlgorithm
```

[C#]
```
[Flags]
public enum SocketWrench.SecureCipherAlgorithm
```

Remarks

The SocketWrench class uses the **SecureCipherAlgorithm** enumeration to identify which encryption algorithm was selected when a secure connection was established with the remote host.

Members

Member Name	Description	Value
cipherNone	No cipher has been selected. A secure connection has not been established with the remote host.	0
cipherRC2	The RC2 block cipher was selected. This is a variable key length cipher which supports keys between 40- and 128-bits in length, in 8-bit increments.	1
cipherRC4	The RC4 stream cipher was selected. This is a variable key length cipher which supports keys between 40- and 128-bits in length, in 8-bit increments.	2
cipherRC5	The RC5 block cipher was selected. This is a variable key length cipher which supports keys up to 2040 bits, in 8-bit increments.	4
cipherDES	The DES (Data Encryption Standard) block cipher was selected. This is a fixed key length cipher using 56-bit keys.	8
cipherDES3	The Triple DES block cipher was selected. This cipher encrypts the data three times using different keys, effectively using a 168-bit key length.	16
cipherDESX	A variant of the DES block cipher which XORs an extra 64-bits of the key before and after the plaintext has been encrypted, increasing the key size to 184 bits.	32
cipherAES	The Advanced Encryption Standard	64

	cipher (also known as the Rijndael cipher) is a fixed block size cipher which use a key size of 128, 192 or 256 bits. This cipher is supported on Windows XP SP3 SP3 and later versions of the operating system.	
cipherSkipjack	The Skipjack block cipher was selected. This is a fixed key length cipher, using 80-bit keys.	128

SocketTools Namespace

SocketWrench.SecureHashAlgorithm Enumeration

Specifies the hash algorithms that the SocketWrench class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

```
[Visual Basic]
<Flags>
Public Enum SocketWrench.SecureHashAlgorithm
```

```
[C#]
[Flags]
public enum SocketWrench.SecureHashAlgorithm
```

Remarks

The SocketWrench class uses the **SecureHashAlgorithm** enumeration to identify the message digest (hash) algorithm that was selected when a secure connection was established with the remote host.

Members

Member Name	Description	Value
hashNone	No hash algorithm has been selected. This is not a secure connection with the server.	0
hashMD5	The MD5 algorithm was selected. This algorithm produces a 128-bit message digest. This algorithm is no longer considered to be cryptographically secure.	1
hashSHA	The SHA-1 algorithm was selected. This algorithm produces a 160-bit message digest. This algorithm is no longer considered to be cryptographically secure.	2
hashSHA256	The SHA-256 algorithm was selected. This algorithm produces a 256-bit message digest.	4
hashSHA384	The SHA-384 algorithm was selected. This algorithm produces a 384-bit message digest.	8
hashSHA512	The SHA-512 algorithm was selected. This algorithm produces a 512-bit message digest.	16

Requirements

Namespace: SocketTools

SocketTools Namespace

SocketWrench.SecurityCertificate Enumeration

Specifies the security certificate status values that may be returned by the SocketWrench class.

[Visual Basic]

```
Public Enum SocketWrench.SecurityCertificate
```

[C#]

```
public enum SocketWrench.SecurityCertificate
```

Remarks

The SocketWrench class uses the **SecurityCertificate** enumeration to identify the current status of the certificate that was provided by the remote host when a secure connection was established.

Members

Member Name	Description
certificateNone	No certificate information is available. A secure connection was not established with the server.
certificateValid	The certificate is valid.
certificateNoMatch	The certificate is valid, however the domain name specified in the certificate does not match the domain name of the remote host. The application can examine the **CertificateSubject** property to determine the site the certificate was issued to.
certificateExpired	The certificate has expired and is no longer valid. The application can examine the **CertificateExpires** property to determine when the certificate expired.
certificateRevoked	The certificate has been revoked and is no longer valid. It is recommended that the application immediately terminate the connection if this status is returned.
certificateUntrusted	The certificate has not been issued by a trusted authority, or the certificate is not trusted on the local host. It is recommended that the application immediately terminate the connection if this status is returned.
certificateInvalid	The certificate is invalid. This typically indicates that the internal structure of the certificate is damaged. It is recommended that the application immediately terminate the connection if this status is returned.

SocketWrench.SecurityProtocols Enumeration

Specifies the security protocols that the SocketWrench class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]
```
<Flags>
Public Enum SocketWrench.SecurityProtocols
```

[C#]
```
[Flags]
public enum SocketWrench.SecurityProtocols
```

Remarks

The SocketWrench class uses the **SecurityProtocols** enumeration to specify one or more security protocols to be used when establishing a connection with a remote host. Multiple protocols may be specified if necessary and the actual protocol used will be negotiated with the remote host. It is recommended that most applications use **protocolDefault** when creating a secure connection.

Members

Member Name	Description	Value
protocolNone	No security protocol will be used, a secure connection will not be established.	0
protocolSSL2	The SSL 2.0 protocol has been selected. This protocol has been deprecated and is no longer widely used. It is not recommended that this protocol be used when establishing secure connections.	1
protocolSSL3	The SSL 3.0 protocol has been selected. This protocol has been deprecated and is no longer widely used. It is not recommended that this protocol be used when establishing secure connections. In most cases, this protocol is only selected if TLS is not supported by the server.	2
protocolTLS10	The TLS 1.0 protocol has been selected. This version of the protocol is commonly used by older servers and is the only version of TLS supported on Windows platforms prior to Windows 7 SP1 and Windows Server 2008 R2.	4
protocolTLS11	The TLS 1.1 protocol has been selected. This version of TLS is supported on Windows 7 SP1 and Windows Server 2008 R2 and later versions of the	8

	operating system.	
protocolTLS12	The TLS 1.2 protocol has been selected. This is the default version of the protocol and is supported on Windows 7 SP1 and Windows Server 2008 R2 and later versions of Windows. It is recommended that you use this version of TLS.	16
protocolSSL	Any version of the Secure Sockets Layer (SSL) protocol should be used. The actual protocol version used will be negotiated with the remote host.	3
protocolTLS	Any version of the the Transport Layer Security (TLS) protocol should be used. The actual protocol version used will be negotiated with the remote host, with with preference for TLS 1.2.	28
protocolTLS1	Version 1.0, 1.1 or 1.2 of the the Transport Layer Security (TLS) protocol should be used. The actual protocol version used will be negotiated with the remote host, with preference for TLS 1.2.	28
protocolDefault	The default selection of security protocols will be used when establishing a connection. The TLS 1.2, 1.1 and 1.0 protocols will be negotiated with the host, in that order of preference. This option will always request the latest version of the preferred security protocols and is the recommended value.	16
protocolUnknown	An unknown or unsupported security protocol has been specified. This value indicates an error condition.	4096

SocketWrench.ShutdownOptions Enumeration

Specifies the shutdown options that the SocketWrench class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]

```
<Flags>
Public Enum SocketWrench.ShutdownOptions
```

[C#]

```
[Flags]
public enum SocketWrench.ShutdownOptions
```

Remarks

The SocketWrench class uses the **ShutdownOptions** enumeration to specify how reading and writing on the socket should be handled when the **Shutdown** method is called.

Members

Member Name	Description	Value
shutdownRead	Disable any further reading of data. The application will be able to continue to send data. The remote host will see this as the connection being closed.	0
shutdownWrite	Disable any further sending of data. The application will be able to continue to read data until the remote host closes the connection.	1
shutdownReadWrite	Disable any further reading or writing to the socket. The remote host will see this as the connection being closed.	2

Requirements

Namespace: SocketTools

Assembly: SocketTools.SocketWrench (in SocketTools.SocketWrench.dll)

SocketTools Namespace

SocketWrench.SocketByteOrder Enumeration

Specifies the byte-order in which integer data may exchanged with a remote host.

[Visual Basic]

```
Public Enum SocketWrench.SocketByteOrder
```

[C#]

```
public enum SocketWrench.SocketByteOrder
```

Remarks

The byte-order is used to specify how 16-bit (short) integer and 32-bit (long) integer data is written to and read from the socket.

Members

Member Name	Description
byteOrderNative	Integer data will be sent and received using the native byte order.
byteOrderNetwork	Integer data will be sent and received using network byte order.

Requirements

Namespace: SocketTools

Assembly: SocketTools.SocketWrench (in SocketTools.SocketWrench.dll)

SocketTools Namespace

SocketWrench.SocketOptions Enumeration

Specifies the options that the SocketWrench class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]
```
<Flags>
Public Enum SocketWrench.SocketOptions
```

[C#]
```
[Flags]
public enum SocketWrench.SocketOptions
```

Remarks

The SocketWrench class uses the **SocketOptions** enumeration to specify one or more options to be used when establishing a connection with a remote host. Multiple options may be specified if necessary.

Members

Member Name	Description	Value
optionNone	No option specified.	0
optionBroadcast	This option specifies that broadcasting should be enabled for datagrams. This option is invalid for stream sockets.	1
optionDontRoute	This option specifies default routing should not be used. This option should not be specified unless absolutely necessary.	2
optionKeepAlive	This option specifies that packets are to be sent to the remote system when no data is being exchanged to keep the connection active. This option is only valid for stream sockets.	4
optionReuseAddress	This option specifies the local address can be reused. This option is commonly used by server applications.	8
optionNoDelay	This option disables the Nagle algorithm, which buffers unacknowledged data and insures that a full-size packet can be sent to the remote host.	16
optionInLine	This option specifies that out-of-band data should be received inline with the standard data stream. This option is only valid for stream sockets.	32
optionTrustedSite	This option specifies the sever should be trusted. The server certificate will not be validated and the connection will always	2048

	be permitted. This option only affects secure client connections.	
optionSecure	This option specifies that a secure, encrypted connection will be established with the remote host.	4096
optionSecureFallback	This option specifies the class should permit the use of less secure cipher suites for compatibility with legacy clients and servers. If this option is specified, it will enable connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.	32768
optionPreferIPv6	This option specifies the client should prefer the use of IPv6 if the remote hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.	262144
optionFreeThread	This option specifies that class methods may be called from any thread, and not only the thread that established the connection. Using this option disables certain internal safety checks that are made by the class and may result in unexpected behavior unless you ensure that access to the class instance is synchronized across multiple threads.	524288

Requirements

Namespace: SocketTools

Assembly: SocketTools.SocketWrench (in SocketTools.SocketWrench.dll)

SocketTools Namespace

SocketWrench.SocketProtocol Enumeration

Specifies the protocols that the SocketWrench class supports.

[Visual Basic]
```
Public Enum SocketWrench.SocketProtocol
```

[C#]
```
public enum SocketWrench.SocketProtocol
```

Remarks

The SocketWrench class uses the **SocketProtocol** enumeration to specify which network protocol will be used when a socket is created. The default protocol used by the class is **socketStream**.

Members

Member Name	Description
socketStream	Transmission Control Protocol (TCP). This protocol should be used with stream sockets, where data is sent and received as an arbitrary stream of bytes.
socketDatagram	User Datagram Protocol (UDP). This protocol should be used with datagram sockets, where data is sent and received in discrete packets.
socketRaw	Raw sockets. This socket type is for special purpose applications which need access to the IP datagram.

Requirements

Namespace: SocketTools

Assembly: SocketTools.SocketWrench (in SocketTools.SocketWrench.dll)

See Also

SocketTools Namespace

SocketWrench.SocketStatus Enumeration

Specifies the status values that may be returned by the SocketWrench class.

[Visual Basic]
```
Public Enum SocketWrench.SocketStatus
```

[C#]
```
public enum SocketWrench.SocketStatus
```

Remarks

The SocketWrench class uses the **SocketStatus** enumeration to identify the current status of the socket.

Members

Member Name	Description
statusUnused	A socket has not been created. Attempts to perform any network operations, such as sending or receiving data, will generate an error.
statusIdle	A socket has been created, but is not currently in use. A blocking socket operation can be executed at this point.
statusListen	The socket is listening for connections from remote hosts.
statusConnect	The socket is in the process of establishing a connection with a remote host.
statusAccept	The socket is in the process of accepting a connection from a remote client.
statusRead	The socket is in the process of receiving data from a remote host.
statusWrite	The socket is in the process of sending data to a remote host.
statusFlush	The control buffers are in the process of being flushed. Any data in the socket receive buffers will be discarded.
statusDisconnect	The socket is being closed and subsequent attempts to access the socket will result in an error.

Requirements

Namespace: SocketTools

Assembly: SocketTools.SocketWrench (in SocketTools.SocketWrench.dll)

See Also

SocketTools Namespace

SocketWrench.SocketStream Enumeration

Specifies the data stream options that the SocketWrench class supports.

[Visual Basic]

```
Public Enum SocketWrench.SocketStream
```

[C#]

```
public enum SocketWrench.SocketStream
```

Remarks

The SocketWrench class uses the **SocketStream** enumeration to specify how data should be processed when read from a socket using either the **ReadStream** or **StoreStream** methods.

Members

Member Name	Description
streamDefault	The data stream will be returned to the caller unmodified. This option should always be used with binary data or data being stored in a byte array. If no options are specified, this is the default option used by this method.
streamConvert	The data stream is considered to be textual and will be modified so that end-of-line character sequences are converted to follow standard Windows conventions. This will ensure that all lines of text are terminated with a carriage-return and linefeed sequence. Because this option modifies the data stream, it should never be used with binary data. Using this option may result in the amount of data returned in the buffer to be larger than the source data. For example, if the source data only terminates a line of text with a single linefeed, this option will have the effect of inserting a carriage-return character before each linefeed.

Requirements

Namespace: SocketTools

Assembly: SocketTools.SocketWrench (in SocketTools.SocketWrench.dll)

SocketTools Namespace | ReadStream Method | StoreStream Method

SocketWrench.TraceOptions Enumeration

Specifies the logging options that the SocketWrench class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]
```
<Flags>
Public Enum SocketWrench.TraceOptions
```

[C#]
```
[Flags]
public enum SocketWrench.TraceOptions
```

Remarks

The SocketWrench class uses the **TraceOptions** enumeration to specify what kind of debugging information is written to the trace logfile. These options are only meaningful when trace logging is enabled by setting the **Trace** property to **true**.

Members

Member Name	Description	Value
traceDefault	The default trace logging option. This is the same as specifying the **traceInfo** option.	0
traceInfo	All network function calls are written to the trace file. This is the default value.	0
traceError	Only those network function calls which fail are recorded in the trace file.	1
traceWarning	Only those network function calls which fail, or return values which indicate a warning, are recorded in the trace file.	2
traceHexDump	All network function calls are written to the trace file, plus all the data that is sent or received is displayed, in both ASCII and hexadecimal format.	4
traceProcess	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for multithreaded applications that are using worker threads.	4096

Requirements

SocketTools Namespace

SocketWrench.OnAcceptEventHandler Delegate

Represents the method that will handle the OnAccept event.

[Visual Basic]

```
Public Delegate Sub SocketWrench.OnAcceptEventHandler( _
   ByVal sender As Object, _
   ByVal e As AcceptEventArgs _
)
```

[C#]

```
public delegate void SocketWrench.OnAcceptEventHandler(
      object sender,
      AcceptEventArgs e
   );
```

Parameters

sender

The source of the event.

e

An AcceptEventArgs that contains the event data.

Remarks

When you create an **OnAcceptEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnAcceptEventHandler** delegate declaration.

Requirements

Namespace: SocketTools

Assembly: SocketTools.SocketWrench (in SocketTools.SocketWrench.dll)

See Also

SocketTools Namespace | Accept Method | OnAccept Event

SocketWrench.OnErrorEventHandler Delegate

Represents the method that will handle the OnError event.

[Visual Basic]

```
Public Delegate Sub SocketWrench.OnErrorEventHandler( _
   ByVal sender As Object, _
   ByVal e As ErrorEventArgs _
)
```

[C#]

```
public delegate void SocketWrench.OnErrorEventHandler(
      object sender,
      ErrorEventArgs e
   );
```

Parameters

sender

The source of the event.

e

An ErrorEventArgs that contains the event data.

Remarks

When you create an **OnErrorEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnErrorEventHandler** delegate declaration.

Requirements

Namespace: SocketTools

Assembly: SocketTools.SocketWrench (in SocketTools.SocketWrench.dll)

See Also

SocketTools Namespace

SocketWrench.OnProgressEventHandler Delegate

Represents the method that will handle the OnProgress event.

[Visual Basic]

```
Public Delegate Sub SocketWrench.OnProgressEventHandler( _
   ByVal sender As Object, _
   ByVal e As ProgressEventArgs _
)
```

[C#]

```
public delegate void SocketWrench.OnProgressEventHandler(
      object sender,
      ProgressEventArgs e
   );
```

Parameters

sender

The source of the event.

e

A ProgressEventArgs that contains the event data.

Remarks

When you create an **OnProgressEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnProgressEventHandler** delegate declaration.

SocketTools Namespace

SocketWrench.RuntimeLicenseAttribute Class

Attribute that defines the runtime license key for the class.

For a list of all members of this type, see SocketWrench.RuntimeLicenseAttribute Members.

System.Object
  System.Attribute
    SocketTools.SocketWrench.RuntimeLicenseAttribute

[Visual Basic]

```
<AttributeUsage(ValidOn:=AttributeTargets.Assembly, AllowMultiple:=False,
   Inherited:=True)>
Public Class SocketWrench.RuntimeLicenseAttribute
    Inherits Attribute
```

[C#]

```
[AttributeUsage(ValidOn=AttributeTargets.Assembly, AllowMultiple=False,
   Inherited=True)]
public class SocketWrench.RuntimeLicenseAttribute : Attribute
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

The RuntimeLicense attribute is used to define the runtime license key that will be used when an instance of the class is created. This attribute is defined in the assembly information module for the language, such as AssemblyInfo.cs when programming C#. The runtime license key must be defined if you wish to redistribute your application.

The runtime license key for your copy of SocketWrench can be generated using the License Manager utility that is included with the product. Note that if you have installed an evaluation license, you will not have a runtime license key and cannot redistribute any applications which use the SocketWrench class.

Example

```
<Assembly: SocketTools.SocketWrench.RuntimeLicense("abcdefghijklmnop")>
```

```
[assembly: SocketTools.SocketWrench.RuntimeLicense("abcdefghijklmnop")]
```

Requirements

Namespace: SocketTools

Assembly: SocketTools.SocketWrench (in SocketTools.SocketWrench.dll)

SocketWrench.RuntimeLicenseAttribute Members

SocketWrench.RuntimeLicenseAttribute overview

Public Instance Constructors

SocketWrench.RuntimeLicenseAttribute Constructor	Constructor for the RuntimeLicense attribute which defines the runtime license key.

Public Instance Properties

LicenseKey	Returns the value of the runtime license key.
TypeId (inherited from Attribute)	When implemented in a derived class, gets a unique identifier for this Attribute.

Public Instance Methods

Equals (inherited from Attribute)	
GetHashCode (inherited from Attribute)	Returns the hash code for this instance.
GetType (inherited from Object)	Gets the Type of the current instance.
IsDefaultAttribute (inherited from Attribute)	When overridden in a derived class, returns an indication whether the value of this instance is the default value for the derived class.
Match (inherited from Attribute)	When overridden in a derived class, returns a value indicating whether this instance equals a specified object.
ToString (inherited from Object)	Returns a String that represents the current Object.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

SocketWrench.RuntimeLicenseAttribute Class | SocketTools Namespace

SocketWrench.RuntimeLicenseAttribute Constructor

Constructor for the RuntimeLicense attribute which defines the runtime license key.

[Visual Basic]

```
Public Sub New( _
   ByVal licenseKey As String _
)
```

[C#]

```
public SocketWrench.RuntimeLicenseAttribute(
   string licenseKey
);
```

Parameters

licenseKey

A string argument which specifies the runtime license key which will be used to initialize the class library.

Remarks

The runtime license key for your copy of SocketWrench can be generated using the License Manager utility that is included with the product. Note that if you have installed an evaluation license, you will not have a runtime license key and cannot redistribute any applications which use the SocketWrench class.

See Also

SocketWrench.RuntimeLicenseAttribute Class | SocketTools Namespace

SocketWrench.RuntimeLicenseAttribute Properties

The properties of the **SocketWrench.RuntimeLicenseAttribute** class are listed below. For a complete list of **SocketWrench.RuntimeLicenseAttribute** class members, see the SocketWrench.RuntimeLicenseAttribute Members topic.

Public Instance Properties

LicenseKey	Returns the value of the runtime license key.
TypeId (inherited from Attribute)	When implemented in a derived class, gets a unique identifier for this Attribute.

See Also

SocketWrench.RuntimeLicenseAttribute Class | SocketTools Namespace

SocketWrench.RuntimeLicenseAttribute.LicenseKey Property

Returns the value of the runtime license key.

[Visual Basic]

```
Public Property LicenseKey As String
```

[C#]

```
public string LicenseKey {get; set;}
```

Property Value

A string which contains the runtime license key.

See Also

SocketWrench.RuntimeLicenseAttribute Class | SocketTools Namespace

SocketWrenchException Class

The exception that is thrown when a socket error occurs.

For a list of all members of this type, see SocketWrenchException Members.

System.Object
  System.Exception
    System.ApplicationException
      SocketTools.SocketWrenchException

[Visual Basic]

```
Public Class SocketWrenchException
    Inherits ApplicationException
```

[C#]

```
public class SocketWrenchException : ApplicationException
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

A SocketWrenchException is thrown by the SocketWrench class when an error occurs.

The default constructor for the SocketWrenchException class sets the **ErrorCode** property to the last socket error that occurred.

Requirements

Namespace: SocketTools

Assembly: SocketTools.SocketWrench (in SocketTools.SocketWrench.dll)

SocketWrenchException Members | SocketTools Namespace

SocketWrenchException Members

SocketWrenchException overview

Public Instance Constructors

SocketWrenchException	Overloaded. Initializes a new instance of the SocketWrenchException class.

Public Instance Properties

ErrorCode	Gets a value which specifies the error that caused the exception.
HelpLink (inherited from Exception)	Gets or sets a link to the help file associated with this exception.
InnerException (inherited from Exception)	Gets the Exception instance that caused the current exception.
Message	Gets a value which describes the error that caused the exception.
Number	Gets a value which specifies the numeric value of the error that caused the exception.
Source (inherited from Exception)	Gets or sets the name of the application or the object that causes the error.
StackTrace (inherited from Exception)	Gets a string representation of the frames on the call stack at the time the current exception was thrown.
TargetSite (inherited from Exception)	Gets the method that throws the current exception.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetBaseException (inherited from Exception)	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetObjectData (inherited from Exception)	When overridden in a derived class, sets the SerializationInfo with information about the exception.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString	Creates and returns a string representation of the current exception.

Protected Instance Properties

HResult (inherited from Exception)	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

SocketWrenchException Class | SocketTools Namespace

SocketWrenchException Constructor

Initializes a new instance of the SocketWrenchException class with the last network error code.

Overload List

Initializes a new instance of the SocketWrenchException class with the last network error code.

public SocketWrenchException();

Initializes a new instance of the SocketWrenchException class with a specified error number.

public SocketWrenchException(int);

Initializes a new instance of the SocketWrenchException class with a specified error message.

public SocketWrenchException(string);

Initializes a new instance of the SocketWrenchException class with a specified error message and a reference to the inner exception that is the cause of this exception.

public SocketWrenchException(string,Exception);

See Also

SocketWrenchException Class | SocketTools Namespace

SocketWrenchException Constructor ()

Initializes a new instance of the SocketWrenchException class with the last network error code.

[Visual Basic]
```
Overloads Public Sub New()
```

[C#]
```
public SocketWrenchException();
```

Remarks

The ctor constructor sets the **ErrorCode** property to the last socket error that occurred. For more information about the errors that may occur, refer to the SocketWrench.ErrorCode enumeration.

See Also

SocketWrenchException Class | SocketTools Namespace | SocketWrenchException Constructor Overload List

SocketWrenchException Constructor (String)

Initializes a new instance of the SocketWrenchException class with a specified error message.

[Visual Basic]

```
Overloads Public Sub New( _
   ByVal message As String _
)
```

[C#]

```
public SocketWrenchException(
   string message
);
```

Parameters

message

The error message that explains the reason for the exception.

Remarks

The content of the ***message*** parameter is intended to be understood by humans. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

See Also

SocketWrenchException Class | SocketTools Namespace | SocketWrenchException Constructor Overload List

SocketWrenchException Constructor (String, Exception)

Initializes a new instance of the SocketWrenchException class with a specified error message and a reference to the inner exception that is the cause of this exception.

[Visual Basic]

```
Overloads Public Sub New( _
   ByVal message As String, _
   ByVal innerException As Exception _
)
```

[C#]

```
public SocketWrenchException(
   string message,
   Exception innerException
);
```

Parameters

message

The error message that explains the reason for the exception.

innerException

The exception that is the cause of the current exception. If the ***innerException*** parameter is not a null reference, the current exception is raised in a **catch** block that handles the inner exception.

Remarks

The content of the message parameter is intended to be understood by humans. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

An exception that is thrown as a direct result of a previous exception should include a reference to the previous exception in the **InnerException** property. The **InnerException** property returns the same value that is passed into the constructor, or a null reference if the **InnerException** property does not supply the inner exception value to the constructor.

SocketWrenchException Constructor (Int32)

Initializes a new instance of the SocketWrenchException class with a specified error number.

[Visual Basic]

```
Overloads Public Sub New( _
   ByVal code As Integer _
)
```

[C#]

```
public SocketWrenchException(
   int code
);
```

Parameters

code

An integer value which specifies an error code.

Remarks

This constructor sets the **ErrorCode** property to the specified error code. For more information about the errors that may occur, refer to the SocketWrench.ErrorCode enumeration.

See Also

SocketWrenchException Class | SocketTools Namespace | SocketWrenchException Constructor Overload List

SocketWrenchException Properties

The properties of the **SocketWrenchException** class are listed below. For a complete list of **SocketWrenchException** class members, see the SocketWrenchException Members topic.

Public Instance Properties

ErrorCode	Gets a value which specifies the error that caused the exception.
HelpLink (inherited from Exception)	Gets or sets a link to the help file associated with this exception.
InnerException (inherited from Exception)	Gets the Exception instance that caused the current exception.
Message	Gets a value which describes the error that caused the exception.
Number	Gets a value which specifies the numeric value of the error that caused the exception.
Source (inherited from Exception)	Gets or sets the name of the application or the object that causes the error.
StackTrace (inherited from Exception)	Gets a string representation of the frames on the call stack at the time the current exception was thrown.
TargetSite (inherited from Exception)	Gets the method that throws the current exception.

Protected Instance Properties

HResult (inherited from Exception)	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception.

SocketWrenchException Class | SocketTools Namespace

SocketWrenchException.ErrorCode Property

Gets a value which specifies the error that caused the exception.

[Visual Basic]

```
Public ReadOnly Property ErrorCode As ErrorCode
```

[C#]

```
public SocketWrench.ErrorCode ErrorCode {get;}
```

Property Value

Returns a SocketWrench.ErrorCode enumeration value which specifies the error code.

Remarks

The **ErrorCode** property returns the error code that specifies the cause of the exception.

The default constructor for the SocketWrenchException class sets the error code to the last network error that occurred. For more information about the errors that may occur, refer to the SocketWrench.ErrorCode enumeration.

See Also

SocketWrenchException Class | SocketTools Namespace

SocketWrenchException.Message Property

Gets a value which describes the error that caused the exception.

[Visual Basic]

```
Overrides Public ReadOnly Property Message As String
```

[C#]

```
public override string Message {get;}
```

Property Value

A string which describes the error that caused the exception.

Remarks

The **Message** property returns a string which describes the error that caused the exception.

See Also

SocketWrenchException Class | SocketTools Namespace

SocketWrenchException.Number Property

Gets a value which specifies the numeric value of the error that caused the exception.

[Visual Basic]

```
Public ReadOnly Property Number As Integer
```

[C#]

```
public int Number {get;}
```

Property Value

An integer value that specifies the error that caused the exception.

Remarks

The **Number** property returns an integer value which specifies the numeric value of the error that caused the exception. This value is the same as the values returned by the Windows Sockets API. For more information about socket error codes, see the Windows Socket Version 2 API error code documentation in MSDN.

SocketWrenchException Methods

The methods of the **SocketWrenchException** class are listed below. For a complete list of **SocketWrenchException** class members, see the SocketWrenchException Members topic.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetBaseException (inherited from Exception)	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetObjectData (inherited from Exception)	When overridden in a derived class, sets the SerializationInfo with information about the exception.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString	Creates and returns a string representation of the current exception.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

SocketWrenchException Class | SocketTools Namespace

SocketWrenchException.ToString Method

Creates and returns a string representation of the current exception.

[Visual Basic]
```
Overrides Public Function ToString() As String
```

[C#]
```
public override string ToString();
```

Return Value

A string representation of the current exception.

Remarks

The **ToString** method returns a representation of the current exception that is intended to be understood by humans. Where the exception contains culture-sensitive data, the string representation returned by **ToString** is required to take into account the current system culture. Although there are no exact requirements for the format of the returned string, it should attempt to reflect the value of the object as perceived by the user.

This implementation of **ToString** obtains the numeric error code value and a description of the error that caused the current exception. If there is no error message or it is an empty string, then no error message is returned.

This method overrides **ApplicationException.ToString**.

SshClient Class

Implements the Secure Shell protocol.

For a list of all members of this type, see SshClient Members.

System.Object
  SocketTools.SshClient

[Visual Basic]
```
Public Class SshClient
    Implements IDisposable
```

[C#]
```
public class SshClient : IDisposable
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

The Secure Shell (SSH) protocol is used to establish a secure connection with a server which provides a virtual terminal session for a user. Its functionality is similar to how character based consoles and serial terminals work, enabling a user to login to the server, execute commands and interact with applications running on the remote host. The class provides an interface for establishing the connection and handling the standard I/O functions needed by the program.

This class also includes methods which enable a program to easily execute a command on the server and scan the output for specific sequences of characters, making it very simple to write light-weight client interfaces to remote applications. This class can be combined with the **SocketTools.Terminal** component to provide complete terminal emulation services for a standard ANSI or DEC-VT220 terminal.

Requirements

Namespace: SocketTools

Assembly: SocketTools.SshClient (in SocketTools.SshClient.dll)

SshClient Members | SocketTools Namespace

SshClient Members

SshClient overview

Public Static (Shared) Fields

sshPortDefault	A constant value which specifies the default port number.
sshTimeout	A constant value which specifies the default timeout period.

Public Instance Constructors

SshClient Constructor	Initializes a new instance of the SshClient class.

Public Instance Properties

AutoResolve	Gets and sets a value that determines if host names and addresses are automatically resolved.
Blocking	Gets and sets a value which indicates if the client is in blocking mode.
CipherStrength	Gets a value that indicates the length of the key used by the encryption algorithm for a secure connection.
CodePage	Gets and sets the code page used when reading and writing text.
Columns	Gets and sets the number of columns for the virtual terminal session.
Command	Gets and sets the command that will be executed on the server.
ExitCode	Returns the exit code from the command executed on the server.
Fingerprint	Returns a string that uniquely identifies the server.
Handle	Gets a value that specifies the client handle allocated for the current session.
HashStrength	Gets a value which specifies the length of the message digest that was selected for a secure connection.
HostAddress	Gets and sets a value which specifies the Internet address used to establish a connection.
HostName	Gets and sets a value which specifies the host name used to establish a connection.
IsBlocked	Gets a value which indicates if the current thread is performing a blocking client operation.
IsConnected	Gets a value which indicates if a connection to the remote host has been established.

IsInitialized	Gets a value which indicates if the current instance of the class has been initialized successfully.
IsReadable	Gets a value which indicates if there is data available to be read from the socket connection to the server.
IsWritable	Gets a value which indicates if data can be written to the client without blocking.
KeepAlive	Gets and sets a value which determines if the client session should kept active.
LastError	Gets and sets a value which specifies the last error that has occurred.
LastErrorString	Gets a value which describes the last error that has occurred.
LocalAddress	Gets the local Internet address that the client is bound to.
LocalName	Gets a value which specifies the host name for the local system.
LocalPort	Gets the local port number the client is bound to.
NewLine	Gets and sets the end-of-line character sequences sent to the server.
Options	Gets and sets a value which specifies one or more client options.
Password	Gets and sets the password used to authenticate the client session.
PrivateKey	Gets and sets the name of the private key file used to authenticate the client session.
ProxyHost	Gets and sets the hostname or IP address of a proxy server.
ProxyPassword	Gets and sets the password used to authenticate the connection to a proxy server.
ProxyPort	Gets and sets a value that specifies the proxy server port number.
ProxyType	Gets and sets the type of proxy server the client will use to establish a connection.
ProxyUser	Gets and sets the username used to authenticate the connection to a proxy server.
RemotePort	Gets and sets a value which specifies the remote port number.
RemoteService	Gets and sets a value which specifies the remote service.
Rows	Gets and sets the number of rows for the virtual terminal session.

Secure	Gets and sets a value which specifies if a secure connection is established.
SecureCipher	Gets a value that specifies the encryption algorithm used for a secure connection.
SecureHash	Gets a value that specifies the message digest algorithm used for a secure connection.
SecureKeyExchange	Gets a value that specifies the key exchange algorithm used for a secure connection.
SecureProtocol	Gets and sets a value which specifies the protocol used for a secure connection.
Status	Gets a value which specifies the current status of the client.
Terminal	Gets and sets the terminal type used for a remote login session.
ThreadModel	Gets and sets a value which specifies the threading model for the class instance.
ThrowError	Gets and sets a value which specifies if method calls should throw exceptions when an error occurs.
Timeout	Gets and sets a value which specifies a timeout period in seconds.
Trace	Gets and sets a value which indicates if network function logging is enabled.
TraceFile	Gets and sets a value which specifies the name of the logfile.
TraceFlags	Gets and sets a value which specifies the client function tracing flags.
UserName	Gets and sets the username used to authenticate the client session.
Version	Gets a value which returns the current version of the SshClient class library.

Public Instance Methods

AttachThread	Attach an instance of the class to the current thread
Break	Sends a break signal to the remote host.
Cancel	Cancel the current blocking client operation.
Connect	Overloaded. Establish a connection with a remote host.
Control	Send a control message to the server.
Disconnect	Terminate the connection with a remote host.
Dispose	Overloaded. Releases all resources used by

	SshClient.
Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
Execute	Overloaded. Execute a command on the server and return the output.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from Object)	Gets the Type of the current instance.
Initialize	Overloaded. Initialize an instance of the SshClient class.
Peek	Overloaded. Read data returned by the server, but do not remove it from the receive buffer.
Read	Overloaded. Read data from the server and store it in a byte array.
ReadLine	Overloaded. Read up to a line of data from the server and return it in a string buffer.
Reset	Reset the internal state of the object, resetting all properties to their default values.
Search	Overloaded. Search for a specific character sequence in the data stream.
ToString (inherited from Object)	Returns a String that represents the current Object.
Uninitialize	Uninitialize the class library and release any resources allocated for the current thread.
Write	Overloaded. Write one or more bytes of data to the server.
WriteLine	Overloaded. Send a line of text to the server, terminated by a carriage-return and linefeed.

Public Instance Events

OnCancel	Occurs when a blocking client operation is canceled.
OnConnect	Occurs when a connection is established with the remote host.
OnDisconnect	Occurs when the remote host disconnects from the local system.
OnError	Occurs when an client operation fails.
OnRead	Occurs when data is available to be read from the client.
OnTimeout	Occurs when a blocking operation fails to complete before the timeout period elapses.
OnWrite	Occurs when data can be written to the client.

Protected Instance Methods

Dispose	Overloaded. Releases the unmanaged resources allocated by the SshClient class and optionally releases the managed resources.
Finalize	Destroys an instance of the class, releasing the resources allocated for the session and unloading the networking library.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

SshClient Properties

The properties of the **SshClient** class are listed below. For a complete list of **SshClient** class members, see the SshClient Members topic.

Public Instance Properties

AutoResolve	Gets and sets a value that determines if host names and addresses are automatically resolved.
Blocking	Gets and sets a value which indicates if the client is in blocking mode.
CipherStrength	Gets a value that indicates the length of the key used by the encryption algorithm for a secure connection.
CodePage	Gets and sets the code page used when reading and writing text.
Columns	Gets and sets the number of columns for the virtual terminal session.
Command	Gets and sets the command that will be executed on the server.
ExitCode	Returns the exit code from the command executed on the server.
Fingerprint	Returns a string that uniquely identifies the server.
Handle	Gets a value that specifies the client handle allocated for the current session.
HashStrength	Gets a value which specifies the length of the message digest that was selected for a secure connection.
HostAddress	Gets and sets a value which specifies the Internet address used to establish a connection.
HostName	Gets and sets a value which specifies the host name used to establish a connection.
IsBlocked	Gets a value which indicates if the current thread is performing a blocking client operation.
IsConnected	Gets a value which indicates if a connection to the remote host has been established.
IsInitialized	Gets a value which indicates if the current instance of the class has been initialized successfully.
IsReadable	Gets a value which indicates if there is data available to be read from the socket connection to the server.
IsWritable	Gets a value which indicates if data can be written to the client without blocking.
KeepAlive	Gets and sets a value which determines if the client

	session should kept active.
LastError	Gets and sets a value which specifies the last error that has occurred.
LastErrorString	Gets a value which describes the last error that has occurred.
LocalAddress	Gets the local Internet address that the client is bound to.
LocalName	Gets a value which specifies the host name for the local system.
LocalPort	Gets the local port number the client is bound to.
NewLine	Gets and sets the end-of-line character sequences sent to the server.
Options	Gets and sets a value which specifies one or more client options.
Password	Gets and sets the password used to authenticate the client session.
PrivateKey	Gets and sets the name of the private key file used to authenticate the client session.
ProxyHost	Gets and sets the hostname or IP address of a proxy server.
ProxyPassword	Gets and sets the password used to authenticate the connection to a proxy server.
ProxyPort	Gets and sets a value that specifies the proxy server port number.
ProxyType	Gets and sets the type of proxy server the client will use to establish a connection.
ProxyUser	Gets and sets the username used to authenticate the connection to a proxy server.
RemotePort	Gets and sets a value which specifies the remote port number.
RemoteService	Gets and sets a value which specifies the remote service.
Rows	Gets and sets the number of rows for the virtual terminal session.
Secure	Gets and sets a value which specifies if a secure connection is established.
SecureCipher	Gets a value that specifies the encryption algorithm used for a secure connection.
SecureHash	Gets a value that specifies the message digest algorithm used for a secure connection.
SecureKeyExchange	Gets a value that specifies the key exchange algorithm used for a secure connection.

SecureProtocol	Gets and sets a value which specifies the protocol used for a secure connection.
Status	Gets a value which specifies the current status of the client.
Terminal	Gets and sets the terminal type used for a remote login session.
ThreadModel	Gets and sets a value which specifies the threading model for the class instance.
ThrowError	Gets and sets a value which specifies if method calls should throw exceptions when an error occurs.
Timeout	Gets and sets a value which specifies a timeout period in seconds.
Trace	Gets and sets a value which indicates if network function logging is enabled.
TraceFile	Gets and sets a value which specifies the name of the logfile.
TraceFlags	Gets and sets a value which specifies the client function tracing flags.
UserName	Gets and sets the username used to authenticate the client session.
Version	Gets a value which returns the current version of the SshClient class library.

See Also

SshClient Class | SocketTools Namespace

SshClient.AutoResolve Property

Gets and sets a value that determines if host names and addresses are automatically resolved.

[Visual Basic]

```
Public Property AutoResolve As Boolean
```

[C#]

```
public bool AutoResolve {get; set;}
```

Property Value

Returns **true** if host names are automatically resolved to Internet addresses. The default value is **false**.

Remarks

Setting the **AutoResolve** property determines if the class automatically resolves host names and addresses specified by the **HostName** and **HostAddress** properties. If set to **true**, setting the **HostName** property will cause the class to automatically determine the corresponding IP address and update the **HostAddress** property accordingly. Likewise, setting the **HostAddress** property will cause the class to determine the host name and update the **HostName** property. Setting this property to **false** prevents the class from resolving host names until a connection attempt is made.

It is important to note that setting the **HostName** or **HostAddress** property may cause the current thread to block, sometimes for several seconds, until the name or address is resolved. To prevent this behavior, set this property value to **false**.

See Also

SshClient Class | SocketTools Namespace

SshClient.Blocking Property

Gets and sets a value which indicates if the client is in blocking mode.

[Visual Basic]

```
Public Property Blocking As Boolean
```

[C#]

```
public bool Blocking {get; set;}
```

Property Value

Returns **true** if the client is in blocking mode; otherwise it returns **false**. The default value is **true**.

Remarks

Setting the **Blocking** property determines if client operations complete synchronously or asynchronously. If set to **true**, then each client operation (such as sending or receiving data) will return when the operation has completed or timed-out. If set to **false**, client operations will return immediately. If the operation would result in the client blocking (such as attempting to read data when no data has been sent by the remote host), an error is generated.

It is important to note that certain events, such as **OnDisconnect, OnRead** and **OnWrite** are only fired if the client is in non-blocking mode.

See Also

SshClient Class | SocketTools Namespace

SshClient.CipherStrength Property

Gets a value that indicates the length of the key used by the encryption algorithm for a secure connection.

[Visual Basic]
```
Public ReadOnly Property CipherStrength As Integer
```

[C#]
```
public int CipherStrength {get;}
```

Property Value

An integer value which specifies the encryption key length if a secure connection has been established; otherwise a value of 0 is returned.

Remarks

The **CipherStrength** property returns the number of bits in the key used to encrypt the secure data stream. Common values returned by this property are 128 and 256. A key length of 40 or 56 bits is considered insecure and subject to brute force attacks. 128-bit and 256-bit keys are considered secure. If this property returns a value of 0, this means that a secure connection has not been established with the remote host.

See Also

SshClient Class | SocketTools Namespace

SshClient.CodePage Property

Gets and sets the code page used when reading and writing text.

[Visual Basic]

```
Public Property CodePage As Integer
```

[C#]

```
public int CodePage {get; set;}
```

Property Value

An integer value which specifies the current code page. A value of zero specifies the default code page for the current locale should be used. To preserve the original Unicode text, you can use code page 65001 which specifies UTF-8 character encoding.

Remarks

All data which is exchanged over a socket is sent and received as 8-bit bytes, typically referred to as "octets" in networking terminology. However, strings in .NET are Unicode where each character is represented by 16 bits. To send and receive data using strings, these Unicode strings are converted to a stream of bytes.

By default, strings are converted to an array of bytes using the code page for the current locale, mapping the 16-bit Unicode characters to bytes. Similarly, when reading data from the socket into a string buffer, the stream of bytes received from the remote host are converted to Unicode before they are returned to your application.

If you are exchanging text with another system and it appears to corrupted or characters are being replaced with question marks or other symbols, it is likely the system is sending text which is using a different character encoding. Most services use UTF-8 encoding to represent non-ASCII characters and selecting the UTF-8 code page will typically resolve the issue.

Strings are only guaranteed to be safe when sending and receiving text. Using a string data type is not recommended when reading or writing binary data to a socket. If possible, you should always use a byte array as the buffer parameter for the Read and Write methods whenever you are exchanging binary data.

For backwards compatibility, this class defaults to using the code page for the current locale. This property value directly corresponds to Windows code page identifiers, and will accept any valid code page supported by the .NET Framework. Setting this property to an invalid code page will generate an exception.

See Also

SshClient Class | SocketTools Namespace

SshClient.Columns Property

Gets and sets the number of columns for the virtual terminal session.

[Visual Basic]
```
Public Property Columns As Integer
```

[C#]
```
public int Columns {get; set;}
```

Property Value

An integer value that specifies the number of character columns for the virtual display.

Remarks

The **Columns** property returns the number of character columns for the virtual display. Setting this property prior to calling the **Connect** method requests that the server create a pseudoterminal with the specified number of columns. This property value is only meaningful for interactive terminal sessions, and is not used when executing a command on the remote host.

See Also

SshClient Class | SocketTools Namespace

SshClient.Command Property

Gets and sets the command that will be executed on the server.

[Visual Basic]

```
Public Property Command As String
```

[C#]

```
public string Command {get; set;}
```

Property Value

A string value that specifies the command which will be executed on the server.

Remarks

The **Command** property is used to specify a command and its arguments that should be executed on the server. The output of the command will be returned to the application and can be read using the **Read** or **ReadLine** method. If no command is specified, then the control will establish an interactive terminal session instead.

The command and its arguments must follow the conventions used by the SSH server, and the command will execute in the context of the authenticated user. The **ExitCode** property can be used to obtain the numerical exit code of the remote program, if one is available.

See Also

SshClient Class | SocketTools Namespace

SshClient.Fingerprint Property

Returns a string that uniquely identifies the server.

[Visual Basic]

```
Public ReadOnly Property Fingerprint As String
```

[C#]

```
public string Fingerprint {get;}
```

Property Value

A string which represents an MD5 hash value that can be used to uniquely identify the server.

Remarks

The **Fingerprint** property returns a string that consists of a series of hexadecimal values separated by colons. The value is unique to the server, and is an MD5 hash of the RSA host key. An application can use this value to determine if a connection has been established with the server previously by storing the server's host name, IP address and fingerprint in a file, registry key or a database.

See Also

SshClient Class | SocketTools Namespace

SshClient.Handle Property

Gets a value that specifies the client handle allocated for the current session.

[Visual Basic]

```
Public ReadOnly Property Handle As Integer
```

[C#]

```
public int Handle {get;}
```

Property Value

An integer which represents a client handle. If there is no active connection, a value of -1 is returned.

Remarks

The **Handle** property specifies the numeric descriptor of the current client session.

See Also

SshClient Class | SocketTools Namespace

SshClient.HashStrength Property

Gets a value which specifies the length of the message digest that was selected for a secure connection.

[Visual Basic]

```
Public ReadOnly Property HashStrength As Integer
```

[C#]

```
public int HashStrength {get;}
```

Property Value

An integer value which specifies the length of the message digest if a secure connection has been established; otherwise a value of 0 is returned.

Remarks

The **HashStrength** property returns the number of bits used in the message digest (hash) that was selected. Common values returned by this property are 128 and 160. If this property returns a value of 0, this means that a secure connection has not been established with the remote host.

See Also

SshClient Class | SocketTools Namespace

SshClient.HostAddress Property

Gets and sets a value which specifies the Internet address used to establish a connection.

[Visual Basic]

```
Public Property HostAddress As String
```

[C#]

```
public string HostAddress {get; set;}
```

Property Value

A string which specifies an Internet address.

Remarks

The **HostAddress** property can be used to set the Internet address for a remote system that you wish to communicate with. If the **AutoResolve** property is set to **true** and the address is assigned to a valid host name, the **HostName** property will be updated with that value.

See Also

SshClient Class | SocketTools Namespace

SshClient.HostName Property

Gets and sets a value which specifies the host name used to establish a connection.

[Visual Basic]

```
Public Property HostName As String
```

[C#]

```
public string HostName {get; set;}
```

Property Value

A string which specifies a host name.

Remarks

The **HostName** property can be used to set the host name for a remote system that you wish to communicate with. If the **AutoResolve** property is set to **true** and the name can be resolved to a valid Internet address, the **HostAddress** property will be updated with that value.

See Also

SshClient Class | SocketTools Namespace

SshClient.IsBlocked Property

Gets a value which indicates if the current thread is performing a blocking client operation.

[Visual Basic]

```
Public ReadOnly Property IsBlocked As Boolean
```

[C#]

```
public bool IsBlocked {get;}
```

Property Value

Returns **true** if the current thread is blocking, otherwise returns **false**.

Remarks

The **IsBlocked** property returns **true** if the current thread is blocked performing an operation. Because the Windows Sockets API only permits one blocking operation per thread of execution, this property should be checked before starting any blocking operation in response to an event.

If the **IsBlocked** property returns **false**, this means there are no blocking operations on the current thread at that time. However, this does not guarantee that the next client operation will not fail. An application should always check the return value from a client operation and check the value of the **LastError** property if an error occurs.

Note that this property will return **true** if there is any blocking operation being performed by the current thread, regardless of whether this specific instance of the class is responsible for the blocking operation or not.

See Also

SshClient Class | SocketTools Namespace

SshClient.IsConnected Property

Gets a value which indicates if a connection to the remote host has been established.

[Visual Basic]

```
Public ReadOnly Property IsConnected As Boolean
```

[C#]

```
public bool IsConnected {get;}
```

Property Value

Returns **true** if the connection has been established; otherwise returns **false**.

Remarks

The **IsConnected** property can only be used to indicate if there is still a logical connection to the remote host. It cannot be used to detect abnormal conditions such as the remote host aborting the connection, the physical network connection being lost or other critical errors.

See Also

SshClient Class | SocketTools Namespace

SshClient.IsInitialized Property

Gets a value which indicates if the current instance of the class has been initialized successfully.

[Visual Basic]

```
Public ReadOnly Property IsInitialized As Boolean
```

[C#]

```
public bool IsInitialized {get;}
```

Property Value

Returns **true** if the class instance has been initialized; otherwise returns **false**.

Remarks

The **IsInitialized** property is used to determine if the current instance of the class has been initialized properly. Normally this is done automatically by the class constructor, however there are circumstances where the class may not be able to initialize itself.

The most common reasons that a class instance may not initialize correctly is that no runtime license key has been defined in the assembly or the license key provided is invalid. It may also indicate a problem with the system configuration or user access rights, such as not being able to load the required networking libraries or not being able to access the system registry.

See Also

SshClient Class | SocketTools Namespace

SshClient.IsReadable Property

Gets a value which indicates if there is data available to be read from the socket connection to the server.

[Visual Basic]

```
Public ReadOnly Property IsReadable As Boolean
```

[C#]

```
public bool IsReadable {get;}
```

Property Value

Returns **true** if there is data available to be read; otherwise returns **false**.

Remarks

The **IsReadable** property returns **true** if data can be read from the client without blocking. For non-blocking sessions, this property can be checked before the application attempts to read the client. Note that even if this property does return **true** indicating that there is data available to be read, applications should always check the return value from the **Read** method.

See Also

SshClient Class | SocketTools Namespace

SshClient.IsWritable Property

Gets a value which indicates if data can be written to the client without blocking.

[Visual Basic]

```
Public ReadOnly Property IsWritable As Boolean
```

[C#]

```
public bool IsWritable {get;}
```

Property Value

Returns **true** if data can be written to the client; otherwise returns **false**.

Remarks

The **IsWritable** property returns **true** if data can be written to the client without blocking. For non-blocking sessions, this property can be checked before the application attempts to write data to the client. Note that even if this property does return **true** indicating that data can be written to the client, applications should always check the return value from the **Write** method.

See Also

SshClient Class | SocketTools Namespace

SshClient.KeepAlive Property

Gets and sets a value which determines if the client session should kept active.

[Visual Basic]

```
Public Property KeepAlive As Boolean
```

[C#]

```
public bool KeepAlive {get; set;}
```

Property Value

A boolean value which specifies if the client connection should be maintained over a long period of time. A value of **true** indicates that the client should attempt to keep the connection active, even if it is idle for more than two hours. A value of **false** specifies that the connection should be established normally.

Remarks

Setting the **KeepAlive** property to a value of true indicates that the client wishes to maintain a long-duration session with the server. It is only necessary to set this property to a value of true if the client session is interactive and the connection must be held open for more than two hours.

See Also

SshClient Class | SocketTools Namespace

SshClient.LastError Property

Gets and sets a value which specifies the last error that has occurred.

[Visual Basic]

```
Public Property LastError As ErrorCode
```

[C#]

```
public SshClient.ErrorCode LastError {get; set;}
```

Property Value

Returns an ErrorCode enumeration value which specifies the last error code.

Remarks

The **LastError** property returns the error code associated with the last error that occurred for the current instance of the class. It is important to note that this value only has meaning if the previous method indicates that an error has actually occurred.

It is possible to explicitly clear the last error code by assigning the property to the value **ErrorCode.errorNone**.

The error code value can be cast to an integer value for display purposes if required. For a description of the error that can be displayed using a message box or some other similar mechanism, get the value of the **LastErrorString** property.

See Also

SshClient Class | SocketTools Namespace

SshClient.LastErrorString Property

Gets a value which describes the last error that has occurred.

[Visual Basic]

```
Public ReadOnly Property LastErrorString As String
```

[C#]

```
public string LastErrorString {get;}
```

Property Value

A string which describes the last error that has occurred.

Remarks

The **LastErrorString** property can be used to obtain a description of the last error that occurred for the current instance of the class. It is important to note that this value only has meaning if the previous method indicates that an error has actually occurred.

See Also

SshClient Class | SocketTools Namespace

SshClient.LocalAddress Property

Gets the local Internet address that the client is bound to.

[Visual Basic]

```
Public ReadOnly Property LocalAddress As String
```

[C#]

```
public string LocalAddress {get;}
```

Property Value

A string which specifies an Internet address.

Remarks

The **LocalAddress** property returns the local Internet address that the client is bound to when a connection is established with a remote host. This property may return either an IPv4 or IPv6 formatted address, depending on the type of connection that was established.

See Also

SshClient Class | SocketTools Namespace

SshClient.LocalName Property

Gets a value which specifies the host name for the local system.

[Visual Basic]
```
Public ReadOnly Property LocalName As String
```

[C#]
```
public string LocalName {get;}
```

Property Value

A string which specifies the local host name.

Remarks

The **LocalName** property returns the fully-qualified host name assigned to the local system. If the system has not been configured with an Internet domain name, then this property will return the NetBIOS name assigned to the local system.

See Also

SshClient Class | SocketTools Namespace

SshClient.LocalPort Property

Gets the local port number the client is bound to.

[Visual Basic]
```
Public ReadOnly Property LocalPort As Integer
```

[C#]
```
public int LocalPort {get;}
```

Property Value

An integer value which specifies a port number. The default value is 0.

Remarks

The **LocalPort** property is used to identify the local port number that the client is bound to to when a connection is established with a remote host.

See Also

SshClient Class | SocketTools Namespace

SshClient.NewLine Property

Gets and sets the end-of-line character sequences sent to the server.

[Visual Basic]
```
Public Property NewLine As LineMode
```

[C#]
```
public SshClient.LineMode NewLine {get; set;}
```

Property Value

Returns an LineMode enumeration value which specify the current line mode for the client. The default value for this property is **newLineDefault**.

Remarks

When a connection is initially established with the server, it determines what characters are used to indicate the end-of-line and how they are displayed. On UNIX based systems, this is controlled by the settings for the pseudo-terminal that is allocated for the client session, and can be changed using the **stty** command. In most cases, the client line mode can be left at the default. However, in some cases you may need to change the line mode, particularly if you intend to send data from a Windows text file or copied from the clipboard.

Windows uses a carriage return and linefeed (CRLF) sequence to indicate the end-of-line and a UNIX based server may interpret that as multiple newlines. To prevent this, set the **NewLine** property to **LineMode.newLineCR** and the CRLF sequence in the text will be replaced by a single carriage return.

See Also

SshClient Class | SocketTools Namespace | Write Method | WriteLine Method

SshClient.Options Property

Gets and sets a value which specifies one or more client options.

[Visual Basic]

```
Public Property Options As ClientOptions
```

[C#]

```
public SshClient.ClientOptions Options {get; set;}
```

Property Value

Returns one or more ClientOptions enumeration flags which specify the options for the client. The default value for this property is **clientOptionNone**.

Remarks

The **Options** property specifies one or more default options options which are used when establishing a connection using the **Connect** method.

See Also

SshClient Class | SocketTools Namespace

SshClient.Password Property

Gets and sets the password used to authenticate the client session.

[Visual Basic]

```
Public Property Password As String
```

[C#]

```
public string Password {get; set;}
```

Property Value

A string which specifies the password.

Remarks

If a password is not specified when the **Login** method is called, the value of this property will be used as the default password when authenticating the client session.

See Also

SshClient Class | SocketTools Namespace

SshClient.PrivateKey Property

Gets and sets the name of the private key file used to authenticate the client session.

[Visual Basic]

```
Public Property PrivateKey As String
```

[C#]

```
public string PrivateKey {get; set;}
```

Property Value

A string value which specifies the name of the private key file. An empty string specifies that no private key is required to establish a connection with the server.

Remarks

The **PrivateKey** property specifies the name of the file that contains the private key that is used to authenticate the client session. It is only necessary to set this property if the server requires the user to provide a private key to establish the connection.

See Also

SshClient Class | SocketTools Namespace

SshClient.ProxyHost Property

Gets and sets the hostname or IP address of a proxy server.

[Visual Basic]

```
Public Property ProxyHost As String
```

[C#]

```
public string ProxyHost {get; set;}
```

Property Value

A string which specifies the hostname or IP address of the proxy server that will be used when establishing a connection.

Remarks

The **ProxyHost** property should be set to the name of the proxy server that you want to connect to. This property may be set to either a fully qualified domain name, or an IP address. This property is only used if the **ProxyType** property specifies a proxy server type other than **proxyNone**.

See Also

SshClient Class | SocketTools Namespace

SshClient.ProxyPassword Property

Gets and sets the password used to authenticate the connection to a proxy server.

[Visual Basic]

```
Public Property ProxyPassword As String
```

[C#]

```
public string ProxyPassword {get; set;}
```

Property Value

A string which specifies a password.

Remarks

The **ProxyPassword** property specifies the password used to authenticate the user to the proxy server. If a password is not required by the server, this property is ignored.

See Also

SshClient Class | SocketTools Namespace

SshClient.ProxyPort Property

Gets and sets a value that specifies the proxy server port number.

[Visual Basic]

```
Public Property ProxyPort As Integer
```

[C#]

```
public int ProxyPort {get; set;}
```

Property Value

An integer value which specifies the proxy port number.

Remarks

The **ProxyPort** property is used to set the port number that the control will use to establish a connection with the proxy server. A value of zero specifies that the client will connect to the proxy server using the standard HTTP service port.

See Also

SshClient Class | SocketTools Namespace

SshClient.ProxyType Property

Gets and sets the type of proxy server the client will use to establish a connection.

[Visual Basic]

```
Public Property ProxyType As ProxyTypes
```

[C#]

```
public SshClient.ProxyTypes ProxyType {get; set;}
```

Property Value

An ProxyTypes enumeration which specifies the type of proxy that the client will connect through.

See Also

SshClient Class | SocketTools Namespace

SshClient.ProxyUser Property

Gets and sets the username used to authenticate the connection to a proxy server.

[Visual Basic]

```
Public Property ProxyUser As String
```

[C#]

```
public string ProxyUser {get; set;}
```

Property Value

A string which specifies the username.

Remarks

The **ProxyUser** property specifies the user that is logging in to the proxy server. If the proxy server does not require the user to login, then this property is ignored.

See Also

SshClient Class | SocketTools Namespace

SshClient.RemotePort Property

Gets and sets a value which specifies the remote port number.

[Visual Basic]

```
Public Property RemotePort As Integer
```

[C#]

```
public int RemotePort {get; set;}
```

Property Value

An integer value which specifies a port number.

Remarks

The **RemotePort** property is used to set the port number that will be used to establish a connection with a remote host. If the port number specifies a well-known port, the **RemoteService** property will be updated with that name.

See Also

SshClient Class | SocketTools Namespace

SshClient.Rows Property

Gets and sets the number of rows for the virtual terminal session.

[Visual Basic]

```
Public Property Rows As Integer
```

[C#]

```
public int Rows {get; set;}
```

Property Value

An integer value that specifies the number of character rows for the virtual display.

Remarks

The **Rows** property returns the number of character rows for the virtual display. Setting this property prior to calling the **Connect** method requests that the server create a pseudoterminal with the specified number of rows. This property value is only meaningful for interactive terminal sessions, and is not used when executing a command on the remote host.

The default value for this property is 24.

See Also

SshClient Class | SocketTools Namespace

SshClient.Secure Property

Gets and sets a value which specifies if a secure connection is established.

[Visual Basic]

```
Public Property Secure As Boolean
```

[C#]

```
public bool Secure {get; set;}
```

Property Value

Returns **true** if a secure connection is established; otherwise returns **false**. The default value is **false**.

Remarks

The **Secure** property determines if a secure connection is established to the server. The default value for this property is true, and it is included only for compatibility with the other SocketTools components. Because all SSH connections must be secure, attempting to set this property to a value of false will result in an error.

See Also

SshClient Class | SocketTools Namespace

SshClient.SecureCipher Property

Gets a value that specifies the encryption algorithm used for a secure connection.

[Visual Basic]

```
Public ReadOnly Property SecureCipher As SecureCipherAlgorithm
```

[C#]

```
public SshClient.SecureCipherAlgorithm SecureCipher {get;}
```

Property Value

A SecureCipherAlgorithm enumeration value which identifies the algorithm.

Remarks

The **SecureCipher** property returns a value which identifies the algorithm used to encrypt the data stream. If a secure connection has not been established, this property will return a value of **cipherNone**.

See Also

SshClient Class | SocketTools Namespace

SshClient.SecureHash Property

Gets a value that specifies the message digest algorithm used for a secure connection.

[Visual Basic]

```
Public ReadOnly Property SecureHash As SecureHashAlgorithm
```

[C#]

```
public SshClient.SecureHashAlgorithm SecureHash {get;}
```

Property Value

A SecureHashAlgorithm enumeration value which identifies the algorithm.

Remarks

The **SecureHash** property returns a value which identifies the message digest (hash) algorithm that was selected when a secure connection was established. If a secure connection has not been established, this property will return a value of **hashNone**.

See Also

SshClient Class | SocketTools Namespace

SshClient.SecureKeyExchange Property

Gets a value that specifies the key exchange algorithm used for a secure connection.

[Visual Basic]

```
Public ReadOnly Property SecureKeyExchange As SecureKeyAlgorithm
```

[C#]

```
public SshClient.SecureKeyAlgorithm SecureKeyExchange {get;}
```

Property Value

A SecureKeyAlgorithm enumeration value which identifies the algorithm.

Remarks

The **SecureKeyExchange** property returns a value which identifies the key exchange algorithm that was selected when a secure connection was established. If a secure connection has not been established, this property will return a value of **keyExchangeNone**.

See Also

SshClient Class | SocketTools Namespace

SshClient.SecureProtocol Property

Gets and sets a value which specifies the protocol used for a secure connection.

[Visual Basic]
```
Public Property SecureProtocol As SecurityProtocols
```

[C#]
```
public SshClient.SecurityProtocols SecureProtocol {get; set;}
```

Property Value

A SecurityProtocols enumeration value which identifies the protocol to be used when establishing a secure connection.

Remarks

The **SecureProtocol** property can be used to specify the security protocol to be used when establishing a secure connection with a server. By default, the control will attempt to use either SSH-1 or SSH-2 to establish the connection, with the appropriate protocol automatically selected based on the capabilities of the server. It is recommended that you only change this property value if you fully understand the implications of doing so. Assigning a value to this property will override the default and force the class to attempt to use only the protocol specified.

Multiple security protocols may be specified by combining the SecurityProtocols using a bitwise Or operator. After a connection has been established, reading this property will identify the protocol that was selected to establish the connection. Attempting to set this property after a connection has been established will result in an exception being thrown. This property should only be set before calling the **Connect** method.

See Also

SshClient Class | SocketTools Namespace

SshClient.Status Property

Gets a value which specifies the current status of the client.

[Visual Basic]

```
Public ReadOnly Property Status As ClientStatus
```

[C#]

```
public SshClient.ClientStatus Status {get;}
```

Property Value

A ClientStatus enumeration value which specifies the current client status.

Remarks

The **Status** property returns the current status of the client. This property can be used to check on blocking connections to determine if the client is interacting with the remote host before taking some action.

See Also

SshClient Class | SocketTools Namespace

SshClient.Terminal Property

Gets and sets the terminal type used for a remote login session.

[Visual Basic]

```
Public Property Terminal As String
```

[C#]

```
public string Terminal {get; set;}
```

Property Value

A string which specifies the terminal type.

Remarks

The **Terminal** property specifies the terminal type of the remote host for display purposes. On UNIX based systems, the terminal name corresponds to a termcap or terminfo entry as set in the TERM environment variable. On Windows based systems which implement the rlogin service, this property may be ignored and the server will assume that the client is capable of displaying ANSI escape sequences. On VMS systems, the terminal name should correspond to the terminal type used with the SET TERMINAL/DEVICE command.

If this property is set to an empty string and no terminal type is specified when the **Login** method is called, a default terminal type named "unknown" will be used. On most UNIX and VMS systems this defines a terminal which is not capable of cursor positioning using control or escape sequences. This terminal type may not be recognized and an error may be displayed when the user logs in indicating that the terminal type is invalid.

Refer to the documentation for the server system to determine what terminal type names are available to you. Remember that on UNIX systems, the terminal type is case-sensitive. Some of the more common terminal types are:

Terminal	Description
ansi	This terminal type is usually available on UNIX based servers. This specifies that the client is capable of displaying standard ANSI escape sequences for cursor control.
dumb	This terminal type typically specifies a terminal display which does not support control or escape sequences for cursor positioning. If you do not want escape sequences embedded in the data stream and the server returns an error if the terminal type is not specified, try using this terminal type.
pcansi	This terminal type is usually available on UNIX based servers. This specifies that the client is a using a PC terminal emulator that supports basic ANSI escape sequences for cursor control. This may also enable escape sequences which can set the display colors.
vt100	This terminal type is usually available on UNIX and VMS based servers. On some VMS systems this

	string may need to be specified as DEC-VT100. This specifies that the client is capable of emulating a DEC VT100 terminal. The VT100 supports many of the same cursor control sequences as an ANSI terminal.
vt220	This terminal type is usually available on UNIX and VMS based servers. On some VMS systems this string may need to be specified as DEC-VT220. This specifies that the client is capable of emulating a DEC VT220 terminal, which is a later version of the VT100.
vt320	This terminal type is usually available on UNIX and VMS based servers. On some VMS systems this string may need to be specified as DEC-VT320. This specifies that the client is capable of emulating a DEC VT320 terminal, which is similar to the VT100 and VT220 and provides advanced features such as the ability to set display colors.
xterm	This terminal type is may be available on UNIX based servers which have X Windows installed. This specifies that the client is a using the X Windows xterm emulator which supports standard ANSI escape sequences for cursor control.

See Also

SshClient Class | SocketTools Namespace

SshClient.ThreadModel Property

Gets and sets a value which specifies the threading model for the class instance.

[Visual Basic]

```
Public Property ThreadModel As ThreadingModel
```

[C#]

```
public SshClient.ThreadingModel ThreadModel {get; set;}
```

Property Value

Returns one or more ThreadingModel enumeration value which specifies the threading model for the client. The default value for this property is **modelSingleThread**.

Remarks

The **ThreadModel** property specifies the threading model that is used by the class instance when a connection is established. The default value for this property is **modelSingleThread**, which specifies that only the thread that established the connection should be permitted to invoke methods. It is important to note that this threading model does not limit the application to a single thread of execution. When a session is established using the **Connect** method, that session is attached to the thread that created it. From that point on, until the session is terminated, only the owner may invoke methods in that instance of the class. The ownership of the class instance may be transferred from one thread to another using the **AttachThread** method.

Setting this property to **modelFreeThread** disables certain internal safety checks that are performed by the class and may result in unexpected behavior unless you ensure that access to the class instance is synchronized across multiple threads. The application must ensure that no two threads will attempt to invoke a blocking method at the same time. In other words, if one thread invokes a method, the application must ensure that another thread will not attempt to invoke any other method at the same time using the same instance of the class.

Changing the value of this property will not affect an active client session. The threading model must be specified prior to invoking the **Connect** method.

See Also

SshClient Class | SocketTools Namespace | AttachThread Method | ThreadingModel Enumeration | ThreadModel Attribute

SshClient.ThrowError Property

Gets and sets a value which specifies if method calls should throw exceptions when an error occurs.

[Visual Basic]

```
Public Property ThrowError As Boolean
```

[C#]

```
public bool ThrowError {get; set;}
```

Property Value

Returns **true** if method calls will generate exceptions when an error occurs; otherwise returns **false**. The default value is **false**.

Remarks

Error handling for when calling class methods can be done in either of two different styles, according to the value of this property.

If the **ThrowError** property is set to **false**, the application should check the return value of any method that is used, and report errors based upon the documented value of the return code. It is the responsibility of the application to interpret the error code, if it is desired to explain the error in addition to reporting it. This is the default behavior.

If the **ThrowError** property is set to **true**, then exceptions will be generated whenever a method call fails. The program must be written to catch these exceptions and take the appropriate action when an error occurs. Failure to handle an exception will cause the program to terminate abnormally.

Note that if an error occurs while a property is being read or modified, an exception will be raised regardless of the value of the **ThrowError** property.

See Also

SshClient Class | SocketTools Namespace

SshClient.Timeout Property

Gets and sets a value which specifies a timeout period in seconds.

[Visual Basic]

```
Public Property Timeout As Integer
```

[C#]

```
public int Timeout {get; set;}
```

Property Value

An integer value which specifies a timeout period in seconds.

Remarks

Setting the **Timeout** property specifies the number of seconds until a blocking operation fails and returns an error.

The timeout period is only used when the client is in blocking mode. Although this property can be changed when the client is in non-blocking mode, the value will be ignored until the client is returned to blocking mode.

For most applications it is recommended the timeout period be set between 10 and 20 seconds.

See Also

SshClient Class | SocketTools Namespace

SshClient.Trace Property

Gets and sets a value which indicates if network function logging is enabled.

[Visual Basic]
```
Public Property Trace As Boolean
```

[C#]
```
public bool Trace {get; set;}
```

Property Value

Returns **true** if network function tracing is enabled; otherwise returns **false**. The default value is **false**.

Remarks

The **Trace** property is used to enable (or disable) the tracing of network function calls. When enabled, each function call is logged to a file, including the function parameters, return value and error code if applicable. This facility can be enabled and disabled at run time, and the trace log file can be specified by setting the **TraceFile** property. All function calls that are being logged are appended to the trace file, if it exists. If no trace file exists when tracing is enabled, the trace file is created.

The tracing facility is available in all of the SocketTools networking classes and is enabled or disabled for an entire process. This means that once trace logging is enabled for a given component, all of the function calls made by the process using any of the SocketTools classes will be logged. For example, if you have an application using both the File Transfer Protocol and Post Office Protocol classes, and you set the **Trace** property to **true**, function calls made by both classes will be logged. Additionally, enabling a trace is cumulative, and tracing is not stopped until it is disabled for all classes used by the process.

If trace logging is not enabled, there is no negative impact on performance or throughput. Once enabled, application performance can degrade, especially in those situations in which multiple processes are being traced or the logfile is fairly large. Since logfiles can grow very quickly, even with modest applications, it is recommended that you delete the file when it is no longer needed.

When redistributing your application, make sure that you include the **SocketTools10.TraceLog.dll** module with your installation. If this library is not present, then no trace output will be generated and the value of the **Trace** property will be ignored. Only those function calls made by the SocketTools networking classes will be logged. Calls made directly to the Windows Sockets API, or calls made by other classes, will not be logged.

See Also

SshClient Class | SocketTools Namespace

SshClient.TraceFile Property

Gets and sets a value which specifies the name of the logfile.

[Visual Basic]
```
Public Property TraceFile As String
```

[C#]
```
public string TraceFile {get; set;}
```

Property Value

A string which specifies the name of the file.

Remarks

The **TraceFile** property is used to specify the name of the trace file that is created when network function tracing is enabled. If this property is set to an empty string (the default value), then a file named **SocketTools.log** is created in the system's temporary directory. If no temporary directory exists, then the file is created in the current working directory.

If the file exists, the trace output is appended to the file, otherwise the file is created. Since network function tracing is enabled per-process, the trace file is shared by all instances of the class being used. If multiple class instances have tracing enabled, the **TraceFile** property should be set to the same value for each instance. Since trace files can grow very quickly, even with modest applications, it is recommended that you delete the file when it is no longer needed.

The trace file has the following format:

```
 MyApp INF: WSAAsyncSelect(46, 0xcc4, 0x7e9, 0x27) returned 0 MyApp WRN:
connect(46, 192.0.0.1:1234, 16) returned -1 [10035] MyApp ERR: accept(46,
NULL, 0x0) returned -1 [10038]
```

The first column contains the name of the process that is being traced. The second column identifies if the trace record is reporting information, a warning, or an error. What follows is the name of the function being called, the arguments passed to the function and the function's return value. If a warning or error is reported, the error code is appended to the record (the value is placed inside brackets).

If parameters are passed as integer values, they are recorded in decimal. If the parameter or return value is a pointer (a memory address), it is recorded as a hexadecimal value preceded with "0x". A special type of pointer, called a null pointer, is recorded as NULL. Those functions which expect socket addresses are displayed in the following format:

```
aa.bb.cc.dd:nnnn
```

The first four numbers separated by periods represent the IP address, and the number following the colon represents the port number in host byte order. Note that in the second line of the above example, the control is attempting to connect to a system with the IP address 192.0.0.1 on port 1234.

Note that if the specified file cannot be created, or the user does not have permission to modify an existing file, the error is silently ignored and no trace output will be generated.

See Also

SshClient Class | SocketTools Namespace

SshClient.TraceFlags Property

Gets and sets a value which specifies the client function tracing flags.

[Visual Basic]

```
Public Property TraceFlags As TraceOptions
```

[C#]

```
public SshClient.TraceOptions TraceFlags {get; set;}
```

Property Value

A TraceOptions enumeration which specifies the amount of detail written to the trace logfile.

Remarks

The **TraceFlags** property is used to specify the type of information written to the trace file when network function tracing is enabled.

Because network function tracing is enabled per-process, the trace flags are shared by all instances of the class being used. If multiple class instances have tracing enabled, the **TraceFlags** property should be set to the same value for each instance. Changing the trace flags for any one instance of the class will affect the logging performed for all SocketTools classes used by the application.

Warnings are generated when a non-fatal error is returned by a network function. For example, if data is being written and the error **errorOperationWouldBlock** occurs, a warning is generated because the application simply needs to attempt to write the data at a later time.

See Also

SshClient Class | SocketTools Namespace

SshClient.UserName Property

Gets and sets the username used to authenticate the client session.

[Visual Basic]

```
Public Property UserName As String
```

[C#]

```
public string UserName {get; set;}
```

Property Value

A string which specifies the username.

Remarks

If a username is not specified when the **Login** method is called, the value of this property will be used as the default username when authenticating the client session.

See Also

SshClient Class | SocketTools Namespace

SshClient.Version Property

Gets a value which returns the current version of the SshClient class library.

[Visual Basic]

```
Public ReadOnly Property Version As String
```

[C#]

```
public string Version {get;}
```

Property Value

A string which specifies the version of the class library.

Remarks

The **Version** property returns a string which identifies the current version and build of the SshClient class library. This value can be used by an application for validation and debugging purposes.

See Also

SshClient Class | SocketTools Namespace

SshClient Methods

The methods of the **SshClient** class are listed below. For a complete list of **SshClient** class members, see the SshClient Members topic.

Public Instance Methods

AttachThread	Attach an instance of the class to the current thread
Break	Sends a break signal to the remote host.
Cancel	Cancel the current blocking client operation.
Connect	Overloaded. Establish a connection with a remote host.
Control	Send a control message to the server.
Disconnect	Terminate the connection with a remote host.
Dispose	Overloaded. Releases all resources used by SshClient.
Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
Execute	Overloaded. Execute a command on the server and return the output.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from Object)	Gets the Type of the current instance.
Initialize	Overloaded. Initialize an instance of the SshClient class.
Peek	Overloaded. Read data returned by the server, but do not remove it from the receive buffer.
Read	Overloaded. Read data from the server and store it in a byte array.
ReadLine	Overloaded. Read up to a line of data from the server and return it in a string buffer.
Reset	Reset the internal state of the object, resetting all properties to their default values.
Search	Overloaded. Search for a specific character sequence in the data stream.
ToString (inherited from Object)	Returns a String that represents the current Object.
Uninitialize	Uninitialize the class library and release any resources allocated for the current thread.
Write	Overloaded. Write one or more bytes of data to the server.

WriteLine	Overloaded. Send a line of text to the server, terminated by a carriage-return and linefeed.

Protected Instance Methods

Dispose	Overloaded. Releases the unmanaged resources allocated by the SshClient class and optionally releases the managed resources.
Finalize	Destroys an instance of the class, releasing the resources allocated for the session and unloading the networking library.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

SshClient Class | SocketTools Namespace

SshClient.AttachThread Method

Attach an instance of the class to the current thread

[Visual Basic]
```
Public Function AttachThread() As Boolean
```

[C#]
```
public bool AttachThread();
```

Return Value

A boolean value which specifies if the client could be attached to the current thread. If this method returns **false**, the client could not be attached to the thread and the application should check the value of the LastError property to determine the cause of the failure.

Remarks

When an instance of the class is created it is associated with the current thread that created it. Normally, if another thread attempts to perform an operation using that instance, an error is returned. This is used to ensure that other threads cannot interfere with an operation being performed by the owner thread. In some cases, it may be desirable for one thread in an application to create an instance of the class, establish a connection and then pass that instance to another worker thread. The **AttachThread** method can be used to change the ownership of the class instance to the new worker thread.

This method should be called by the new thread immediately after it has been created, and if the new thread does not release the handle itself, the ownership of the handle should be restored by the original thread. Under no circumstances should **AttachThread** be used to forcibly destroy an instance of a class allocated by another thread while a blocking operation is in progress. To cancel a blocking operation, use the **Cancel** method and then delete the class instance after the blocking function exits and control is returned to the current thread.

See Also

SshClient Class | SocketTools Namespace

SshClient.Break Method

Sends a break signal to the remote host.

[Visual Basic]

```
Public Function Break() As Boolean
```

[C#]

```
public bool Break();
```

Return Value

This method returns a Boolean value which specifies if the break signal was sent to the server. A value of **true** indicates the method was successful. If an error occurs, the method will return **false**.

Remarks

The **Break** method a control message to the remote host which simulates a break signal on a physical terminal. This is used by some operating systems as an instruction to enter a privileged configuration mode. Note that this is not the same as sending an interrupt character such as Ctrl+C to the remote host. This method is ignored for SSH 1.0 sessions.

SshClient.Cancel Method

Cancel the current blocking client operation.

[Visual Basic]

```
Public Sub Cancel()
```

[C#]

```
public void Cancel();
```

Remarks

When the **Cancel** method is called, the blocking client operation will not immediately fail. An internal flag is set which causes the blocking operation to exit with an error. This means that the application cannot cancel an operation and immediately perform some other blocking function. Instead it must allow the calling stack to unwind, returning back to the blocking operation before making any further function calls.

SshClient Class | SocketTools Namespace

SshClient.Connect Method ()

Establish a connection with a remote host.

[Visual Basic]
```
Overloads Public Function Connect() As Boolean
```

[C#]
```
public bool Connect();
```

Return Value

A boolean value which specifies if the connection has been established. If the client is in blocking mode, a return value of **true** indicates that the connection has completed and the application may send and receive data from the remote host. If the client is in non-blocking mode, a return value of **true** indicates that the client has successfully created a socket and the connection is in progress.

When a non-blocking connection has completed, the OnConnect event will be fired. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

Remarks

This method establishes a connection using assigned property values.

The value of the **HostName** or **HostAddress** property will be used to determine the host name or address to connect to.

The value of the **RemotePort** property will be used to determine the port number to connect to.

The value of the **Timeout** property will be used to specify the timeout period.

The value of the **Options** property will be used to specify the default options for the connection.

SshClient.Connect Method (String)

Establish a connection with a remote host.

[Visual Basic]

```
Overloads Public Function Connect( _
   ByVal hostName As String _
) As Boolean
```

[C#]

```
public bool Connect(
   string hostName
);
```

Parameters

hostName

A string which specifies the remote host to establish a connection with. This may specify a host name or an Internet address in dot-notation.

Return Value

A boolean value which specifies if the connection has been established. If the client is in blocking mode, a return value of **true** indicates that the connection has completed and the application may send and receive data from the remote host. If the client is in non-blocking mode, a return value of **true** indicates that the client has successfully created a socket and the connection is in progress.

When a non-blocking connection has completed, the OnConnect event will be fired. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

Remarks

This method establishes a connection by using assigned property values.

The value of the **RemotePort** property will be used to determine the port number to connect to.

The value of the **UserName** and **Password** properties will be used to authenticate the session.

The value of the **Timeout** property will be used to specify the timeout period.

The value of the **Options** property will be used to specify the default options for the connection.

SshClient.Connect Method (String, Int32)

Establish a connection with a remote host.

[Visual Basic]

```
Overloads Public Function Connect( _
   ByVal hostName As String, _
   ByVal hostPort As Integer _
) As Boolean
```

[C#]

```
public bool Connect(
   string hostName,
   int hostPort
);
```

Parameters

hostName

A string which specifies the remote host to establish a connection with. This may specify a host name or an Internet address in dot-notation.

hostPort

An integer which specifies the port number for the connection. This value must be greater than zero and the maximum valid port number is 65535.

Return Value

A boolean value which specifies if the connection has been established. If the client is in blocking mode, a return value of **true** indicates that the connection has completed and the application may send and receive data from the remote host. If the client is in non-blocking mode, a return value of **true** indicates that the client has successfully created a socket and the connection is in progress.

When a non-blocking connection has completed, the OnConnect event will be fired. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

Remarks

This method establishes a connection by using assigned property values.

The value of the **UserName** and **Password** properties will be used to authenticate the session.

The value of the **Timeout** property will be used to specify the timeout period.

The value of the **Options** property will be used to specify the default options for the connection.

SshClient.Connect Method (String, Int32, Int32)

Establish a connection with a remote host.

[Visual Basic]

```
Overloads Public Function Connect( _
   ByVal hostName As String, _
   ByVal hostPort As Integer, _
   ByVal timeout As Integer _
) As Boolean
```

[C#]

```
public bool Connect(
   string hostName,
   int hostPort,
   int timeout
);
```

Parameters

hostName

A string which specifies the remote host to establish a connection with. This may specify a host name or an Internet address in dot-notation.

hostPort

An integer which specifies the port number for the connection. This value must be greater than zero and the maximum valid port number is 65535.

timeout

An integer value that specifies the number of seconds that the method will wait for the connection to complete before failing the operation and returning to the caller. This value is only meaningful for blocking connections.

Return Value

A boolean value which specifies if the connection has been established. If the client is in blocking mode, a return value of **true** indicates that the connection has completed and the application may send and receive data from the remote host. If the client is in non-blocking mode, a return value of **true** indicates that the client has successfully created a socket and the connection is in progress.

When a non-blocking connection has completed, the OnConnect event will be fired. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

Remarks

This method establishes a connection by using assigned property values.

The value of the **UserName** and **Password** properties will be used to authenticate the session.

The value of the **Options** property will be used to specify the default options for the connection.

```
Overloads Public Function Connect( _
   ByVal hostName As String, _
   ByVal hostPort As Integer, _
   ByVal userName As String, _
   ByVal password As String _
) As Boolean
```

[C#]

```
public bool Connect(
   string hostName,
   int hostPort,
   string userName,
   string password
);
```

Parameters

hostName
A string which specifies the remote host to establish a connection with. This may specify a host name or an Internet address in dot-notation.

hostPort
An integer which specifies the port number for the connection. This value must be greater than zero and the maximum valid port number is 65535.

userName
A string which specifies the user name which will be used to authenticate the client session.

password
A string which specifies the password which will be used to authenticate the client session.

Return Value

A boolean value which specifies if the connection has been established. If the client is in blocking mode, a return value of **true** indicates that the connection has completed and the application may send and receive data from the remote host. If the client is in non-blocking mode, a return value of **true** indicates that the client has successfully created a socket and the connection is in progress.

When a non-blocking connection has completed, the OnConnect event will be fired. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

Remarks

This method establishes a connection by using assigned property values.

The value of the **Timeout** property will be used to specify the timeout period.

The value of the **Options** property will be used to specify the default options for the connection.

SshClient Class | SocketTools Namespace | SshClient.Connect Overload List

SshClient.Connect Method (String, Int32, String, String, Int32, ClientOptions)

Establish a connection with a remote host.

[Visual Basic]

```
Overloads Public Function Connect( _
   ByVal hostName As String, _
   ByVal hostPort As Integer, _
   ByVal userName As String, _
   ByVal password As String, _
   ByVal timeout As Integer, _
   ByVal options As ClientOptions _
) As Boolean
```

[C#]

```
public bool Connect(
   string hostName,
   int hostPort,
   string userName,
   string password,
   int timeout,
   ClientOptions options
);
```

Parameters

hostName

A string which specifies the remote host to establish a connection with. This may specify a host name or an Internet address in dot-notation.

hostPort

An integer which specifies the port number for the connection. This value must be greater than zero and the maximum valid port number is 65535.

userName

A string which specifies the user name which will be used to authenticate the client session.

password

A string which specifies the password which will be used to authenticate the client session.

timeout

An integer value that specifies the number of seconds that the method will wait for the connection to complete before failing the operation and returning to the caller. This value is only meaningful for blocking connections.

options

One or more of the ClientOptions enumeration flags.

Return Value

A boolean value which specifies if the connection has been established. If the client is in blocking mode, a return value of **true** indicates that the connection has completed and the application may send and receive data from the remote host. If the client is in non-blocking mode, a return value of **true** indicates that the client has successfully created a socket and the connection is in progress.

When a non-blocking connection has completed, the OnConnect event will be fired. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

   ByVal userName As String, _
   ByVal password As String _
) As Boolean
```

```
[C#]
public bool Connect(
   string hostName,
   string userName,
   string password
);
```

Parameters

hostName
A string which specifies the remote host to establish a connection with. This may specify a host name or an Internet address in dot-notation.

userName
A string which specifies the user name which will be used to authenticate the client session.

password
A string which specifies the password which will be used to authenticate the client session.

Return Value

A boolean value which specifies if the connection has been established. If the client is in blocking mode, a return value of **true** indicates that the connection has completed and the application may send and receive data from the remote host. If the client is in non-blocking mode, a return value of **true** indicates that the client has successfully created a socket and the connection is in progress.

When a non-blocking connection has completed, the OnConnect event will be fired. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

Remarks

This method establishes a connection by using assigned property values.

The value of the **Timeout** property will be used to specify the timeout period.

The value of the **Options** property will be used to specify the default options for the connection.

See Also

SshClient Class | SocketTools Namespace | SshClient.Connect Overload List

SshClient.Control Method

Send a control message to the server.

```
[Visual Basic]
Public Function Control( _
   ByVal code As ControlCodes _
) As Boolean
```

```
[C#]
public bool Control(
   ControlCodes code
);
```

Parameters

code

A numeric control code which specifies the control message which should be sent to the server. This argument must specify one of the ControlCodes enumeration values.

Return Value

This method returns a Boolean value which specifies if the control code was sent to the server. A value of **true** indicates the method was successful. If an error occurs, the method will return **false**.

Remarks

The **Control** method enables an application to send control messages to the server, which can cause it to take specific actions such as simulate a terminal break or request that the key exchange be performed again. Some control messages are not supported by the SSH 1.0 protocol, in which case the control message is ignored.

See Also

SshClient Class | SocketTools Namespace

SshClient.Disconnect Method

Terminate the connection with a remote host.

[Visual Basic]

```
Public Sub Disconnect()
```

[C#]

```
public void Disconnect();
```

Remarks

The **Disconnect** method terminates the connection with the remote host and releases the client handle allocated by the class. Note that the client socket is not immediately released when the connection is terminated and will enter a wait state for two minutes. After the time wait period has elapsed, the client will be released by the operating system. This is a normal safety mechanism to handle any packets that may arrive after the connection has been closed.

The value of the **ExitCode** property is updated when the **Disconnect** method is called. This enables an application to check the exit code returned by the shell or program that was executed on the server. In most cases, an exit code value of zero indicates success, while any other value indicates an error condition.

SshClient.Dispose Method

Releases all resources used by SshClient.

Overload List

Releases all resources used by SshClient.

public void Dispose();

Releases the unmanaged resources allocated by the SshClient class and optionally releases the managed resources.

protected virtual void Dispose(bool);

See Also

SshClient Class | SocketTools Namespace

SshClient.Dispose Method ()

Releases all resources used by SshClient.

[Visual Basic]

```
NotOverridable Overloads Public Sub Dispose() _
    Implements IDisposable.Dispose
```

[C#]

```
public void Dispose();
```

Implements

IDisposable.Dispose

Remarks

The **Dispose** method terminates any active connection and explicitly releases the resources allocated for this instance of the class. In some cases, better performance can be achieved if the programmer explicitly releases resources when they are no longer being used. The **Dispose** method provides explicit control over these resources.

Unlike the **Uninitialize** method, once the **Dispose** method has been called, that instance of the class cannot be re-initialized and you should not attempt to access class properties or invoke any methods. Note that this method can be called even if other references to the object are active.

See Also

SshClient Class | SocketTools Namespace | SshClient.Dispose Overload List

SshClient.Dispose Method (Boolean)

Releases the unmanaged resources allocated by the SshClient class and optionally releases the managed resources.

[Visual Basic]

```
Overridable Overloads Protected Sub Dispose( _
   ByVal disposing As Boolean _
)
```

[C#]

```
protected virtual void Dispose(
   bool disposing
);
```

Parameters

disposing

A boolean value which should be specified as **true** to release both managed and unmanaged resources; **false** to release only unmanaged resources.

Remarks

The **Dispose** method terminates any active connection and explicitly releases the resources allocated for this instance of the class. In some cases, better performance can be achieved if the programmer explicitly releases resources when they are no longer being used. The **Dispose** method provides explicit control over these resources.

Unlike the **Uninitialize** method, once the **Dispose** method has been called, that instance of the class cannot be re-initialized and you should not attempt to access class properties or invoke any methods. Note that this method can be called even if other references to the object are active.

You should call **Dispose** in your derived class when you are finished using the derived class. The **Dispose** method leaves the derived class in an unusable state. After calling **Dispose**, you must release all references to the derived class and the **SshClient** class so the memory they were occupying can be reclaimed by garbage collection.

SshClient.Execute Method

Execute a command on the server and return the output.

Overload List

Execute a command on the server and return the output.

public string Execute();

Execute a command on the server and return the output.

public string Execute(string);

Execute a command on the server and return the output.

public string Execute(string,int);

Execute a command on the server and return the output.

public string Execute(string,int,string);

Execute a command on the server and return the output.

public string Execute(string,int,string,int);

Execute a command on the server and return the output.

public string Execute(string,int,string,string,string);

Execute a command on the server and return the output.

public string Execute(string,int,string,string,string,int);

Execute a command on the server and return the output.

public string Execute(string,int,string,string,string,int,ClientOptions);

Execute a command on the server and return the output.

public string Execute(string,string);

See Also

SshClient Class | SocketTools Namespace

SshClient.Execute Method ()

Execute a command on the server and return the output.

[Visual Basic]
```
Overloads Public Function Execute() As String
```

[C#]
```
public string Execute();
```

Return Value

A string that contains the output of the command that was executed on the server. To get the exit code returned by the program, check the value of the **ExitCode** property. If an empty string is returned, this indicates that there was either no data available, or an error has occurred and the **LastError** property will return a non-zero value.

Remarks

The **Execute** method establishes a network connection with a remote server and executes the specified command. The output from the command is returned as a string. This method uses the following property values:

The value of the **HostName** or **HostAddress** property will be used to determine the server hostname or IP address.

The value of the **RemotePort** property will be used to determine the port number to connect to.

The value of the **UserName** and **Password** properties will be used to authenticate the session.

The value of the **Command** property will be used to specify the command that should executed on the server.

The value of the **Timeout** property will be used to specify the timeout period.

The value of the **Options** property will be used to specify the default options for the connection.

This method should not be used if the connection to the server must be established through a proxy server. If the connection must be made through a proxy server, then you should set the **Command** property to the specify the command to execute, call the **Connect** method to establish the connection, and then use either the **Read** or **ReadLine** methods to read the output.

When the command output is being read from the server, this method will automatically convert the data to match the end-of-line convention used on the Windows platform. This is useful when executing a command on a UNIX based system where the end-of-line is indicated by a single linefeed, while on Windows it is a carriage-return and linefeed pair. If the output contains embedded nulls or escape sequences, then this conversion will not be performed.

SshClient.Execute Method (String)

Execute a command on the server and return the output.

[Visual Basic]
```
Overloads Public Function Execute( _
   ByVal command As String _
) As String
```

[C#]
```
public string Execute(
   string command
);
```

Parameters

command

A string which specifies the command that will be executed on the server.

Return Value

A string that contains the output of the command that was executed on the server. To get the exit code returned by the program, check the value of the **ExitCode** property. If an empty string is returned, this indicates that there was either no data available, or an error has occurred and the **LastError** property will return a non-zero value.

Remarks

The **Execute** method establishes a network connection with a remote server and executes the specified command. The output from the command is returned as a string. This method uses the following property values:

The value of the **HostName** or **HostAddress** property will be used to determine the server hostname or IP address.

The value of the **RemotePort** property will be used to determine the port number to connect to.

The value of the **UserName** and **Password** properties will be used to authenticate the session.

The value of the **Timeout** property will be used to specify the timeout period.

The value of the **Options** property will be used to specify the default options for the connection.

This method should not be used if the connection to the server must be established through a proxy server. If the connection must be made through a proxy server, then you should set the **Command** property to the specify the command to execute, call the **Connect** method to establish the connection, and then use either the **Read** or **ReadLine** methods to read the output.

When the command output is being read from the server, this method will automatically convert the data to match the end-of-line convention used on the Windows platform. This is useful when executing a command on a UNIX based system where the end-of-line is indicated by a single linefeed, while on Windows it is a carriage-return and linefeed pair. If the output contains embedded nulls or escape sequences, then this conversion will not be performed.

SshClient.Execute Method (String, Int32, String, String, String)

Execute a command on the server and return the output.

[Visual Basic]

```
Overloads Public Function Execute( _
   ByVal hostName As String, _
   ByVal hostPort As Integer, _
   ByVal userName As String, _
   ByVal password As String, _
   ByVal command As String _
) As String
```

[C#]

```
public string Execute(
   string hostName,
   int hostPort,
   string userName,
   string password,
   string command
);
```

Parameters

hostName
: A string which specifies the remote host to establish a connection with. This may specify a host name or an Internet address in dot-notation.

hostPort
: An integer which specifies the port number for the connection. This value must be greater than zero and the maximum valid port number is 65535.

userName
: A string which specifies the user name which will be used to authenticate the client session.

password
: A string which specifies the password which will be used to authenticate the client session.

command
: A string which specifies the command that will be executed on the server.

Return Value

A string that contains the output of the command that was executed on the server. To get the exit code returned by the program, check the value of the **ExitCode** property. If an empty string is returned, this indicates that there was either no data available, or an error has occurred and the **LastError** property will return a non-zero value.

Remarks

The **Execute** method establishes a network connection with a remote server and executes the specified command. The output from the command is returned as a string. This method uses the following property values:

The value of the **Timeout** property will be used to specify the timeout period.

The value of the **Options** property will be used to specify the default options for the connection.

This method should not be used if the connection to the server must be established through a proxy server. If the connection must be made through a proxy server, then you should set the **Command** property to the specify the command to execute, call the **Connect** method to establish the connection, and then use either the **Read** or **ReadLine** methods to read the output.

When the command output is being read from the server, this method will automatically convert the data to match the end-of-line convention used on the Windows platform. This is useful when executing a command on a UNIX based system where the end-of-line is indicated by a single linefeed, while on Windows it is a carriage-return and linefeed pair. If the output contains embedded nulls or escape sequences, then this conversion will not be performed.

See Also

SshClient Class | SocketTools Namespace | SshClient.Execute Overload List

SshClient.Execute Method (String, Int32, String)

Execute a command on the server and return the output.

[Visual Basic]

```
Overloads Public Function Execute( _
   ByVal hostName As String, _
   ByVal hostPort As Integer, _
   ByVal command As String _
) As String
```

[C#]

```
public string Execute(
   string hostName,
   int hostPort,
   string command
);
```

Parameters

hostName

A string which specifies the remote host to establish a connection with. This may specify a host name or an Internet address in dot-notation.

hostPort

An integer which specifies the port number for the connection. This value must be greater than zero and the maximum valid port number is 65535.

command

A string which specifies the command that will be executed on the server.

Return Value

A string that contains the output of the command that was executed on the server. To get the exit code returned by the program, check the value of the **ExitCode** property. If an empty string is returned, this indicates that there was either no data available, or an error has occurred and the **LastError** property will return a non-zero value.

Remarks

The **Execute** method establishes a network connection with a remote server and executes the specified command. The output from the command is returned as a string. This method uses the following property values:

The value of the **UserName** and **Password** properties will be used to authenticate the session.

The value of the **Timeout** property will be used to specify the timeout period.

The value of the **Options** property will be used to specify the default options for the connection.

This method should not be used if the connection to the server must be established through a proxy server. If the connection must be made through a proxy server, then you should set the **Command** property to the specify the command to execute, call the **Connect** method to establish the connection, and then use either the **Read** or **ReadLine** methods to read the output.

When the command output is being read from the server, this method will automatically convert the data to match the end-of-line convention used on the Windows platform. This is useful when executing a command on a UNIX based system where the end-of-line is indicated by a single linefeed, while on Windows it is a carriage-return and linefeed pair. If the output contains embedded nulls or escape sequences, then this conversion will not be performed.

SshClient Class | SocketTools Namespace | SshClient.Execute Overload List

SshClient.Execute Method (String, Int32, String, String, String, Int32)

Execute a command on the server and return the output.

[Visual Basic]

```
Overloads Public Function Execute( _
   ByVal hostName As String, _
   ByVal hostPort As Integer, _
   ByVal userName As String, _
   ByVal password As String, _
   ByVal command As String, _
   ByVal timeout As Integer _
) As String
```

[C#]

```
public string Execute(
   string hostName,
   int hostPort,
   string userName,
   string password,
   string command,
   int timeout
);
```

Parameters

hostName
: A string which specifies the remote host to establish a connection with. This may specify a host name or an Internet address in dot-notation.

hostPort
: An integer which specifies the port number for the connection. This value must be greater than zero and the maximum valid port number is 65535.

userName
: A string which specifies the user name which will be used to authenticate the client session.

password
: A string which specifies the password which will be used to authenticate the client session.

command
: A string which specifies the command that will be executed on the server.

timeout
: The number of seconds that the client will wait for a response before failing the operation.

Return Value

A string that contains the output of the command that was executed on the server. To get the exit code returned by the program, check the value of the **ExitCode** property. If an empty string is returned, this indicates that there was either no data available, or an error has occurred and the **LastError** property will return a non-zero value.

Remarks

The **Execute** method establishes a network connection with a remote server and executes the specified command. The output from the command is returned as a string.

This method should not be used if the connection to the server must be established through a proxy server. If the connection must be made through a proxy server, then you should set the **Command** property to the specify the command to execute, call the **Connect** method to establish the connection, and then use either the **Read** or **ReadLine** methods to read the output.

When the command output is being read from the server, this method will automatically convert the data to match the end-of-line convention used on the Windows platform. This is useful when executing a command on a UNIX based system where the end-of-line is indicated by a single linefeed, while on Windows it is a carriage-return and linefeed pair. If the output contains embedded nulls or escape sequences, then this conversion will not be performed.

SshClient Class | SocketTools Namespace | SshClient.Execute Overload List

SshClient.Execute Method (String, Int32, String, String, String, Int32, ClientOptions)

Execute a command on the server and return the output.

[Visual Basic]

```
Overloads Public Function Execute( _
   ByVal hostName As String, _
   ByVal hostPort As Integer, _
   ByVal userName As String, _
   ByVal password As String, _
   ByVal command As String, _
   ByVal timeout As Integer, _
   ByVal options As ClientOptions _
) As String
```

[C#]

```
public string Execute(
   string hostName,
   int hostPort,
   string userName,
   string password,
   string command,
   int timeout,
   ClientOptions options
);
```

Parameters

hostName

A string which specifies the remote host to establish a connection with. This may specify a host name or an Internet address in dot-notation.

hostPort

An integer which specifies the port number for the connection. This value must be greater than zero and the maximum valid port number is 65535.

userName

A string which specifies the user name which will be used to authenticate the client session.

password

A string which specifies the password which will be used to authenticate the client session.

command

A string which specifies the command that will be executed on the server.

timeout

The number of seconds that the client will wait for a response before failing the operation.

options

One or more of the ClientOptions enumeration flags.

Return Value

A string that contains the output of the command that was executed on the server. To get the exit code returned by the program, check the value of the **ExitCode** property. If an empty string is returned, this indicates that there was either no data available, or an error has occurred and the **LastError** property will return a non-zero value.

Remarks

The **Execute** method establishes a network connection with a remote server and executes the specified command. The output from the command is returned as a string.

This method should not be used if the connection to the server must be established through a proxy server. If the connection must be made through a proxy server, then you should set the **Command** property to the specify the command to execute, call the **Connect** method to establish the connection, and then use either the **Read** or **ReadLine** methods to read the output.

When the command output is being read from the server, this method will automatically convert the data to match the end-of-line convention used on the Windows platform. This is useful when executing a command on a UNIX based system where the end-of-line is indicated by a single linefeed, while on Windows it is a carriage-return and linefeed pair. If the output contains embedded nulls or escape sequences, then this conversion will not be performed.

SshClient.Initialize Method

Initialize an instance of the SshClient class.

Overload List

Initialize an instance of the SshClient class.

public bool Initialize();

Initialize an instance of the SshClient class.

public bool Initialize(string);

See Also

SshClient Class | SocketTools Namespace | Uninitialize Method

SshClient.Initialize Method ()

Initialize an instance of the SshClient class.

[Visual Basic]
```
Overloads Public Function Initialize() As Boolean
```

[C#]
```
public bool Initialize();
```

Return Value

A boolean value which specifies if the class was initialized successfully.

Remarks

The Initialize method can be used to explicitly initialize an instance of the SshClient class, loading the networking library and allocating resources for the current thread. Typically it is not necessary to explicitly call this method because the instance of the class is initialized by the class constructor. However, if the **Uninitialize** method is called, the class must be re-initialized before any other methods are called.

See Also

SshClient Class | SocketTools Namespace | SshClient.Initialize Overload List | Uninitialize Method

SshClient.Initialize Method (String)

Initialize an instance of the SshClient class.

[Visual Basic]

```
Overloads Public Function Initialize( _
   ByVal licenseKey As String _
) As Boolean
```

[C#]

```
public bool Initialize(
   string licenseKey
);
```

Return Value

A boolean value which specifies if the class was initialized successfully.

Remarks

The Initialize method can be used to explicitly initialize an instance of the SshClient class, loading the networking library and allocating resources for the current thread. Typically an application would define the license key as a custom attribute, however this method can be used to initialize the class directly.

The runtime license key for your copy of SocketTools can be generated using the License Manager utility that is included with the product. Note that if you have installed an evaluation license, you will not have a runtime license key and cannot redistribute any applications which use the SshClient class.

Example

The following example shows how to use the Initialize method to initialize an instance of the class. This example assumes that the license key string has been defined in code.

```
SocketTools.SshClient sshClient = new SocketTools.SshClient();

if (sshClient.Initialize(strLicenseKey) == false)
{
    MessageBox.Show(sshClient.LastErrorString, "Error",
                    MessageBoxButtons.OK, MessageBoxIcon.Exclamation);
    return;
}
```

```
Dim sshClient As New SocketTools.SshClient

If sshClient.Initialize(strLicenseKey) = False Then
    MsgBox(sshClient.LastErrorString, vbIconExclamation)
    Exit Sub
End If
```

SshClient.Read Method

Read data from the server and store it in a byte array.

Overload List

Read data from the server and store it in a byte array.

public int Read(byte[]);

Read data from the server and store it in a byte array.

public int Read(byte[],int);

Read data from the server and store it in a string.

public int Read(ref string);

Read data from the server and store it in a string.

public int Read(ref string,int);

See Also

SshClient Class | SocketTools Namespace

SshClient.Read Method (Byte[])

Read data from the server and store it in a byte array.

[Visual Basic]

```
Overloads Public Function Read( _
   ByVal buffer As Byte() _
) As Integer
```

[C#]

```
public int Read(
   byte[] buffer
);
```

Parameters

buffer

A byte array that the data will be stored in.

Return Value

An integer value which specifies the number of bytes actually read from the server. A return value of zero specifies that the remote host has closed the connection and there is no more data available to be read. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Read** method returns data that has been read from the server, up to the size of the byte array passed to the method. If no data is available to be read, an error will be generated if the client is in non-blocking mode. If the client is in blocking mode, the program will stop until data is received from the server or the connection is closed.

See Also

SshClient Class | SocketTools Namespace | SshClient.Read Overload List

SshClient.Read Method (Byte[], Int32)

Read data from the server and store it in a byte array.

[Visual Basic]

```
Overloads Public Function Read( _
   ByVal buffer As Byte(), _
   ByVal length As Integer _
) As Integer
```

[C#]

```
public int Read(
   byte[] buffer,
   int length
);
```

Parameters

buffer

A byte array that the data will be stored in.

length

An integer value which specifies the maximum number of bytes of data to read. This value cannot be larger than the size of the buffer specified by the caller.

Return Value

An integer value which specifies the number of bytes actually read from the server. A return value of zero specifies that the remote host has closed the connection and there is no more data available to be read. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Read** method returns data that has been read from the server, up to the number of bytes specified. If no data is available to be read, an error will be generated if the client is in non-blocking mode. If the client is in blocking mode, the program will stop until data is received from the server or the connection is closed.

See Also

SshClient Class | SocketTools Namespace | SshClient.Read Overload List

SshClient.Read Method (String)

Read data from the server and store it in a string.

[Visual Basic]

```
Overloads Public Function Read( _
   ByRef buffer As String _
) As Integer
```

[C#]

```
public int Read(
   ref string buffer
);
```

Parameters

buffer

A string that will contain the data read from the client.

Return Value

An integer value which specifies the number of bytes actually read from the server. A return value of zero specifies that the remote host has closed the connection and there is no more data available to be read. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Read** method returns data that has been read from the server, up to a maximum of 4096 bytes. If no data is available to be read, an error will be generated if the client is in non-blocking mode. If the client is in blocking mode, the program will stop until data is received from the server or the connection is closed.

This method should only be used if the remote host is sending data that consists of printable characters. Binary data should be read using the method that accepts a byte array as the buffer parameter.

See Also

SshClient Class | SocketTools Namespace | SshClient.Read Overload List

SshClient.Read Method (String, Int32)

Read data from the server and store it in a string.

[Visual Basic]

```
Overloads Public Function Read( _
   ByRef buffer As String, _
   ByVal length As Integer _
) As Integer
```

[C#]

```
public int Read(
   ref string buffer,
   int length
);
```

Parameters

buffer

A string that will contain the data read from the client.

length

An integer value which specifies the maximum number of bytes of data to read.

Return Value

An integer value which specifies the number of bytes actually read from the server. A return value of zero specifies that the remote host has closed the connection and there is no more data available to be read. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Read** method returns data that has been read from the server, up to the number of bytes specified. If no data is available to be read, an error will be generated if the client is in non-blocking mode. If the client is in blocking mode, the program will stop until data is received from the server or the connection is closed.

This method should only be used if the remote host is sending data that consists of printable characters. Binary data should be read using the method that accepts a byte array as the buffer parameter.

SshClient.ReadLine Method

Read up to a line of data from the server and return it in a string buffer.

Overload List

Read up to a line of data from the server and return it in a string buffer.

public bool ReadLine(ref string);

Read up to a line of data from the server and return it in a string buffer.

public bool ReadLine(ref string,int);

See Also

SshClient Class | SocketTools Namespace

SshClient.ReadLine Method (String)

Read up to a line of data from the server and return it in a string buffer.

[Visual Basic]

```
Overloads Public Function ReadLine( _
   ByRef buffer As String _
) As Boolean
```

[C#]

```
public bool ReadLine(
   ref string buffer
);
```

Parameters

buffer

A string which will contain the data read from the socket.

Return Value

This method returns a Boolean value which specifies if a line of data has been read. A value of **true** indicates a line of data has been read. If an error occurs or there is no more data available to read, then the method will return **false**. It is possible for data to be returned in the string buffer even if the return value is **false**. Applications should check the length of the string after the method returns to determine if any data was copied into the buffer. For example, if a timeout occurs while the method is waiting for more data to arrive on the socket, it will return zero; however, data may have already been copied into the string buffer prior to the error condition. It is the responsibility of the application to process that data, regardless of the method return value.

Remarks

The **ReadLine** method reads data from the server up to 4096 bytes in length or until an end-of-line character sequence is encountered. Unlike the **Read** method which reads arbitrary bytes of data, this method is specifically designed to return a single line of text data in a string variable. When an end-of-line character sequence is encountered, the method will stop and return the data up to that point; the string will not contain the carriage-return or linefeed characters.

There are some limitations when using the **ReadLine** method. The method should only be used to read text, never binary data. In particular, it will discard nulls, linefeed and carriage return control characters. This method will force the current thread to block until an end-of-line character sequence is processed, the read operation times out or the remote host closes its end of the socket connection. If the **Blocking** property is set to **false**, calling this method will automatically switch the client into a blocking mode, read the data and then restore the client to non-blocking mode. If another network operation is attempted while **ReadLine** is blocked waiting for data from the remote host, an error will occur. It is recommended that this method only be used with blocking connections.

The **Read** and **ReadLine** methods can be intermixed, however be aware that the **Read** method will consume any data that has already been buffered by the **ReadLine** method and this may have unexpected results.

See Also

SshClient Class | SocketTools Namespace | SshClient.ReadLine Overload List

SshClient.ReadLine Method (String, Int32)

Read up to a line of data from the server and return it in a string buffer.

[Visual Basic]

```
Overloads Public Function ReadLine( _
   ByRef buffer As String, _
   ByVal length As Integer _
) As Boolean
```

[C#]

```
public bool ReadLine(
   ref string buffer,
   int length
);
```

Parameters

buffer

A string which will contain the data read from the socket.

length

An integer value which specifies the maximum number of bytes of data to read.

Return Value

This method returns a Boolean value which specifies if a line of data has been read. A value of **true** indicates a line of data has been read. If an error occurs or there is no more data available to read, then the method will return **false**. It is possible for data to be returned in the string buffer even if the return value is **false**. Applications should check the length of the string after the method returns to determine if any data was copied into the buffer. For example, if a timeout occurs while the method is waiting for more data to arrive on the socket, it will return zero; however, data may have already been copied into the string buffer prior to the error condition. It is the responsibility of the application to process that data, regardless of the method return value.

Remarks

The **ReadLine** method reads data from the server up to the specified number of bytes or until an end-of-line character sequence is encountered. Unlike the **Read** method which reads arbitrary bytes of data, this method is specifically designed to return a single line of text data in a string variable. When an end-of-line character sequence is encountered, the method will stop and return the data up to that point; the string will not contain the carriage-return or linefeed characters.

There are some limitations when using the **ReadLine** method. The method should only be used to read text, never binary data. In particular, it will discard nulls, linefeed and carriage return control characters. This method will force the current thread to block until an end-of-line character sequence is processed, the read operation times out or the remote host closes its end of the socket connection. If the **Blocking** property is set to **false**, calling this method will automatically switch the client into a blocking mode, read the data and then restore the client to non-blocking mode. If another network operation is attempted while **ReadLine** is blocked waiting for data from the remote host, an error will occur. It is recommended that this method only be used with blocking connections.

The **Read** and **ReadLine** methods can be intermixed, however be aware that the **Read** method will consume any data that has already been buffered by the **ReadLine** method and this may have unexpected results.

SshClient.Search Method

Search for a specific character sequence in the data stream.

Overload List

Search for a specific character sequence in the data stream.

public bool Search(string);

Search for a specific character sequence in the data stream.

public bool Search(string,byte[],ref int);

Search for a specific character sequence in the data stream.

public bool Search(string,ref string);

See Also

SshClient Class | SocketTools Namespace

SshClient.Search Method (String)

Search for a specific character sequence in the data stream.

[Visual Basic]

```
Overloads Public Function Search( _
   ByVal value As String _
) As Boolean
```

[C#]

```
public bool Search(
   string value
);
```

Parameters

value

A string argument which specifies the sequence of characters to search for in the data stream. When this sequence of characters is found, the method will return.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **Search** method searches for a character sequence in the data stream and stops reading when it is found. This is useful when the client wants to automate responses to the server, such as executing a command and processing the output. The method will discard any data received up to and including the specified character sequence.

See Also

SshClient Class | SocketTools Namespace | SshClient.Search Overload List

SshClient.Search Method (String, Byte[], Int32)

Search for a specific character sequence in the data stream.

[Visual Basic]
```
Overloads Public Function Search( _
   ByVal value As String, _
   ByVal buffer As Byte(), _
   ByRef length As Integer _
) As Boolean
```

[C#]
```
public bool Search(
   string value,
   byte[] buffer,
   ref int length
);
```

Parameters

value
A string argument which specifies the sequence of characters to search for in the data stream. When this sequence of characters is found, the method will return.

buffer
An byte array that will contain the output sent by the server, up to and including the search string character sequence.

length
An integer value passed by reference which should be initialized to the maximum number of bytes of data to store in the buffer. When the method returns, this value will be updated with the actual number of bytes stored in the buffer.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **Search** method searches for a character sequence in the data stream and stops reading when it is found. This is useful when the client wants to automate responses to the server, such as executing a command and processing the output. The method collects the output from the server and stores it in a buffer provided by the caller. When the method returns, the buffer will contain everything sent by the server up to and including the search string.

See Also

SshClient Class | SocketTools Namespace | SshClient.Search Overload List

SshClient.Search Method (String, String)

Search for a specific character sequence in the data stream.

[Visual Basic]

```
Overloads Public Function Search( _
   ByVal value As String, _
   ByRef buffer As String _
) As Boolean
```

[C#]

```
public bool Search(
   string value,
   ref string buffer
);
```

Parameters

value

A string argument which specifies the sequence of characters to search for in the data stream. When this sequence of characters is found, the method will return.

buffer

An string that will contain the output sent by the server, up to and including the search string character sequence.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **Search** method searches for a character sequence in the data stream and stops reading when it is found. This is useful when the client wants to automate responses to the server, such as executing a command and processing the output. The method collects the output from the server and stores it in a buffer provided by the caller. When the method returns, the buffer will contain everything sent by the server up to and including the search string.

SshClient Class | SocketTools Namespace | SshClient.Search Overload List

SshClient.Uninitialize Method

Uninitialize the class library and release any resources allocated for the current thread.

[Visual Basic]

```
Public Sub Uninitialize()
```

[C#]

```
public void Uninitialize();
```

Remarks

The **Uninitialize** method terminates any active connection, releases resources allocated for the current thread and unloads the networking library. After this method has been called, no further client operations may be performed until the class instance has been re-initialized.

If the **Initialize** method is explicitly called by the application, it should be matched by a call to the **Uninitialize** method when that instance of the class is no longer needed.

SshClient.Write Method

Write one or more bytes of data to the server.

Overload List

Write one or more bytes of data to the server.

public int Write(byte[]);

Write one or more bytes of data to the server.

public int Write(byte[],int);

Write a character to the server.

public int Write(char);

Write one or more characters to the server.

public int Write(char,int);

Write a string of characters to the server.

public int Write(string);

Write a string of characters to the server.

public int Write(string,int);

See Also

SshClient Class | SocketTools Namespace

SshClient.Write Method (Byte[])

Write one or more bytes of data to the server.

[Visual Basic]

```
Overloads Public Function Write( _
   ByVal buffer As Byte() _
) As Integer
```

[C#]

```
public int Write(
   byte[] buffer
);
```

Parameters

buffer

A byte array that contains the data to be written to the server.

Return Value

An integer value which specifies the number of bytes actually written to the server. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Write** method sends one or more bytes of data to the server. If there is enough room in the client's internal send buffer to accommodate all of the data, it is copied to the send buffer and control immediately returns to the caller. If amount of data exceeds the available buffer space and the client is in blocking mode, then the method will block until the data can be sent. If the client is in non-blocking mode and the send buffer is full, an error will occur.

See Also

SshClient Class | SocketTools Namespace | SshClient.Write Overload List

SshClient.Write Method (Byte[], Int32)

Write one or more bytes of data to the server.

```
Overloads Public Function Write( _
   ByVal buffer As Byte(), _
   ByVal length As Integer _
) As Integer
```

[C#]

```
public int Write(
   byte[] buffer,
   int length
);
```

Parameters

buffer
A byte array that contains the data to be written to the server.

length
An integer value which specifies the maximum number of bytes of data to write. This value cannot be larger than the size of the buffer specified by the caller.

Return Value

An integer value which specifies the number of bytes actually written to the server. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Write** method sends one or more bytes of data to the server. If there is enough room in the client's internal send buffer to accommodate all of the data, it is copied to the send buffer and control immediately returns to the caller. If amount of data exceeds the available buffer space and the client is in blocking mode, then the method will block until the data can be sent. If the client is in non-blocking mode and the send buffer is full, an error will occur.

See Also

SshClient Class | SocketTools Namespace | SshClient.Write Overload List

SshClient.Write Method (Char)

Write a character to the server.

[Visual Basic]

```
Overloads Public Function Write( _
   ByVal key As Char _
) As Integer
```

[C#]

```
public int Write(
   char key
);
```

Parameters

key

A character which will be written to the server.

Return Value

An integer value which specifies the number of characters actually written to the server. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Write** method sends one character to the server. If the client is in non-blocking mode and the send buffer is full, an error will occur.

See Also

SshClient Class | SocketTools Namespace | SshClient.Write Overload List

SshClient.Write Method (Char, Int32)

Write one or more characters to the server.

[Visual Basic]

```
Overloads Public Function Write( _
   ByVal key As Char, _
   ByVal repeat As Integer _
) As Integer
```

[C#]

```
public int Write(
   char key,
   int repeat
);
```

Parameters

key

A character which will be written to the server.

repeat

The number of characters that will be written to the server.

Return Value

An integer value which specifies the number of characters actually written to the server. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Write** method sends one or more characters to the server. If there is enough room in the client's internal send buffer to accommodate all of the data, it is copied to the send buffer and control immediately returns to the caller. If amount of data exceeds the available buffer space and the client is in blocking mode, then the method will block until the data can be sent. If the client is in non-blocking mode and the send buffer is full, an error will occur.

SshClient Class | SocketTools Namespace | SshClient.Write Overload List

SshClient.Write Method (String)

Write a string of characters to the server.

[Visual Basic]

```
Overloads Public Function Write( _
   ByVal buffer As String _
) As Integer
```

[C#]

```
public int Write(
   string buffer
);
```

Parameters

buffer

A string which contains the data to be written to the server.

Return Value

An integer value which specifies the number of characters actually written to the server. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Write** method sends a string of characters to the server. If there is enough room in the client's internal send buffer to accommodate all of the data, it is copied to the send buffer and control immediately returns to the caller. If amount of data exceeds the available buffer space and the client is in blocking mode, then the method will block until the data can be sent. If the client is in non-blocking mode and the send buffer is full, an error will occur.

The string will be converted to an array of bytes before being written to the socket. By default, the character encoding used will be for the current locale. Depending on the contents of the string, the number of bytes written may be different than the string length specified. This is because the conversion from Unicode to a byte array may result in a multi-byte character sequence.

SshClient.Write Method (String, Int32)

Write a string of characters to the server.

[Visual Basic]

```
Overloads Public Function Write( _
   ByVal buffer As String, _
   ByVal length As Integer _
) As Integer
```

[C#]

```
public int Write(
   string buffer,
   int length
);
```

Parameters

buffer

A string which contains the data to be written to the server.

length

An integer value which specifies the maximum number of characters to write. This value cannot be larger than the length of the string specified by the caller.

Return Value

An integer value which specifies the number of characters actually written to the server. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Write** method sends a string of characters to the server. If there is enough room in the client's internal send buffer to accommodate all of the data, it is copied to the send buffer and control immediately returns to the caller. If amount of data exceeds the available buffer space and the client is in blocking mode, then the method will block until the data can be sent. If the client is in non-blocking mode and the send buffer is full, an error will occur.

The string will be converted to an array of bytes before being written to the socket. By default, the character encoding used will be for the current locale. Depending on the contents of the string, the number of bytes written may be different than the string length specified. This is because the conversion from Unicode to a byte array may result in a multi-byte character sequence.

SshClient Class | SocketTools Namespace | SshClient.Write Overload List

SshClient.WriteLine Method

Send an empty line of text to the server, terminated by a carriage-return and linefeed.

Overload List

Send an empty line of text to the server, terminated by a carriage-return and linefeed.

```
public bool WriteLine();
```

Send a line of text to the server, terminated by a carriage-return and linefeed.

```
public bool WriteLine(string);
```

Send a line of text to the server, terminated by a carriage-return and linefeed.

```
public bool WriteLine(string,ref int);
```

See Also

SshClient Class | SocketTools Namespace

SshClient.WriteLine Method ()

Send an empty line of text to the server, terminated by a carriage-return and linefeed.

[Visual Basic]

```
Overloads Public Function WriteLine() As Boolean
```

[C#]

```
public bool WriteLine();
```

Return Value

A boolean value which specifies if the operation completed successfully. A return value of **false** indicates an error has occurred. To get extended error information, check the value of the **LastError** property.

Remarks

The **WriteLine** method will send an empty line of text, terminated by a carriage-return and linefeed. Calling this method will force the application to block until the complete line of text has been written, the write operation times out or the remote host aborts the connection. If this method is called with the **Blocking** property set to **false**, it will automatically switch the client into a blocking mode, send the data and then restore the client to non-blocking mode. If another network operation is attempted while the **WriteLine** method is blocked sending data to the remote host, an error will occur. It is recommended that this method only be used with blocking connections.

The **Write** and **WriteLine** methods can be safely intermixed.

See Also

SshClient Class | SocketTools Namespace | SshClient.WriteLine Overload List

SshClient.WriteLine Method (String)

Send a line of text to the server, terminated by a carriage-return and linefeed.

[Visual Basic]

```
Overloads Public Function WriteLine( _
   ByVal buffer As String _
) As Boolean
```

[C#]

```
public bool WriteLine(
   string buffer
);
```

Parameters

buffer

A string which contains the data that will be sent to the remote host. The data will always be terminated with a carriage-return and linefeed control character sequence. If the string is empty, then a only a carriage-return and linefeed are written to the socket. Note that if the string contains a null character, any data that follows the null character will be discarded.

Return Value

A boolean value which specifies if the operation completed successfully. A return value of **false** indicates an error has occurred. To get extended error information, check the value of the **LastError** property.

Remarks

The **WriteLine** method should only be used to send text, never binary data. In particular, this method will discard any data that follows a null character and will append linefeed and carriage return control characters to the data stream. Calling this method will force the current thread to block until the complete line of text has been written, the write operation times out or the remote host aborts the connection. If this method is called with the **Blocking** property set to **false**, it will automatically switch the client into a blocking mode, send the data and then restore the client to non-blocking mode. If another network operation is attempted while the **WriteLine** method is blocked sending data to the remote host, an error will occur. It is recommended that this method only be used with blocking connections.

The string will be converted to an array of bytes before being written to the socket. By default, the character encoding used will be for the current locale. Depending on the contents of the string, the number of bytes written may be different than the string length specified. This is because the conversion from Unicode to a byte array may result in a multi-byte character sequence.

The **Write** and **WriteLine** methods can be safely intermixed.

SshClient.WriteLine Method (String, Int32)

Send a line of text to the server, terminated by a carriage-return and linefeed.

[Visual Basic]

```
Overloads Public Function WriteLine( _
   ByVal buffer As String, _
   ByRef length As Integer _
) As Boolean
```

[C#]

```
public bool WriteLine(
   string buffer,
   ref int length
);
```

Parameters

buffer

A string which contains the data that will be sent to the remote host. The data will always be terminated with a carriage-return and linefeed control character sequence. If the string is empty, then a only a carriage-return and linefeed are written to the socket. Note that if the string contains a null character, any data that follows the null character will be discarded.

length

An integer value which specifies the maximum number of characters to write. This value cannot be larger than the length of the string specified by the caller.

Return Value

A boolean value which specifies if the operation completed successfully. A return value of **false** indicates an error has occurred. To get extended error information, check the value of the **LastError** property.

Remarks

The **WriteLine** method should only be used to send text, never binary data. In particular, this method will discard any data that follows a null character and will append linefeed and carriage return control characters to the data stream. Calling this method will force the current thread to block until the complete line of text has been written, the write operation times out or the remote host aborts the connection. If this method is called with the **Blocking** property set to **false**, it will automatically switch the client into a blocking mode, send the data and then restore the client to non-blocking mode. If another network operation is attempted while the **WriteLine** method is blocked sending data to the remote host, an error will occur. It is recommended that this method only be used with blocking connections.

The string will be converted to an array of bytes before being written to the socket. By default, the character encoding used will be for the current locale. Depending on the contents of the string, the number of bytes written may be different than the string length specified. This is because the conversion from Unicode to a byte array may result in a multi-byte character sequence.

The **Write** and **WriteLine** methods can be safely intermixed.

SshClient Events

The events of the **SshClient** class are listed below. For a complete list of **SshClient** class members, see the SshClient Members topic.

Public Instance Events

⚡ OnCancel	Occurs when a blocking client operation is canceled.
⚡ OnConnect	Occurs when a connection is established with the remote host.
⚡ OnDisconnect	Occurs when the remote host disconnects from the local system.
⚡ OnError	Occurs when an client operation fails.
⚡ OnRead	Occurs when data is available to be read from the client.
⚡ OnTimeout	Occurs when a blocking operation fails to complete before the timeout period elapses.
⚡ OnWrite	Occurs when data can be written to the client.

See Also

SshClient Class | SocketTools Namespace

SshClient.OnCancel Event

Occurs when a blocking client operation is canceled.

[Visual Basic]

```
Public Event OnCancel As EventHandler
```

[C#]

```
public event EventHandler OnCancel;
```

Remarks

The **OnCancel** event is generated when a blocking client operation, such as sending or receiving data, is canceled with the **Cancel** method. To assist in determining which operation was canceled, check the value of the **Status** property.

See Also

SshClient Class | SocketTools Namespace

SshClient.OnConnect Event

Occurs when a connection is established with the remote host.

[Visual Basic]
```
Public Event OnConnect As EventHandler
```

[C#]
```
public event EventHandler OnConnect;
```

Remarks

The **OnConnect** event occurs when a connection is made with a remote host as a result of a **Connect** method call. When the **Connect** method is called and the **Blocking** property is set to **false**, a socket is created but the connection is not actually established until after this event occurs. Between the time connection process is started and this event fires, no operation may be performed on the client other than calling the **Disconnect** method.

This event is only generated if the client is in non-blocking mode.

See Also

SshClient Class | SocketTools Namespace

SshClient.OnDisconnect Event

Occurs when the remote host disconnects from the local system.

[Visual Basic]
```
Public Event OnDisconnect As EventHandler
```

[C#]
```
public event EventHandler OnDisconnect;
```

Remarks

The **OnDisconnect** event occurs when the remote host closes its connection, terminating the client session with the application. Because there may still be data in the client receive buffers, you should continue to read data from the client until the **Read** method returns a value of 0. Once all of the data has been read, you should call the **Disconnect** method to close the local socket and release the resources allocated for the client.

This event is only generated if the client is in non-blocking mode.

See Also

SshClient Class | SocketTools Namespace

SshClient.OnError Event

Occurs when an client operation fails.

[Visual Basic]

```
Public Event OnError As OnErrorEventHandler
```

[C#]

```
public event OnErrorEventHandler OnError;
```

Event Data

The event handler receives an argument of type SshClient.ErrorEventArgs containing data related to this event. The following **SshClient.ErrorEventArgs** properties provide information specific to this event.

Property	Description
Description	Gets a value which describes the last error that has occurred.
Error	Gets a value which specifies the last error that has occurred.

Remarks

The **OnError** event occurs when a client operation fails.

See Also

SshClient Class | SocketTools Namespace

SshClient.ErrorEventArgs Class

Provides data for the OnError event.

For a list of all members of this type, see SshClient.ErrorEventArgs Members.

System.Object
  System.EventArgs
    SocketTools.SshClient.ErrorEventArgs

[Visual Basic]

```
Public Class SshClient.ErrorEventArgs
    Inherits EventArgs
```

[C#]

```
public class SshClient.ErrorEventArgs : EventArgs
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

ErrorEventArgs specifies the numeric error code and a description of the error that has occurred.

An OnError event occurs when a method fails.

Requirements

Namespace: SocketTools

Assembly: SocketTools.SshClient (in SocketTools.SshClient.dll)

SshClient.ErrorEventArgs Members

SshClient.ErrorEventArgs overview

Public Instance Constructors

SshClient.ErrorEventArgs Constructor	Initializes a new instance of the SshClient.ErrorEventArgs class.

Public Instance Properties

Description	Gets a value which describes the last error that has occurred.
Error	Gets a value which specifies the last error that has occurred.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString (inherited from Object)	Returns a String that represents the current Object.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

SshClient.ErrorEventArgs Class | SocketTools Namespace

SshClient.ErrorEventArgs Constructor

Initializes a new instance of the SshClient.ErrorEventArgs class.

[Visual Basic]
```
Public Sub New()
```

[C#]
```
public SshClient.ErrorEventArgs();
```

See Also

SshClient.ErrorEventArgs Class | SocketTools Namespace

SshClient.ErrorEventArgs Properties

The properties of the **SshClient.ErrorEventArgs** class are listed below. For a complete list of **SshClient.ErrorEventArgs** class members, see the SshClient.ErrorEventArgs Members topic.

Public Instance Properties

Description	Gets a value which describes the last error that has occurred.
Error	Gets a value which specifies the last error that has occurred.

See Also

SshClient.ErrorEventArgs Class | SocketTools Namespace

SshClient.ErrorEventArgs.Description Property

Gets a value which describes the last error that has occurred.

[Visual Basic]
```
Public ReadOnly Property Description As String
```

[C#]
```
public string Description {get;}
```

Property Value

A string which describes the last error that has occurred.

See Also

SshClient.ErrorEventArgs Class | SocketTools Namespace | Error Property

SshClient.ErrorEventArgs.Error Property

Gets a value which specifies the last error that has occurred.

[Visual Basic]

```
Public ReadOnly Property Error As ErrorCode
```

[C#]

```
public SshClient.ErrorCode Error {get;}
```

Property Value

ErrorCode enumeration which specifies the error.

See Also

SshClient.ErrorEventArgs Class | SocketTools Namespace | Description Property

SshClient.OnRead Event

Occurs when data is available to be read from the client.

[Visual Basic]

```
Public Event OnRead As EventHandler
```

[C#]

```
public event EventHandler OnRead;
```

Remarks

The **OnRead** event occurs when data is available to be read from the client. This event is level-triggered, which means that once this event fires, it will not occur again until some data has been read from the client. This design prevents an application from being flooded with event notifications. It is recommended that your application read all of the available data from the server and store it in a local buffer for processing. See the example below.

This event is only generated if the client is in non-blocking mode.

Example

```
Private Sub Socket_OnRead(ByVal sender As Object, ByVal e As System.EventArgs)
Handles Socket.OnRead
    Dim strBuffer As String
    Dim nRead As Integer

    Do
        ' Read up to m_nBufferSize bytes of data from the server
        nRead = Socket.Read(strBuffer, m_nBufferSize)

        If nRead > 0 Then
            ' Append the data to an internal buffer for processing
            m_dataBuffer = m_dataBuffer + strBuffer
        End If
    Loop Until nRead < 1

    ProcessData()
End Sub
```

See Also

SshClient Class | SocketTools Namespace

SshClient.OnTimeout Event

Occurs when a blocking operation fails to complete before the timeout period elapses.

[Visual Basic]

```
Public Event OnTimeout As EventHandler
```

[C#]

```
public event EventHandler OnTimeout;
```

Remarks

The **OnTimeout** event occurs when a blocking operation, such as sending or receiving data on the client, fails to complete before the specified timeout period elapses. The timeout period for a blocking operation can be adjusted by setting the **Timeout** property.

This event is only generated if the client is in blocking mode.

See Also

SshClient Class | SocketTools Namespace

SshClient.OnWrite Event

Occurs when data can be written to the client.

[Visual Basic]

```
Public Event OnWrite As EventHandler
```

[C#]

```
public event EventHandler OnWrite;
```

Remarks

The **OnWrite** event occurs when the application can write data to the client. This event will typically occur when a connection is first established with the remote host, and after the **Write** method has failed because there was insufficient memory available in the client send buffers. In the second case, when some of the buffered data has been successfully sent to the remote host and there is space available in the send buffers, this event is used to signal the application that it may attempt to send more data.

This event is only generated if the client is in non-blocking mode.

SshClient Class | SocketTools Namespace

SshClient.ClientOptions Enumeration

Specifies the options that the SshClient class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

```
[Visual Basic]
<Flags>
Public Enum SshClient.ClientOptions
```

```
[C#]
[Flags]
public enum SshClient.ClientOptions
```

Remarks

The SshClient class uses the **ClientOptions** enumeration to specify one or more options to be used when establishing a connection with a remote host. Multiple options may be specified if necessary.

Members

Member Name	Description	Value
optionNone	No option specified.	0
optionDefault	The default connection option. This is the same as specifying **optionNone**.	0
optionKeepAlive	This option specifies the library should attempt to maintain an idle client session for long periods of time. This option is only necessary if you expect that the connection will be held open for more than two hours. This option is the same as setting the **KeepAlive** property to a value of true.	1
optionNoPTY	This option specifies that a pseudoterminal (PTY) should not be created for the client session. This option is automatically set if the **Command** property specifies a command to be executed on the server.	2
optionNoShell	This option specifies that a command shell should not be used when executing a command on the remote host.	4
optionNoAuthRSA	This option specifies that RSA authentication should not be used with SSH-1 connections. This option is ignored with SSH-2 connections and should only be specified if required by the remote host.	8
optionNoPwdNul	This option specifies the user password	16

	cannot be terminated with a null byte. This option is ignored with SSH-2 connections and should only be specified if required by the remote host.	
optionNoRekey	This option specifies the client should never attempt a repeat key exchange with the server. Some SSH servers do not support rekeying the session, and this can cause the client to become non-responsive or abort the connection after being connected for an hour.	32
optionCompatSID	This compatibility option changes how the session ID is handled during public key authentication with older SSH servers. This option should only be specified when connecting to servers that use OpenSSH 2.2.0 or earlier versions.	64
optionCompatHMAC	This compatibility option changes how the HMAC authentication codes are generated. This option should only be specified when connecting to servers that use OpenSSH 2.2.0 or earlier versions.	128
optionFreeThread	This option specifies that class methods may be called from any thread, and not only the thread that established the connection. Using this option disables certain internal safety checks that are made by the class and may result in unexpected behavior unless you ensure that access to the class instance is synchronized across multiple threads.	524288

Requirements

Namespace: SocketTools

Assembly: SocketTools.SshClient (in SocketTools.SshClient.dll)

See Also

SocketTools Namespace

SshClient.ClientStatus Enumeration

Specifies the status values that may be returned by the SshClient class.

[Visual Basic]
```
Public Enum SshClient.ClientStatus
```

[C#]
```
public enum SshClient.ClientStatus
```

Remarks

The SshClient class uses the **ClientStatus** enumeration to identify the current status of the client.

Members

Member Name	Description
statusUnused	A client session has not been created. Attempts to perform any network operations, such as sending or receiving data, will generate an error.
statusIdle	A client session has been created, but is not currently in use. A blocking socket operation can be executed at this point.
statusConnect	The client is in the process of establishing a connection with a remote host.
statusAuthenticate	The client is authenticating the session.
statusRead	The client is in the process of receiving data from a remote host.
statusWrite	The client is in the process of sending data to a remote host.
statusDisconnect	The client session is being closed and subsequent attempts to access the client will result in an error.

Requirements

Namespace: SocketTools

Assembly: SocketTools.SshClient (in SocketTools.SshClient.dll)

See Also

SocketTools Namespace

SshClient.ControlCodes Enumeration

Specifies the control codes that the SshClient class may send to the server.

[Visual Basic]

```
Public Enum SshClient.ControlCodes
```

[C#]

```
public enum SshClient.ControlCodes
```

Remarks

The SshClient class uses the **ControlCodes** enumeration to specify the control code that should be sent to the server using the **Control** method. This enables an application to send control messages to the server, which can cause it to take specific actions such as simulate a terminal break or request that the key exchange be performed again. Note that some control messages are not supported by the SSH 1.0 protocol, in which case the control message is ignored.

Members

Member Name	Description
controlBreak	Sends a control message to the remote host which simulates a break signal on a physical terminal. This is used by some operating systems as an instruction to enter a privileged configuration mode. Note that this is not the same as sending an interrupt character such as Ctrl+C to the remote host. This control code is ignored for SSH 1.0 sessions. This is the same as calling the **Break** method.
controlNoop	Sends a control message to the remote host, but it does not perform any operation. This is typically used by clients to prevent the server from automatically closing a session that has been idle for a long period of time.
controlEof	Sends a control message to the remote host indicating that the client has finished sending data. Note that this option is normally not used with interactive terminal sessions, and should only be used when required by the server.
controlPing	Sends a control message to the remote host which is used to test whether or not the remote host is responsive to the client. This is typically used by clients to attempt to detect if the connection to the remote host is still active.
controlRekey	Sends a control message to the remote host requesting that the key exchange be performed again. This control code is ignored for SSH 1.0 sessions.

Requirements

Namespace: SocketTools

Assembly: SocketTools.SshClient (in SocketTools.SshClient.dll)

See Also

SocketTools Namespace

SshClient.ErrorCode Enumeration

Specifies the error codes returned by the SshClient class.

[Visual Basic]

```
Public Enum SshClient.ErrorCode
```

[C#]

```
public enum SshClient.ErrorCode
```

Remarks

The SshClient class uses the **ErrorCode** enumeration to specify what error has occurred when a method fails. The current error code may be determined by checking the value of the **LastError** property.

Note that the last error code is only meaningful if the previous operation has failed.

Members

Member Name	Description
errorNone	No error.
errorNotHandleOwner	Handle not owned by the current thread.
errorFileNotFound	The specified file or directory does not exist.
errorFileNotCreated	The specified file could not be created.
errorOperationCanceled	The blocking operation has been canceled.
errorInvalidFileType	The specified file is a block or character device, not a regular file.
errorInvalidDevice	The specified file type is invalid or not a regular file.
errorTooManyParameters	The maximum number of function parameters has been exceeded.
errorInvalidFileName	The specified file name contains invalid characters or is too long.
errorInvalidFileHandle	Invalid file handle passed to function.
errorFileReadFailed	Unable to read data from the specified file.
errorFileWriteFailed	Unable to write data to the specified file.
errorOutOfMemory	Out of memory.
errorAccessDenied	Access denied.
errorInvalidParameter	Invalid argument passed to function.
errorClipboardUnavailable	The system clipboard is currently unavailable.
errorClipboardEmpty	The system clipboard is empty or does not contain any text data.
errorFileEmpty	The specified file does not contain any data.
errorFileExists	The specified file already exists.

errorEndOfFile	End of file.
errorDeviceNotFound	The specified device could not be found.
errorDirectoryNotFound	The specified directory could not be found.
errorInvalidbuffer	Invalid memory address passed to function.
errorBufferTooSmall	The specified buffer is not large enough to contain the data.
errorNoHandles	No more handles are available to this process.
errorOperationWouldBlock	The specified operation would block the current thread.
errorOperationInProgress	A blocking operation is currently in progress.
errorAlreadyInProgress	The specified operation is already in progress.
errorInvalidHandle	Invalid handle passed to function.
errorInvalidAddress	Invalid network address specified.
errorInvalidSize	Datagram is too large to fit in specified buffer.
errorInvalidProtocol	Invalid network protocol specified.
errorProtocolNotAvailable	The specified network protocol is not available.
errorProtocolNotSupported	The specified protocol is not supported.
errorSocketNotSupported	The specified socket type is not supported.
errorInvalidOption	The specified option is invalid.
errorProtocolFamily	Specified protocol family is not supported.
errorProtocolAddress	The specified address is invalid for this protocol family.
errorAddressInUse	The specified address is in use by another process.
errorAddressUnavailable	The specified address cannot be assigned.
errorNetworkUnavailable	The networking subsystem is unavailable.
errorNetworkUnreachable	The specified network is unreachable.
errorNetworkReset	Network dropped connection on remote reset.
errorConnectionAborted	Connection was aborted due to timeout or other failure.
errorConnectionReset	Connection was reset by remote network.
errorOutOfBuffers	No buffer space is available.
errorAlreadyConnected	Connection already established with remote host.
errorNotConnected	No connection established with remote host.
errorConnectionShutdown	Unable to send or receive data after connection shutdown.
errorOperationTimeout	The specified operation has timed out.
errorConnectionRefused	The connection has been refused by the remote host.

errorHostUnavailable	The specified host is unavailable.
errorHostUnreachable	Remote host is unreachable.
errorTooManyProcesses	Too many processes are using the networking subsystem.
errorTooManyThreads	Too many threads have been created by the current process.
errorTooManySessions	Too many client sessions have been created by the current process.
errorInternalFailure	An unexpected internal error has occurred.
errorNetworkNotReady	Network subsystem is not ready for communication.
errorInvalidVersion	This version of the operating system is not supported.
errorNetworkNotInitialized	The networking subsystem has not been initialized.
errorRemoteShutdown	The remote host has initiated a graceful shutdown sequence.
errorInvalidHostName	The specified hostname is invalid or could not be resolved.
errorHostNameNotFound	The specified hostname could not be found.
errorHostNameRefused	Unable to resolve hostname, request refused.
errorHostNameNotResolved	Unable to resolve hostname, no address for specified host.
errorInvalidLicense	The license for this product is invalid.
errorProductNotLicensed	This product is not licensed to perform this operation.
errorNotImplemented	This function has not been implemented on this platform.
errorUnknownLocalhost	Unable to determine local host name.
errorInvalidHostAddress	Invalid host address specified.
errorInvalidServicePort	Invalid service port number specified.
errorInvalidServiceName	Invalid or unknown service name specified.
errorInvalidEventId	Invalid event identifier specified.
errorOperationNotBlocking	No blocking operation in progress on this socket.
errorSecurityNotInitialized	Unable to initialize security interface for this process.
errorSecurityContext	Unable to establish security context for this session.
errorSecurityCredentials	Unable to open certificate store or establish security credentials.
errorSecurityCertificate	Unable to validate the certificate chain for this

	session.
errorSecurityDecryption	Unable to decrypt data stream.
errorSecurityEncryption	Unable to encrypt data stream.
errorOperationNotSupported	The specified operation is not supported.
errorInvalidProtocolVersion	Invalid application protocol version specified.
errorNoServerResponse	No data returned from server.
errorInvalidServerResponse	Invalid data returned from server.
errorUnexpectedServerResponse	Unexpected response code returned from server.
errorServerTransactionFailed	Server transaction failed.
errorServiceUnavailable	The service is currently unavailable.
errorServiceNotReady	The service is not ready, try again later.
errorServerResyncFailed	Unable to resynchronize with server.
errorInvalidProxyType	Invalid proxy server type specified.
errorProxyRequired	Resource must be accessed through specified proxy.
errorInvalidProxyLogin	Unable to login to proxy server using specified credentials.
errorProxyResyncFailed	Unable to resynchronize with proxy server.
errorInvalidCommand	Invalid command specified.
errorInvalidCommandParameter	Invalid command parameter specified.
errorInvalidCommandSequence	Invalid command sequence specified.
errorCommandNotImplemented	Specified command not implemented on this server.
errorCommandNotAuthorized	Specified command not authorized for the current user.
errorCommandAborted	Specified command was aborted by the remote host.
errorOptionNotSupported	The specified option is not supported on this server.
errorRequestNotCompleted	The current client request has not been completed.
errorInvalidUserName	The specified username is invalid.
errorInvalidPassword	The specified password is invalid.
errorInvalidAccount	The specified account name is invalid.
errorAccountRequired	Account name has not been specified.
errorInvalidAuthenticationType	Invalid authentication protocol specified.
errorAuthenticationRequired	User authentication is required.
errorProxyAuthenticationRequired	Proxy authentication required.

errorAlreadyAuthenticated	User has already been authenticated.
errorAuthenticationFailed	Unable to authenticate the specified user.
errorNetworkAdapter	Unable to determine network adapter configuration.
errorInvalidRecordType	Invalid record type specified.
errorInvalidRecordName	Invalid record name specified.
errorInvalidRecordData	Invalid record data specified.
errorConnectionOpen	Data connection already established.
errorConnectionClosed	Server closed data connection.
errorConnectionPassive	Data connection is passive.
errorConnectionFailed	Unable to open data connection to server.
errorInvalidSecurityLevel	Data connection cannot be opened with this security setting.
errorCachedTLSRequired	Data connection requires cached TLS session.
errorDataReadOnly	Data connection is read-only.
errorDataWriteOnly	Data connection is write-only.
errorEndOfData	End of data.
errorRemoteFileUnavailable	Remote file is unavailable.
errorInsufficientStorage	Insufficient storage on server.
errorStorageallocation	File exceeded storage allocation on server.
errorDirectoryExists	The specified directory already exists.
errorDirectoryEmpty	No files returned by the server for the specified directory.
errorEndOfDirectory	End of directory listing.
errorUnknownDirectoryFormat	Unknown directory format.
errorInvalidResource	Invalid resource name specified.
errorResourceRedirected	The specified resource has been redirected.
errorResourceRestricted	Access to this resource has been restricted.
errorResourceNotModified	The specified resource has not been modified.
errorResourceNotFound	The specified resource cannot be found.
errorResourceConflict	Request could not be completed due to the current state of the resource.
errorResourceRemoved	The specified resource has been permanently removed from this server.
errorContentLengthRequired	Request must include the content length.
errorRequestPrecondition	Request could not be completed due to server precondition.
errorUnsupportedMediaType	Request specified an unsupported media type.

errorInvalidContentRange	Content range specified for this resource is invalid.
errorInvalidMessagePart	Message is not multipart or an invalid message part was specified.
errorInvalidMessageHeader	The specified message header is invalid or has not been defined.
errorInvalidMessageBoundary	The multipart message boundary has not been defined.
errorNoFileAttachment	The current message part does not contain a file attachment.
errorUnknownFileType	The specified file type could not be determined.
errorDataNotEncoded	The specified data block could not be encoded.
errorDataNotDecoded	The specified data block could not be decoded.
errorFileNotEncoded	The specified file could not be encoded.
errorFileNotDecoded	The specified file could not be decoded.
errorNoMessageText	No message text.
errorInvalidCharacterSet	Invalid character set specified.
errorInvalidEncodingType	Invalid encoding type specified.
errorInvalidMessageNumber	Invalid message number specified.
errorNoReturnAddress	No valid return address specified.
errorNoValidRecipients	No valid recipients specified.
errorInvalidRecipient	The specified recipient address is invalid.
errorRelayNotAuthorized	The specified domain is invalid or server will not relay messages.
errorMailboxUnavailable	Specified mailbox is currently unavailable.
errorMailboxReadOnly	The selected mailbox cannot be modified.
errorMailboxNotSelected	No mailbox has been selected.
errorInvalidMailbox	Specified mailbox is invalid.
errorInvalidDomain	The specified domain name is invalid or not recognized.
errorInvalidSender	The specified sender address is invalid or not recognized.
errorMessageNotDelivered	Message not delivered to any of the specified recipients.
errorEndOfMessageData	No more message data available to be read
errorInvalidmessageSize	The specified message size is invalid.
errorMessageNotCreated	The message could not be created in the specified mailbox.
errorNoMoreMailboxes	No more mailboxes exist on this server.

errorInvalidEmulationType	The specified terminal emulation type is invalid.
errorInvalidFontHandle	The specified font handle is invalid.
errorInvalidFontName	The specified font name is invalid or unavailable.
errorInvalidPacketSize	The specified packet size is invalid.
errorInvalidPacketData	The specified packet data is invalid.
errorInvalidPacketId	The unique packet identifier is invalid.
errorPacketTTLExpired	The specified packet time-to-live period has expired.
errorInvalidNewsGroup	Invalid newsgroup specified.
errorNoNewsgroupSelected	No newsgroup selected.
errorEmptyNewsgroup	No articles in specified newsgroup.
errorInvalidArticle	Invalid article number specified.
errorNoArticleSelected	No article selected in the current newsgroup.
errorFirstArticle	First article in current newsgroup.
errorLastArticle	Last article in current newsgroup.
errorArticleExists	Unable to transfer article, article already exists.
errorArticleRejected	Unable to transfer article, article rejected.
errorArticleTransferFailed	Article transfer failed.
errorArticlePostingDenied	Posting is not permitted on this server.
errorArticlePostingFailed	Unable to post article on this server.
errorInvalidDateFormat	The specified date format is not recognized.
errorFeatureNotSupported	The specified feature is not supported on this server.
errorInvalidFormHandle	The specified form handle is invalid or a form has not been created.
errorInvalidFormAction	The specified form action is invalid or has not been specified.
errorInvalidFormMethod	The specified form method is invalid or not supported.
errorInvalidFormType	The specified form type is invalid or not supported.
errorInvalidFormField	The specified form field name is invalid or does not exist.
errorEmptyForm	The specified form does not contain any field values.
errorMaximumConnections	The maximum number of client connections exceeded.
errorThreadCreationFailed	Unable to create a new thread for the current process.
errorInvalidThreadHandle	The specified thread handle is no longer valid.

errorThreadTerminated	The specified thread has been terminated.
errorThreadDeadlock	The operation would result in the current thread becoming deadlocked.
errorInvalidClientMoniker	The specified moniker is not associated with any client session.
errorClientMonikerExists	The specified moniker has been assigned to another client session.
errorServerInactive	The specified server is not listening for client connections.
errorServerSuspended	The specified server is suspended and not accepting client connections.
errorNoMessageStore	No message store has been specified.
errorMessageStoreChanged	The message store has changed since it was last accessed.
errorMessageNotFound	No message was found that matches the specified criteria.
errorMessageDeleted	The specified message has been deleted.
errorFileChecksumMismatch	The local and remote file checksums do not match.
errorFileSizeMismatch	The local and remote file sizes do not match.
errorInvalidFeedUrl	The news feed URL is invalid or specifies an unsupported protocol.
errorInvalidFeedFormat	The internal format of the news feed is invalid.
errorInvalidFeedVersion	This version of the news feed is not supported.
errorChannelEmpty	There are no valid items found in this news feed.
errorInvalidItemNumber	The specified channel item identifier is invalid.
errorItemNotFound	The specified channel item could not be found.
errorItemEmpty	The specified channel item does not contain any data.
errorInvalidItemProperty	The specified item property name is invalid.
errorItemPropertyNotFound	The specified item property has not been defined.
errorInvalidChannelTitle	The channel title is invalid or has not been defined.
errorInvalidChannelLink	The channel hyperlink is invalid or has not been defined.
errorInvalidChannelDescription	The channel description is invalid or has not been defined.
errorInvalidItemText	The description for an item is invalid or has not been defined.
errorInvalidItemLink	The hyperlink for an item is invalid or has not been defined.

errorInvalidServiceType	The specified service type is invalid.
errorServiceSuspended	Access to the specified service has been suspended.
errorServiceRestricted	Access to the specified service has been restricted.
errorInvalidProviderName	The specified provider name is invalid or unknown.
errorInvalidPhoneNumber	The specified phone number is invalid or not supported in this region.
errorGatewayNotFound	A message gateway cannot be found for the specified provider.
errorMessageTooLong	The message exceeds the maximum number of characters permitted.
errorInvalidProviderData	The request returned invalid or incomplete service provider data.
errorInvalidGatewayData	The request returned invalid or incomplete message gateway data.
errorMultipleProviders	The request has returned multiple service providers.
errorProviderNotFound	The specified service provider could not be found.
errorInvalidMessageService	The specified message is not supported with this service type.
errorInvalidMessageFormat	The specified message format is invalid.
errorInvalidConfiguration	The specified configuration options are invalid.
errorServerActive	The requested action is not permitted while the server is active.
errorServerPortBound	Unable to obtain exclusive use of the specified local port.
errorInvalidClientSession	The specified client identifier is invalid for this session.
errorClientNotIdentified	The specified client has not provided user credentials.
errorInvalidClientState	The requested action cannot be performed at this time.
errorInvalidResultCode	The specified result code is not valid for this protocol
errorCommandRequired	The specified command is required and cannot be disabled.
errorCommandDisabled	The specified command has been disabled.
errorCommandSequence	The command cannot be processed at this time.
errorCommandCompleted	The previous command has completed.
errorInvalidProgramName	The specified program name is invalid or unrecognized.

errorInvalidRequestHeader	The request header contains one or more invalid values.
errorInvalidVirtualHost	The specified virtual host name is invalid.
errorVirtualHostNotFound	The specified virtual host does not exist.
errorTooManyVirtualHosts	Too many virtual hosts created for this server.
errorInvalidVirtualPath	The specified virtual path name is invalid.
errorVirtualPathNotFound	The specified virtual path does not exist.
errorTooManyVirtualPaths	Too many virtual paths created for this server.
errorInvalidTask	The asynchronous task identifier is invalid.
errorTaskActive	The asynchronous task has not finished.
errorTaskQueued	The asynchronous task has been queued.
errorTaskSuspended	The asynchronous task has been suspended.
errorTaskFinished	The asynchronous task has finished.

SshClient.LineMode Enumeration

Specifies how end-of-line character sequences are sent to the server.

[Visual Basic]
```
Public Enum SshClient.LineMode
```

[C#]
```
public enum SshClient.LineMode
```

Members

Member Name	Description
newLineDefault	There are no changes to how data is sent to the server. Any carriage return or linefeed characters that are sent using the **Write** method will be sent as-is. The **WriteLine** method will terminate each line of text with a carriage return and linefeed (CRLF) sequence. This is the default line mode that is set when a new connection is established.
newLineCR	A carriage return is used as the end-of-line character. Any data sent using the **Write** method that contains only a linefeed (LF) character or a carriage return and linefeed (CRLF) sequence to indicate the end-of-line will be replaced by a carriage return (CR) character. The **WriteLine** method will terminate each line of text with a single carriage return character.
newLineLF	A linefeed is used as the end-of-line character. Any data sent using the **Write** method that contains only a carriage return (CR) character or a carriage return an linefeed (CRLF) sequence to indicate the end-of-line will be replaced by a linefeed (LF) character. The **WriteLine** method will terminate each line of text with a single linefeed character.
newLineCRLF	A carriage return and linefeed (CRLF) character sequence is used to indicate the end-of-line. Any data sent using the Write method that contains only a carriage return (CR) or linefeed (LF) will be replaced by a carriage return and linefeed. The **WriteLine** method will terminate each line of text with a carriage return and linefeed sequence.

SocketTools Namespace | NewLine Property (SocketTools.SshClient)

SshClient.ProxyTypes Enumeration

Specifies the type of proxy servers that the SshClient class supports.

[Visual Basic]

```
Public Enum SshClient.ProxyTypes
```

[C#]

```
public enum SshClient.ProxyTypes
```

Remarks

The SshClient class uses the **ProxyTypes** enumeration to specify the type of proxy server that the connection should be established through, if any. By default, no proxy server is used when establishing a connection.

Members

Member Name	Description
proxyNone	No proxy server. A direct connection will be established with the server.
proxyHttp	Establish a connection through a proxy server using the Hypertext Transfer Protocol.
proxyTelnet	Establish a connection through a proxy server using the Telnet protocol.

Requirements

Namespace: SocketTools

Assembly: SocketTools.SshClient (in SocketTools.SshClient.dll)

See Also

SocketTools Namespace

SshClient.SecureCipherAlgorithm Enumeration

Specifies the encryption algorithms that the SshClient class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]

```
<Flags>
Public Enum SshClient.SecureCipherAlgorithm
```

[C#]

```
[Flags]
public enum SshClient.SecureCipherAlgorithm
```

Remarks

The SshClient class uses the **SecureCipherAlgorithm** enumeration to identify which encryption algorithm was selected when a secure connection was established with the remote host.

Members

Member Name	Description	Value
cipherNone	No cipher has been selected. A secure connection has not been established with the remote host.	0
cipherRC2	The RC2 block cipher was selected. This is a variable key length cipher which supports keys between 40- and 128-bits in length, in 8-bit increments.	1
cipherRC4	The RC4 stream cipher was selected. This is a variable key length cipher which supports keys between 40- and 128-bits in length, in 8-bit increments.	2
cipherRC5	The RC5 block cipher was selected. This is a variable key length cipher which supports keys up to 2040 bits, in 8-bit increments.	4
cipherDES	The DES (Data Encryption Standard) block cipher was selected. This is a fixed key length cipher using 56-bit keys.	8
cipherDES3	The Triple DES block cipher was selected. This cipher encrypts the data three times using different keys, effectively using a 168-bit key length.	16
cipherDESX	A variant of the DES block cipher which XORs an extra 64-bits of the key before and after the plaintext has been encrypted, increasing the key size to 184 bits.	32
cipherAES	The Advanced Encryption Standard	64

	cipher (also known as the Rijndael cipher) is a fixed block size cipher which use a key size of 128, 192 or 256 bits. This cipher is supported on Windows XP SP3 SP3 and later versions of the operating system.	
cipherSkipjack	The Skipjack block cipher was selected. This is a fixed key length cipher, using 80-bit keys.	128
cipherBlowfish	The Blowfish block cipher was selected. This is a variable key length cipher up to 448 bits, using a 64-bit block size.	256

SshClient.SecureHashAlgorithm Enumeration

Specifies the hash algorithms that the SshClient class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]

```
<Flags>
Public Enum SshClient.SecureHashAlgorithm
```

[C#]

```
[Flags]
public enum SshClient.SecureHashAlgorithm
```

Remarks

The SshClient class uses the **SecureHashAlgorithm** enumeration to identify the message digest (hash) algorithm that was selected when a secure connection was established with the remote host.

Members

Member Name	Description	Value
hashNone	No hash algorithm has been selected. This is not a secure connection with the server.	0
hashMD5	The MD5 algorithm was selected. This algorithm produces a 128-bit message digest. This algorithm is no longer considered to be cryptographically secure.	1
hashSHA	The SHA-1 algorithm was selected. This algorithm produces a 160-bit message digest. This algorithm is no longer considered to be cryptographically secure.	2
hashSHA256	The SHA-256 algorithm was selected. This algorithm produces a 256-bit message digest.	4

Requirements

Namespace: SocketTools

Assembly: SocketTools.SshClient (in SocketTools.SshClient.dll)

SocketTools Namespace

SshClient.SecureKeyAlgorithm Enumeration

Specifies the key exchange algorithms that the SshClient class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]
```
<Flags>
Public Enum SshClient.SecureKeyAlgorithm
```

[C#]
```
[Flags]
public enum SshClient.SecureKeyAlgorithm
```

Remarks

The SshClient class uses the **SecureKeyAlgorithm** enumeration to identify the key exchange algorithm that was selected when a secure connection was established with the remote host.

Members

Member Name	Description	Value
keyExchangeNone	No key exchange algorithm has been selected. This is not a secure connection with the server.	0
keyExchangeRSA	The RSA public key exchange algorithm has been selected.	1
keyExchangeKEA	The KEA public key exchange algorithm has been selected. This is an improved version of the Diffie-Hellman public key algorithm.	2
keyExchangeDH	The Diffie-Hellman public key exchange algorithm has been selected.	4
keyExchangeECDH	The Elliptic Curve Diffie-Hellman key exchange algorithm was selected. This is a variant of the Diffie-Hellman algorithm which uses elliptic curve cryptography. This key exchange algorithm is only supported on Windows XP SP3 SP3 and later versions of the operating system.	8

Requirements

Namespace: SocketTools

Assembly: SocketTools.SshClient (in SocketTools.SshClient.dll)

SocketTools Namespace

SshClient.SecurityProtocols Enumeration

Specifies the security protocols that the SshClient class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]
```
<Flags>
Public Enum SshClient.SecurityProtocols
```

[C#]
```
[Flags]
public enum SshClient.SecurityProtocols
```

Remarks

The SshClient class uses the **SecurityProtocols** enumeration to specify one or more security protocols to be used when establishing a connection with a remote host. Multiple protocols may be specified if necessary and the actual protocol used will be negotiated with the remote host. It is recommended that most applications use **protocolDefault** when creating a secure connection.

Members

Member Name	Description	Value
protocolNone	No security protocol has been selected. Because all connections to an SSH server are secure, this value indicates that a connection has not been established.	0
protocolSSH1	The Secure Shell 1.0 protocol has been selected. This version of the protocol has been deprecated and is no longer widely used. It is not recommended that this version of the protocol be used to establish a connection.	256
protocolSSH2	The Secure Shell 2.0 protocol has been selected. This is the most commonly used version of the protocol. It is recommended that this version of the protocol be used unless the server explicitly requires the client to use an earlier version.	512
protocolDefault	Either version 1.0 or 2.0 of the protocol should be used when establishing the connection. The correct version of the protocol will be automatically selected, based on which version is supported by the server.	512
protocolUnknown	An unknown or unsupported security protocol has been specified. This value indicates an error condition.	4096

Requirements

Namespace: SocketTools

Assembly: SocketTools.SshClient (in SocketTools.SshClient.dll)

SocketTools Namespace

SshClient.TraceOptions Enumeration

Specifies the logging options that the SshClient class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]

```
<Flags>
Public Enum SshClient.TraceOptions
```

[C#]

```
[Flags]
public enum SshClient.TraceOptions
```

Remarks

The SshClient class uses the **TraceOptions** enumeration to specify what kind of debugging information is written to the trace logfile. These options are only meaningful when trace logging is enabled by setting the **Trace** property to **true**.

Members

Member Name	Description	Value
traceDefault	The default trace logging option. This is the same as specifying the **traceInfo** option.	0
traceInfo	All network function calls are written to the trace file. This is the default value.	0
traceError	Only those network function calls which fail are recorded in the trace file.	1
traceWarning	Only those network function calls which fail, or return values which indicate a warning, are recorded in the trace file.	2
traceHexDump	All network function calls are written to the trace file, plus all the data that is sent or received is displayed, in both ASCII and hexadecimal format.	4
traceProcess	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for multithreaded applications that are using worker threads.	4096

Requirements

Namespace: SocketTools

Assembly: SocketTools.SshClient (in SocketTools.SshClient.dll)

SocketTools Namespace

SshClient.OnErrorEventHandler Delegate

Represents the method that will handle the OnError event.

[Visual Basic]

```
Public Delegate Sub SshClient.OnErrorEventHandler( _
   ByVal sender As Object, _
   ByVal e As ErrorEventArgs _
)
```

[C#]

```
public delegate void SshClient.OnErrorEventHandler(
      object sender,
      ErrorEventArgs e
   );
```

Parameters

sender

The source of the event.

e

An ErrorEventArgs that contains the event data.

Remarks

When you create an **OnErrorEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnErrorEventHandler** delegate declaration.

Requirements

Namespace: SocketTools

Assembly: SocketTools.SshClient (in SocketTools.SshClient.dll)

See Also

SocketTools Namespace

SshClient.RuntimeLicenseAttribute Class

Attribute that defines the runtime license key for the class.

For a list of all members of this type, see SshClient.RuntimeLicenseAttribute Members.

System.Object
  System.Attribute
    SocketTools.SshClient.RuntimeLicenseAttribute

[Visual Basic]

```
<AttributeUsage(ValidOn:=AttributeTargets.Assembly, AllowMultiple:=False,
   Inherited:=True)>
Public Class SshClient.RuntimeLicenseAttribute
    Inherits Attribute
```

[C#]

```
[AttributeUsage(ValidOn=AttributeTargets.Assembly, AllowMultiple=False,
   Inherited=True)]
public class SshClient.RuntimeLicenseAttribute : Attribute
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

The RuntimeLicense attribute is used to define the runtime license key that will be used when an instance of the class is created. This attribute is defined in the assembly information module for the language, such as AssemblyInfo.cs when programming C#. The runtime license key must be defined if you wish to redistribute your application.

The runtime license key for your copy of SocketTools can be generated using the License Manager utility that is included with the product. Note that if you have installed an evaluation license, you will not have a runtime license key and cannot redistribute any applications which use the SshClient class.

Example

```
<Assembly: SocketTools.SshClient.RuntimeLicense("abcdefghijklmnop")>
```

```
[assembly: SocketTools.SshClient.RuntimeLicense("abcdefghijklmnop")]
```

Requirements

Namespace: SocketTools

Assembly: SocketTools.SshClient (in SocketTools.SshClient.dll)

SshClient.RuntimeLicenseAttribute Members

SshClient.RuntimeLicenseAttribute overview

Public Instance Constructors

SshClient.RuntimeLicenseAttribute Constructor	Constructor for the RuntimeLicense attribute which defines the runtime license key.

Public Instance Properties

LicenseKey	Returns the value of the runtime license key.
TypeId (inherited from Attribute)	When implemented in a derived class, gets a unique identifier for this Attribute.

Public Instance Methods

Equals (inherited from Attribute)	
GetHashCode (inherited from Attribute)	Returns the hash code for this instance.
GetType (inherited from Object)	Gets the Type of the current instance.
IsDefaultAttribute (inherited from Attribute)	When overridden in a derived class, returns an indication whether the value of this instance is the default value for the derived class.
Match (inherited from Attribute)	When overridden in a derived class, returns a value indicating whether this instance equals a specified object.
ToString (inherited from Object)	Returns a String that represents the current Object.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

SshClient.RuntimeLicenseAttribute Class | SocketTools Namespace

SshClient.RuntimeLicenseAttribute Constructor

Constructor for the RuntimeLicense attribute which defines the runtime license key.

[Visual Basic]

```
Public Sub New( _
   ByVal licenseKey As String _
)
```

[C#]

```
public SshClient.RuntimeLicenseAttribute(
   string licenseKey
);
```

Parameters

licenseKey

A string argument which specifies the runtime license key which will be used to initialize the class library.

Remarks

The runtime license key for your copy of SocketTools can be generated using the License Manager utility that is included with the product. Note that if you have installed an evaluation license, you will not have a runtime license key and cannot redistribute any applications which use the SshClient class.

See Also

SshClient.RuntimeLicenseAttribute Class | SocketTools Namespace

SshClient.RuntimeLicenseAttribute Properties

The properties of the **SshClient.RuntimeLicenseAttribute** class are listed below. For a complete list of **SshClient.RuntimeLicenseAttribute** class members, see the SshClient.RuntimeLicenseAttribute Members topic.

Public Instance Properties

LicenseKey	Returns the value of the runtime license key.
TypeId (inherited from Attribute)	When implemented in a derived class, gets a unique identifier for this Attribute.

See Also

SshClient.RuntimeLicenseAttribute Class | SocketTools Namespace

SshClient.RuntimeLicenseAttribute.LicenseKey Property

Returns the value of the runtime license key.

[Visual Basic]

```
Public Property LicenseKey As String
```

[C#]

```
public string LicenseKey {get; set;}
```

Property Value

A string which contains the runtime license key.

See Also

SshClient.RuntimeLicenseAttribute Class | SocketTools Namespace

SshClientException Class

The exception that is thrown when a client error occurs.

For a list of all members of this type, see SshClientException Members.

System.Object
  System.Exception
    System.ApplicationException
      SocketTools.SshClientException

[Visual Basic]
```
Public Class SshClientException
    Inherits ApplicationException
```

[C#]
```
public class SshClientException : ApplicationException
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

A SshClientException is thrown by the SshClient class when an error occurs.

The default constructor for the SshClientException class sets the **ErrorCode** property to the last client error that occurred.

Requirements

Namespace: SocketTools

Assembly: SocketTools.SshClient (in SocketTools.SshClient.dll)

See Also

SshClientException Members | SocketTools Namespace

SshClientException Members

SshClientException overview

Public Instance Constructors

SshClientException	Overloaded. Initializes a new instance of the SshClientException class.

Public Instance Properties

ErrorCode	Gets a value which specifies the error that caused the exception.
HelpLink (inherited from Exception)	Gets or sets a link to the help file associated with this exception.
InnerException (inherited from Exception)	Gets the Exception instance that caused the current exception.
Message	Gets a value which describes the error that caused the exception.
Number	Gets a value which specifies the numeric value of the error that caused the exception.
Source (inherited from Exception)	Gets or sets the name of the application or the object that causes the error.
StackTrace (inherited from Exception)	Gets a string representation of the frames on the call stack at the time the current exception was thrown.
TargetSite (inherited from Exception)	Gets the method that throws the current exception.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetBaseException (inherited from Exception)	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetObjectData (inherited from Exception)	When overridden in a derived class, sets the SerializationInfo with information about the exception.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString	Creates and returns a string representation of the current exception.

Protected Instance Properties

HResult (inherited from Exception)	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

SshClientException Constructor

Initializes a new instance of the SshClientException class with the last network error code.

Overload List

Initializes a new instance of the SshClientException class with the last network error code.

public SshClientException();

Initializes a new instance of the SshClientException class with a specified error number.

public SshClientException(int);

Initializes a new instance of the SshClientException class with a specified error message.

public SshClientException(string);

Initializes a new instance of the SshClientException class with a specified error message and a reference to the inner exception that is the cause of this exception.

public SshClientException(string,Exception);

See Also

SshClientException Class | SocketTools Namespace

SshClientException Constructor ()

Initializes a new instance of the SshClientException class with the last network error code.

[Visual Basic]

```
Overloads Public Sub New()
```

[C#]

```
public SshClientException();
```

Remarks

The ctor constructor sets the **ErrorCode** property to the last client error that occurred. For more information about the errors that may occur, refer to the SshClient.ErrorCode enumeration.

See Also

SshClientException Class | SocketTools Namespace | SshClientException Constructor Overload List

SshClientException Constructor (String)

Initializes a new instance of the SshClientException class with a specified error message.

[Visual Basic]

```
Overloads Public Sub New( _
   ByVal message As String _
)
```

[C#]

```
public SshClientException(
   string message
);
```

Parameters

message

The error message that explains the reason for the exception.

Remarks

The content of the ***message*** parameter is intended to be understood by humans. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

See Also

SshClientException Class | SocketTools Namespace | SshClientException Constructor Overload List

SshClientException Constructor (String, Exception)

Initializes a new instance of the SshClientException class with a specified error message and a reference to the inner exception that is the cause of this exception.

[Visual Basic]

```
Overloads Public Sub New( _
   ByVal message As String, _
   ByVal innerException As Exception _
)
```

[C#]

```
public SshClientException(
   string message,
   Exception innerException
);
```

Parameters

message

The error message that explains the reason for the exception.

innerException

The exception that is the cause of the current exception. If the ***innerException*** parameter is not a null reference, the current exception is raised in a **catch** block that handles the inner exception.

Remarks

The content of the message parameter is intended to be understood by humans. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

An exception that is thrown as a direct result of a previous exception should include a reference to the previous exception in the **InnerException** property. The **InnerException** property returns the same value that is passed into the constructor, or a null reference if the **InnerException** property does not supply the inner exception value to the constructor.

SshClientException Class | SocketTools Namespace | SshClientException Constructor Overload List

SshClientException Constructor (Int32)

Initializes a new instance of the SshClientException class with a specified error number.

[Visual Basic]

```
Overloads Public Sub New( _
   ByVal code As Integer _
)
```

[C#]

```
public SshClientException(
   int code
);
```

Parameters

code
An integer value which specifies an error code.

Remarks

This constructor sets the **ErrorCode** property to the specified error code. For more information about the errors that may occur, refer to the SshClient.ErrorCode enumeration.

SshClientException Class | SocketTools Namespace | SshClientException Constructor Overload List

SshClientException Properties

The properties of the **SshClientException** class are listed below. For a complete list of **SshClientException** class members, see the SshClientException Members topic.

Public Instance Properties

ErrorCode	Gets a value which specifies the error that caused the exception.
HelpLink (inherited from Exception)	Gets or sets a link to the help file associated with this exception.
InnerException (inherited from Exception)	Gets the Exception instance that caused the current exception.
Message	Gets a value which describes the error that caused the exception.
Number	Gets a value which specifies the numeric value of the error that caused the exception.
Source (inherited from Exception)	Gets or sets the name of the application or the object that causes the error.
StackTrace (inherited from Exception)	Gets a string representation of the frames on the call stack at the time the current exception was thrown.
TargetSite (inherited from Exception)	Gets the method that throws the current exception.

Protected Instance Properties

HResult (inherited from Exception)	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception.

See Also

SshClientException Class | SocketTools Namespace

SshClientException.ErrorCode Property

Gets a value which specifies the error that caused the exception.

[Visual Basic]

```
Public ReadOnly Property ErrorCode As ErrorCode
```

[C#]

```
public SshClient.ErrorCode ErrorCode {get;}
```

Property Value

Returns a SshClient.ErrorCode enumeration value which specifies the error code.

Remarks

The **ErrorCode** property returns the error code that specifies the cause of the exception.

The default constructor for the SshClientException class sets the error code to the last network error that occurred. For more information about the errors that may occur, refer to the SshClient.ErrorCode enumeration.

See Also

SshClientException Class | SocketTools Namespace

SshClientException.Message Property

Gets a value which describes the error that caused the exception.

[Visual Basic]

```
Overrides Public ReadOnly Property Message As String
```

[C#]

```
public override string Message {get;}
```

Property Value

A string which describes the error that caused the exception.

Remarks

The **Message** property returns a string which describes the error that caused the exception.

See Also

SshClientException Class | SocketTools Namespace

SshClientException.Number Property

Gets a value which specifies the numeric value of the error that caused the exception.

[Visual Basic]

```
Public ReadOnly Property Number As Integer
```

[C#]

```
public int Number {get;}
```

Property Value

An integer value that specifies the error that caused the exception.

Remarks

The **Number** property returns an integer value which specifies the numeric value of the error that caused the exception. This value is the same as the values returned by the Windows Sockets API. For more information about socket error codes, see the Windows Socket Version 2 API error code documentation in MSDN.

SshClientException Class | SocketTools Namespace

SshClientException Methods

The methods of the **SshClientException** class are listed below. For a complete list of **SshClientException** class members, see the SshClientException Members topic.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetBaseException (inherited from Exception)	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetObjectData (inherited from Exception)	When overridden in a derived class, sets the SerializationInfo with information about the exception.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString	Creates and returns a string representation of the current exception.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

SshClientException Class | SocketTools Namespace

SshClientException.ToString Method

Creates and returns a string representation of the current exception.

[Visual Basic]

```
Overrides Public Function ToString() As String
```

[C#]

```
public override string ToString();
```

Return Value

A string representation of the current exception.

Remarks

The **ToString** method returns a representation of the current exception that is intended to be understood by humans. Where the exception contains culture-sensitive data, the string representation returned by **ToString** is required to take into account the current system culture. Although there are no exact requirements for the format of the returned string, it should attempt to reflect the value of the object as perceived by the user.

This implementation of **ToString** obtains the numeric error code value and a description of the error that caused the current exception. If there is no error message or it is an empty string, then no error message is returned.

This method overrides **ApplicationException.ToString**.

SshClientException Class | SocketTools Namespace

TelnetClient Class

Implements the Telnet protocol.

For a list of all members of this type, see TelnetClient Members.

System.Object
  SocketTools.TelnetClient

[Visual Basic]

```
Public Class TelnetClient
    Implements IDisposable
```

[C#]

```
public class TelnetClient : IDisposable
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

The Telnet protocol is used to establish a connection with a server which provides a virtual terminal session for a user. Its functionality is similar to how character based consoles and serial terminals work, enabling a user to login to the server, execute commands and interact with applications running on the remote host. The TelnetClient class provides an interface for establishing the connection, negotiating certain options (such as whether characters will be echoed back to the client) and handling the standard I/O functions needed by the program. The class also provides functions that enable a program to easily scan the data stream for specific sequences of characters, making it very simple to write light-weight client interfaces to applications running on the server. This class can be combined with the **SocketTools.Terminal** component to provide complete terminal emulation services for a standard ANSI or DEC-VT220 terminal.

Requirements

Namespace: SocketTools

Assembly: SocketTools.TelnetClient (in SocketTools.TelnetClient.dll)

TelnetClient Members

TelnetClient overview

Public Static (Shared) Fields

telnetPortDefault	A constant value which specifies the default port number.
telnetPortSecure	A constant value which specifies the default port number for a secure connection.
telnetTimeout	A constant value which specifies the default timeout period.

Public Instance Constructors

TelnetClient Constructor	Initializes a new instance of the TelnetClient class.

Public Instance Properties

AutoResolve	Gets and sets a value that determines if host names and addresses are automatically resolved.
Blocking	Gets and sets a value which indicates if the client is in blocking mode.
CertificateExpires	Get a value that specifies the date that the security certificate expires.
CertificateIssued	Get a value that specifies the date that the security certificate was issued.
CertificateIssuer	Get a value that provides information about the organization that issued the certificate.
CertificateName	Gets and sets a value that specifies the name of the client certificate.
CertificatePassword	Gets and sets the password associated with the client certificate.
CertificateStatus	Gets a value which indicates the status of the security certificate returned by the remote host.
CertificateStore	Gets and sets a value that specifies the name of the local certificate store.
CertificateSubject	Gets a value that provides information about the organization that the server certificate was issued to.
CertificateUser	Gets and sets the user that owns the client certificate.
CipherStrength	Gets a value that indicates the length of the key used by the encryption algorithm for a secure connection.
CodePage	Gets and sets the code page used when reading

	and writing text.
Handle	Gets a value that specifies the client handle allocated for the current session.
HashStrength	Gets a value which specifies the length of the message digest that was selected for a secure connection.
HostAddress	Gets and sets a value which specifies the Internet address used to establish a connection.
HostName	Gets and sets a value which specifies the host name used to establish a connection.
IsBlocked	Gets a value which indicates if the current thread is performing a blocking client operation.
IsConnected	Gets a value which indicates if a connection to the remote host has been established.
IsInitialized	Gets a value which indicates if the current instance of the class has been initialized successfully.
IsReadable	Gets a value which indicates if there is data available to be read from the socket connection to the server.
IsThere	Gets a value which indicates if the the remote host is responsive
IsWritable	Gets a value which indicates if data can be written to the client without blocking.
LastError	Gets and sets a value which specifies the last error that has occurred.
LastErrorString	Gets a value which describes the last error that has occurred.
LocalAddress	Gets the local Internet address that the client is bound to.
LocalEcho	Enables and disables the echoing of characters by the remote host.
LocalName	Gets a value which specifies the host name for the local system.
LocalPort	Gets the local port number the client is bound to.
Options	Gets and sets a value which specifies one or more client options.
Password	Gets and sets the password used to authenticate the client session.
RemotePort	Gets and sets a value which specifies the remote port number.
RemoteService	Gets and sets a value which specifies the remote service.

Secure	Gets and sets a value which specifies if a secure connection is established.
SecureCipher	Gets a value that specifies the encryption algorithm used for a secure connection.
SecureHash	Gets a value that specifies the message digest algorithm used for a secure connection.
SecureKeyExchange	Gets a value that specifies the key exchange algorithm used for a secure connection.
SecureProtocol	Gets and sets a value which specifies the protocol used for a secure connection.
Status	Gets a value which specifies the current status of the client.
Terminal	Gets and sets the terminal type used for a remote login session.
ThreadModel	Gets and sets a value which specifies the threading model for the class instance.
ThrowError	Gets and sets a value which specifies if method calls should throw exceptions when an error occurs.
Timeout	Gets and sets a value which specifies a timeout period in seconds.
Trace	Gets and sets a value which indicates if network function logging is enabled.
TraceFile	Gets and sets a value which specifies the name of the logfile.
TraceFlags	Gets and sets a value which specifies the client function tracing flags.
UserName	Gets and sets the username used to authenticate the client session.
Version	Gets a value which returns the current version of the TelnetClient class library.

Public Instance Methods

Abort	Aborts the current session and terminates the connection.
AttachThread	Attach an instance of the class to the current thread
Break	Sends a break signal to the remote host.
Cancel	Cancel the current blocking client operation.
Connect	Overloaded. Establish a connection with a remote host.
Disconnect	Terminate the connection with a remote host.

Dispose	Overloaded. Releases all resources used by TelnetClient.
Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from Object)	Gets the Type of the current instance.
Initialize	Overloaded. Initialize an instance of the TelnetClient class.
Login	Overloaded. Login to the remote server.
Read	Overloaded. Read data from the server and store it in a byte array.
ReadLine	Overloaded. Read up to a line of data from the server and return it in a string buffer.
Reset	Reset the internal state of the object, resetting all properties to their default values.
Search	Overloaded. Search for a specific character sequence in the data stream.
ToString (inherited from Object)	Returns a String that represents the current Object.
Uninitialize	Uninitialize the class library and release any resources allocated for the current thread.
Write	Overloaded. Write one or more bytes of data to the server.
WriteLine	Overloaded. Send a line of text to the server, terminated by a carriage-return and linefeed.

Public Instance Events

OnCancel	Occurs when a blocking client operation is canceled.
OnConnect	Occurs when a connection is established with the remote host.
OnDisconnect	Occurs when the remote host disconnects from the local system.
OnError	Occurs when an client operation fails.
OnRead	Occurs when data is available to be read from the client.
OnTimeout	Occurs when a blocking operation fails to complete before the timeout period elapses.
OnWrite	Occurs when data can be written to the client.

Protected Instance Methods

Dispose	Overloaded. Releases the unmanaged resources allocated by the TelnetClient class and optionally releases the managed resources.
Finalize	Destroys an instance of the class, releasing the resources allocated for the session and unloading the networking library.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

TelnetClient Properties

The properties of the **TelnetClient** class are listed below. For a complete list of **TelnetClient** class members, see the TelnetClient Members topic.

Public Instance Properties

AutoResolve	Gets and sets a value that determines if host names and addresses are automatically resolved.
Blocking	Gets and sets a value which indicates if the client is in blocking mode.
CertificateExpires	Get a value that specifies the date that the security certificate expires.
CertificateIssued	Get a value that specifies the date that the security certificate was issued.
CertificateIssuer	Get a value that provides information about the organization that issued the certificate.
CertificateName	Gets and sets a value that specifies the name of the client certificate.
CertificatePassword	Gets and sets the password associated with the client certificate.
CertificateStatus	Gets a value which indicates the status of the security certificate returned by the remote host.
CertificateStore	Gets and sets a value that specifies the name of the local certificate store.
CertificateSubject	Gets a value that provides information about the organization that the server certificate was issued to.
CertificateUser	Gets and sets the user that owns the client certificate.
CipherStrength	Gets a value that indicates the length of the key used by the encryption algorithm for a secure connection.
CodePage	Gets and sets the code page used when reading and writing text.
Handle	Gets a value that specifies the client handle allocated for the current session.
HashStrength	Gets a value which specifies the length of the message digest that was selected for a secure connection.
HostAddress	Gets and sets a value which specifies the Internet address used to establish a connection.
HostName	Gets and sets a value which specifies the host name used to establish a connection.

IsBlocked	Gets a value which indicates if the current thread is performing a blocking client operation.
IsConnected	Gets a value which indicates if a connection to the remote host has been established.
IsInitialized	Gets a value which indicates if the current instance of the class has been initialized successfully.
IsReadable	Gets a value which indicates if there is data available to be read from the socket connection to the server.
IsThere	Gets a value which indicates if the the remote host is responsive
IsWritable	Gets a value which indicates if data can be written to the client without blocking.
LastError	Gets and sets a value which specifies the last error that has occurred.
LastErrorString	Gets a value which describes the last error that has occurred.
LocalAddress	Gets the local Internet address that the client is bound to.
LocalEcho	Enables and disables the echoing of characters by the remote host.
LocalName	Gets a value which specifies the host name for the local system.
LocalPort	Gets the local port number the client is bound to.
Options	Gets and sets a value which specifies one or more client options.
Password	Gets and sets the password used to authenticate the client session.
RemotePort	Gets and sets a value which specifies the remote port number.
RemoteService	Gets and sets a value which specifies the remote service.
Secure	Gets and sets a value which specifies if a secure connection is established.
SecureCipher	Gets a value that specifies the encryption algorithm used for a secure connection.
SecureHash	Gets a value that specifies the message digest algorithm used for a secure connection.
SecureKeyExchange	Gets a value that specifies the key exchange algorithm used for a secure connection.
SecureProtocol	Gets and sets a value which specifies the protocol used for a secure connection.

Status	Gets a value which specifies the current status of the client.
Terminal	Gets and sets the terminal type used for a remote login session.
ThreadModel	Gets and sets a value which specifies the threading model for the class instance.
ThrowError	Gets and sets a value which specifies if method calls should throw exceptions when an error occurs.
Timeout	Gets and sets a value which specifies a timeout period in seconds.
Trace	Gets and sets a value which indicates if network function logging is enabled.
TraceFile	Gets and sets a value which specifies the name of the logfile.
TraceFlags	Gets and sets a value which specifies the client function tracing flags.
UserName	Gets and sets the username used to authenticate the client session.
Version	Gets a value which returns the current version of the TelnetClient class library.

See Also

TelnetClient Class | SocketTools Namespace

TelnetClient.AutoResolve Property

Gets and sets a value that determines if host names and addresses are automatically resolved.

[Visual Basic]

```
Public Property AutoResolve As Boolean
```

[C#]

```
public bool AutoResolve {get; set;}
```

Property Value

Returns **true** if host names are automatically resolved to Internet addresses. The default value is **false**.

Remarks

Setting the **AutoResolve** property determines if the class automatically resolves host names and addresses specified by the **HostName** and **HostAddress** properties. If set to **true**, setting the **HostName** property will cause the class to automatically determine the corresponding IP address and update the **HostAddress** property accordingly. Likewise, setting the **HostAddress** property will cause the class to determine the host name and update the **HostName** property. Setting this property to **false** prevents the class from resolving host names until a connection attempt is made.

It is important to note that setting the **HostName** or **HostAddress** property may cause the current thread to block, sometimes for several seconds, until the name or address is resolved. To prevent this behavior, set this property value to **false**.

See Also

TelnetClient Class | SocketTools Namespace

TelnetClient.Blocking Property

Gets and sets a value which indicates if the client is in blocking mode.

[Visual Basic]

```
Public Property Blocking As Boolean
```

[C#]

```
public bool Blocking {get; set;}
```

Property Value

Returns **true** if the client is in blocking mode; otherwise it returns **false**. The default value is **true**.

Remarks

Setting the **Blocking** property determines if client operations complete synchronously or asynchronously. If set to **true**, then each client operation (such as sending or receiving data) will return when the operation has completed or timed-out. If set to **false**, client operations will return immediately. If the operation would result in the client blocking (such as attempting to read data when no data has been sent by the remote host), an error is generated.

It is important to note that certain events, such as **OnDisconnect, OnRead** and **OnWrite** are only fired if the client is in non-blocking mode.

See Also

TelnetClient Class | SocketTools Namespace

TelnetClient.CertificateExpires Property

Get a value that specifies the date that the security certificate expires.

[Visual Basic]
```
Public ReadOnly Property CertificateExpires As String
```

[C#]
```
public string CertificateExpires {get;}
```

Property Value

A string which specifies a date using the local date and time format.

Remarks

The **CertificateExpires** property returns a string that specifies the date and time that the security certificate expires. This property will return an empty string if a secure connection has not been established with the remote host.

See Also

TelnetClient Class | SocketTools Namespace

TelnetClient.CertificateIssued Property

Get a value that specifies the date that the security certificate was issued.

[Visual Basic]

```
Public ReadOnly Property CertificateIssued As String
```

[C#]

```
public string CertificateIssued {get;}
```

Property Value

A string which specifies a date using the local date and time format.

Remarks

The **CertificateIssued** property returns a string that specifies the date and time that the security certificate was issued. This property will return an empty string if a secure connection has not been established with the remote host.

See Also

TelnetClient Class | SocketTools Namespace

TelnetClient.CertificateIssuer Property

Get a value that provides information about the organization that issued the certificate.

[Visual Basic]

```
Public ReadOnly Property CertificateIssuer As String
```

[C#]

```
public string CertificateIssuer {get;}
```

Property Value

A string that contains a comma separated list of name value pairs.

Remarks

The **CertificateIssuer** property returns a string that contains information about the organization that issued the server certificate. The string value is a comma separated list of tagged name and value pairs. In the nomenclature of the X.500 standard, each of these pairs are called a relative distinguished name (RDN), and when concatenated together, forms the issuer's distinguished name (DN). For example:

```
C=US, O="RSA Data Security, Inc.", OU=Secure Server Certification Authority
```

To obtain a specific value, such as the name of the issuer or the issuer's country, the application must parse the string returned by this property. Some of the common tokens used in the distinguished name are:

Token	Description
C	The ISO standard two character country code.
S	The name of the state or province.
L	The name of the city or locality.
O	The name of the company or organization.
OU	The name of the department or organizational unit
CN	The common name; with X.509 certificates, this is the domain name of the site the certificate was issued for.

This property will return an empty string if a secure connection has not been established with the remote host.

See Also

TelnetClient Class | SocketTools Namespace

TelnetClient.CertificateName Property

Gets and sets a value that specifies the name of the client certificate.

[Visual Basic]

```
Public Property CertificateName As String
```

[C#]

```
public string CertificateName {get; set;}
```

Property Value

A string which specifies the certificate name.

Remarks

The **CertificateName** property is used to specify the name of a client certificate to use when establishing a secure connection. It is only required that you set this property value if the server requires a client certificate for authentication. If this property is not set, a client certificate will not be provided to the server. If a certificate name is specified, the certificate must have a private key associated with it, otherwise the connection attempt will fail because the control will be unable to create a security context for the session.

When the certificate store is searched for a matching certificate, it will first search for any certificate with a friendly name that matches the property value. If no valid certificate is found, it will then search for a certificate with a matching common name.

Certificates may be installed and viewed on the local system using the Certificate Manager that is included with the Windows operating system. For more information, refer to the documentation for the Microsoft Management Console.

See Also

TelnetClient Class | SocketTools Namespace | CertificateStore Property | Secure Property

TelnetClient.CertificateStatus Property

Gets a value which indicates the status of the security certificate returned by the remote host.

[Visual Basic]
```
Public ReadOnly Property CertificateStatus As SecurityCertificate
```

[C#]
```
public TelnetClient.SecurityCertificate CertificateStatus {get;}
```

Property Value

A SecurityCertificate enumeration value which specifies the status of the certificate.

Remarks

The **CertificateStatus** property is used to determine the status of the security certificate returned by the remote host when a secure connection has been established. This property value should be checked after the connection to the server has completed, but prior to beginning a transaction.

Note that if the certificate cannot be validated, the secure connection will not be automatically terminated. It is the responsibility of your application to determine the best course of action to take if the certificate is invalid. Even if the security certificate cannot be validated, the data exchanged with the remote host will still be encrypted.

See Also

TelnetClient Class | SocketTools Namespace

TelnetClient.CertificateStore Property

Gets and sets a value that specifies the name of the local certificate store.

[Visual Basic]
```
Public Property CertificateStore As String
```

[C#]
```
public string CertificateStore {get; set;}
```

Property Value

A string which specifies the certificate store name. The default value is the current user's personal certificate store.

Remarks

The **CertificateStore** property is used to specify the name of the certificate store which contains the security certificate to use when establishing a secure connection. The certificate may either be stored in the registry or in a file. If the certificate is stored in the registry, then this property should be set to one of the following predefined values:

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as VeriSign and Thawte act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. If a certificate store is not specified, this is the default value that is used.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as VeriSign and Thawte are installed as part of the operating system and periodically updated by Microsoft.

In most cases the client certificate will be installed in the user's personal certificate store, and therefore it is not necessary to set this property value because that is the default location that will be used to search for the certificate. This property is only used if the **CertificateName** property is also set to a valid certificate name.

If you are using a local certificate store, with the certificate and private key stored in the registry, you can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU" for the current user, or "HKLM" for the local machine. For example, a certificate store name of "HKLM:MY" would specify the personal certificate store for the local machine, rather than the current user. If neither prefix is specified, it will default to the certificate store for the current user.

This property may also be used to specify a file that contains the client certificate. In this case, the property should specify the full path to the file and must contain both the certificate and private key in PKCS12

format. If the file is protected by a password, the **CertificatePassword** property must also be set to specify the password.

See Also

TelnetClient Class | SocketTools Namespace | CertificatePassword Property | Secure Property

TelnetClient.CertificateSubject Property

Gets a value that provides information about the organization that the server certificate was issued to.

[Visual Basic]

```
Public ReadOnly Property CertificateSubject As String
```

[C#]

```
public string CertificateSubject {get;}
```

Property Value

A string that contains a comma separated list of name value pairs.

Remarks

The **CertificateSubject** property returns a string that contains information about the organization that the server certificate was issued to. The string value is a comma separated list of tagged name and value pairs. In the nomenclature of the X.500 standard, each of these pairs are called a relative distinguished name (RDN), and when concatenated together, forms the issuer's distinguished name (DN). For example:

```
C=US, O="RSA Data Security, Inc.", OU=Secure Server Certification Authority
```

To obtain a specific value, such as the name of the issuer or the issuer's country, the application must parse the string returned by this property. Some of the common tokens used in the distinguished name are:

Token	Description
C	The ISO standard two character country code.
S	The name of the state or province.
L	The name of the city or locality.
O	The name of the company or organization.
OU	The name of the department or organizational unit
CN	The common name; with X.509 certificates, this is the domain name of the site the certificate was issued for.

This property will return an empty string if a secure connection has not been established with the remote host.

See Also

TelnetClient Class | SocketTools Namespace

TelnetClient.CipherStrength Property

Gets a value that indicates the length of the key used by the encryption algorithm for a secure connection.

[Visual Basic]

```
Public ReadOnly Property CipherStrength As Integer
```

[C#]

```
public int CipherStrength {get;}
```

Property Value

An integer value which specifies the encryption key length if a secure connection has been established; otherwise a value of 0 is returned.

Remarks

The **CipherStrength** property returns the number of bits in the key used to encrypt the secure data stream. Common values returned by this property are 128 and 256. A key length of 40 or 56 bits is considered insecure and subject to brute force attacks. 128-bit and 256-bit keys are considered secure. If this property returns a value of 0, this means that a secure connection has not been established with the remote host.

TelnetClient Class | SocketTools Namespace

TelnetClient.CodePage Property

Gets and sets the code page used when reading and writing text.

[Visual Basic]

```
Public Property CodePage As Integer
```

[C#]

```
public int CodePage {get; set;}
```

Property Value

An integer value which specifies the current code page. A value of zero specifies the default code page for the current locale should be used. To preserve the original Unicode text, you can use code page 65001 which specifies UTF-8 character encoding.

Remarks

All data which is exchanged over a socket is sent and received as 8-bit bytes, typically referred to as "octets" in networking terminology. However, strings in .NET are Unicode where each character is represented by 16 bits. To send and receive data using strings, these Unicode strings are converted to a stream of bytes.

By default, strings are converted to an array of bytes using the code page for the current locale, mapping the 16-bit Unicode characters to bytes. Similarly, when reading data from the socket into a string buffer, the stream of bytes received from the remote host are converted to Unicode before they are returned to your application.

If you are exchanging text with another system and it appears to corrupted or characters are being replaced with question marks or other symbols, it is likely the system is sending text which is using a different character encoding. Most services use UTF-8 encoding to represent non-ASCII characters and selecting the UTF-8 code page will typically resolve the issue.

Strings are only guaranteed to be safe when sending and receiving text. Using a string data type is not recommended when reading or writing binary data to a socket. If possible, you should always use a byte array as the buffer parameter for the Read and Write methods whenever you are exchanging binary data.

For backwards compatibility, this class defaults to using the code page for the current locale. This property value directly corresponds to Windows code page identifiers, and will accept any valid code page supported by the .NET Framework. Setting this property to an invalid code page will generate an exception.

See Also

TelnetClient Class | SocketTools Namespace

TelnetClient.Handle Property

Gets a value that specifies the client handle allocated for the current session.

[Visual Basic]

```
Public ReadOnly Property Handle As Integer
```

[C#]

```
public int Handle {get;}
```

Property Value

An integer which represents a client handle. If there is no active connection, a value of -1 is returned.

Remarks

The **Handle** property specifies the numeric descriptor of the current client session.

See Also

TelnetClient Class | SocketTools Namespace

TelnetClient.HashStrength Property

Gets a value which specifies the length of the message digest that was selected for a secure connection.

[Visual Basic]

```
Public ReadOnly Property HashStrength As Integer
```

[C#]

```
public int HashStrength {get;}
```

Property Value

An integer value which specifies the length of the message digest if a secure connection has been established; otherwise a value of 0 is returned.

Remarks

The **HashStrength** property returns the number of bits used in the message digest (hash) that was selected. Common values returned by this property are 128 and 160. If this property returns a value of 0, this means that a secure connection has not been established with the remote host.

See Also

TelnetClient Class | SocketTools Namespace

TelnetClient.HostAddress Property

Gets and sets a value which specifies the Internet address used to establish a connection.

[Visual Basic]

```
Public Property HostAddress As String
```

[C#]

```
public string HostAddress {get; set;}
```

Property Value

A string which specifies an Internet address.

Remarks

The **HostAddress** property can be used to set the Internet address for a remote system that you wish to communicate with. If the **AutoResolve** property is set to **true** and the address is assigned to a valid host name, the **HostName** property will be updated with that value.

See Also

TelnetClient Class | SocketTools Namespace

TelnetClient.HostName Property

Gets and sets a value which specifies the host name used to establish a connection.

[Visual Basic]

```
Public Property HostName As String
```

[C#]

```
public string HostName {get; set;}
```

Property Value

A string which specifies a host name.

Remarks

The **HostName** property can be used to set the host name for a remote system that you wish to communicate with. If the **AutoResolve** property is set to **true** and the name can be resolved to a valid Internet address, the **HostAddress** property will be updated with that value.

See Also

TelnetClient Class | SocketTools Namespace

TelnetClient.IsBlocked Property

Gets a value which indicates if the current thread is performing a blocking client operation.

[Visual Basic]

```
Public ReadOnly Property IsBlocked As Boolean
```

[C#]

```
public bool IsBlocked {get;}
```

Property Value

Returns **true** if the current thread is blocking, otherwise returns **false**.

Remarks

The **IsBlocked** property returns **true** if the current thread is blocked performing an operation. Because the Windows Sockets API only permits one blocking operation per thread of execution, this property should be checked before starting any blocking operation in response to an event.

If the **IsBlocked** property returns **false**, this means there are no blocking operations on the current thread at that time. However, this does not guarantee that the next client operation will not fail. An application should always check the return value from a client operation and check the value of the **LastError** property if an error occurs.

Note that this property will return **true** if there is any blocking operation being performed by the current thread, regardless of whether this specific instance of the class is responsible for the blocking operation or not.

See Also

TelnetClient Class | SocketTools Namespace

TelnetClient.IsConnected Property

Gets a value which indicates if a connection to the remote host has been established.

[Visual Basic]

```
Public ReadOnly Property IsConnected As Boolean
```

[C#]

```
public bool IsConnected {get;}
```

Property Value

Returns **true** if the connection has been established; otherwise returns **false**.

Remarks

The **IsConnected** property can only be used to indicate if there is still a logical connection to the remote host. It cannot be used to detect abnormal conditions such as the remote host aborting the connection, the physical network connection being lost or other critical errors.

See Also

TelnetClient Class | SocketTools Namespace

TelnetClient.IsInitialized Property

Gets a value which indicates if the current instance of the class has been initialized successfully.

[Visual Basic]
```
Public ReadOnly Property IsInitialized As Boolean
```

[C#]
```
public bool IsInitialized {get;}
```

Property Value

Returns **true** if the class instance has been initialized; otherwise returns **false**.

Remarks

The **IsInitialized** property is used to determine if the current instance of the class has been initialized properly. Normally this is done automatically by the class constructor, however there are circumstances where the class may not be able to initialize itself.

The most common reasons that a class instance may not initialize correctly is that no runtime license key has been defined in the assembly or the license key provided is invalid. It may also indicate a problem with the system configuration or user access rights, such as not being able to load the required networking libraries or not being able to access the system registry.

See Also

TelnetClient Class | SocketTools Namespace

TelnetClient.IsReadable Property

Gets a value which indicates if there is data available to be read from the socket connection to the server.

[Visual Basic]

```
Public ReadOnly Property IsReadable As Boolean
```

[C#]

```
public bool IsReadable {get;}
```

Property Value

Returns **true** if there is data available to be read; otherwise returns **false**.

Remarks

The **IsReadable** property returns **true** if data can be read from the client without blocking. For non-blocking sessions, this property can be checked before the application attempts to read the client. Note that even if this property does return **true** indicating that there is data available to be read, applications should always check the return value from the **Read** method.

See Also

TelnetClient Class | SocketTools Namespace

TelnetClient.IsThere Property

Gets a value which indicates if the the remote host is responsive

[Visual Basic]

```
Public ReadOnly Property IsThere As Boolean
```

[C#]

```
public bool IsThere {get;}
```

Property Value

Returns **true** if the connection is active and the remote host is responsive to the client; otherwise returns **false**.

See Also

TelnetClient Class | SocketTools Namespace

TelnetClient.IsWritable Property

Gets a value which indicates if data can be written to the client without blocking.

[Visual Basic]

```
Public ReadOnly Property IsWritable As Boolean
```

[C#]

```
public bool IsWritable {get;}
```

Property Value

Returns **true** if data can be written to the client; otherwise returns **false**.

Remarks

The **IsWritable** property returns **true** if data can be written to the client without blocking. For non-blocking sessions, this property can be checked before the application attempts to write data to the client. Note that even if this property does return **true** indicating that data can be written to the client, applications should always check the return value from the **Write** method.

See Also

TelnetClient Class | SocketTools Namespace

TelnetClient.LastError Property

Gets and sets a value which specifies the last error that has occurred.

[Visual Basic]

```
Public Property LastError As ErrorCode
```

[C#]

```
public TelnetClient.ErrorCode LastError {get; set;}
```

Property Value

Returns an ErrorCode enumeration value which specifies the last error code.

Remarks

The **LastError** property returns the error code associated with the last error that occurred for the current instance of the class. It is important to note that this value only has meaning if the previous method indicates that an error has actually occurred.

It is possible to explicitly clear the last error code by assigning the property to the value **ErrorCode.errorNone**.

The error code value can be cast to an integer value for display purposes if required. For a description of the error that can be displayed using a message box or some other similar mechanism, get the value of the **LastErrorString** property.

See Also

TelnetClient Class | SocketTools Namespace

TelnetClient.LastErrorString Property

Gets a value which describes the last error that has occurred.

[Visual Basic]

```
Public ReadOnly Property LastErrorString As String
```

[C#]

```
public string LastErrorString {get;}
```

Property Value

A string which describes the last error that has occurred.

Remarks

The **LastErrorString** property can be used to obtain a description of the last error that occurred for the current instance of the class. It is important to note that this value only has meaning if the previous method indicates that an error has actually occurred.

See Also

TelnetClient Class | SocketTools Namespace

TelnetClient.LocalAddress Property

Gets the local Internet address that the client is bound to.

[Visual Basic]

```
Public ReadOnly Property LocalAddress As String
```

[C#]

```
public string LocalAddress {get;}
```

Property Value

A string which specifies an Internet address.

Remarks

The **LocalAddress** property returns the local Internet address that the client is bound to when a connection is established with a remote host. This property may return either an IPv4 or IPv6 formatted address, depending on the type of connection that was established.

See Also

TelnetClient Class | SocketTools Namespace

TelnetClient.LocalEcho Property

Enables and disables the echoing of characters by the remote host.

[Visual Basic]

```
Public Property LocalEcho As Boolean
```

[C#]

```
public bool LocalEcho {get; set;}
```

Property Value

A boolean value which specifies if local echo has been enabled.

Remarks

The **LocalEcho** property enables or disables the echoing of characters by the remote host. If set to **true**, the remote host will be instructed to not echo characters, making the client responsible for displaying user input. The default value for this property is **false**, specifying that the server should echo user input back to the client.

See Also

TelnetClient Class | SocketTools Namespace

TelnetClient.LocalName Property

Gets a value which specifies the host name for the local system.

[Visual Basic]

```
Public ReadOnly Property LocalName As String
```

[C#]

```
public string LocalName {get;}
```

Property Value

A string which specifies the local host name.

Remarks

The **LocalName** property returns the fully-qualified host name assigned to the local system. If the system has not been configured with an Internet domain name, then this property will return the NetBIOS name assigned to the local system.

See Also

TelnetClient Class | SocketTools Namespace

TelnetClient.LocalPort Property

Gets the local port number the client is bound to.

[Visual Basic]

```
Public ReadOnly Property LocalPort As Integer
```

[C#]

```
public int LocalPort {get;}
```

Property Value

An integer value which specifies a port number. The default value is 0.

Remarks

The **LocalPort** property is used to identify the local port number that the client is bound to to when a connection is established with a remote host.

See Also

TelnetClient Class | SocketTools Namespace

TelnetClient.Options Property

Gets and sets a value which specifies one or more client options.

[Visual Basic]

```
Public Property Options As TelnetOptions
```

[C#]

```
public TelnetClient.TelnetOptions Options {get; set;}
```

Property Value

Returns one or more TelnetOptions enumeration flags which specify the options for the client. The default value for this property is **clientOptionNone**.

Remarks

The **Options** property specifies one or more default options options which are used when establishing a connection using the **Connect** method.

See Also

TelnetClient Class | SocketTools Namespace

TelnetClient.Password Property

Gets and sets the password used to authenticate the client session.

[Visual Basic]

```
Public Property Password As String
```

[C#]

```
public string Password {get; set;}
```

Property Value

A string which specifies the password.

Remarks

If a password is not specified when the **Login** method is called, the value of this property will be used as the default password when authenticating the client session.

See Also

TelnetClient Class | SocketTools Namespace

TelnetClient.RemotePort Property

Gets and sets a value which specifies the remote port number.

[Visual Basic]

```
Public Property RemotePort As Integer
```

[C#]

```
public int RemotePort {get; set;}
```

Property Value

An integer value which specifies a port number.

Remarks

The **RemotePort** property is used to set the port number that will be used to establish a connection with a remote host. If the port number specifies a well-known port, the **RemoteService** property will be updated with that name.

See Also

TelnetClient Class | SocketTools Namespace

TelnetClient.Secure Property

Gets and sets a value which specifies if a secure connection is established.

[Visual Basic]

```
Public Property Secure As Boolean
```

[C#]

```
public bool Secure {get; set;}
```

Property Value

Returns **true** if a secure connection is established; otherwise returns **false**. The default value is **false**.

Remarks

The **Secure** property determines if a secure connection is established with the remote host. The default value for this property is **false**, which specifies that a standard connection to the server is used. To establish a secure connection, the application should set this property value to **true** prior to calling the **Connect** method. Once the connection has been established, the client may exchange data with the server as with standard connections.

It is strongly recommended that any application that sets this property **true** use error handling to trap an errors that may occur. If the control is unable to initialize the security libraries, or otherwise cannot create a secure session for the client, an exception may be generated when this property value is set.

See Also

TelnetClient Class | SocketTools Namespace

TelnetClient.SecureCipher Property

Gets a value that specifies the encryption algorithm used for a secure connection.

[Visual Basic]

```
Public ReadOnly Property SecureCipher As SecureCipherAlgorithm
```

[C#]

```
public TelnetClient.SecureCipherAlgorithm SecureCipher {get;}
```

Property Value

A SecureCipherAlgorithm enumeration value which identifies the algorithm.

Remarks

The **SecureCipher** property returns a value which identifies the algorithm used to encrypt the data stream. If a secure connection has not been established, this property will return a value of **cipherNone**.

See Also

TelnetClient Class | SocketTools Namespace

TelnetClient.SecureHash Property

Gets a value that specifies the message digest algorithm used for a secure connection.

[Visual Basic]

```
Public ReadOnly Property SecureHash As SecureHashAlgorithm
```

[C#]

```
public TelnetClient.SecureHashAlgorithm SecureHash {get;}
```

Property Value

A SecureHashAlgorithm enumeration value which identifies the algorithm.

Remarks

The **SecureHash** property returns a value which identifies the message digest (hash) algorithm that was selected when a secure connection was established. If a secure connection has not been established, this property will return a value of **hashNone**.

See Also

TelnetClient Class | SocketTools Namespace

TelnetClient.SecureKeyExchange Property

Gets a value that specifies the key exchange algorithm used for a secure connection.

[Visual Basic]

```
Public ReadOnly Property SecureKeyExchange As SecureKeyAlgorithm
```

[C#]

```
public TelnetClient.SecureKeyAlgorithm SecureKeyExchange {get;}
```

Property Value

A SecureKeyAlgorithm enumeration value which identifies the algorithm.

Remarks

The **SecureKeyExchange** property returns a value which identifies the key exchange algorithm that was selected when a secure connection was established. If a secure connection has not been established, this property will return a value of **keyExchangeNone**.

See Also

TelnetClient Class | SocketTools Namespace

TelnetClient.SecureProtocol Property

Gets and sets a value which specifies the protocol used for a secure connection.

[Visual Basic]
```
Public Property SecureProtocol As SecurityProtocols
```

[C#]
```
public TelnetClient.SecurityProtocols SecureProtocol {get; set;}
```

Property Value

A SecurityProtocols enumeration value which identifies the protocol to be used when establishing a secure connection.

Remarks

The **SecureProtocol** property can be used to specify the security protocol to be used when establishing a secure connection with a server or accepting a secure connection from a client. By default, the class will attempt to use either SSL v3 or TLS v1 to establish the connection, with the appropriate protocol automatically selected based on the capabilities of the remote host. It is recommended that you only change this property value if you fully understand the implications of doing so. Assigning a value to this property will override the default protocol and force the class to attempt to use only the protocol specified.

Multiple security protocols may be specified by combining them using a bitwise **or** operator. After a connection has been established, this property will identify the protocol that was selected. Attempting to set this property after a connection has been established will result in an exception being thrown. This property should only be set after setting the **Secure** property to **true** and before calling the **Accept** or **Connect** methods.

In some cases, a server may only accept a secure connection if the TLS v1 protocol is specified. If the security protocol is not compatible with the server, then the connection will fail with an error indicating that the control is unable to establish a security context for the session. In this case, try assigning the property to **protocolTLS1** and attempt the connection again.

See Also

TelnetClient Class | SocketTools Namespace

TelnetClient.Status Property

Gets a value which specifies the current status of the client.

[Visual Basic]

```
Public ReadOnly Property Status As TelnetStatus
```

[C#]

```
public TelnetClient.TelnetStatus Status {get;}
```

Property Value

A TelnetStatus enumeration value which specifies the current client status.

Remarks

The **Status** property returns the current status of the client. This property can be used to check on blocking connections to determine if the client is interacting with the remote host before taking some action.

See Also

TelnetClient Class | SocketTools Namespace

TelnetClient.Terminal Property

Gets and sets the terminal type used for a remote login session.

[Visual Basic]

```
Public Property Terminal As String
```

[C#]

```
public string Terminal {get; set;}
```

Property Value

A string which specifies the terminal type.

Remarks

The **Terminal** property specifies the terminal type of the remote host for display purposes. On UNIX based systems, the terminal name corresponds to a termcap or terminfo entry as set in the TERM environment variable. On Windows based systems which implement the rlogin service, this property may be ignored and the server will assume that the client is capable of displaying ANSI escape sequences. On VMS systems, the terminal name should correspond to the terminal type used with the SET TERMINAL/DEVICE command.

If this property is set to an empty string and no terminal type is specified when the **Login** method is called, a default terminal type named "unknown" will be used. On most UNIX and VMS systems this defines a terminal which is not capable of cursor positioning using control or escape sequences. This terminal type may not be recognized and an error may be displayed when the user logs in indicating that the terminal type is invalid.

Refer to the documentation for the server system to determine what terminal type names are available to you. Remember that on UNIX systems, the terminal type is case-sensitive. Some of the more common terminal types are:

Terminal	Description
ansi	This terminal type is usually available on UNIX based servers. This specifies that the client is capable of displaying standard ANSI escape sequences for cursor control.
dumb	This terminal type typically specifies a terminal display which does not support control or escape sequences for cursor positioning. If you do not want escape sequences embedded in the data stream and the server returns an error if the terminal type is not specified, try using this terminal type.
pcansi	This terminal type is usually available on UNIX based servers. This specifies that the client is a using a PC terminal emulator that supports basic ANSI escape sequences for cursor control. This may also enable escape sequences which can set the display colors.
vt100	This terminal type is usually available on UNIX and VMS based servers. On some VMS systems this

	string may need to be specified as DEC-VT100. This specifies that the client is capable of emulating a DEC VT100 terminal. The VT100 supports many of the same cursor control sequences as an ANSI terminal.
vt220	This terminal type is usually available on UNIX and VMS based servers. On some VMS systems this string may need to be specified as DEC-VT220. This specifies that the client is capable of emulating a DEC VT220 terminal, which is a later version of the VT100.
vt320	This terminal type is usually available on UNIX and VMS based servers. On some VMS systems this string may need to be specified as DEC-VT320. This specifies that the client is capable of emulating a DEC VT320 terminal, which is similar to the VT100 and VT220 and provides advanced features such as the ability to set display colors.
xterm	This terminal type is may be available on UNIX based servers which have X Windows installed. This specifies that the client is a using the X Windows xterm emulator which supports standard ANSI escape sequences for cursor control.

See Also

TelnetClient Class | SocketTools Namespace

TelnetClient.ThreadModel Property

Gets and sets a value which specifies the threading model for the class instance.

[Visual Basic]

```
Public Property ThreadModel As ThreadingModel
```

[C#]

```
public TelnetClient.ThreadingModel ThreadModel {get; set;}
```

Property Value

Returns one or more ThreadingModel enumeration value which specifies the threading model for the client. The default value for this property is **modelSingleThread**.

Remarks

The **ThreadModel** property specifies the threading model that is used by the class instance when a connection is established. The default value for this property is **modelSingleThread**, which specifies that only the thread that established the connection should be permitted to invoke methods. It is important to note that this threading model does not limit the application to a single thread of execution. When a session is established using the **Connect** method, that session is attached to the thread that created it. From that point on, until the session is terminated, only the owner may invoke methods in that instance of the class. The ownership of the class instance may be transferred from one thread to another using the **AttachThread** method.

Setting this property to **modelFreeThread** disables certain internal safety checks that are performed by the class and may result in unexpected behavior unless you ensure that access to the class instance is synchronized across multiple threads. The application must ensure that no two threads will attempt to invoke a blocking method at the same time. In other words, if one thread invokes a method, the application must ensure that another thread will not attempt to invoke any other method at the same time using the same instance of the class.

Changing the value of this property will not affect an active client session. The threading model must be specified prior to invoking the **Connect** method.

See Also

TelnetClient Class | SocketTools Namespace | AttachThread Method | ThreadingModel Enumeration | ThreadModel Attribute

TelnetClient.ThrowError Property

Gets and sets a value which specifies if method calls should throw exceptions when an error occurs.

[Visual Basic]
```
Public Property ThrowError As Boolean
```

[C#]
```
public bool ThrowError {get; set;}
```

Property Value

Returns **true** if method calls will generate exceptions when an error occurs; otherwise returns **false**. The default value is **false**.

Remarks

Error handling for when calling class methods can be done in either of two different styles, according to the value of this property.

If the **ThrowError** property is set to **false**, the application should check the return value of any method that is used, and report errors based upon the documented value of the return code. It is the responsibility of the application to interpret the error code, if it is desired to explain the error in addition to reporting it. This is the default behavior.

If the **ThrowError** property is set to **true**, then exceptions will be generated whenever a method call fails. The program must be written to catch these exceptions and take the appropriate action when an error occurs. Failure to handle an exception will cause the program to terminate abnormally.

Note that if an error occurs while a property is being read or modified, an exception will be raised regardless of the value of the **ThrowError** property.

See Also

TelnetClient Class | SocketTools Namespace

TelnetClient.Timeout Property

Gets and sets a value which specifies a timeout period in seconds.

[Visual Basic]

```
Public Property Timeout As Integer
```

[C#]

```
public int Timeout {get; set;}
```

Property Value

An integer value which specifies a timeout period in seconds.

Remarks

Setting the **Timeout** property specifies the number of seconds until a blocking operation fails and returns an error.

The timeout period is only used when the client is in blocking mode. Although this property can be changed when the client is in non-blocking mode, the value will be ignored until the client is returned to blocking mode.

For most applications it is recommended the timeout period be set between 10 and 20 seconds.

See Also

TelnetClient Class | SocketTools Namespace

TelnetClient.Trace Property

Gets and sets a value which indicates if network function logging is enabled.

[Visual Basic]
```
Public Property Trace As Boolean
```

[C#]
```
public bool Trace {get; set;}
```

Property Value

Returns **true** if network function tracing is enabled; otherwise returns **false**. The default value is **false**.

Remarks

The **Trace** property is used to enable (or disable) the tracing of network function calls. When enabled, each function call is logged to a file, including the function parameters, return value and error code if applicable. This facility can be enabled and disabled at run time, and the trace log file can be specified by setting the **TraceFile** property. All function calls that are being logged are appended to the trace file, if it exists. If no trace file exists when tracing is enabled, the trace file is created.

The tracing facility is available in all of the SocketTools networking classes and is enabled or disabled for an entire process. This means that once trace logging is enabled for a given component, all of the function calls made by the process using any of the SocketTools classes will be logged. For example, if you have an application using both the File Transfer Protocol and Post Office Protocol classes, and you set the **Trace** property to **true**, function calls made by both classes will be logged. Additionally, enabling a trace is cumulative, and tracing is not stopped until it is disabled for all classes used by the process.

If trace logging is not enabled, there is no negative impact on performance or throughput. Once enabled, application performance can degrade, especially in those situations in which multiple processes are being traced or the logfile is fairly large. Since logfiles can grow very quickly, even with modest applications, it is recommended that you delete the file when it is no longer needed.

When redistributing your application, make sure that you include the **SocketTools10.TraceLog.dll** module with your installation. If this library is not present, then no trace output will be generated and the value of the **Trace** property will be ignored. Only those function calls made by the SocketTools networking classes will be logged. Calls made directly to the Windows Sockets API, or calls made by other classes, will not be logged.

See Also

TelnetClient Class | SocketTools Namespace

TelnetClient.TraceFile Property

Gets and sets a value which specifies the name of the logfile.

[Visual Basic]

```
Public Property TraceFile As String
```

[C#]

```
public string TraceFile {get; set;}
```

Property Value

A string which specifies the name of the file.

Remarks

The **TraceFile** property is used to specify the name of the trace file that is created when network function tracing is enabled. If this property is set to an empty string (the default value), then a file named **SocketTools.log** is created in the system's temporary directory. If no temporary directory exists, then the file is created in the current working directory.

If the file exists, the trace output is appended to the file, otherwise the file is created. Since network function tracing is enabled per-process, the trace file is shared by all instances of the class being used. If multiple class instances have tracing enabled, the **TraceFile** property should be set to the same value for each instance. Since trace files can grow very quickly, even with modest applications, it is recommended that you delete the file when it is no longer needed.

The trace file has the following format:

```
 MyApp INF: WSAAsyncSelect(46, 0xcc4, 0x7e9, 0x27) returned 0 MyApp WRN:
connect(46, 192.0.0.1:1234, 16) returned -1 [10035] MyApp ERR: accept(46,
NULL, 0x0) returned -1 [10038]
```

The first column contains the name of the process that is being traced. The second column identifies if the trace record is reporting information, a warning, or an error. What follows is the name of the function being called, the arguments passed to the function and the function's return value. If a warning or error is reported, the error code is appended to the record (the value is placed inside brackets).

If parameters are passed as integer values, they are recorded in decimal. If the parameter or return value is a pointer (a memory address), it is recorded as a hexadecimal value preceded with "0x". A special type of pointer, called a null pointer, is recorded as NULL. Those functions which expect socket addresses are displayed in the following format:

```
aa.bb.cc.dd:nnnn
```

The first four numbers separated by periods represent the IP address, and the number following the colon represents the port number in host byte order. Note that in the second line of the above example, the control is attempting to connect to a system with the IP address 192.0.0.1 on port 1234.

Note that if the specified file cannot be created, or the user does not have permission to modify an existing file, the error is silently ignored and no trace output will be generated.

See Also

TelnetClient Class | SocketTools Namespace

TelnetClient.TraceFlags Property

Gets and sets a value which specifies the client function tracing flags.

[Visual Basic]

```
Public Property TraceFlags As TraceOptions
```

[C#]

```
public TelnetClient.TraceOptions TraceFlags {get; set;}
```

Property Value

A TraceOptions enumeration which specifies the amount of detail written to the trace logfile.

Remarks

The **TraceFlags** property is used to specify the type of information written to the trace file when network function tracing is enabled.

Because network function tracing is enabled per-process, the trace flags are shared by all instances of the class being used. If multiple class instances have tracing enabled, the **TraceFlags** property should be set to the same value for each instance. Changing the trace flags for any one instance of the class will affect the logging performed for all SocketTools classes used by the application.

Warnings are generated when a non-fatal error is returned by a network function. For example, if data is being written and the error **errorOperationWouldBlock** occurs, a warning is generated because the application simply needs to attempt to write the data at a later time.

TelnetClient.UserName Property

Gets and sets the username used to authenticate the client session.

[Visual Basic]

```
Public Property UserName As String
```

[C#]

```
public string UserName {get; set;}
```

Property Value

A string which specifies the username.

Remarks

If a username is not specified when the **Login** method is called, the value of this property will be used as the default username when authenticating the client session.

See Also

TelnetClient Class | SocketTools Namespace

TelnetClient.Version Property

Gets a value which returns the current version of the TelnetClient class library.

[Visual Basic]
```
Public ReadOnly Property Version As String
```

[C#]
```
public string Version {get;}
```

Property Value

A string which specifies the version of the class library.

Remarks

The **Version** property returns a string which identifies the current version and build of the TelnetClient class library. This value can be used by an application for validation and debugging purposes.

TelnetClient Class | SocketTools Namespace

TelnetClient Methods

The methods of the **TelnetClient** class are listed below. For a complete list of **TelnetClient** class members, see the TelnetClient Members topic.

Public Instance Methods

Abort	Aborts the current session and terminates the connection.
AttachThread	Attach an instance of the class to the current thread
Break	Sends a break signal to the remote host.
Cancel	Cancel the current blocking client operation.
Connect	Overloaded. Establish a connection with a remote host.
Disconnect	Terminate the connection with a remote host.
Dispose	Overloaded. Releases all resources used by TelnetClient.
Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from Object)	Gets the Type of the current instance.
Initialize	Overloaded. Initialize an instance of the TelnetClient class.
Login	Overloaded. Login to the remote server.
Read	Overloaded. Read data from the server and store it in a byte array.
ReadLine	Overloaded. Read up to a line of data from the server and return it in a string buffer.
Reset	Reset the internal state of the object, resetting all properties to their default values.
Search	Overloaded. Search for a specific character sequence in the data stream.
ToString (inherited from Object)	Returns a String that represents the current Object.
Uninitialize	Uninitialize the class library and release any resources allocated for the current thread.
Write	Overloaded. Write one or more bytes of data to the server.
WriteLine	Overloaded. Send a line of text to the server, terminated by a carriage-return and linefeed.

Protected Instance Methods

Dispose	Overloaded. Releases the unmanaged resources allocated by the TelnetClient class and optionally releases the managed resources.
Finalize	Destroys an instance of the class, releasing the resources allocated for the session and unloading the networking library.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

TelnetClient Class | SocketTools Namespace

TelnetClient.Abort Method

Aborts the current session and terminates the connection.

[Visual Basic]

```
Public Function Abort() As Boolean
```

[C#]

```
public bool Abort();
```

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **Abort** method sends an abort sequence to the server and the connection to the server is terminated. Once this method returns, the client is no longer connected to the server. If a program is currently executing on the server at the time this method is called, that program may be terminated as a result of the session being aborted. Applications should normally call the **Disconnect** method to gracefully disconnect from the server and should only use this method when the connection must be aborted immediately.

See Also

TelnetClient Class | SocketTools Namespace

TelnetClient.AttachThread Method

Attach an instance of the class to the current thread

[Visual Basic]

```
Public Function AttachThread() As Boolean
```

[C#]

```
public bool AttachThread();
```

Return Value

A boolean value which specifies if the client could be attached to the current thread. If this method returns **false**, the client could not be attached to the thread and the application should check the value of the LastError property to determine the cause of the failure.

Remarks

When an instance of the class is created it is associated with the current thread that created it. Normally, if another thread attempts to perform an operation using that instance, an error is returned. This is used to ensure that other threads cannot interfere with an operation being performed by the owner thread. In some cases, it may be desirable for one thread in an application to create an instance of the class, establish a connection and then pass that instance to another worker thread. The **AttachThread** method can be used to change the ownership of the class instance to the new worker thread.

This method should be called by the new thread immediately after it has been created, and if the new thread does not release the handle itself, the ownership of the handle should be restored by the original thread. Under no circumstances should **AttachThread** be used to forcibly destroy an instance of a class allocated by another thread while a blocking operation is in progress. To cancel a blocking operation, use the **Cancel** method and then delete the class instance after the blocking function exits and control is returned to the current thread.

See Also

TelnetClient Class | SocketTools Namespace

TelnetClient.Break Method

Sends a break signal to the remote host.

[Visual Basic]
```
Public Function Break() As Boolean
```

[C#]
```
public bool Break();
```

Remarks

The **Break** method sends a signal to the server which may terminate an application that is currently running. The actual response to the break signal depends on the application.

See Also

TelnetClient Class | SocketTools Namespace

TelnetClient.Cancel Method

Cancel the current blocking client operation.

[Visual Basic]

```
Public Sub Cancel()
```

[C#]

```
public void Cancel();
```

Remarks

When the **Cancel** method is called, the blocking client operation will not immediately fail. An internal flag is set which causes the blocking operation to exit with an error. This means that the application cannot cancel an operation and immediately perform some other blocking function. Instead it must allow the calling stack to unwind, returning back to the blocking operation before making any further function calls.

TelnetClient.Connect Method

Establish a connection with a remote host.

Overload List

Establish a connection with a remote host.

public bool Connect();

Establish a connection with a remote host.

public bool Connect(string);

Establish a connection with a remote host.

public bool Connect(string,int);

Establish a connection with a remote host.

public bool Connect(string,int,int);

Establish a connection with a remote host.

public bool Connect(string,int,int,TelnetOptions);

See Also

TelnetClient Class | SocketTools Namespace

TelnetClient.Connect Method ()

Establish a connection with a remote host.

[Visual Basic]
```
Overloads Public Function Connect() As Boolean
```

[C#]
```
public bool Connect();
```

Return Value

A boolean value which specifies if the connection has been established. If the client is in blocking mode, a return value of **true** indicates that the connection has completed and the application may send and receive data from the remote host. If the client is in non-blocking mode, a return value of **true** indicates that the client has successfully created a socket and the connection is in progress.

When a non-blocking connection has completed, the OnConnect event will be fired. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

Remarks

This method establishes a connection using assigned property values.

The value of the **HostName** or **HostAddress** property will be used to determine the host name or address to connect to.

The value of the **RemotePort** property will be used to determine the port number to connect to.

The value of the **Timeout** property will be used to specify the timeout period.

The value of the **Options** property will be used to specify the default options for the connection.

See Also

TelnetClient Class | SocketTools Namespace | TelnetClient.Connect Overload List

TelnetClient.Connect Method (String)

Establish a connection with a remote host.

[Visual Basic]

```
Overloads Public Function Connect( _
   ByVal hostName As String _
) As Boolean
```

[C#]

```
public bool Connect(
   string hostName
);
```

Parameters

hostName

A string which specifies the remote host to establish a connection with. This may specify a host name or an Internet address in dot-notation.

Return Value

A boolean value which specifies if the connection has been established. If the client is in blocking mode, a return value of **true** indicates that the connection has completed and the application may send and receive data from the remote host. If the client is in non-blocking mode, a return value of **true** indicates that the client has successfully created a socket and the connection is in progress.

When a non-blocking connection has completed, the OnConnect event will be fired. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

See Also

TelnetClient Class | SocketTools Namespace | TelnetClient.Connect Overload List

TelnetClient.Connect Method (String, Int32)

Establish a connection with a remote host.

[Visual Basic]

```
Overloads Public Function Connect( _
   ByVal hostName As String, _
   ByVal hostPort As Integer _
) As Boolean
```

[C#]

```
public bool Connect(
   string hostName,
   int hostPort
);
```

Parameters

hostName
A string which specifies the remote host to establish a connection with. This may specify a host name or an Internet address in dot-notation.

hostPort
An integer which specifies the port number for the connection. This value must be greater than zero and the maximum valid port number is 65535.

Return Value

A boolean value which specifies if the connection has been established. If the client is in blocking mode, a return value of **true** indicates that the connection has completed and the application may send and receive data from the remote host. If the client is in non-blocking mode, a return value of **true** indicates that the client has successfully created a socket and the connection is in progress.

When a non-blocking connection has completed, the OnConnect event will be fired. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

See Also

TelnetClient Class | SocketTools Namespace | TelnetClient.Connect Overload List

TelnetClient.Connect Method (String, Int32, Int32)

Establish a connection with a remote host.

[Visual Basic]

```
Overloads Public Function Connect( _
   ByVal hostName As String, _
   ByVal hostPort As Integer, _
   ByVal timeout As Integer _
) As Boolean
```

[C#]

```
public bool Connect(
   string hostName,
   int hostPort,
   int timeout
);
```

Parameters

hostName

A string which specifies the remote host to establish a connection with. This may specify a host name or an Internet address in dot-notation.

hostPort

An integer which specifies the port number for the connection. This value must be greater than zero and the maximum valid port number is 65535.

timeout

An integer value that specifies the number of seconds that the method will wait for the connection to complete before failing the operation and returning to the caller. This value is only meaningful for blocking connections.

Return Value

A boolean value which specifies if the connection has been established. If the client is in blocking mode, a return value of **true** indicates that the connection has completed and the application may send and receive data from the remote host. If the client is in non-blocking mode, a return value of **true** indicates that the client has successfully created a socket and the connection is in progress.

When a non-blocking connection has completed, the OnConnect event will be fired. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

See Also

TelnetClient Class | SocketTools Namespace | TelnetClient.Connect Overload List

TelnetClient.Connect Method (String, Int32, Int32, TelnetOptions)

Establish a connection with a remote host.

[Visual Basic]

```
Overloads Public Function Connect( _
   ByVal hostName As String, _
   ByVal hostPort As Integer, _
   ByVal timeout As Integer, _
   ByVal options As TelnetOptions _
) As Boolean
```

[C#]

```
public bool Connect(
   string hostName,
   int hostPort,
   int timeout,
   TelnetOptions options
);
```

Parameters

hostName

A string which specifies the remote host to establish a connection with. This may specify a host name or an Internet address in dot-notation.

hostPort

An integer which specifies the port number for the connection. This value must be greater than zero and the maximum valid port number is 65535.

timeout

An integer value that specifies the number of seconds that the method will wait for the connection to complete before failing the operation and returning to the caller. This value is only meaningful for blocking connections.

options

One or more of the TelnetOptions enumeration flags.

Return Value

A boolean value which specifies if the connection has been established. If the client is in blocking mode, a return value of **true** indicates that the connection has completed and the application may send and receive data from the remote host. If the client is in non-blocking mode, a return value of **true** indicates that the client has successfully created a socket and the connection is in progress.

When a non-blocking connection has completed, the OnConnect event will be fired. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

See Also

TelnetClient Class | SocketTools Namespace | TelnetClient.Connect Overload List

TelnetClient.Disconnect Method

Terminate the connection with a remote host.

[Visual Basic]

```
Public Sub Disconnect()
```

[C#]

```
public void Disconnect();
```

Remarks

The **Disconnect** method terminates the connection with the remote host and releases the client handle allocated by the class. Note that the socket is not immediately released when the connection is terminated and will enter a wait state for two minutes. After the time wait period has elapsed, the client will be released by the operating system. This is a normal safety mechanism to handle any packets that may arrive after the connection has been closed.

See Also

TelnetClient Class | SocketTools Namespace

TelnetClient.Dispose Method

Releases all resources used by TelnetClient.

Overload List

Releases all resources used by TelnetClient.

public void Dispose();

Releases the unmanaged resources allocated by the TelnetClient class and optionally releases the managed resources.

protected virtual void Dispose(bool);

See Also

TelnetClient Class | SocketTools Namespace

TelnetClient.Dispose Method ()

Releases all resources used by TelnetClient.

[Visual Basic]

```
NotOverridable Overloads Public Sub Dispose() _
    Implements IDisposable.Dispose
```

[C#]

```
public void Dispose();
```

Implements

IDisposable.Dispose

Remarks

The **Dispose** method terminates any active connection and explicitly releases the resources allocated for this instance of the class. In some cases, better performance can be achieved if the programmer explicitly releases resources when they are no longer being used. The **Dispose** method provides explicit control over these resources.

Unlike the **Uninitialize** method, once the **Dispose** method has been called, that instance of the class cannot be re-initialized and you should not attempt to access class properties or invoke any methods. Note that this method can be called even if other references to the object are active.

See Also

TelnetClient Class | SocketTools Namespace | TelnetClient.Dispose Overload List

TelnetClient.Dispose Method (Boolean)

Releases the unmanaged resources allocated by the TelnetClient class and optionally releases the managed resources.

[Visual Basic]

```
Overridable Overloads Protected Sub Dispose( _
   ByVal disposing As Boolean _
)
```

[C#]

```
protected virtual void Dispose(
   bool disposing
);
```

Parameters

disposing

A boolean value which should be specified as **true** to release both managed and unmanaged resources; **false** to release only unmanaged resources.

Remarks

The **Dispose** method terminates any active connection and explicitly releases the resources allocated for this instance of the class. In some cases, better performance can be achieved if the programmer explicitly releases resources when they are no longer being used. The **Dispose** method provides explicit control over these resources.

Unlike the **Uninitialize** method, once the **Dispose** method has been called, that instance of the class cannot be re-initialized and you should not attempt to access class properties or invoke any methods. Note that this method can be called even if other references to the object are active.

You should call **Dispose** in your derived class when you are finished using the derived class. The **Dispose** method leaves the derived class in an unusable state. After calling **Dispose**, you must release all references to the derived class and the **TelnetClient** class so the memory they were occupying can be reclaimed by garbage collection.

See Also

TelnetClient Class | SocketTools Namespace | TelnetClient.Dispose Overload List

TelnetClient.Finalize Method

Destroys an instance of the class, releasing the resources allocated for the session and unloading the networking library.

[Visual Basic]

```
Overrides Protected Sub Finalize()
```

[C#]

```
protected override void Finalize();
```

See Also

TelnetClient Class | SocketTools Namespace

TelnetClient.Initialize Method

Initialize an instance of the TelnetClient class.

Overload List

Initialize an instance of the TelnetClient class.

public bool Initialize();

Initialize an instance of the TelnetClient class.

public bool Initialize(string);

See Also

TelnetClient Class | SocketTools Namespace | Uninitialize Method

TelnetClient.Initialize Method ()

Initialize an instance of the TelnetClient class.

[Visual Basic]

```
Overloads Public Function Initialize() As Boolean
```

[C#]

```
public bool Initialize();
```

Return Value

A boolean value which specifies if the class was initialized successfully.

Remarks

The Initialize method can be used to explicitly initialize an instance of the TelnetClient class, loading the networking library and allocating resources for the current thread. Typically it is not necessary to explicitly call this method because the instance of the class is initialized by the class constructor. However, if the **Uninitialize** method is called, the class must be re-initialized before any other methods are called.

See Also

TelnetClient Class | SocketTools Namespace | TelnetClient.Initialize Overload List | Uninitialize Method

TelnetClient.Initialize Method (String)

Initialize an instance of the TelnetClient class.

[Visual Basic]

```
Overloads Public Function Initialize( _
   ByVal licenseKey As String _
) As Boolean
```

[C#]

```
public bool Initialize(
   string licenseKey
);
```

Return Value

A boolean value which specifies if the class was initialized successfully.

Remarks

The Initialize method can be used to explicitly initialize an instance of the TelnetClient class, loading the networking library and allocating resources for the current thread. Typically an application would define the license key as a custom attribute, however this method can be used to initialize the class directly.

The runtime license key for your copy of SocketTools can be generated using the License Manager utility that is included with the product. Note that if you have installed an evaluation license, you will not have a runtime license key and cannot redistribute any applications which use the TelnetClient class.

Example

The following example shows how to use the Initialize method to initialize an instance of the class. This example assumes that the license key string has been defined in code.

```
SocketTools.TelnetClient telnetClient = new SocketTools.TelnetClient();

if (telnetClient.Initialize(strLicenseKey) == false)
{
    MessageBox.Show(telnetClient.LastErrorString, "Error",
                    MessageBoxButtons.OK, MessageBoxIcon.Exclamation);
    return;
}
```

```
Dim telnetClient As New SocketTools.TelnetClient

If telnetClient.Initialize(strLicenseKey) = False Then
    MsgBox(telnetClient.LastErrorString, vbIconExclamation)
    Exit Sub
End If
```

See Also

TelnetClient Class | SocketTools Namespace | TelnetClient.Initialize Overload List | RuntimeLicenseAttribute Class | Uninitialize Method

TelnetClient.Login Method

Login to the remote server.

Overload List

Login to the remote server.

public bool Login();

Login to the remote server.

public bool Login(string,string);

See Also

TelnetClient Class | SocketTools Namespace

TelnetClient.Login Method ()

Login to the remote server.

[Visual Basic]
```
Overloads Public Function Login() As Boolean
```

[C#]
```
public bool Login();
```

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **Login** method identifies the user to the remote server. The value of the **UserName** and **Password** properties will be used to authenticate the client session. If the user name or password is invalid, an error will occur. By default, when a connection is established, the user is automatically authenticated. This method is typically used if you wish to log in as another user during the same session.

See Also

TelnetClient Class | SocketTools Namespace | TelnetClient.Login Overload List

TelnetClient.Login Method (String, String)

Login to the remote server.

[Visual Basic]

```
Overloads Public Function Login( _
   ByVal userName As String, _
   ByVal userPassword As String _
) As Boolean
```

[C#]

```
public bool Login(
   string userName,
   string userPassword
);
```

Parameters

userName

A string that specifies the name of the user logging into the server.

userPassword

A string that specifies the password used to authenticate the user.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **Login** method identifies the user to the remote server. If the user name or password is invalid, an error will occur. By default, when a connection is established, the **UserName**, **Password** and **Account** properties are used to automatically log the user in to the server. This method is typically used if you wish to log in as another user during the same session.

TelnetClient Class | SocketTools Namespace | TelnetClient.Login Overload List

TelnetClient.Read Method

Read data from the server and store it in a byte array.

Overload List

Read data from the server and store it in a byte array.

public int Read(byte[]);

Read data from the server and store it in a byte array.

public int Read(byte[],int);

Read data from the server and store it in a string.

public int Read(ref string);

Read data from the server and store it in a string.

public int Read(ref string,int);

See Also

TelnetClient Class | SocketTools Namespace

TelnetClient.Read Method (Byte[])

Read data from the server and store it in a byte array.

[Visual Basic]

```
Overloads Public Function Read( _
   ByVal buffer As Byte() _
) As Integer
```

[C#]

```
public int Read(
   byte[] buffer
);
```

Parameters

buffer

A byte array that the data will be stored in.

Return Value

An integer value which specifies the number of bytes actually read from the server. A return value of zero specifies that the remote host has closed the connection and there is no more data available to be read. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Read** method returns data that has been read from the server, up to the size of the byte array passed to the method. If no data is available to be read, an error will be generated if the client is in non-blocking mode. If the client is in blocking mode, the program will stop until data is received from the server or the connection is closed.

See Also

TelnetClient Class | SocketTools Namespace | TelnetClient.Read Overload List

TelnetClient.Read Method (Byte[], Int32)

Read data from the server and store it in a byte array.

[Visual Basic]

```
Overloads Public Function Read( _
   ByVal buffer As Byte(), _
   ByVal length As Integer _
) As Integer
```

[C#]

```
public int Read(
   byte[] buffer,
   int length
);
```

Parameters

buffer

A byte array that the data will be stored in.

length

An integer value which specifies the maximum number of bytes of data to read. This value cannot be larger than the size of the buffer specified by the caller.

Return Value

An integer value which specifies the number of bytes actually read from the server. A return value of zero specifies that the remote host has closed the connection and there is no more data available to be read. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Read** method returns data that has been read from the server, up to the number of bytes specified. If no data is available to be read, an error will be generated if the client is in non-blocking mode. If the client is in blocking mode, the program will stop until data is received from the server or the connection is closed.

See Also

TelnetClient Class | SocketTools Namespace | TelnetClient.Read Overload List

TelnetClient.Read Method (String)

Read data from the server and store it in a string.

[Visual Basic]

```
Overloads Public Function Read( _
   ByRef buffer As String _
) As Integer
```

[C#]

```
public int Read(
   ref string buffer
);
```

Parameters

buffer

A string that will contain the data read from the client.

Return Value

An integer value which specifies the number of bytes actually read from the server. A return value of zero specifies that the remote host has closed the connection and there is no more data available to be read. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Read** method returns data that has been read from the server, up to a maximum of 4096 bytes. If no data is available to be read, an error will be generated if the client is in non-blocking mode. If the client is in blocking mode, the program will stop until data is received from the server or the connection is closed.

This method should only be used if the remote host is sending data that consists of printable characters. Binary data should be read using the method that accepts a byte array as the buffer parameter.

See Also

TelnetClient Class | SocketTools Namespace | TelnetClient.Read Overload List

TelnetClient.Read Method (String, Int32)

Read data from the server and store it in a string.

[Visual Basic]

```
Overloads Public Function Read( _
   ByRef buffer As String, _
   ByVal length As Integer _
) As Integer
```

[C#]

```
public int Read(
   ref string buffer,
   int length
);
```

Parameters

buffer
A string that will contain the data read from the client.

length
An integer value which specifies the maximum number of bytes of data to read.

Return Value

An integer value which specifies the number of bytes actually read from the server. A return value of zero specifies that the remote host has closed the connection and there is no more data available to be read. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Read** method returns data that has been read from the server, up to the number of bytes specified. If no data is available to be read, an error will be generated if the client is in non-blocking mode. If the client is in blocking mode, the program will stop until data is received from the server or the connection is closed.

This method should only be used if the remote host is sending data that consists of printable characters. Binary data should be read using the method that accepts a byte array as the buffer parameter.

TelnetClient.ReadLine Method

Read up to a line of data from the server and return it in a string buffer.

Overload List

Read up to a line of data from the server and return it in a string buffer.

public bool ReadLine(ref string);

Read up to a line of data from the server and return it in a string buffer.

public bool ReadLine(ref string,int);

See Also

TelnetClient Class | SocketTools Namespace

TelnetClient.ReadLine Method (String)

Read up to a line of data from the server and return it in a string buffer.

[Visual Basic]

```
Overloads Public Function ReadLine( _
   ByRef buffer As String _
) As Boolean
```

[C#]

```
public bool ReadLine(
   ref string buffer
);
```

Parameters

buffer

A string which will contain the data read from the socket.

Return Value

This method returns a Boolean value which specifies if a line of data has been read. A value of **true** indicates a line of data has been read. If an error occurs or there is no more data available to read, then the method will return **false**. It is possible for data to be returned in the string buffer even if the return value is **false**. Applications should check the length of the string after the method returns to determine if any data was copied into the buffer. For example, if a timeout occurs while the method is waiting for more data to arrive on the socket, it will return zero; however, data may have already been copied into the string buffer prior to the error condition. It is the responsibility of the application to process that data, regardless of the method return value.

Remarks

The **ReadLine** method reads data from the server up to 4096 bytes in length or until an end-of-line character sequence is encountered. Unlike the **Read** method which reads arbitrary bytes of data, this method is specifically designed to return a single line of text data in a string variable. When an end-of-line character sequence is encountered, the method will stop and return the data up to that point; the string will not contain the carriage-return or linefeed characters.

There are some limitations when using the **ReadLine** method. The method should only be used to read text, never binary data. In particular, it will discard nulls, linefeed and carriage return control characters. This method will force the current thread to block until an end-of-line character sequence is processed, the read operation times out or the remote host closes its end of the socket connection. If the **Blocking** property is set to **false**, calling this method will automatically switch the client into a blocking mode, read the data and then restore the client to non-blocking mode. If another network operation is attempted while **ReadLine** is blocked waiting for data from the remote host, an error will occur. It is recommended that this method only be used with blocking connections.

The **Read** and **ReadLine** methods can be intermixed, however be aware that the **Read** method will consume any data that has already been buffered by the **ReadLine** method and this may have unexpected results.

See Also

TelnetClient Class | SocketTools Namespace | TelnetClient.ReadLine Overload List

TelnetClient.ReadLine Method (String, Int32)

Read up to a line of data from the server and return it in a string buffer.

[Visual Basic]

```
Overloads Public Function ReadLine( _
   ByRef buffer As String, _
   ByVal length As Integer _
) As Boolean
```

[C#]

```
public bool ReadLine(
   ref string buffer,
   int length
);
```

Parameters

buffer

A string which will contain the data read from the socket.

length

An integer value which specifies the maximum number of bytes of data to read.

Return Value

This method returns a Boolean value which specifies if a line of data has been read. A value of **true** indicates a line of data has been read. If an error occurs or there is no more data available to read, then the method will return **false**. It is possible for data to be returned in the string buffer even if the return value is **false**. Applications should check the length of the string after the method returns to determine if any data was copied into the buffer. For example, if a timeout occurs while the method is waiting for more data to arrive on the socket, it will return zero; however, data may have already been copied into the string buffer prior to the error condition. It is the responsibility of the application to process that data, regardless of the method return value.

Remarks

The **ReadLine** method reads data from the server up to the specified number of bytes or until an end-of-line character sequence is encountered. Unlike the **Read** method which reads arbitrary bytes of data, this method is specifically designed to return a single line of text data in a string variable. When an end-of-line character sequence is encountered, the method will stop and return the data up to that point; the string will not contain the carriage-return or linefeed characters.

There are some limitations when using the **ReadLine** method. The method should only be used to read text, never binary data. In particular, it will discard nulls, linefeed and carriage return control characters. This method will force the current thread to block until an end-of-line character sequence is processed, the read operation times out or the remote host closes its end of the socket connection. If the **Blocking** property is set to **false**, calling this method will automatically switch the client into a blocking mode, read the data and then restore the client to non-blocking mode. If another network operation is attempted while **ReadLine** is blocked waiting for data from the remote host, an error will occur. It is recommended that this method only be used with blocking connections.

The **Read** and **ReadLine** methods can be intermixed, however be aware that the **Read** method will consume any data that has already been buffered by the **ReadLine** method and this may have unexpected results.

TelnetClient Class | SocketTools Namespace | TelnetClient.ReadLine Overload List

TelnetClient.Reset Method

Reset the internal state of the object, resetting all properties to their default values.

[Visual Basic]

```
Public Sub Reset()
```

[C#]

```
public void Reset();
```

Remarks

The **Reset** method returns the object to its default state. If a socket has been allocated, it will be released and any active connections will be terminated. All properties will be reset to their default values.

TelnetClient.Search Method

Search for a specific character sequence in the data stream.

Overload List

Search for a specific character sequence in the data stream.

public bool Search(string);

Search for a specific character sequence in the data stream.

public bool Search(string,byte[],ref int);

Search for a specific character sequence in the data stream.

public bool Search(string,ref string);

See Also

TelnetClient Class | SocketTools Namespace

TelnetClient.Search Method (String)

Search for a specific character sequence in the data stream.

[Visual Basic]

```
Overloads Public Function Search( _
   ByVal value As String _
) As Boolean
```

[C#]

```
public bool Search(
   string value
);
```

Parameters

value

A string argument which specifies the sequence of characters to search for in the data stream. When this sequence of characters is found, the method will return.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **Search** method searches for a character sequence in the data stream and stops reading when it is found. This is useful when the client wants to automate responses to the server, such as executing a command and processing the output. The method will discard any data received up to and including the specified character sequence.

See Also

TelnetClient Class | SocketTools Namespace | TelnetClient.Search Overload List

TelnetClient.Search Method (String, Byte[], Int32)

Search for a specific character sequence in the data stream.

[Visual Basic]

```
Overloads Public Function Search( _
   ByVal value As String, _
   ByVal buffer As Byte(), _
   ByRef length As Integer _
) As Boolean
```

[C#]

```
public bool Search(
   string value,
   byte[] buffer,
   ref int length
);
```

Parameters

value
A string argument which specifies the sequence of characters to search for in the data stream. When this sequence of characters is found, the method will return.

buffer
An byte array that will contain the output sent by the server, up to and including the search string character sequence.

length
An integer value passed by reference which should be initialized to the maximum number of bytes of data to store in the buffer. When the method returns, this value will be updated with the actual number of bytes stored in the buffer.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **Search** method searches for a character sequence in the data stream and stops reading when it is found. This is useful when the client wants to automate responses to the server, such as executing a command and processing the output. The method collects the output from the server and stores it in a buffer provided by the caller. When the method returns, the buffer will contain everything sent by the server up to and including the search string.

See Also

TelnetClient Class | SocketTools Namespace | TelnetClient.Search Overload List

TelnetClient.Search Method (String, String)

Search for a specific character sequence in the data stream.

[Visual Basic]

```
Overloads Public Function Search( _
   ByVal value As String, _
   ByRef buffer As String _
) As Boolean
```

[C#]

```
public bool Search(
   string value,
   ref string buffer
);
```

Parameters

value

A string argument which specifies the sequence of characters to search for in the data stream. When this sequence of characters is found, the method will return.

buffer

An string that will contain the output sent by the server, up to and including the search string character sequence.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **Search** method searches for a character sequence in the data stream and stops reading when it is found. This is useful when the client wants to automate responses to the server, such as executing a command and processing the output. The method collects the output from the server and stores it in a buffer provided by the caller. When the method returns, the buffer will contain everything sent by the server up to and including the search string.

TelnetClient Class | SocketTools Namespace | TelnetClient.Search Overload List

TelnetClient.Uninitialize Method

Uninitialize the class library and release any resources allocated for the current thread.

[Visual Basic]

```
Public Sub Uninitialize()
```

[C#]

```
public void Uninitialize();
```

Remarks

The **Uninitialize** method terminates any active connection, releases resources allocated for the current thread and unloads the networking library. After this method has been called, no further client operations may be performed until the class instance has been re-initialized.

If the **Initialize** method is explicitly called by the application, it should be matched by a call to the **Uninitialize** method when that instance of the class is no longer needed.

TelnetClient Class | SocketTools Namespace | Initialize Method

TelnetClient.Write Method

Write one or more bytes of data to the server.

Overload List

Write one or more bytes of data to the server.

public int Write(byte[]);

Write one or more bytes of data to the server.

public int Write(byte[],int);

Write a character to the server.

public int Write(char);

Write one or more characters to the server.

public int Write(char,int);

Write a string of characters to the server.

public int Write(string);

Write a string of characters to the server.

public int Write(string,int);

See Also

TelnetClient Class | SocketTools Namespace

TelnetClient.Write Method (Byte[])

Write one or more bytes of data to the server.

[Visual Basic]

```
Overloads Public Function Write( _
   ByVal buffer As Byte() _
) As Integer
```

[C#]

```
public int Write(
   byte[] buffer
);
```

Parameters

buffer

A byte array that contains the data to be written to the server.

Return Value

An integer value which specifies the number of bytes actually written to the server. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Write** method sends one or more bytes of data to the server. If there is enough room in the client's internal send buffer to accommodate all of the data, it is copied to the send buffer and control immediately returns to the caller. If amount of data exceeds the available buffer space and the client is in blocking mode, then the method will block until the data can be sent. If the client is in non-blocking mode and the send buffer is full, an error will occur.

See Also

TelnetClient.Write Method (Byte[], Int32)

Write one or more bytes of data to the server.

[Visual Basic]

```
Overloads Public Function Write( _
   ByVal buffer As Byte(), _
   ByVal length As Integer _
) As Integer
```

[C#]

```
public int Write(
   byte[] buffer,
   int length
);
```

Parameters

buffer

A byte array that contains the data to be written to the server.

length

An integer value which specifies the maximum number of bytes of data to write. This value cannot be larger than the size of the buffer specified by the caller.

Return Value

An integer value which specifies the number of bytes actually written to the server. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Write** method sends one or more bytes of data to the server. If there is enough room in the client's internal send buffer to accommodate all of the data, it is copied to the send buffer and control immediately returns to the caller. If amount of data exceeds the available buffer space and the client is in blocking mode, then the method will block until the data can be sent. If the client is in non-blocking mode and the send buffer is full, an error will occur.

See Also

TelnetClient Class | SocketTools Namespace | TelnetClient.Write Overload List

TelnetClient.Write Method (Char)

Write a character to the server.

[Visual Basic]

```
Overloads Public Function Write( _
   ByVal key As Char _
) As Integer
```

[C#]

```
public int Write(
   char key
);
```

Parameters

key

A character which will be written to the server.

Return Value

An integer value which specifies the number of characters actually written to the server. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Write** method sends one character to the server. If the client is in non-blocking mode and the send buffer is full, an error will occur.

See Also

TelnetClient Class | SocketTools Namespace | TelnetClient.Write Overload List

TelnetClient.Write Method (Char, Int32)

Write one or more characters to the server.

[Visual Basic]

```
Overloads Public Function Write( _
   ByVal key As Char, _
   ByVal repeat As Integer _
) As Integer
```

[C#]

```
public int Write(
   char key,
   int repeat
);
```

Parameters

key

A character which will be written to the server.

repeat

The number of characters that will be written to the server.

Return Value

An integer value which specifies the number of characters actually written to the server. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Write** method sends one or more characters to the server. If there is enough room in the client's internal send buffer to accommodate all of the data, it is copied to the send buffer and control immediately returns to the caller. If amount of data exceeds the available buffer space and the client is in blocking mode, then the method will block until the data can be sent. If the client is in non-blocking mode and the send buffer is full, an error will occur.

See Also

TelnetClient Class | SocketTools Namespace | TelnetClient.Write Overload List

TelnetClient.Write Method (String)

Write a string of characters to the server.

[Visual Basic]

```
Overloads Public Function Write( _
   ByVal buffer As String _
) As Integer
```

[C#]

```
public int Write(
   string buffer
);
```

Parameters

buffer

A string which contains the data to be written to the server.

Return Value

An integer value which specifies the number of characters actually written to the server. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Write** method sends a string of characters to the server. If there is enough room in the client's internal send buffer to accommodate all of the data, it is copied to the send buffer and control immediately returns to the caller. If amount of data exceeds the available buffer space and the client is in blocking mode, then the method will block until the data can be sent. If the client is in non-blocking mode and the send buffer is full, an error will occur.

The string will be converted to an array of bytes before being written to the socket. By default, the character encoding used will be for the current locale. Depending on the contents of the string, the number of bytes written may be different than the string length specified. This is because the conversion from Unicode to a byte array may result in a multi-byte character sequence.

You should never use strings to read and write binary data. Always use byte arrays to ensure that no character conversion is performed.

TelnetClient.Write Method (String, Int32)

Write a string of characters to the server.

[Visual Basic]

```
Overloads Public Function Write( _
   ByVal buffer As String, _
   ByVal length As Integer _
) As Integer
```

[C#]

```
public int Write(
   string buffer,
   int length
);
```

Parameters

buffer
A string which contains the data to be written to the server.

length
An integer value which specifies the maximum number of characters to write. This value cannot be larger than the length of the string specified by the caller.

Return Value

An integer value which specifies the number of characters actually written to the server. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Write** method sends a string of characters to the server. If there is enough room in the client's internal send buffer to accommodate all of the data, it is copied to the send buffer and control immediately returns to the caller. If amount of data exceeds the available buffer space and the client is in blocking mode, then the method will block until the data can be sent. If the client is in non-blocking mode and the send buffer is full, an error will occur.

The string will be converted to an array of bytes before being written to the socket. By default, the character encoding used will be for the current locale. Depending on the contents of the string, the number of bytes written may be different than the string length specified. This is because the conversion from Unicode to a byte array may result in a multi-byte character sequence.

You should never use strings to read and write binary data. Always use byte arrays to ensure that no character conversion is performed.

Send an empty line of text to the server, terminated by a carriage-return and linefeed.

Overload List

Send an empty line of text to the server, terminated by a carriage-return and linefeed.

public bool WriteLine();

Send a line of text to the server, terminated by a carriage-return and linefeed.

public bool WriteLine(string);

Send a line of text to the server, terminated by a carriage-return and linefeed.

public bool WriteLine(string,ref int);

See Also

TelnetClient Class | SocketTools Namespace

TelnetClient.WriteLine Method ()

Send an empty line of text to the server, terminated by a carriage-return and linefeed.

[Visual Basic]

```
Overloads Public Function WriteLine() As Boolean
```

[C#]

```
public bool WriteLine();
```

Return Value

A boolean value which specifies if the operation completed successfully. A return value of **false** indicates an error has occurred. To get extended error information, check the value of the **LastError** property.

Remarks

The **WriteLine** method will send an empty line of text, terminated by a carriage-return and linefeed. Calling this method will force the application to block until the complete line of text has been written, the write operation times out or the remote host aborts the connection. If this method is called with the **Blocking** property set to **false**, it will automatically switch the client into a blocking mode, send the data and then restore the client to non-blocking mode. If another network operation is attempted while the **WriteLine** method is blocked sending data to the remote host, an error will occur. It is recommended that this method only be used with blocking connections.

The **Write** and **WriteLine** methods can be safely intermixed.

See Also

TelnetClient.WriteLine Method (String)

Send a line of text to the server, terminated by a carriage-return and linefeed.

[Visual Basic]

```
Overloads Public Function WriteLine( _
   ByVal buffer As String _
) As Boolean
```

[C#]

```
public bool WriteLine(
   string buffer
);
```

Parameters

buffer

A string which contains the data that will be sent to the remote host. The data will always be terminated with a carriage-return and linefeed control character sequence. If the string is empty, then a only a carriage-return and linefeed are written to the socket. Note that if the string contains a null character, any data that follows the null character will be discarded.

Return Value

A boolean value which specifies if the operation completed successfully. A return value of **false** indicates an error has occurred. To get extended error information, check the value of the **LastError** property.

Remarks

The **WriteLine** method should only be used to send text, never binary data. In particular, this method will discard any data that follows a null character and will append linefeed and carriage return control characters to the data stream. Calling this method will force the current thread to block until the complete line of text has been written, the write operation times out or the remote host aborts the connection. If this method is called with the **Blocking** property set to **false**, it will automatically switch the client into a blocking mode, send the data and then restore the client to non-blocking mode. If another network operation is attempted while the **WriteLine** method is blocked sending data to the remote host, an error will occur. It is recommended that this method only be used with blocking connections.

The string will be converted to an array of bytes before being written to the socket. By default, the character encoding used will be for the current locale. Depending on the contents of the string, the number of bytes written may be different than the string length specified. This is because the conversion from Unicode to a byte array may result in a multi-byte character sequence.

You should never use strings to read and write binary data. Always use byte arrays to ensure that no character conversion is performed.

The **Write** and **WriteLine** methods can be safely intermixed.

) As Boolean
```

[C#]

```
public bool WriteLine(
   string buffer,
   ref int length
);
```

Parameters

buffer

A string which contains the data that will be sent to the remote host. The data will always be terminated with a carriage-return and linefeed control character sequence. If the string is empty, then a only a carriage-return and linefeed are written to the socket. Note that if the string contains a null character, any data that follows the null character will be discarded.

length

An integer value which specifies the maximum number of characters to write. This value cannot be larger than the length of the string specified by the caller.

Return Value

A boolean value which specifies if the operation completed successfully. A return value of **false** indicates an error has occurred. To get extended error information, check the value of the **LastError** property.

Remarks

The **WriteLine** method should only be used to send text, never binary data. In particular, this method will discard any data that follows a null character and will append linefeed and carriage return control characters to the data stream. Calling this method will force the current thread to block until the complete line of text has been written, the write operation times out or the remote host aborts the connection. If this method is called with the **Blocking** property set to **false**, it will automatically switch the client into a blocking mode, send the data and then restore the client to non-blocking mode. TelnetClient Events

The events of the **TelnetClient** class are listed below. For a complete list of **TelnetClient** class members, see the TelnetClient Members topic.

Public Instance Events

⚡ OnCancel	Occurs when a blocking client operation is canceled.
⚡ OnConnect	Occurs when a connection is established with the remote host.
⚡ OnDisconnect	Occurs when the remote host disconnects from the local system.
⚡ OnError	Occurs when an client operation fails.
⚡ OnRead	Occurs when data is available to be read from the client.
⚡ OnTimeout	Occurs when a blocking operation fails to complete before the timeout period elapses.
⚡ OnWrite	Occurs when data can be written to the client.

See Also

TelnetClient Class | SocketTools Namespace

TelnetClient.OnCancel Event

Occurs when a blocking client operation is canceled.

[Visual Basic]

```
Public Event OnCancel As EventHandler
```

[C#]

```
public event EventHandler OnCancel;
```

Remarks

The **OnCancel** event is generated when a blocking client operation, such as sending or receiving data, is canceled with the **Cancel** method. To assist in determining which operation was canceled, check the value of the **Status** property.

See Also

TelnetClient Class | SocketTools Namespace

TelnetClient.OnConnect Event

Occurs when a connection is established with the remote host.

[Visual Basic]

```
Public Event OnConnect As EventHandler
```

[C#]

```
public event EventHandler OnConnect;
```

Remarks

The **OnConnect** event occurs when a connection is made with a remote host as a result of a **Connect** method call. When the **Connect** method is called and the **Blocking** property is set to **false**, a socket is created but the connection is not actually established until after this event occurs. Between the time connection process is started and this event fires, no operation may be performed on the client other than calling the **Disconnect** method.

This event is only generated if the client is in non-blocking mode.

See Also

TelnetClient Class | SocketTools Namespace

TelnetClient.OnDisconnect Event

Occurs when the remote host disconnects from the local system.

[Visual Basic]

```
Public Event OnDisconnect As EventHandler
```

[C#]

```
public event EventHandler OnDisconnect;
```

Remarks

The **OnDisconnect** event occurs when the remote host closes its connection, terminating the client session with the application. Because there may still be data in the client receive buffers, you should continue to read data from the client until the **Read** method returns a value of 0. Once all of the data has been read, you should call the **Disconnect** method to close the local socket and release the resources allocated for the client.

This event is only generated if the client is in non-blocking mode.

See Also

TelnetClient Class | SocketTools Namespace

TelnetClient.OnError Event

Occurs when an client operation fails.

[Visual Basic]

```
Public Event OnError As OnErrorEventHandler
```

[C#]

```
public event OnErrorEventHandler OnError;
```

Event Data

The event handler receives an argument of type TelnetClient.ErrorEventArgs containing data related to this event. The following **TelnetClient.ErrorEventArgs** properties provide information specific to this event.

Property	Description
Description	Gets a value which describes the last error that has occurred.
Error	Gets a value which specifies the last error that has occurred.

Remarks

The **OnError** event occurs when a client operation fails.

See Also

TelnetClient Class | SocketTools Namespace

TelnetClient.ErrorEventArgs Class

Provides data for the OnError event.

For a list of all members of this type, see TelnetClient.ErrorEventArgs Members.

System.Object
  System.EventArgs
    SocketTools.TelnetClient.ErrorEventArgs

[Visual Basic]

```
Public Class TelnetClient.ErrorEventArgs
    Inherits EventArgs
```

[C#]

```
public class TelnetClient.ErrorEventArgs : EventArgs
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

ErrorEventArgs specifies the numeric error code and a description of the error that has occurred.

An OnError event occurs when a method fails.

Requirements

Namespace: SocketTools

Assembly: SocketTools.TelnetClient (in SocketTools.TelnetClient.dll)

TelnetClient.ErrorEventArgs Members | SocketTools Namespace

TelnetClient.ErrorEventArgs Members

TelnetClient.ErrorEventArgs overview

Public Instance Constructors

TelnetClient.ErrorEventArgs Constructor	Initializes a new instance of the TelnetClient.ErrorEventArgs class.

Public Instance Properties

Description	Gets a value which describes the last error that has occurred.
Error	Gets a value which specifies the last error that has occurred.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString (inherited from Object)	Returns a String that represents the current Object.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

TelnetClient.ErrorEventArgs Class | SocketTools Namespace

TelnetClient.ErrorEventArgs Constructor

Initializes a new instance of the TelnetClient.ErrorEventArgs class.

[Visual Basic]

```
Public Sub New()
```

[C#]

```
public TelnetClient.ErrorEventArgs();
```

See Also

TelnetClient.ErrorEventArgs Class | SocketTools Namespace

TelnetClient.ErrorEventArgs Properties

The properties of the **TelnetClient.ErrorEventArgs** class are listed below. For a complete list of **TelnetClient.ErrorEventArgs** class members, see the TelnetClient.ErrorEventArgs Members topic.

Public Instance Properties

Description	Gets a value which describes the last error that has occurred.
Error	Gets a value which specifies the last error that has occurred.

See Also

TelnetClient.ErrorEventArgs Class | SocketTools Namespace

TelnetClient.ErrorEventArgs.Description Property

Gets a value which describes the last error that has occurred.

[Visual Basic]

```
Public ReadOnly Property Description As String
```

[C#]

```
public string Description {get;}
```

Property Value

A string which describes the last error that has occurred.

See Also

TelnetClient.ErrorEventArgs Class | SocketTools Namespace | Error Property

TelnetClient.ErrorEventArgs.Error Property

Gets a value which specifies the last error that has occurred.

[Visual Basic]

```
Public ReadOnly Property Error As ErrorCode
```

[C#]

```
public TelnetClient.ErrorCode Error {get;}
```

Property Value

ErrorCode enumeration which specifies the error.

See Also

TelnetClient.ErrorEventArgs Class | SocketTools Namespace | Description Property

TelnetClient.OnRead Event

Occurs when data is available to be read from the client.

[Visual Basic]

```
Public Event OnRead As EventHandler
```

[C#]

```
public event EventHandler OnRead;
```

Remarks

The **OnRead** event occurs when data is available to be read from the client. This event is level-triggered, which means that once this event fires, it will not occur again until some data has been read from the client. This design prevents an application from being flooded with event notifications. It is recommended that your application read all of the available data from the server and store it in a local buffer for processing. See the example below.

This event is only generated if the client is in non-blocking mode.

Example

```
Private Sub Socket_OnRead(ByVal sender As Object, ByVal e As System.EventArgs)
Handles Socket.OnRead
    Dim strBuffer As String
    Dim nRead As Integer

    Do
        ' Read up to m_nBufferSize bytes of data from the server
        nRead = Socket.Read(strBuffer, m_nBufferSize)

        If nRead > 0 Then
            ' Append the data to an internal buffer for processing
            m_dataBuffer = m_dataBuffer + strBuffer
        End If
    Loop Until nRead < 1

    ProcessData()
End Sub

TelnetClient.OnTimeout Event

Occurs when a blocking operation fails to complete before the timeout period elapses.

[Visual Basic]

```
Public Event OnTimeout As EventHandler
```

[C#]

```
public event EventHandler OnTimeout;
```

Remarks

The **OnTimeout** event occurs when a blocking operation, such as sending or receiving data on the client, fails to complete before the specified timeout period elapses. The timeout period for a blocking operation can be adjusted by setting the **Timeout** property.

This event is only generated if the client is in blocking mode.

See Also

TelnetClient Class | SocketTools Namespace

TelnetClient.OnWrite Event

Occurs when data can be written to the client.

[Visual Basic]

```
Public Event OnWrite As EventHandler
```

[C#]

```
public event EventHandler OnWrite;
```

Remarks

The **OnWrite** event occurs when the application can write data to the client. This event will typically occur when a connection is first established with the remote host, and after the **Write** method has failed because there was insufficient memory available in the client send buffers. In the second case, when some of the buffered data has been successfully sent to the remote host and there is space available in the send buffers, this event is used to signal the application that it may attempt to send more data.

This event is only generated if the client is in non-blocking mode.

TelnetClient.ErrorCode Enumeration

Specifies the error codes returned by the TelnetClient class.

[Visual Basic]
```
Public Enum TelnetClient.ErrorCode
```

[C#]
```
public enum TelnetClient.ErrorCode
```

Remarks

The TelnetClient class uses the **ErrorCode** enumeration to specify what error has occurred when a method fails. The current error code may be determined by checking the value of the **LastError** property.

Note that the last error code is only meaningful if the previous operation has failed.

Members

Member Name	Description
errorNone	No error.
errorNotHandleOwner	Handle not owned by the current thread.
errorFileNotFound	The specified file or directory does not exist.
errorFileNotCreated	The specified file could not be created.
errorOperationCanceled	The blocking operation has been canceled.
errorInvalidFileType	The specified file is a block or character device, not a regular file.
errorInvalidDevice	The specified file type is invalid or not a regular file.
errorTooManyParameters	The maximum number of function parameters has been exceeded.
errorInvalidFileName	The specified file name contains invalid characters or is too long.
errorInvalidFileHandle	Invalid file handle passed to function.
errorFileReadFailed	Unable to read data from the specified file.
errorFileWriteFailed	Unable to write data to the specified file.
errorOutOfMemory	Out of memory.
errorAccessDenied	Access denied.
errorInvalidParameter	Invalid argument passed to function.
errorClipboardUnavailable	The system clipboard is currently unavailable.
errorClipboardEmpty	The system clipboard is empty or does not contain any text data.
errorFileEmpty	The specified file does not contain any data.
errorFileExists	The specified file already exists.

errorEndOfFile	End of file.
errorDeviceNotFound	The specified device could not be found.
errorDirectoryNotFound	The specified directory could not be found.
errorInvalidbuffer	Invalid memory address passed to function.
errorBufferTooSmall	The specified buffer is not large enough to contain the data.
errorNoHandles	No more handles are available to this process.
errorOperationWouldBlock	The specified operation would block the current thread.
errorOperationInProgress	A blocking operation is currently in progress.
errorAlreadyInProgress	The specified operation is already in progress.
errorInvalidHandle	Invalid handle passed to function.
errorInvalidAddress	Invalid network address specified.
errorInvalidSize	Datagram is too large to fit in specified buffer.
errorInvalidProtocol	Invalid network protocol specified.
errorProtocolNotAvailable	The specified network protocol is not available.
errorProtocolNotSupported	The specified protocol is not supported.
errorSocketNotSupported	The specified socket type is not supported.
errorInvalidOption	The specified option is invalid.
errorProtocolFamily	Specified protocol family is not supported.
errorProtocolAddress	The specified address is invalid for this protocol family.
errorAddressInUse	The specified address is in use by another process.
errorAddressUnavailable	The specified address cannot be assigned.
errorNetworkUnavailable	The networking subsystem is unavailable.
errorNetworkUnreachable	The specified network is unreachable.
errorNetworkReset	Network dropped connection on remote reset.
errorConnectionAborted	Connection was aborted due to timeout or other failure.
errorConnectionReset	Connection was reset by remote network.
errorOutOfBuffers	No buffer space is available.
errorAlreadyConnected	Connection already established with remote host.
errorNotConnected	No connection established with remote host.
errorConnectionShutdown	Unable to send or receive data after connection shutdown.
errorOperationTimeout	The specified operation has timed out.
errorConnectionRefused	The connection has been refused by the remote host.

errorHostUnavailable	The specified host is unavailable.
errorHostUnreachable	Remote host is unreachable.
errorTooManyProcesses	Too many processes are using the networking subsystem.
errorTooManyThreads	Too many threads have been created by the current process.
errorTooManySessions	Too many client sessions have been created by the current process.
errorInternalFailure	An unexpected internal error has occurred.
errorNetworkNotReady	Network subsystem is not ready for communication.
errorInvalidVersion	This version of the operating system is not supported.
errorNetworkNotInitialized	The networking subsystem has not been initialized.
errorRemoteShutdown	The remote host has initiated a graceful shutdown sequence.
errorInvalidHostName	The specified hostname is invalid or could not be resolved.
errorHostNameNotFound	The specified hostname could not be found.
errorHostNameRefused	Unable to resolve hostname, request refused.
errorHostNameNotResolved	Unable to resolve hostname, no address for specified host.
errorInvalidLicense	The license for this product is invalid.
errorProductNotLicensed	This product is not licensed to perform this operation.
errorNotImplemented	This function has not been implemented on this platform.
errorUnknownLocalhost	Unable to determine local host name.
errorInvalidHostAddress	Invalid host address specified.
errorInvalidServicePort	Invalid service port number specified.
errorInvalidServiceName	Invalid or unknown service name specified.
errorInvalidEventId	Invalid event identifier specified.
errorOperationNotBlocking	No blocking operation in progress on this socket.
errorSecurityNotInitialized	Unable to initialize security interface for this process.
errorSecurityContext	Unable to establish security context for this session.
errorSecurityCredentials	Unable to open certificate store or establish security credentials.
errorSecurityCertificate	Unable to validate the certificate chain for this

	session.
errorSecurityDecryption	Unable to decrypt data stream.
errorSecurityEncryption	Unable to encrypt data stream.
errorOperationNotSupported	The specified operation is not supported.
errorInvalidProtocolVersion	Invalid application protocol version specified.
errorNoServerResponse	No data returned from server.
errorInvalidServerResponse	Invalid data returned from server.
errorUnexpectedServerResponse	Unexpected response code returned from server.
errorServerTransactionFailed	Server transaction failed.
errorServiceUnavailable	The service is currently unavailable.
errorServiceNotReady	The service is not ready, try again later.
errorServerResyncFailed	Unable to resynchronize with server.
errorInvalidProxyType	Invalid proxy server type specified.
errorProxyRequired	Resource must be accessed through specified proxy.
errorInvalidProxyLogin	Unable to login to proxy server using specified credentials.
errorProxyResyncFailed	Unable to resynchronize with proxy server.
errorInvalidCommand	Invalid command specified.
errorInvalidCommandParameter	Invalid command parameter specified.
errorInvalidCommandSequence	Invalid command sequence specified.
errorCommandNotImplemented	Specified command not implemented on this server.
errorCommandNotAuthorized	Specified command not authorized for the current user.
errorCommandAborted	Specified command was aborted by the remote host.
errorOptionNotSupported	The specified option is not supported on this server.
errorRequestNotCompleted	The current client request has not been completed.
errorInvalidUserName	The specified username is invalid.
errorInvalidPassword	The specified password is invalid.
errorInvalidAccount	The specified account name is invalid.
errorAccountRequired	Account name has not been specified.
errorInvalidAuthenticationType	Invalid authentication protocol specified.
errorAuthenticationRequired	User authentication is required.
errorProxyAuthenticationRequired	Proxy authentication required.

errorAlreadyAuthenticated	User has already been authenticated.
errorAuthenticationFailed	Unable to authenticate the specified user.
errorNetworkAdapter	Unable to determine network adapter configuration.
errorInvalidRecordType	Invalid record type specified.
errorInvalidRecordName	Invalid record name specified.
errorInvalidRecordData	Invalid record data specified.
errorConnectionOpen	Data connection already established.
errorConnectionClosed	Server closed data connection.
errorConnectionPassive	Data connection is passive.
errorConnectionFailed	Unable to open data connection to server.
errorInvalidSecurityLevel	Data connection cannot be opened with this security setting.
errorCachedTLSRequired	Data connection requires cached TLS session.
errorDataReadOnly	Data connection is read-only.
errorDataWriteOnly	Data connection is write-only.
errorEndOfData	End of data.
errorRemoteFileUnavailable	Remote file is unavailable.
errorInsufficientStorage	Insufficient storage on server.
errorStorageallocation	File exceeded storage allocation on server.
errorDirectoryExists	The specified directory already exists.
errorDirectoryEmpty	No files returned by the server for the specified directory.
errorEndOfDirectory	End of directory listing.
errorUnknownDirectoryFormat	Unknown directory format.
errorInvalidResource	Invalid resource name specified.
errorResourceRedirected	The specified resource has been redirected.
errorResourceRestricted	Access to this resource has been restricted.
errorResourceNotModified	The specified resource has not been modified.
errorResourceNotFound	The specified resource cannot be found.
errorResourceConflict	Request could not be completed due to the current state of the resource.
errorResourceRemoved	The specified resource has been permanently removed from this server.
errorContentLengthRequired	Request must include the content length.
errorRequestPrecondition	Request could not be completed due to server precondition.
errorUnsupportedMediaType	Request specified an unsupported media type.

errorInvalidContentRange	Content range specified for this resource is invalid.
errorInvalidMessagePart	Message is not multipart or an invalid message part was specified.
errorInvalidMessageHeader	The specified message header is invalid or has not been defined.
errorInvalidMessageBoundary	The multipart message boundary has not been defined.
errorNoFileAttachment	The current message part does not contain a file attachment.
errorUnknownFileType	The specified file type could not be determined.
errorDataNotEncoded	The specified data block could not be encoded.
errorDataNotDecoded	The specified data block could not be decoded.
errorFileNotEncoded	The specified file could not be encoded.
errorFileNotDecoded	The specified file could not be decoded.
errorNoMessageText	No message text.
errorInvalidCharacterSet	Invalid character set specified.
errorInvalidEncodingType	Invalid encoding type specified.
errorInvalidMessageNumber	Invalid message number specified.
errorNoReturnAddress	No valid return address specified.
errorNoValidRecipients	No valid recipients specified.
errorInvalidRecipient	The specified recipient address is invalid.
errorRelayNotAuthorized	The specified domain is invalid or server will not relay messages.
errorMailboxUnavailable	Specified mailbox is currently unavailable.
errorMailboxReadOnly	The selected mailbox cannot be modified.
errorMailboxNotSelected	No mailbox has been selected.
errorInvalidMailbox	Specified mailbox is invalid.
errorInvalidDomain	The specified domain name is invalid or not recognized.
errorInvalidSender	The specified sender address is invalid or not recognized.
errorMessageNotDelivered	Message not delivered to any of the specified recipients.
errorEndOfMessageData	No more message data available to be read
errorInvalidmessageSize	The specified message size is invalid.
errorMessageNotCreated	The message could not be created in the specified mailbox.
errorNoMoreMailboxes	No more mailboxes exist on this server.

errorInvalidEmulationType	The specified terminal emulation type is invalid.
errorInvalidFontHandle	The specified font handle is invalid.
errorInvalidFontName	The specified font name is invalid or unavailable.
errorInvalidPacketSize	The specified packet size is invalid.
errorInvalidPacketData	The specified packet data is invalid.
errorInvalidPacketId	The unique packet identifier is invalid.
errorPacketTTLExpired	The specified packet time-to-live period has expired.
errorInvalidNewsGroup	Invalid newsgroup specified.
errorNoNewsgroupSelected	No newsgroup selected.
errorEmptyNewsgroup	No articles in specified newsgroup.
errorInvalidArticle	Invalid article number specified.
errorNoArticleSelected	No article selected in the current newsgroup.
errorFirstArticle	First article in current newsgroup.
errorLastArticle	Last article in current newsgroup.
errorArticleExists	Unable to transfer article, article already exists.
errorArticleRejected	Unable to transfer article, article rejected.
errorArticleTransferFailed	Article transfer failed.
errorArticlePostingDenied	Posting is not permitted on this server.
errorArticlePostingFailed	Unable to post article on this server.
errorInvalidDateFormat	The specified date format is not recognized.
errorFeatureNotSupported	The specified feature is not supported on this server.
errorInvalidFormHandle	The specified form handle is invalid or a form has not been created.
errorInvalidFormAction	The specified form action is invalid or has not been specified.
errorInvalidFormMethod	The specified form method is invalid or not supported.
errorInvalidFormType	The specified form type is invalid or not supported.
errorInvalidFormField	The specified form field name is invalid or does not exist.
errorEmptyForm	The specified form does not contain any field values.
errorMaximumConnections	The maximum number of client connections exceeded.
errorThreadCreationFailed	Unable to create a new thread for the current process.
errorInvalidThreadHandle	The specified thread handle is no longer valid.

errorThreadTerminated	The specified thread has been terminated.
errorThreadDeadlock	The operation would result in the current thread becoming deadlocked.
errorInvalidClientMoniker	The specified moniker is not associated with any client session.
errorClientMonikerExists	The specified moniker has been assigned to another client session.
errorServerInactive	The specified server is not listening for client connections.
errorServerSuspended	The specified server is suspended and not accepting client connections.
errorNoMessageStore	No message store has been specified.
errorMessageStoreChanged	The message store has changed since it was last accessed.
errorMessageNotFound	No message was found that matches the specified criteria.
errorMessageDeleted	The specified message has been deleted.
errorFileChecksumMismatch	The local and remote file checksums do not match.
errorFileSizeMismatch	The local and remote file sizes do not match.
errorInvalidFeedUrl	The news feed URL is invalid or specifies an unsupported protocol.
errorInvalidFeedFormat	The internal format of the news feed is invalid.
errorInvalidFeedVersion	This version of the news feed is not supported.
errorChannelEmpty	There are no valid items found in this news feed.
errorInvalidItemNumber	The specified channel item identifier is invalid.
errorItemNotFound	The specified channel item could not be found.
errorItemEmpty	The specified channel item does not contain any data.
errorInvalidItemProperty	The specified item property name is invalid.
errorItemPropertyNotFound	The specified item property has not been defined.
errorInvalidChannelTitle	The channel title is invalid or has not been defined.
errorInvalidChannelLink	The channel hyperlink is invalid or has not been defined.
errorInvalidChannelDescription	The channel description is invalid or has not been defined.
errorInvalidItemText	The description for an item is invalid or has not been defined.
errorInvalidItemLink	The hyperlink for an item is invalid or has not been defined.

errorInvalidServiceType	The specified service type is invalid.
errorServiceSuspended	Access to the specified service has been suspended.
errorServiceRestricted	Access to the specified service has been restricted.
errorInvalidProviderName	The specified provider name is invalid or unknown.
errorInvalidPhoneNumber	The specified phone number is invalid or not supported in this region.
errorGatewayNotFound	A message gateway cannot be found for the specified provider.
errorMessageTooLong	The message exceeds the maximum number of characters permitted.
errorInvalidProviderData	The request returned invalid or incomplete service provider data.
errorInvalidGatewayData	The request returned invalid or incomplete message gateway data.
errorMultipleProviders	The request has returned multiple service providers.
errorProviderNotFound	The specified service provider could not be found.
errorInvalidMessageService	The specified message is not supported with this service type.
errorInvalidMessageFormat	The specified message format is invalid.
errorInvalidConfiguration	The specified configuration options are invalid.
errorServerActive	The requested action is not permitted while the server is active.
errorServerPortBound	Unable to obtain exclusive use of the specified local port.
errorInvalidClientSession	The specified client identifier is invalid for this session.
errorClientNotIdentified	The specified client has not provided user credentials.
errorInvalidClientState	The requested action cannot be performed at this time.
errorInvalidResultCode	The specified result code is not valid for this protocol
errorCommandRequired	The specified command is required and cannot be disabled.
errorCommandDisabled	The specified command has been disabled.
errorCommandSequence	The command cannot be processed at this time.
errorCommandCompleted	The previous command has completed.
errorInvalidProgramName	The specified program name is invalid or unrecognized.

errorInvalidRequestHeader	The request header contains one or more invalid values.
errorInvalidVirtualHost	The specified virtual host name is invalid.
errorVirtualHostNotFound	The specified virtual host does not exist.
errorTooManyVirtualHosts	Too many virtual hosts created for this server.
errorInvalidVirtualPath	The specified virtual path name is invalid.
errorVirtualPathNotFound	The specified virtual path does not exist.
errorTooManyVirtualPaths	Too many virtual paths created for this server.
errorInvalidTask	The asynchronous task identifier is invalid.
errorTaskActive	The asynchronous task has not finished.
errorTaskQueued	The asynchronous task has been queued.
errorTaskSuspended	The asynchronous task has been suspended.
errorTaskFinished	The asynchronous task has finished.

TelnetClient.SecureCipherAlgorithm Enumeration

Specifies the encryption algorithms that the TelnetClient class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]

```
<Flags>
Public Enum TelnetClient.SecureCipherAlgorithm
```

[C#]

```
[Flags]
public enum TelnetClient.SecureCipherAlgorithm
```

Remarks

The TelnetClient class uses the **SecureCipherAlgorithm** enumeration to identify which encryption algorithm was selected when a secure connection was established with the remote host.

Members

Member Name	Description	Value
cipherNone	No cipher has been selected. A secure connection has not been established with the remote host.	0
cipherRC2	The RC2 block cipher was selected. This is a variable key length cipher which supports keys between 40- and 128-bits in length, in 8-bit increments.	1
cipherRC4	The RC4 stream cipher was selected. This is a variable key length cipher which supports keys between 40- and 128-bits in length, in 8-bit increments.	2
cipherRC5	The RC5 block cipher was selected. This is a variable key length cipher which supports keys up to 2040 bits, in 8-bit increments.	4
cipherDES	The DES (Data Encryption Standard) block cipher was selected. This is a fixed key length cipher using 56-bit keys.	8
cipherDES3	The Triple DES block cipher was selected. This cipher encrypts the data three times using different keys, effectively using a 168-bit key length.	16
cipherDESX	A variant of the DES block cipher which XORs an extra 64-bits of the key before and after the plaintext has been encrypted, increasing the key size to 184 bits.	32
cipherAES	The Advanced Encryption Standard	64

	cipher (also known as the Rijndael cipher) is a fixed block size cipher which use a key size of 128, 192 or 256 bits. This cipher is supported on Windows XP SP3 SP3 and later versions of the operating system.	
cipherSkipjack	The Skipjack block cipher was selected. This is a fixed key length cipher, using 80-bit keys.	128

TelnetClient.SecureHashAlgorithm Enumeration

Specifies the hash algorithms that the TelnetClient class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]

```
<Flags>
Public Enum TelnetClient.SecureHashAlgorithm
```

[C#]

```
[Flags]
public enum TelnetClient.SecureHashAlgorithm
```

Remarks

The TelnetClient class uses the **SecureHashAlgorithm** enumeration to identify the message digest (hash) algorithm that was selected when a secure connection was established with the remote host.

Members

Member Name	Description	Value
hashNone	No hash algorithm has been selected. This is not a secure connection with the server.	0
hashMD5	The MD5 algorithm was selected. This algorithm produces a 128-bit message digest. This algorithm is no longer considered to be cryptographically secure.	1
hashSHA	The SHA-1 algorithm was selected. This algorithm produces a 160-bit message digest. This algorithm is no longer considered to be cryptographically secure.	2
hashSHA256	The SHA-256 algorithm was selected. This algorithm produces a 256-bit message digest.	4
hashSHA384	The SHA-384 algorithm was selected. This algorithm produces a 384-bit message digest.	8
hashSHA512	The SHA-512 algorithm was selected. This algorithm produces a 512-bit message digest.	16

TelnetClient.SecureKeyAlgorithm Enumeration

Specifies the key exchange algorithms that the TelnetClient class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]
```
<Flags>
Public Enum TelnetClient.SecureKeyAlgorithm
```

[C#]
```
[Flags]
public enum TelnetClient.SecureKeyAlgorithm
```

Remarks

The TelnetClient class uses the **SecureKeyAlgorithm** enumeration to identify the key exchange algorithm that was selected when a secure connection was established with the remote host.

Members

Member Name	Description	Value
keyExchangeNone	No key exchange algorithm has been selected. This is not a secure connection with the server.	0
keyExchangeRSA	The RSA public key exchange algorithm has been selected.	1
keyExchangeKEA	The KEA public key exchange algorithm has been selected. This is an improved version of the Diffie-Hellman public key algorithm.	2
keyExchangeDH	The Diffie-Hellman public key exchange algorithm has been selected.	4
keyExchangeECDH	The Elliptic Curve Diffie-Hellman key exchange algorithm was selected. This is a variant of the Diffie-Hellman algorithm which uses elliptic curve cryptography. This key exchange algorithm is only supported on Windows XP SP3 SP3 and later versions of the operating system.	8

TelnetClient.SecurityCertificate Enumeration

Specifies the security certificate status values that may be returned by the TelnetClient class.

[Visual Basic]
```
Public Enum TelnetClient.SecurityCertificate
```

[C#]
```
public enum TelnetClient.SecurityCertificate
```

Remarks

The TelnetClient class uses the **SecurityCertificate** enumeration to identify the current status of the certificate that was provided by the remote host when a secure connection was established.

Members

Member Name	Description
certificateNone	No certificate information is available. A secure connection was not established with the server.
certificateValid	The certificate is valid.
certificateNoMatch	The certificate is valid, however the domain name specified in the certificate does not match the domain name of the remote host. The application can examine the **CertificateSubject** property to determine the site the certificate was issued to.
certificateExpired	The certificate has expired and is no longer valid. The application can examine the **CertificateExpires** property to determine when the certificate expired.
certificateRevoked	The certificate has been revoked and is no longer valid. It is recommended that the application immediately terminate the connection if this status is returned.
certificateUntrusted	The certificate has not been issued by a trusted authority, or the certificate is not trusted on the local host. It is recommended that the application immediately terminate the connection if this status is returned.
certificateInvalid	The certificate is invalid. This typically indicates that the internal structure of the certificate is damaged. It is recommended that the application immediately terminate the connection if this status is returned.

TelnetClient.SecurityProtocols Enumeration

Specifies the security protocols that the TelnetClient class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]

```
<Flags>
Public Enum TelnetClient.SecurityProtocols
```

[C#]

```
[Flags]
public enum TelnetClient.SecurityProtocols
```

Remarks

The TelnetClient class uses the **SecurityProtocols** enumeration to specify one or more security protocols to be used when establishing a connection with a remote host. Multiple protocols may be specified if necessary and the actual protocol used will be negotiated with the remote host. It is recommended that most applications use **protocolDefault** when creating a secure connection.

Members

Member Name	Description	Value
protocolNone	No security protocol will be used, a secure connection will not be established.	0
protocolSSL2	The SSL 2.0 protocol has been selected. This protocol has been deprecated and is no longer widely used. It is not recommended that this protocol be used when establishing secure connections.	1
protocolSSL3	The SSL 3.0 protocol has been selected. This protocol has been deprecated and is no longer widely used. It is not recommended that this protocol be used when establishing secure connections. In most cases, this protocol is only selected if TLS is not supported by the server.	2
protocolTLS10	The TLS 1.0 protocol has been selected. This version of the protocol is commonly used by older servers and is the only version of TLS supported on Windows platforms prior to Windows 7 SP1 and Windows Server 2008 R2.	4
protocolTLS11	The TLS 1.1 protocol has been selected. This version of TLS is supported on Windows 7 SP1 and Windows Server 2008 R2 and later versions of the	8

	operating system.	
protocolTLS12	The TLS 1.2 protocol has been selected. This is the default version of the protocol and is supported on Windows 7 SP1 and Windows Server 2008 R2 and later versions of Windows. It is recommended that you use this version of TLS.	16
protocolSSL	Any version of the Secure Sockets Layer (SSL) protocol should be used. The actual protocol version used will be negotiated with the remote host.	3
protocolTLS	Any version of the the Transport Layer Security (TLS) protocol should be used. The actual protocol version used will be negotiated with the remote host, with with preference for TLS 1.2.	28
protocolTLS1	Version 1.0, 1.1 or 1.2 of the the Transport Layer Security (TLS) protocol should be used. The actual protocol version used will be negotiated with the remote host, with preference for TLS 1.2.	28
protocolDefault	The default selection of security protocols will be used when establishing a connection. The TLS 1.2, 1.1 and 1.0 protocols will be negotiated with the host, in that order of preference. This option will always request the latest version of the preferred security protocols and is the recommended value.	16
protocolUnknown	An unknown or unsupported security protocol has been specified. This value indicates an error condition.	4096

TelnetClient.TelnetOptions Enumeration

Specifies the options that the TelnetClient class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]
```
<Flags>
Public Enum TelnetClient.TelnetOptions
```

[C#]
```
[Flags]
public enum TelnetClient.TelnetOptions
```

Remarks

The TelnetClient class uses the **TelnetOptions** enumeration to specify one or more options to be used when establishing a connection with a remote host. Multiple options may be specified if necessary.

Members

Member Name	Description	Value
optionNone	No option specified.	0
optionDefault	The default connection option. This is the same as specifying **optionNone**.	0
optionTunnel	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established. This option also forces all connections to be outbound and enables the firewall compatibility features in the client.	1024
optionTrustedSite	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using either the SSL or TLS protocols.	2048
optionSecure	The default option for establishing a secure connection. This option is the same as specifying **optionSecureImplicit**.	4096
optionSecureImplicit	This option specifies the client should attempt to establish a secure session immediately after connecting to the server. Note that the server must	4096

	support secure connections using either the SSL or TLS protocol.	
optionSecureExplicit	This option specifies the client should attempt to establish a secure connection with the server using standard Telnet option negotiation. This requires that the server support the START_TLS option.	8192
optionSecureFallback	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will permit connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.	32768
optionPreferIPv6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.	262144
optionFreeThread	This option specifies that class methods may be called from any thread, and not only the thread that established the connection. Using this option disables certain internal safety checks that are made by the class and may result in unexpected behavior unless you ensure that access to the class instance is synchronized across multiple threads.	524288

TelnetClient.TelnetStatus Enumeration

Specifies the status values that may be returned by the TelnetClient class.

[Visual Basic]
```
Public Enum TelnetClient.TelnetStatus
```

[C#]
```
public enum TelnetClient.TelnetStatus
```

Remarks

The TelnetClient class uses the **TelnetStatus** enumeration to identify the current status of the client.

Members

Member Name	Description
statusUnused	A client session has not been created. Attempts to perform any network operations, such as sending or receiving data, will generate an error.
statusIdle	A client session has been created, but is not currently in use. A blocking socket operation can be executed at this point.
statusConnect	The client is in the process of establishing a connection with a remote host.
statusRead	The client is in the process of receiving data from a remote host.
statusWrite	The client is in the process of sending data to a remote host.
statusDisconnect	The client session is being closed and subsequent attempts to access the client will result in an error.

TelnetClient.TraceOptions Enumeration

Specifies the logging options that the TelnetClient class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]

```
<Flags>
Public Enum TelnetClient.TraceOptions
```

[C#]

```
[Flags]
public enum TelnetClient.TraceOptions
```

Remarks

The TelnetClient class uses the **TraceOptions** enumeration to specify what kind of debugging information is written to the trace logfile. These options are only meaningful when trace logging is enabled by setting the **Trace** property to **true**.

Members

Member Name	Description	Value
traceDefault	The default trace logging option. This is the same as specifying the **traceInfo** option.	0
traceInfo	All network function calls are written to the trace file. This is the default value.	0
traceError	Only those network function calls which fail are recorded in the trace file.	1
traceWarning	Only those network function calls which fail, or return values which indicate a warning, are recorded in the trace file.	2
traceHexDump	All network function calls are written to the trace file, plus all the data that is sent or received is displayed, in both ASCII and hexadecimal format.	4
traceProcess	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for multithreaded applications that are using worker threads.	4096

Requirements

Namespace: SocketTools

Assembly: SocketTools.TelnetClient (in SocketTools.TelnetClient.dll)

See Also

SocketTools Namespace

TelnetClient.OnErrorEventHandler Delegate

Represents the method that will handle the OnError event.

[Visual Basic]

```
Public Delegate Sub TelnetClient.OnErrorEventHandler( _
   ByVal sender As Object, _
   ByVal e As ErrorEventArgs _
)
```

[C#]

```
public delegate void TelnetClient.OnErrorEventHandler(
      object sender,
      ErrorEventArgs e
   );
```

Parameters

sender

The source of the event.

e

An ErrorEventArgs that contains the event data.

Remarks

When you create an **OnErrorEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnErrorEventHandler** delegate declaration.

Requirements

Namespace: SocketTools

Assembly: SocketTools.TelnetClient (in SocketTools.TelnetClient.dll)

See Also

SocketTools Namespace

TelnetClient.RuntimeLicenseAttribute Class

Attribute that defines the runtime license key for the class.

For a list of all members of this type, see TelnetClient.RuntimeLicenseAttribute Members.

System.Object
  System.Attribute
    SocketTools.TelnetClient.RuntimeLicenseAttribute

[Visual Basic]

```
<AttributeUsage(ValidOn:=AttributeTargets.Assembly, AllowMultiple:=False,
   Inherited:=True)>
Public Class TelnetClient.RuntimeLicenseAttribute
    Inherits Attribute
```

[C#]

```
[AttributeUsage(ValidOn=AttributeTargets.Assembly, AllowMultiple=False,
   Inherited=True)]
public class TelnetClient.RuntimeLicenseAttribute : Attribute
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

The RuntimeLicense attribute is used to define the runtime license key that will be used when an instance of the class is created. This attribute is defined in the assembly information module for the language, such as AssemblyInfo.cs when programming C#. The runtime license key must be defined if you wish to redistribute your application.

The runtime license key for your copy of SocketTools can be generated using the License Manager utility that is included with the product. Note that if you have installed an evaluation license, you will not have a runtime license key and cannot redistribute any applications which use the TelnetClient class.

Example

```
<Assembly: SocketTools.TelnetClient.RuntimeLicense("abcdefghijklmnop")>
```

```
[assembly: SocketTools.TelnetClient.RuntimeLicense("abcdefghijklmnop")]
```

Requirements

Namespace: SocketTools

Assembly: SocketTools.TelnetClient (in SocketTools.TelnetClient.dll)

TelnetClient.RuntimeLicenseAttribute Members | SocketTools Namespace

TelnetClient.RuntimeLicenseAttribute Members

TelnetClient.RuntimeLicenseAttribute overview

Public Instance Constructors

TelnetClient.RuntimeLicenseAttribute Constructor	Constructor for the RuntimeLicense attribute which defines the runtime license key.

Public Instance Properties

LicenseKey	Returns the value of the runtime license key.
TypeId (inherited from Attribute)	When implemented in a derived class, gets a unique identifier for this Attribute.

Public Instance Methods

Equals (inherited from Attribute)	
GetHashCode (inherited from Attribute)	Returns the hash code for this instance.
GetType (inherited from Object)	Gets the Type of the current instance.
IsDefaultAttribute (inherited from Attribute)	When overridden in a derived class, returns an indication whether the value of this instance is the default value for the derived class.
Match (inherited from Attribute)	When overridden in a derived class, returns a value indicating whether this instance equals a specified object.
ToString (inherited from Object)	Returns a String that represents the current Object.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

TelnetClient.RuntimeLicenseAttribute Class | SocketTools Namespace

TelnetClient.RuntimeLicenseAttribute Constructor

Constructor for the RuntimeLicense attribute which defines the runtime license key.

[Visual Basic]

```
Public Sub New( _
   ByVal licenseKey As String _
)
```

[C#]

```
public TelnetClient.RuntimeLicenseAttribute(
   string licenseKey
);
```

Parameters

licenseKey

A string argument which specifies the runtime license key which will be used to initialize the class library.

Remarks

The runtime license key for your copy of SocketTools can be generated using the License Manager utility that is included with the product. Note that if you have installed an evaluation license, you will not have a runtime license key and cannot redistribute any applications which use the TelnetClient class.

See Also

TelnetClient.RuntimeLicenseAttribute Class | SocketTools Namespace

TelnetClient.RuntimeLicenseAttribute Properties

The properties of the **TelnetClient.RuntimeLicenseAttribute** class are listed below. For a complete list of **TelnetClient.RuntimeLicenseAttribute** class members, see the TelnetClient.RuntimeLicenseAttribute Members topic.

Public Instance Properties

LicenseKey	Returns the value of the runtime license key.
TypeId (inherited from Attribute)	When implemented in a derived class, gets a unique identifier for this Attribute.

See Also

TelnetClient.RuntimeLicenseAttribute Class | SocketTools Namespace

TelnetClient.RuntimeLicenseAttribute.LicenseKey Property

Returns the value of the runtime license key.

[Visual Basic]

```
Public Property LicenseKey As String
```

[C#]

```
public string LicenseKey {get; set;}
```

Property Value

A string which contains the runtime license key.

See Also

TelnetClient.RuntimeLicenseAttribute Class | SocketTools Namespace

TelnetClientException Class

The exception that is thrown when a client error occurs.

For a list of all members of this type, see TelnetClientException Members.

System.Object
  System.Exception
    System.ApplicationException
      SocketTools.TelnetClientException

[Visual Basic]

```
Public Class TelnetClientException
    Inherits ApplicationException
```

[C#]

```
public class TelnetClientException : ApplicationException
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

A TelnetClientException is thrown by the TelnetClient class when an error occurs.

The default constructor for the TelnetClientException class sets the **ErrorCode** property to the last client error that occurred.

Requirements

Namespace: SocketTools

Assembly: SocketTools.TelnetClient (in SocketTools.TelnetClient.dll)

See Also

TelnetClientException Members | SocketTools Namespace

TelnetClientException Members

TelnetClientException overview

Public Instance Constructors

TelnetClientException	Overloaded. Initializes a new instance of the TelnetClientException class.

Public Instance Properties

ErrorCode	Gets a value which specifies the error that caused the exception.
HelpLink (inherited from Exception)	Gets or sets a link to the help file associated with this exception.
InnerException (inherited from Exception)	Gets the Exception instance that caused the current exception.
Message	Gets a value which describes the error that caused the exception.
Number	Gets a value which specifies the numeric value of the error that caused the exception.
Source (inherited from Exception)	Gets or sets the name of the application or the object that causes the error.
StackTrace (inherited from Exception)	Gets a string representation of the frames on the call stack at the time the current exception was thrown.
TargetSite (inherited from Exception)	Gets the method that throws the current exception.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetBaseException (inherited from Exception)	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetObjectData (inherited from Exception)	When overridden in a derived class, sets the SerializationInfo with information about the exception.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString	Creates and returns a string representation of the current exception.

Protected Instance Properties

HResult (inherited from Exception)	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

TelnetClientException Class | SocketTools Namespace

TelnetClientException Constructor

Initializes a new instance of the TelnetClientException class with the last network error code.

Overload List

Initializes a new instance of the TelnetClientException class with the last network error code.

public TelnetClientException();

Initializes a new instance of the TelnetClientException class with a specified error number.

public TelnetClientException(int);

Initializes a new instance of the TelnetClientException class with a specified error message.

public TelnetClientException(string);

Initializes a new instance of the TelnetClientException class with a specified error message and a reference to the inner exception that is the cause of this exception.

public TelnetClientException(string,Exception);

See Also

TelnetClientException Class | SocketTools Namespace

TelnetClientException Constructor ()

Initializes a new instance of the TelnetClientException class with the last network error code.

[Visual Basic]

```
Overloads Public Sub New()
```

[C#]

```
public TelnetClientException();
```

Remarks

The ctor constructor sets the **ErrorCode** property to the last client error that occurred. For more information about the errors that may occur, refer to the TelnetClient.ErrorCode enumeration.

See Also

TelnetClientException Class | SocketTools Namespace | TelnetClientException Constructor Overload List

TelnetClientException Constructor (String)

Initializes a new instance of the TelnetClientException class with a specified error message.

[Visual Basic]

```
Overloads Public Sub New( _
   ByVal message As String _
)
```

[C#]

```
public TelnetClientException(
   string message
);
```

Parameters

message

The error message that explains the reason for the exception.

Remarks

The content of the ***message*** parameter is intended to be understood by humans. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

See Also

TelnetClientException Class | SocketTools Namespace | TelnetClientException Constructor Overload List

TelnetClientException Constructor (String, Exception)

Initializes a new instance of the TelnetClientException class with a specified error message and a reference to the inner exception that is the cause of this exception.

[Visual Basic]
```
Overloads Public Sub New( _
   ByVal message As String, _
   ByVal innerException As Exception _
)
```

[C#]
```
public TelnetClientException(
   string message,
   Exception innerException
);
```

Parameters

message
The error message that explains the reason for the exception.

innerException
The exception that is the cause of the current exception. If the ***innerException*** parameter is not a null reference, the current exception is raised in a **catch** block that handles the inner exception.

Remarks

The content of the message parameter is intended to be understood by humans. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

An exception that is thrown as a direct result of a previous exception should include a reference to the previous exception in the **InnerException** property. The **InnerException** property returns the same value that is passed into the constructor, or a null reference if the **InnerException** property does not supply the inner exception value to the constructor.

See Also

TelnetClientException Class | SocketTools Namespace | TelnetClientException Constructor Overload List

TelnetClientException Constructor (Int32)

Initializes a new instance of the TelnetClientException class with a specified error number.

[Visual Basic]

```
Overloads Public Sub New( _
   ByVal code As Integer _
)
```

[C#]

```
public TelnetClientException(
   int code
);
```

Parameters

code

An integer value which specifies an error code.

Remarks

This constructor sets the **ErrorCode** property to the specified error code. For more information about the errors that may occur, refer to the TelnetClient.ErrorCode enumeration.

See Also

TelnetClientException Class | SocketTools Namespace | TelnetClientException Constructor Overload List

TelnetClientException Properties

The properties of the **TelnetClientException** class are listed below. For a complete list of **TelnetClientException** class members, see the TelnetClientException Members topic.

Public Instance Properties

ErrorCode	Gets a value which specifies the error that caused the exception.
HelpLink (inherited from Exception)	Gets or sets a link to the help file associated with this exception.
InnerException (inherited from Exception)	Gets the Exception instance that caused the current exception.
Message	Gets a value which describes the error that caused the exception.
Number	Gets a value which specifies the numeric value of the error that caused the exception.
Source (inherited from Exception)	Gets or sets the name of the application or the object that causes the error.
StackTrace (inherited from Exception)	Gets a string representation of the frames on the call stack at the time the current exception was thrown.
TargetSite (inherited from Exception)	Gets the method that throws the current exception.

Protected Instance Properties

HResult (inherited from Exception)	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception.

See Also

TelnetClientException Class | SocketTools Namespace

TelnetClientException.ErrorCode Property

Gets a value which specifies the error that caused the exception.

[Visual Basic]

```
Public ReadOnly Property ErrorCode As ErrorCode
```

[C#]

```
public TelnetClient.ErrorCode ErrorCode {get;}
```

Property Value

Returns a TelnetClient.ErrorCode enumeration value which specifies the error code.

Remarks

The **ErrorCode** property returns the error code that specifies the cause of the exception.

The default constructor for the TelnetClientException class sets the error code to the last network error that occurred. For more information about the errors that may occur, refer to the TelnetClient.ErrorCode enumeration.

See Also

TelnetClientException Class | SocketTools Namespace

TelnetClientException.Message Property

Gets a value which describes the error that caused the exception.

[Visual Basic]

```
Overrides Public ReadOnly Property Message As String
```

[C#]

```
public override string Message {get;}
```

Property Value

A string which describes the error that caused the exception.

Remarks

The **Message** property returns a string which describes the error that caused the exception.

See Also

TelnetClientException Class | SocketTools Namespace

TelnetClientException.Number Property

Gets a value which specifies the numeric value of the error that caused the exception.

[Visual Basic]

```
Public ReadOnly Property Number As Integer
```

[C#]

```
public int Number {get;}
```

Property Value

An integer value that specifies the error that caused the exception.

Remarks

The **Number** property returns an integer value which specifies the numeric value of the error that caused the exception. This value is the same as the values returned by the Windows Sockets API. For more information about socket error codes, see the Windows Socket Version 2 API error code documentation in MSDN.

See Also

TelnetClientException Class | SocketTools Namespace

TelnetClientException Methods

The methods of the **TelnetClientException** class are listed below. For a complete list of **TelnetClientException** class members, see the TelnetClientException Members topic.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetBaseException (inherited from Exception)	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetObjectData (inherited from Exception)	When overridden in a derived class, sets the SerializationInfo with information about the exception.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString	Creates and returns a string representation of the current exception.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

TelnetClientException Class | SocketTools Namespace

TelnetClientException.ToString Method

Creates and returns a string representation of the current exception.

[Visual Basic]
```
Overrides Public Function ToString() As String
```

[C#]
```
public override string ToString();
```

Return Value

A string representation of the current exception.

Remarks

The **ToString** method returns a representation of the current exception that is intended to be understood by humans. Where the exception contains culture-sensitive data, the string representation returned by **ToString** is required to take into account the current system culture. Although there are no exact requirements for the format of the returned string, it should attempt to reflect the value of the object as perceived by the user.

This implementation of **ToString** obtains the numeric error code value and a description of the error that caused the current exception. If there is no error message or it is an empty string, then no error message is returned.

This method overrides **ApplicationException.ToString**.

public class Terminal : UserControl
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

The Terminal control provides a comprehensive interface for emulating an ANSI, DEC VT100 or DEC VT220 character terminal, with full support for all standard escape and control sequences, color mapping and other advanced features. The control functions provide both a high level interface for parsing escape sequences and updating a display, as well as lower level primitives for directly managing the virtual display, such as controlling the individual display cells, moving the cursor position and specifying display attributes.

This control can be used in conjunction with the SocketTools.SshClient or SocketTools.TelnetClient classes to provide terminal emulation services for an application, or it can be used independently. For example, this control could also be used to provide emulation services for a program that requires serial modem connections to a server.

Requirements

Namespace: SocketTools

Assembly: SocketTools.Terminal (in SocketTools.Terminal.dll)

Terminal Members

Terminal overview

Public Instance Constructors

Terminal Constructor	Initializes a new instance of the Terminal control.

Public Instance Fields

Cell	Gets and sets information about a character cell in the virtual display.
ColorMap	Gets and sets the color values used when displaying text.
KeyMap	Gets and sets the character sequence mapped to a special key.

Public Instance Properties

AccessibilityObject (inherited from Control)	Gets the AccessibleObject assigned to the control.
AccessibleDefaultActionDescription (inherited from Control)	Gets or sets the default action description of the control for use by accessibility client applications.
AccessibleDescription (inherited from Control)	Gets or sets the description of the control used by accessibility client applications.
AccessibleName (inherited from Control)	Gets or sets the name of the control used by accessibility client applications.
AccessibleRole (inherited from Control)	Gets or sets the accessible role of the control
ActiveControl (inherited from ContainerControl)	Gets or sets the active control on the container control.
AllowDrop (inherited from Control)	Gets or sets a value indicating whether the control can accept data that the user drags onto it.
Anchor (inherited from Control)	Gets or sets which edges of the control are anchored to the edges of its container.
Attributes	Gets and sets the current display attribute for the terminal emulator.
AutoRefresh	Enables and disables the automatic refreshing of the virtual display.
AutoScroll (inherited from ScrollableControl)	Gets or sets a value indicating whether the container will allow the user to scroll to any controls placed outside of its visible boundaries.
AutoScrollMargin (inherited from ScrollableControl)	Gets or sets the size of the auto-scroll margin.
AutoScrollMinSize (inherited from ScrollableControl)	Gets or sets the minimum size of the auto-scroll.
AutoScrollPosition (inherited from ScrollableControl)	Gets or sets the location of the auto-scroll position.

AutoSelect	Enables and disables the automatic selection of text in the display.
AutoSize	Enables and disables the automatic resizing of the display.
AutoWrap	Enables and disables the automatic wrapping of text in the virtual display.
BackColor (inherited from Control)	Gets or sets the background color for the control.
BackgroundImage (inherited from Control)	Gets or sets the background image displayed in the control.
Bell	Enables and disables the audible bell.
BindingContext (inherited from ContainerControl)	
BoldColor	Gets and sets the bold color of the control.
Bottom (inherited from Control)	Gets the distance between the bottom edge of the control and the top edge of its container's client area.
Bounds (inherited from Control)	Gets or sets the size and location of the control including its nonclient elements.
CanFocus (inherited from Control)	Gets a value indicating whether the control can receive focus.
CanSelect (inherited from Control)	Gets a value indicating whether the control can be selected.
Capture (inherited from Control)	Gets or sets a value indicating whether the control has captured the mouse.
Caret	Gets and sets the caret style of the control.
CausesValidation (inherited from Control)	Gets or sets a value indicating whether the control causes validation to be performed on any controls that require validation when it receives focus.
CellHeight	Gets the height of a character cell.
CellWidth	Gets the width of a character cell.
ClientRectangle (inherited from Control)	Gets the rectangle that represents the client area of the control.
ClientSize (inherited from Control)	Gets or sets the height and width of the client area of the control.
CodePage	Gets and sets the code page used when displaying text.
Columns	Gets and sets the number of columns in the virtual display.
CompanyName (inherited from Control)	Gets the name of the company or creator of the application containing the control.
Container (inherited from Component)	Gets the IContainer that contains the Component.

ContainsFocus (inherited from Control)	Gets a value indicating whether the control, or one of its child controls, currently has the input focus.
ContextMenu (inherited from Control)	Gets or sets the shortcut menu associated with the control.
Controls (inherited from Control)	Gets the collection of controls contained within the control.
Created (inherited from Control)	Gets a value indicating whether the control has been created.
Cursor (inherited from Control)	Gets or sets the cursor that is displayed when the mouse pointer is over the control.
CursorX	Gets and sets the current cursor position in the display.
CursorY	Gets and sets the current cursor position in the display.
DataBindings (inherited from Control)	Gets the data bindings for the control.
Display	Gets a value that specifies the virtual display handle allocated for the control.
DisplayRectangle (inherited from ScrollableControl)	
Disposing (inherited from Control)	Gets a value indicating whether the control is in the process of being disposed of.
Dock (inherited from Control)	Gets or sets which edge of the parent container a control is docked to.
DockPadding (inherited from ScrollableControl)	Gets the dock padding settings for all edges of the control.
Emulation	Gets and sets the emulation mode used by the control.
Enabled (inherited from Control)	Gets or sets a value indicating whether the control can respond to user interaction.
Focused (inherited from Control)	Gets a value indicating whether the control has input focus.
Font (inherited from Control)	Gets or sets the font of the text displayed by the control.
FontName	Gets and sets the name of the font used by the control.
FontSize	Gets and sets the size of the font used by the control.
ForeColor (inherited from Control)	Gets or sets the foreground color of the control.
Handle (inherited from Control)	Gets the window handle that the control is bound to.
HasChildren (inherited from Control)	Gets a value indicating whether the control contains one or more child controls.

Height (inherited from Control)	Gets or sets the height of the control.
ImeMode (inherited from Control)	Gets or sets the Input Method Editor (IME) mode of the control.
InvokeRequired (inherited from Control)	Gets a value indicating whether the caller must call an invoke method when making method calls to the control because the caller is on a different thread than the one the control was created on.
IsAccessible (inherited from Control)	Gets or sets a value indicating whether the control is visible to accessibility applications.
IsDisposed (inherited from Control)	Gets a value indicating whether the control has been disposed of.
IsHandleCreated (inherited from Control)	Gets a value indicating whether the control has a handle associated with it.
IsInitialized	Gets a value which indicates if the current instance of the control has been initialized successfully.
LastError	Gets or sets a value which specifies the last error that has occurred.
LastErrorString	Gets a value which describes the last error that has occurred.
Left (inherited from Control)	Gets or sets the x-coordinate of a control's left edge in pixels.
Location (inherited from Control)	Gets or sets the coordinates of the upper-left corner of the control relative to the upper-left corner of its container.
MouseX	Return the current mouse position in the display.
MouseY	Return the current mouse position in the display.
Name (inherited from Control)	Gets or sets the name of the control.
NewLine	Gets and sets the newline mode for the virtual display.
Parent (inherited from Control)	Gets or sets the parent container of the control.
ParentForm (inherited from ContainerControl)	Gets the form that the container control is assigned to.
ProductName (inherited from Control)	Gets the product name of the assembly containing the control.
ProductVersion (inherited from Control)	Gets the version of the assembly containing the control.
RecreatingHandle (inherited from Control)	Gets a value indicating whether the control is currently re-creating its handle.
Region (inherited from Control)	Gets or sets the window region associated with the control.
Right (inherited from Control)	Gets the distance between the right edge of the control and the left edge of its container.

RightToLeft (inherited from Control)	Gets or sets a value indicating whether control's elements are aligned to support locales using right-to-left fonts.
Rows	Gets and sets the number of rows in the virtual display.
ScrollBars	Gets and sets the scrollbar display mode for the control.
SelLength	Gets and sets the number of characters selected in the virtual display.
SelStart	Gets and sets the starting position of the current text selection.
SelText	Gets the selected text or text from a specific portion of the display.
Site (inherited from Control)	Gets or sets the site of the control.
Size (inherited from Control)	Gets or sets the height and width of the control.
TabIndex (inherited from Control)	Gets or sets the tab order of the control within its container.
TabStop (inherited from Control)	Gets or sets a value indicating whether the user can give the focus to this control using the TAB key.
Tag (inherited from Control)	Gets or sets the object that contains data about the control.
Text	Gets and sets the text displayed by the control.
ThrowError	Gets and sets a value which specifies if method calls should throw exceptions when an error occurs.
Top (inherited from Control)	Gets or sets the y-coordinate of the control's top edge in pixels.
TopLevelControl (inherited from Control)	Gets the parent control that is not parented by another Windows Forms control. Typically, this is the outermost Form that the control is contained in.
Version	Gets a value which returns the current version of the Terminal control.
Visible (inherited from Control)	Gets or sets a value indicating whether the control is displayed.
Width (inherited from Control)	Gets or sets the width of the control.
WindowTarget (inherited from Control)	

Public Instance Methods

BeginInvoke (inherited from Control)	Overloaded. Executes the specified delegate asynchronously with the specified arguments, on the thread that the control's underlying handle

	was created on.
BringToFront (inherited from Control)	Brings the control to the front of the z-order.
Clear	Clear the terminal emulation window.
ClearEol	Erase all characters from the current column to the end of the line.
Contains (inherited from Control)	Retrieves a value indicating whether the specified control is a child of the control.
CreateControl (inherited from Control)	Forces the creation of the control, including the creation of the handle and any child controls.
CreateGraphics (inherited from Control)	Creates the Graphics object for the control.
CreateObjRef (inherited from MarshalByRefObject)	Creates an object that contains all the relevant information required to generate a proxy used to communicate with a remote object.
DelLine	Delete the current line in the terminal emulation display.
Deselect	Deselects any selected text in the display.
Dispose (inherited from Component)	Overloaded. Releases all resources used by the Component.
DoDragDrop (inherited from Control)	Begins a drag-and-drop operation.
EndInvoke (inherited from Control)	Retrieves the return value of the asynchronous operation represented by the IAsyncResult object passed.
Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
FindForm (inherited from Control)	Retrieves the form that the control is on.
Focus (inherited from Control)	Sets input focus to the control.
GetChildAtPoint (inherited from Control)	Retrieves the child control that is located at the specified coordinates.
GetContainerControl (inherited from Control)	Returns the next ContainerControl up the control's chain of parent controls.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetLifetimeService (inherited from MarshalByRefObject)	Retrieves the current lifetime service object that controls the lifetime policy for this instance.
GetNextControl (inherited from Control)	Retrieves the next control forward or back in the tab order of child controls.
GetType (inherited from Object)	Gets the Type of the current instance.
Hide (inherited from Control)	Conceals the control from the user.
Initialize	Overloaded. Initialize an instance of the Terminal control.

InitializeLifetimeService (inherited from MarshalByRefObject)	Obtains a lifetime service object to control the lifetime policy for this instance.
InsLine	Insert an empty line at the current position in the terminal emulation display.
Invalidate (inherited from Control)	Overloaded. Invalidates the specified region of the control (adds it to the control's update region, which is the area that will be repainted at the next paint operation), and causes a paint message to be sent to the control.
Invoke (inherited from Control)	Overloaded. Executes the specified delegate, on the thread that owns the control's underlying window handle, with the specified list of arguments.
PerformLayout (inherited from Control)	Overloaded. Forces the control to apply layout logic to all its child controls.
PointToClient (inherited from Control)	Computes the location of the specified screen point into client coordinates.
PointToScreen (inherited from Control)	Computes the location of the specified client point into screen coordinates.
PreProcessMessage	Preprocesses input messages within the message loop before they are dispatched.
RectangleToClient (inherited from Control)	Computes the size and location of the specified screen rectangle in client coordinates.
RectangleToScreen (inherited from Control)	Computes the size and location of the specified client rectangle in screen coordinates.
Refresh	Forces a complete redraw of the virtual display.
Reset	Reset the internal state of the control, resetting all properties to their default values.
ResetBackColor (inherited from Control)	Resets the BackColor property to its default value.
ResetBindings (inherited from Control)	Resets the DataBindings property to its default value.
ResetCursor (inherited from Control)	Resets the Cursor property to its default value.
ResetFont (inherited from Control)	Resets the Fontproperty to its default value.
ResetForeColor (inherited from Control)	Resets the ForeColor property to its default value.
ResetImeMode (inherited from Control)	Resets the ImeMode property to its default value.
ResetRightToLeft (inherited from Control)	Resets the RightToLeft property to its default value.
ResetText (inherited from Control)	Resets the Text property to its default value.
ResumeLayout (inherited from Control)	Overloaded. Resumes normal layout logic.
Scale (inherited from Control)	Overloaded. Scales the control and any child controls to the specified ratio.
ScrollControlIntoView (inherited from	

ScrollableControl)	
ScrollDown	Scroll the display down by one line.
ScrollUp	Scroll the display up by one line.
Select (inherited from Control)	Overloaded. Activates the control.
SelectNextControl (inherited from Control)	Activates the next control.
SelectText	Overloaded. Selects a region of the virtual display and returns the selected text.
SendToBack (inherited from Control)	Sends the control to the back of the z-order.
SetAutoScrollMargin (inherited from ScrollableControl)	Sets the size of the auto-scroll margins.
SetBounds (inherited from Control)	Overloaded. Sets the bounds of the control to the specified location and size.
Show (inherited from Control)	Displays the control to the user.
SuspendLayout (inherited from Control)	Temporarily suspends the layout logic for the control.
ToString (inherited from Component)	
Uninitialize	Uninitialize the control and release any resources allocated for the current process.
Update (inherited from Control)	Causes the control to redraw the invalidated regions within its client area.
Validate (inherited from ContainerControl)	Validates the last invalidated control and its ancestors up through, but not including, the current control.
Write	Overloaded. Write the contents of a byte array to the virtual display.

Public Instance Events

BackColorChanged (inherited from Control)	Occurs when the value of the BackColor property changes.
BackgroundImageChanged (inherited from Control)	Occurs when the value of the BackgroundImage property changes.
BindingContextChanged (inherited from Control)	Occurs when the value of the BindingContext property changes.
CausesValidationChanged (inherited from Control)	Occurs when the value of the CausesValidation property changes.
ChangeUICues (inherited from Control)	Occurs when the focus or keyboard user interface (UI) cues change.
Click (inherited from Control)	Occurs when the control is clicked.
ContextMenuChanged (inherited from Control)	Occurs when the value of the ContextMenu property changes.
ControlAdded (inherited from Control)	Occurs when a new control is added to the

	ControlCollection .
⚡ ControlRemoved (inherited from Control)	Occurs when a control is removed from the ControlCollection .
⚡ CursorChanged (inherited from Control)	Occurs when the value of the Cursor property changes.
⚡ Disposed (inherited from Component)	Adds an event handler to listen to the Disposed event on the component.
⚡ DockChanged (inherited from Control)	Occurs when the value of the Dock property changes.
⚡ DoubleClick (inherited from Control)	Occurs when the control is double-clicked.
⚡ DragDrop (inherited from Control)	Occurs when a drag-and-drop operation is completed.
⚡ DragEnter (inherited from Control)	Occurs when an object is dragged into the control's bounds.
⚡ DragLeave (inherited from Control)	Occurs when an object is dragged out of the control's bounds.
⚡ DragOver (inherited from Control)	Occurs when an object is dragged over the control's bounds.
⚡ EnabledChanged (inherited from Control)	Occurs when the Enabled property value has changed.
⚡ Enter (inherited from Control)	Occurs when the control is entered.
⚡ FontChanged (inherited from Control)	Occurs when the Font property value changes.
⚡ ForeColorChanged (inherited from Control)	Occurs when the ForeColor property value changes.
⚡ GiveFeedback (inherited from Control)	Occurs during a drag operation.
⚡ GotFocus (inherited from Control)	Occurs when the control receives focus.
⚡ HandleCreated (inherited from Control)	Occurs when a handle is created for the control.
⚡ HandleDestroyed (inherited from Control)	Occurs when the control's handle is in the process of being destroyed.
⚡ HelpRequested (inherited from Control)	Occurs when the user requests help for a control.
⚡ ImeModeChanged (inherited from Control)	Occurs when the ImeMode property has changed.
⚡ Invalidated (inherited from Control)	Occurs when a control's display requires redrawing.
⚡ KeyDown (inherited from Control)	Occurs when a key is pressed while the control has focus.
⚡ KeyMapped	Occurs when a mapped key is pressed.
⚡ KeyPress (inherited from Control)	Occurs when a key is pressed while the control has focus.
⚡ KeyUp (inherited from Control)	Occurs when a key is released while the control has focus.
⚡ Layout (inherited from Control)	Occurs when a control should reposition its child

	controls.
⚡ Leave (inherited from Control)	Occurs when the input focus leaves the control.
⚡ Load (inherited from UserControl)	Occurs before the control becomes visible for the first time.
⚡ LocationChanged (inherited from Control)	Occurs when the Location property value has changed.
⚡ LostFocus (inherited from Control)	Occurs when the control loses focus.
⚡ MouseDown (inherited from Control)	Occurs when the mouse pointer is over the control and a mouse button is pressed.
⚡ MouseEnter (inherited from Control)	Occurs when the mouse pointer enters the control.
⚡ MouseHover (inherited from Control)	Occurs when the mouse pointer hovers over the control.
⚡ MouseLeave (inherited from Control)	Occurs when the mouse pointer leaves the control.
⚡ MouseMove (inherited from Control)	Occurs when the mouse pointer is moved over the control.
⚡ MouseUp (inherited from Control)	Occurs when the mouse pointer is over the control and a mouse button is released.
⚡ MouseWheel (inherited from Control)	Occurs when the mouse wheel moves while the control has focus.
⚡ Move (inherited from Control)	Occurs when the control is moved.
⚡ Paint (inherited from Control)	Occurs when the control is redrawn.
⚡ ParentChanged (inherited from Control)	Occurs when the Parent property value changes.
⚡ QueryAccessibilityHelp (inherited from Control)	Occurs when AccessibleObject is providing help to accessibility applications.
⚡ QueryContinueDrag (inherited from Control)	Occurs during a drag-and-drop operation and allows the drag source to determine whether the drag-and-drop operation should be canceled.
⚡ Resize (inherited from Control)	Occurs when the control is resized.
⚡ RightToLeftChanged (inherited from Control)	Occurs when the RightToLeft property value changes.
⚡ SizeChanged (inherited from Control)	Occurs when the Size property value changes.
⚡ StyleChanged (inherited from Control)	Occurs when the control style changes.
⚡ SystemColorsChanged (inherited from Control)	Occurs when the system colors change.
⚡ TabIndexChanged (inherited from Control)	Occurs when the TabIndex property value changes.
⚡ TabStopChanged (inherited from Control)	Occurs when the TabStop property value changes.
⚡ TextChanged (inherited from UserControl)	
⚡ Validated (inherited from Control)	Occurs when the control is finished validating.
⚡ Validating (inherited from Control)	Occurs when the control is validating.
⚡	

VisibleChanged (inherited from Control)	Occurs when the Visible property value changes.

Protected Instance Properties

CreateParams (inherited from ContainerControl)	
DefaultImeMode (inherited from Control)	Gets the default Input Method Editor (IME) mode supported by the control.
DefaultSize (inherited from UserControl)	
DesignMode (inherited from Component)	Gets a value that indicates whether the Component is currently in design mode.
Events (inherited from Component)	Gets the list of event handlers that are attached to this Component.
FontHeight (inherited from Control)	Gets or sets the height of the font of the control.
HScroll (inherited from ScrollableControl)	Gets or sets a value indicating whether the horizontal scroll bar is visible.
RenderRightToLeft (inherited from Control)	
ResizeRedraw (inherited from Control)	Gets or sets a value indicating whether the control redraws itself when resized.
ShowFocusCues (inherited from Control)	Gets a value indicating whether the control should display focus rectangles.
ShowKeyboardCues (inherited from Control)	Gets a value indicating whether the control should display keyboard shortcuts.
VScroll (inherited from ScrollableControl)	Gets or sets a value indicating whether the vertical scroll bar is visible.

Protected Instance Methods

AccessibilityNotifyClients (inherited from Control)	Notifies the accessibility client applications of the specified AccessibleEvents for the specified child control.
AdjustFormScrollbars (inherited from ContainerControl)	
CreateAccessibilityInstance (inherited from Control)	Creates a new accessibility object for the control.
CreateControlsInstance (inherited from Control)	Creates a new instance of the control collection for the control.
CreateHandle (inherited from Control)	Creates a handle for the control.
DefWndProc (inherited from Control)	Sends the specified message to the default window procedure.
DestroyHandle (inherited from Control)	Destroys the handle associated with the control.
Dispose	Overloaded. Releases the unmanaged resources allocated by the Terminal class and optionally releases the managed resources.
Finalize	Destroys an instance of the control, releasing the

	resources allocated for the virtual display.
GetScrollState (inherited from ScrollableControl)	
GetService (inherited from Component)	Returns an object that represents a service provided by the Component or by its Container.
GetStyle (inherited from Control)	Retrieves the value of the specified control style bit for the control.
GetTopLevel (inherited from Control)	Determines if the control is a top-level control.
InitLayout (inherited from Control)	Called after the control has been added to another container.
InvokeGotFocus (inherited from Control)	Raises the GotFocus event for the specified control.
InvokeLostFocus (inherited from Control)	Raises the LostFocus event for the specified control.
InvokeOnClick (inherited from Control)	Raises the Click event for the specified control.
InvokePaint (inherited from Control)	Raises the Paint event for the specified control.
InvokePaintBackground (inherited from Control)	Raises the PaintBackground event for the specified control.
IsInputChar (inherited from Control)	Determines if a character is an input character that the control recognizes.
IsInputKey (inherited from Control)	Determines whether the specified key is a regular input key or a special key that requires preprocessing.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.
NotifyInvalidate (inherited from Control)	
OnBackColorChanged	Raises the BackColorChanged event.
OnBackgroundImageChanged (inherited from Control)	Raises the BackgroundImageChanged event.
OnBindingContextChanged (inherited from Control)	Raises the BindingContextChangedevent.
OnCausesValidationChanged (inherited from Control)	Raises the CausesValidationChangedevent.
OnChangeUICues (inherited from Control)	Raises the ChangeUICues event.
OnClick (inherited from Control)	Raises the Click event.
OnContextMenuChanged (inherited from Control)	Raises the ContextMenuChangedevent.
OnControlAdded (inherited from Control)	Raises the ControlAdded event.
OnControlRemoved (inherited from ContainerControl)	
OnCreateControl (inherited from UserControl)	
OnCursorChanged (inherited from Control)	Raises the CursorChangedevent.

OnDockChanged (inherited from Control)	Raises the DockChangedevent.
OnDoubleClick (inherited from Control)	Raises the DoubleClick event.
OnDragDrop (inherited from Control)	Raises the DragDrop event.
OnDragEnter (inherited from Control)	Raises the DragEnter event.
OnDragLeave (inherited from Control)	Raises the DragLeave event.
OnDragOver (inherited from Control)	Raises the DragOver event.
OnEnabledChanged (inherited from Control)	Raises the EnabledChanged event.
OnEnter (inherited from Control)	Raises the Enter event.
OnFontChanged	Raises the FontChanged event.
OnForeColorChanged	Raises the ForeColorChanged event.
OnGiveFeedback (inherited from Control)	Raises the GiveFeedback event.
OnGotFocus	Raises the GotFocus event.
OnHandleCreated (inherited from Control)	Raises the HandleCreated event.
OnHandleDestroyed (inherited from Control)	Raises the HandleDestroyed event.
OnHelpRequested (inherited from Control)	Raises the HelpRequested event.
OnImeModeChanged (inherited from Control)	Raises the ImeModeChanged event.
OnInvalidated (inherited from Control)	Raises the Invalidated event.
OnKeyDown (inherited from Control)	Raises the KeyDown event.
OnKeyPress (inherited from Control)	Raises the KeyPress event.
OnKeyUp (inherited from Control)	Raises the KeyUp event.
OnLayout (inherited from ScrollableControl)	
OnLeave (inherited from Control)	Raises the Leave event.
OnLoad (inherited from UserControl)	Raises the Load event.
OnLocationChanged (inherited from Control)	Raises the LocationChanged event.
OnLostFocus	Raises the LostFocus event.
OnMouseDown	Raises the MouseDown event.
OnMouseEnter (inherited from Control)	Raises the MouseEnter event.
OnMouseHover (inherited from Control)	Raises the MouseHover event.
OnMouseLeave (inherited from Control)	Raises the MouseLeave event.
OnMouseMove	Raises the MouseMove event.
OnMouseUp	Raises the MouseUp event.
OnMouseWheel (inherited from ScrollableControl)	
OnMove (inherited from Control)	Raises the Move event.
OnNotifyMessage (inherited from Control)	Notifies the control of Windows messages.
OnPaint	Raises the Paint event.

OnPaintBackground (inherited from Control)	Paints the background of the control.
OnParentBackColorChanged (inherited from Control)	Raises the BackColorChanged event when the BackColor property value of the control's container changes.
OnParentBackgroundImageChanged (inherited from Control)	Raises the BackgroundImageChanged event when the BackgroundImage property value of the control's container changes.
OnParentBindingContextChanged (inherited from Control)	Raises the BindingContextChanged event when the BindingContext property value of the control's container changes.
OnParentChanged	Raises the ParentChanged event.
OnParentEnabledChanged (inherited from Control)	Raises the EnabledChanged event when the Enabled property value of the control's container changes.
OnParentFontChanged (inherited from Control)	Raises the FontChanged event when the Font property value of the control's container changes.
OnParentForeColorChanged (inherited from Control)	Raises the ForeColorChanged event when the ForeColor property value of the control's container changes.
OnParentRightToLeftChanged (inherited from Control)	Raises the RightToLeftChanged event when the RightToLeft property value of the control's container changes.
OnParentVisibleChanged (inherited from Control)	Raises the VisibleChanged event when the Visible property value of the control's container changes.
OnQueryContinueDrag (inherited from Control)	Raises the QueryContinueDrag event.
OnResize	Raises the Resize event.
OnRightToLeftChanged (inherited from Control)	Raises the RightToLeftChangedevent.
OnSizeChanged (inherited from Control)	Raises the SizeChanged event.
OnStyleChanged (inherited from Control)	Raises the StyleChanged event.
OnSystemColorsChanged (inherited from Control)	Raises the SystemColorsChanged event.
OnTabIndexChanged (inherited from Control)	Raises the TabIndexChanged event.
OnTabStopChanged (inherited from Control)	Raises the TabStopChanged event.
OnTextChanged (inherited from Control)	Raises the TextChanged event.
OnValidated (inherited from Control)	Raises the Validated event.
OnValidating (inherited from Control)	Raises the Validating event.
OnVisibleChanged (inherited from ScrollableControl)	
ProcessCmdKey (inherited from Control)	Processes a command key.
ProcessDialogChar (inherited from ContainerControl)	

ProcessDialogKey (inherited from ContainerControl)	
ProcessKeyEventArgs (inherited from Control)	Processes a key message and generates the appropriate control events.
ProcessKeyPreview (inherited from Control)	Previews a keyboard message.
ProcessMnemonic (inherited from ContainerControl)	
ProcessTabKey (inherited from ContainerControl)	Selects the next available control and makes it the active control.
RaiseDragEvent (inherited from Control)	
RaiseKeyEvent (inherited from Control)	
RaiseMouseEvent (inherited from Control)	
RaisePaintEvent (inherited from Control)	
RecreateHandle (inherited from Control)	Forces the re-creation of the handle for the control.
ResetMouseEventArgs (inherited from Control)	
RtlTranslateAlignment (inherited from Control)	Overloaded. Converts the specified HorizontalAlignment to the appropriate HorizontalAlignment to support right-to-left text.
RtlTranslateContent (inherited from Control)	Converts the specified ContentAlignment to the appropriate ContentAlignment to support right-to-left text.
RtlTranslateHorizontal (inherited from Control)	Converts the specified HorizontalAlignment to the appropriate HorizontalAlignment to support right-to-left text.
RtlTranslateLeftRight (inherited from Control)	Converts the specified LeftRightAlignment to the appropriate LeftRightAlignment to support right-to-left text.
ScaleCore (inherited from ScrollableControl)	
Select (inherited from ContainerControl)	Overloaded.
SetBoundsCore (inherited from Control)	Performs the work of setting the specified bounds of this control.
SetClientSizeCore (inherited from Control)	Sets the size of the client area of the control.
SetDisplayRectLocation (inherited from ScrollableControl)	
SetScrollState (inherited from ScrollableControl)	
SetStyle (inherited from Control)	Sets the specified style bit to the specified value.
SetTopLevel (inherited from Control)	Sets the control as the top-level control.
SetVisibleCore (inherited from Control)	Sets the control to the specified visible state.
UpdateBounds (inherited from Control)	Overloaded. Updates the bounds of the control with the current size and location.

UpdateDefaultButton (inherited from ContainerControl)	
UpdateStyles (inherited from Control)	Forces the assigned styles to be reapplied to the control.
UpdateZOrder (inherited from Control)	Updates the control in its parent's z-order.
WndProc	Processes Windows messages.

Protected Internal Instance Methods

ProcessKeyMessage (inherited from Control)	Processes a keyboard message.

See Also

Terminal Class | SocketTools Namespace

Terminal Constructor

Initializes a new instance of the Terminal control.

[Visual Basic]

```
Public Sub New()
```

[C#]

```
public Terminal();
```

See Also

Terminal Class | SocketTools Namespace

Terminal.TerminalCell Structure

This structure is used by the Cell property to return information about a specific character cell in the virtual display.

For a list of all members of this type, see Terminal.TerminalCell Members.

System.Object
  System.ValueType
    SocketTools.Terminal.TerminalCell

[Visual Basic]
```
Public Structure Terminal.TerminalCell
```

[C#]
```
public struct Terminal.TerminalCell
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Requirements

Namespace: SocketTools

Assembly: SocketTools.Terminal (in SocketTools.Terminal.dll)

Terminal.TerminalCell Members | SocketTools Namespace

Terminal.TerminalCell Members

Terminal.TerminalCell overview

Public Instance Constructors

Terminal.TerminalCell	Overloaded. Initializes a new instance of the Terminal.TerminalCell class.

Public Instance Fields

Attributes	Gets the character attributes.
Character	Gets the character value.

Public Instance Methods

Equals (inherited from ValueType)	Indicates whether this instance and a specified object are equal.
GetHashCode (inherited from ValueType)	Returns the hash code for this instance.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString (inherited from ValueType)	Returns the fully qualified type name of this instance.

See Also

Terminal.TerminalCell Class | SocketTools Namespace

Terminal.TerminalCell Constructor

Initializes a new instance of the TerminalCell structure with the specified character.

Overload List

Initializes a new instance of the TerminalCell structure with the specified character.

public Terminal.TerminalCell(char);

Initializes a new instance of the TerminalCell structure with the specified character and attributes.

public Terminal.TerminalCell(char,TerminalAttributes);

See Also

Terminal.TerminalCell Class | SocketTools Namespace

Terminal.TerminalCell Constructor (Char)

Initializes a new instance of the TerminalCell structure with the specified character.

[Visual Basic]

```
Overloads Public Sub New( _
   ByVal character As Char _
)
```

[C#]

```
public Terminal.TerminalCell(
   char character
);
```

Parameters

character

The character value used to initialize the structure.

Remarks

The **TerminalCell** structure will be initialized with the specified character. The default, normal attributes for the character cell will be used.

See Also

Terminal.TerminalCell Class | SocketTools Namespace | Terminal.TerminalCell Constructor Overload List

Terminal.TerminalCell Constructor (Char, TerminalAttributes)

Initializes a new instance of the TerminalCell structure with the specified character and attributes.

[Visual Basic]

```
Overloads Public Sub New( _
   ByVal character As Char, _
   ByVal attributes As TerminalAttributes _
)
```

[C#]

```
public Terminal.TerminalCell(
   char character,
   TerminalAttributes attributes
);
```

Parameters

character

The character value used to initialize the structure.

attributes

A TerminalAttributes enumeration value which specifies the attributes for the character cell.

Remarks

The **TerminalCell** structure will be initialized with the specified character and attributes.

Terminal Properties

The properties of the **Terminal** class are listed below. For a complete list of **Terminal** class members, see the Terminal Members topic.

Public Instance Properties

AccessibilityObject (inherited from Control)	Gets the AccessibleObject assigned to the control.
AccessibleDefaultActionDescription (inherited from Control)	Gets or sets the default action description of the control for use by accessibility client applications.
AccessibleDescription (inherited from Control)	Gets or sets the description of the control used by accessibility client applications.
AccessibleName (inherited from Control)	Gets or sets the name of the control used by accessibility client applications.
AccessibleRole (inherited from Control)	Gets or sets the accessible role of the control
ActiveControl (inherited from ContainerControl)	Gets or sets the active control on the container control.
AllowDrop (inherited from Control)	Gets or sets a value indicating whether the control can accept data that the user drags onto it.
Anchor (inherited from Control)	Gets or sets which edges of the control are anchored to the edges of its container.
Attributes	Gets and sets the current display attribute for the terminal emulator.
AutoRefresh	Enables and disables the automatic refreshing of the virtual display.
AutoScroll (inherited from ScrollableControl)	Gets or sets a value indicating whether the container will allow the user to scroll to any controls placed outside of its visible boundaries.
AutoScrollMargin (inherited from ScrollableControl)	Gets or sets the size of the auto-scroll margin.
AutoScrollMinSize (inherited from ScrollableControl)	Gets or sets the minimum size of the auto-scroll.
AutoScrollPosition (inherited from ScrollableControl)	Gets or sets the location of the auto-scroll position.
AutoSelect	Enables and disables the automatic selection of text in the display.
AutoSize	Enables and disables the automatic resizing of the display.
AutoWrap	Enables and disables the automatic wrapping of text in the virtual display.
BackColor (inherited from Control)	Gets or sets the background color for the control.
BackgroundImage (inherited from Control)	Gets or sets the background image displayed in the control.

Bell	Enables and disables the audible bell.
BindingContext (inherited from ContainerControl)	
BoldColor	Gets and sets the bold color of the control.
Bottom (inherited from Control)	Gets the distance between the bottom edge of the control and the top edge of its container's client area.
Bounds (inherited from Control)	Gets or sets the size and location of the control including its nonclient elements.
CanFocus (inherited from Control)	Gets a value indicating whether the control can receive focus.
CanSelect (inherited from Control)	Gets a value indicating whether the control can be selected.
Capture (inherited from Control)	Gets or sets a value indicating whether the control has captured the mouse.
Caret	Gets and sets the caret style of the control.
CausesValidation (inherited from Control)	Gets or sets a value indicating whether the control causes validation to be performed on any controls that require validation when it receives focus.
CellHeight	Gets the height of a character cell.
CellWidth	Gets the width of a character cell.
ClientRectangle (inherited from Control)	Gets the rectangle that represents the client area of the control.
ClientSize (inherited from Control)	Gets or sets the height and width of the client area of the control.
CodePage	Gets and sets the code page used when displaying text.
Columns	Gets and sets the number of columns in the virtual display.
CompanyName (inherited from Control)	Gets the name of the company or creator of the application containing the control.
Container (inherited from Component)	Gets the IContainer that contains the Component.
ContainsFocus (inherited from Control)	Gets a value indicating whether the control, or one of its child controls, currently has the input focus.
ContextMenu (inherited from Control)	Gets or sets the shortcut menu associated with the control.
Controls (inherited from Control)	Gets the collection of controls contained within the control.
Created (inherited from Control)	Gets a value indicating whether the control has been created.
Cursor (inherited from Control)	Gets or sets the cursor that is displayed when the mouse pointer is over the control.

CursorX	Gets and sets the current cursor position in the display.
CursorY	Gets and sets the current cursor position in the display.
DataBindings (inherited from Control)	Gets the data bindings for the control.
Display	Gets a value that specifies the virtual display handle allocated for the control.
DisplayRectangle (inherited from ScrollableControl)	
Disposing (inherited from Control)	Gets a value indicating whether the control is in the process of being disposed of.
Dock (inherited from Control)	Gets or sets which edge of the parent container a control is docked to.
DockPadding (inherited from ScrollableControl)	Gets the dock padding settings for all edges of the control.
Emulation	Gets and sets the emulation mode used by the control.
Enabled (inherited from Control)	Gets or sets a value indicating whether the control can respond to user interaction.
Focused (inherited from Control)	Gets a value indicating whether the control has input focus.
Font (inherited from Control)	Gets or sets the font of the text displayed by the control.
FontName	Gets and sets the name of the font used by the control.
FontSize	Gets and sets the size of the font used by the control.
ForeColor (inherited from Control)	Gets or sets the foreground color of the control.
Handle (inherited from Control)	Gets the window handle that the control is bound to.
HasChildren (inherited from Control)	Gets a value indicating whether the control contains one or more child controls.
Height (inherited from Control)	Gets or sets the height of the control.
ImeMode (inherited from Control)	Gets or sets the Input Method Editor (IME) mode of the control.
InvokeRequired (inherited from Control)	Gets a value indicating whether the caller must call an invoke method when making method calls to the control because the caller is on a different thread than the one the control was created on.
IsAccessible (inherited from Control)	Gets or sets a value indicating whether the control is visible to accessibility applications.
IsDisposed (inherited from Control)	Gets a value indicating whether the control has

	been disposed of.
IsHandleCreated (inherited from Control)	Gets a value indicating whether the control has a handle associated with it.
IsInitialized	Gets a value which indicates if the current instance of the control has been initialized successfully.
LastError	Gets or sets a value which specifies the last error that has occurred.
LastErrorString	Gets a value which describes the last error that has occurred.
Left (inherited from Control)	Gets or sets the x-coordinate of a control's left edge in pixels.
Location (inherited from Control)	Gets or sets the coordinates of the upper-left corner of the control relative to the upper-left corner of its container.
MouseX	Return the current mouse position in the display.
MouseY	Return the current mouse position in the display.
Name (inherited from Control)	Gets or sets the name of the control.
NewLine	Gets and sets the newline mode for the virtual display.
Parent (inherited from Control)	Gets or sets the parent container of the control.
ParentForm (inherited from ContainerControl)	Gets the form that the container control is assigned to.
ProductName (inherited from Control)	Gets the product name of the assembly containing the control.
ProductVersion (inherited from Control)	Gets the version of the assembly containing the control.
RecreatingHandle (inherited from Control)	Gets a value indicating whether the control is currently re-creating its handle.
Region (inherited from Control)	Gets or sets the window region associated with the control.
Right (inherited from Control)	Gets the distance between the right edge of the control and the left edge of its container.
RightToLeft (inherited from Control)	Gets or sets a value indicating whether control's elements are aligned to support locales using right-to-left fonts.
Rows	Gets and sets the number of rows in the virtual display.
ScrollBars	Gets and sets the scrollbar display mode for the control.
SelLength	Gets and sets the number of characters selected in the virtual display.
SelStart	Gets and sets the starting position of the current

	text selection.
SelText	Gets the selected text or text from a specific portion of the display.
Site (inherited from Control)	Gets or sets the site of the control.
Size (inherited from Control)	Gets or sets the height and width of the control.
TabIndex (inherited from Control)	Gets or sets the tab order of the control within its container.
TabStop (inherited from Control)	Gets or sets a value indicating whether the user can give the focus to this control using the TAB key.
Tag (inherited from Control)	Gets or sets the object that contains data about the control.
Text	Gets and sets the text displayed by the control.
ThrowError	Gets and sets a value which specifies if method calls should throw exceptions when an error occurs.
Top (inherited from Control)	Gets or sets the y-coordinate of the control's top edge in pixels.
TopLevelControl (inherited from Control)	Gets the parent control that is not parented by another Windows Forms control. Typically, this is the outermost Form that the control is contained in.
Version	Gets a value which returns the current version of the Terminal control.
Visible (inherited from Control)	Gets or sets a value indicating whether the control is displayed.
Width (inherited from Control)	Gets or sets the width of the control.
WindowTarget (inherited from Control)	

Protected Instance Properties

CreateParams (inherited from ContainerControl)	
DefaultImeMode (inherited from Control)	Gets the default Input Method Editor (IME) mode supported by the control.
DefaultSize (inherited from UserControl)	
DesignMode (inherited from Component)	Gets a value that indicates whether the Component is currently in design mode.
Events (inherited from Component)	Gets the list of event handlers that are attached to this Component.
FontHeight (inherited from Control)	Gets or sets the height of the font of the control.
HScroll (inherited from ScrollableControl)	Gets or sets a value indicating whether the horizontal scroll bar is visible.
RenderRightToLeft (inherited from Control)	

ResizeRedraw (inherited from Control)	Gets or sets a value indicating whether the control redraws itself when resized.
ShowFocusCues (inherited from Control)	Gets a value indicating whether the control should display focus rectangles.
ShowKeyboardCues (inherited from Control)	Gets a value indicating whether the control should display keyboard shortcuts.
VScroll (inherited from ScrollableControl)	Gets or sets a value indicating whether the vertical scroll bar is visible.

Terminal Class | SocketTools Namespace

Terminal.Attributes Property

Gets and sets the current display attribute for the terminal emulator.

[Visual Basic]

```
<Description(Description:="Set or return the current display attribute for the
   terminal emulator."), _  Browsable(Browsable:=False)>
Public Property Attributes As TerminalAttributes
```

[C#]

```
[Description(Description="Set or return the current display attribute for the
   terminal emulator.")]
[Browsable(Browsable=False)]
public Terminal.TerminalAttributes Attributes {get; set;}
```

Property Value

A TerminalAttributes enumeration value which specifies one or more display attributes.

Remarks

The **Attributes** property can be used to determine the current display attributes, or to change the current attribute for subsequent text.

See Also

Terminal Class | SocketTools Namespace

Terminal.AutoRefresh Property

Enables and disables the automatic refreshing of the virtual display.

[Visual Basic]

```
<Category(Category:="Design"), _  Description(Description:="Enable or disable the
   automatic refreshing of the virtual display.")>
Public Property AutoRefresh As Boolean
```

[C#]

```
[Category(Category="Design")]
[Description(Description="Enable or disable the automatic refreshing of the virtual
   display.")]
public bool AutoRefresh {get; set;}
```

Property Value

A boolean value which specifies if the display is automatically refreshed.

Remarks

The **AutoRefresh** property is used to enable or disable the automatic refreshing of the virtual display whenever characters are written or the cursor position changes. By setting the property to **false**, the display can be changed and those changes will not be displayed until the property is reset to **true**. This allows an application to make a series of changes to the display text, attributes or cursor position without causing it to flicker.

See Also

Terminal Class | SocketTools Namespace

Terminal.AutoSelect Property

Enables and disables the automatic selection of text in the display.

[Visual Basic]

```
<Description(Description:="Enable or disable the automatic selection of text in the
   display."), _  Category(Category:="Design")>
Public Property AutoSelect As Boolean
```

[C#]

```
[Description(Description="Enable or disable the automatic selection of text in the
   display.")]
[Category(Category="Design")]
public bool AutoSelect {get; set;}
```

Property Value

A boolean value which specifies if text is automatically selected using the mouse.

Remarks

The **AutoSelect** property is used to enable or disable the automatic selection of text in the virtual display. When the property is set to **true**, the user can select text by clicking and dragging the mouse over the text to be selected. When set to **false**, no text is selected if the user drags the mouse over the display.

See Also

Terminal Class | SocketTools Namespace

Terminal.AutoSize Property

Enables and disables the automatic resizing of the display.

[Visual Basic]
```
<Category(Category:="Design"), _  Description(Description:="Enable or disable the
   automatic sizing of the display.")>
Public Property AutoSize As Boolean
```

[C#]
```
[Category(Category="Design")]
[Description(Description="Enable or disable the automatic sizing of the display.")]
public bool AutoSize {get; set;}
```

Property Value

A boolean value which specifies if the display is automatically resized.

Remarks

The **AutoSize** property determines if the control window is automatically resized when the parent window changes size. A value of **true** specifies that the control window should automatically resize itself to the size of its parent window. A value of **false** specifies that the control window should remain unchanged when the parent window is resized.

See Also

Terminal Class | SocketTools Namespace

Terminal.AutoWrap Property

Enables and disables the automatic wrapping of text in the virtual display.

[Visual Basic]

```
<Description(Description:="Enable or disable the wrapping of text in the display."),
   _  Category(Category:="Design")>
Public Property AutoWrap As Boolean
```

[C#]

```
[Description(Description="Enable or disable the wrapping of text in the display.")]
[Category(Category="Design")]
public bool AutoWrap {get; set;}
```

Property Value

A boolean value which specifies if automatic line wrapping is enabled.

Remarks

The **AutoWrap** property enables or disables the wrapping of text in the virtual display. If set to **true**, the cursor is re-positioned to the first column on the next line when text reaches last column in the display. If set to **false**, any text displayed beyond the last column is discarded.

Terminal.Bell Property

Enables and disables the audible bell.

[Visual Basic]

```
<Category(Category:="Design"), _  Description(Description:="Enable or disable the
   audible bell.")>
Public Property Bell As Boolean
```

[C#]

```
[Category(Category="Design")]
[Description(Description="Enable or disable the audible bell.")]
public bool Bell {get; set;}
```

Property Value

A boolean value which specifies if the audible bell is enabled.

Remarks

The **Bell** property enables or disables the audible bell which is played whenever the control character Ctrl+G is encountered. The default property value is **true**.

Terminal Class | SocketTools Namespace

Terminal.BoldColor Property

Gets and sets the bold color of the control.

[Visual Basic]

```
<Category(Category:="Appearance"), _  Description(Description:="Sets or returns the
   bold color for the control.")>
Public Property BoldColor As Color
```

[C#]

```
[Category(Category="Appearance")]
[Description(Description="Sets or returns the bold color for the control.")]
public System.Drawing.Color BoldColor {get; set;}
```

Property Value

A **Color** value which specifies the text foreground color to use when the bold attribute is set.

Remarks

The **BoldColor** property returns the current color used for bold text in the control. Setting the property changes the color to the specified value.

See Also

Terminal Class | SocketTools Namespace

Terminal.Caret Property

Gets and sets the caret style of the control.

[Visual Basic]

```
<Category(Category:="Design"), _  Description(Description:="Set or return the style
   of caret displayed in the emulator.")>
Public Property Caret As TerminalCaret
```

[C#]

```
[Category(Category="Design")]
[Description(Description="Set or return the style of caret displayed in the
   emulator.")]
public Terminal.TerminalCaret Caret {get; set;}
```

Property Value

A TerminalCaret enumeration value which specifies the caret style.

See Also

Terminal Class | SocketTools Namespace

Terminal.Cell Field

Gets and sets information about a character cell in the virtual display.

[Visual Basic]

```
<Browsable(Browsable:=False), _  Description(Description:="Returns information about
   the specified character cell in the display.")>
Public ReadOnly Cell As DisplayCells
```

[C#]

```
[Browsable(Browsable=False)]
[Description(Description="Returns information about the specified character cell in
   the display.")]
public readonly DisplayCells Cell;
```

Remarks

The **Cell** property is used to determine the character and attributes for a specific character cell in the virtual display. The contents of the character cell can also be changed by assigning a value to this property.

See Also

Terminal Class | SocketTools Namespace

Terminal.CellHeight Property

Gets the height of a character cell.

[Visual Basic]

```
<Category(Category:="Layout"), _  ReadOnly(IsReadOnly:=True), _
    Description(Description:="Returns the height of a text cell in pixels.")>
Public ReadOnly Property CellHeight As Integer
```

[C#]

```
[Category(Category="Layout")]
[ReadOnly(IsReadOnly=True)]
[Description(Description="Returns the height of a text cell in pixels.")]
public int CellHeight {get;}
```

Property Value

An integer value which specifies the height of a character cell in pixels.

Remarks

This value can be used in calculating the minimum height of the control window in order to display all lines of text.

See Also

Terminal Class | SocketTools Namespace

Terminal.CellWidth Property

Gets the width of a character cell.

[Visual Basic]

```
<Description(Description:="Returns the width of a text cell in pixels."), _
    Category(Category:="Layout"), _  ReadOnly(IsReadOnly:=True)>
Public ReadOnly Property CellWidth As Integer
```

[C#]

```
[Description(Description="Returns the width of a text cell in pixels.")]
[Category(Category="Layout")]
[ReadOnly(IsReadOnly=True)]
public int CellWidth {get;}
```

Property Value

An integer value which specifies the width of a character cell in pixels.

Remarks

This value can be used in calculating the minimum width of the control window in order to display all lines of text.

See Also

Terminal Class | SocketTools Namespace

Terminal.CodePage Property

Gets and sets the code page used when displaying text.

[Visual Basic]

```
Public Property CodePage As Integer
```

[C#]

```
public int CodePage {get; set;}
```

Property Value

An integer value which specifies the current code page. A value of zero specifies the default code page for the current locale should be used. To preserve the original Unicode text, you can use code page 65001 which specifies UTF-8 character encoding.

Remarks

By default, strings are converted to an array of bytes using the code page for the current locale, mapping the 16-bit Unicode characters to bytes. Similarly, when reading text from the virtual display into a string buffer, the characters are converted to Unicode before they are returned to your application.

If the text appears to corrupted or characters are being replaced with question marks or other symbols, it is likely the text is using a different character encoding. Most services use UTF-8 encoding to represent non-ASCII characters and selecting the UTF-8 code page will typically resolve the issue.

For backwards compatibility, this class defaults to using the code page for the current locale. This property value directly corresponds to Windows code page identifiers, and will accept any valid code page supported by the .NET Framework. Setting this property to an invalid code page will generate an exception.

See Also

Terminal Class | SocketTools Namespace

Terminal.ColorMap Field

Gets and sets the color values used when displaying text.

[Visual Basic]

```
<Browsable(Browsable:=False), _  Description(Description:="Sets or returns the color
   value used when displaying color text attributes.")>
Public ReadOnly ColorMap As DisplayColorMap
```

[C#]

```
[Browsable(Browsable=False)]
[Description(Description="Sets or returns the color value used when displaying color
   text attributes.")]
public readonly DisplayColorMap ColorMap;
```

Remarks

The **ColorMap** array provides access to the virtual display color table which determines what color values are used to display foreground and background text color attributes.

When the emulator processes an escape sequence that changes the current foreground or background color, the actual RGB color value is determined by looking up the value in the virtual display's color table. The **ColorMap** property is useful for determining what values are being used when a color attribute is set and enables an application to change those colors. The emulator currently supports a maximum of sixteen (16) color values, and the index into the table corresponds to the color as defined by the standard for ANSI terminals.

See Also

Terminal Class | SocketTools Namespace

Terminal.Columns Property

Gets and sets the number of columns in the virtual display.

[Visual Basic]

```
<Description(Description:="Set or return the number of columns in the emulation
   display."), _  Category(Category:="Layout")>
Public Property Columns As Integer
```

[C#]

```
[Description(Description="Set or return the number of columns in the emulation
   display.")]
[Category(Category="Layout")]
public int Columns {get; set;}
```

Property Value

An integer value which specifies the number of columns.

Remarks

The **Columns** property returns the number of columns in the virtual display, or allows the application to change the number of columns. Currently, the number of columns may only be set to 80 or 132. Note that changing the number of columns in the display causes the current display to be invalidated, and the window will be cleared.

See Also

Terminal Class | SocketTools Namespace

Terminal.CursorX Property

Gets and sets the current cursor position in the display.

[Visual Basic]

```
<Description(Description:="Set or return the current column in the display."), _
    Browsable(Browsable:=False)>
Public Property CursorX As Integer
```

[C#]

```
[Description(Description="Set or return the current column in the display.")]
[Browsable(Browsable=False)]
public int CursorX {get; set;}
```

Property Value

An integer value which specifies the current cursor column.

Remarks

The **CursorX** property returns the current position of the cursor in the display, or can be used to change the current position. The current position is given in columns and indicates where the next text character will be displayed. To calculate the pixel offset where the cursor is located in the control window, multiply this value by the **CellWidth** property value.

See Also

Terminal Class | SocketTools Namespace

Terminal.CursorY Property

Gets and sets the current cursor position in the display.

[Visual Basic]

```
<Browsable(Browsable:=False), _  Description(Description:="Set or return the current
   row in the display.")>
Public Property CursorY As Integer
```

[C#]

```
[Browsable(Browsable=False)]
[Description(Description="Set or return the current row in the display.")]
public int CursorY {get; set;}
```

Property Value

An integer value which specifies the current cursor row.

Remarks

The **CursorY** property returns the current position of the cursor in the display, or can be used to change the current position. The current position is given in rows and indicates where the next text character will be displayed. To calculate the pixel offset where the cursor is located in the control window, multiply this value by the **CellHeight** property value.

See Also

Terminal Class | SocketTools Namespace

Terminal.Display Property

Gets a value that specifies the virtual display handle allocated for the control.

[Visual Basic]

```
<Description(Description:="Returns the handle to the virtual display."), _
    Browsable(Browsable:=False)>
Public ReadOnly Property Display As Integer
```

[C#]

```
[Description(Description="Returns the handle to the virtual display.")]
[Browsable(Browsable=False)]
public int Display {get;}
```

Property Value

An integer which represents a virtual display handle. If there is no current virtual display, a value of -1 is returned.

Remarks

The **Display** property returns the numeric descriptor for the virtual display created by the control. This is a read-only property value used for diagnostic purposes.

See Also

Terminal Class | SocketTools Namespace

Terminal.Emulation Property

Gets and sets the emulation mode used by the control.

[Visual Basic]

```
<Description(Description:="Set or return the emulation mode for the current
   display."), _  Category(Category:="Design")>
Public Property Emulation As TerminalEmulation
```

[C#]

```
[Description(Description="Set or return the emulation mode for the current
   display.")]
[Category(Category="Design")]
public Terminal.TerminalEmulation Emulation {get; set;}
```

Property Value

A TerminalEmulation enumeration value which specifies the emulation mode.

See Also

Terminal Class | SocketTools Namespace

Terminal.IsInitialized Property

Gets a value which indicates if the current instance of the control has been initialized successfully.

[Visual Basic]

```
<Description(Description:="Return if the control has been initialized."), _
    Browsable(Browsable:=False)>
Public ReadOnly Property IsInitialized As Boolean
```

[C#]

```
[Description(Description="Return if the control has been initialized.")]
[Browsable(Browsable=False)]
public bool IsInitialized {get;}
```

Property Value

Returns **true** if the control has been initialized; otherwise returns **false.**

Remarks

The **IsInitialized** property is used to determine if the current instance of the control has been initialized properly. Normally this is done automatically by the class constructor, however there are circumstances where the control may not be able to initialize itself.

The most common reasons that a control may not initialize correctly is that no runtime license key has been defined in the assembly or the license key provided is invalid. It may also indicate a problem with the system configuration or user access rights, such as not being able to create the control window or not being able to access the system registry.

See Also

Terminal Class | SocketTools Namespace

Terminal.KeyMap Field

Gets and sets the character sequence mapped to a special key.

[Visual Basic]

```
<Description(Description:="Set or return the character sequence mapped to a special
   key."), _  Browsable(Browsable:=False)>
Public ReadOnly KeyMap As DisplayKeyMap
```

[C#]

```
[Description(Description="Set or return the character sequence mapped to a special
   key.")]
[Browsable(Browsable=False)]
public readonly DisplayKeyMap KeyMap;
```

Remarks

The **KeyMap** array allows the application to define character sequences that should be mapped to special keys. When a special key is pressed in the emulation window and there is an entry for it in the key map, the **KeyMapped** event is fired.

The array index identifies the key which will be mapped. Refer to the TerminalKey enumeration for a list of keys and their corresponding values which may be mapped by the application.

See Also

Terminal Class | SocketTools Namespace

Terminal.LastError Property

Gets or sets a value which specifies the last error that has occurred.

[Visual Basic]

```
<Description(Description:="Set or return the last error code for this instance of
   the control."), _  Browsable(Browsable:=False)>
Public Property LastError As ErrorCode
```

[C#]

```
[Description(Description="Set or return the last error code for this instance of the
   control.")]
[Browsable(Browsable=False)]
public Terminal.ErrorCode LastError {get; set;}
```

Property Value

Returns an ErrorCode enumeration value which specifies the last error code.

Remarks

The **LastError** property returns the error code associated with the last error that occurred for the current instance of the control. It is important to note that this value only has meaning if the previous method indicates that an error has actually occurred.

It is possible to explicitly clear the last error code by assigning the property to the value **ErrorCode.errorNone**.

The error code value can be cast to an integer value for display purposes if required. For a description of the error that can be displayed using a message box or some other similar mechanism, get the value of the **LastErrorString** property.

See Also

Terminal Class | SocketTools Namespace

Terminal.LastErrorString Property

Gets a value which describes the last error that has occurred.

[Visual Basic]

```
<Description(Description:="Return a description of the last error that occurred."), 
    _  Browsable(Browsable:=False)>
Public ReadOnly Property LastErrorString As String
```

[C#]

```
[Description(Description="Return a description of the last error that occurred.")]
[Browsable(Browsable=False)]
public string LastErrorString {get;}
```

Property Value

A string which describes the last error that has occurred.

Remarks

The **LastErrorString** property can be used to obtain a description of the last error that occurred for the current instance of the control. It is important to note that this value only has meaning if the previous method indicates that an error has actually occurred.

See Also

Terminal Class | SocketTools Namespace

Terminal.MouseX Property

Return the current mouse position in the display.

[Visual Basic]

```
<Description(Description:="Return the current mouse pointer position in the
   display."), _  Browsable(Browsable:=False)>
Public ReadOnly Property MouseX As Integer
```

[C#]

```
[Description(Description="Return the current mouse pointer position in the
   display.")]
[Browsable(Browsable=False)]
public int MouseX {get;}
```

Property Value

An integer value which specifies the column where the mouse pointer is positioned.

Remarks

The **MouseX** property returns the current position of the mouse pointer in the display. The current position is given in columns, not pixels. To calculate the pixel offset where the mouse pointer is located in the control window, multiply this value by the **CellWidth** property value.

See Also

Terminal Class | SocketTools Namespace

Terminal.MouseY Property

Return the current mouse position in the display.

[Visual Basic]

```
<Browsable(Browsable:=False), _  Description(Description:="Return the current mouse
   pointer position in the display.")>
Public ReadOnly Property MouseY As Integer
```

[C#]

```
[Browsable(Browsable=False)]
[Description(Description="Return the current mouse pointer position in the
   display.")]
public int MouseY {get;}
```

Property Value

An integer value which specifies the row where the mouse pointer is positioned.

Remarks

The **MouseY** property returns the current position of the mouse pointer in the display. The current position is given in rows, not pixels. To calculate the pixel offset where the mouse pointer is located in the control window, multiply this value by the **CellHeight** property value.

See Also

Terminal Class | SocketTools Namespace

Terminal.NewLine Property

Gets and sets the newline mode for the virtual display.

[Visual Basic]

```
<Description(Description:="Determine how carriage returns and linefeeds are
   displayed."), _  Category(Category:="Design")>
Public Property NewLine As TerminalNewLine
```

[C#]

```
[Description(Description="Determine how carriage returns and linefeeds are
   displayed.")]
[Category(Category="Design")]
public Terminal.TerminalNewLine NewLine {get; set;}
```

Property Value

A TerminalNewLine enumeration value which specifies the current newline mode.

Remarks

The **NewLine** property controls how carriage returns and linefeeds are processed by the emulator. The default is for a carriage return to position the cursor to the first column, and a linefeed to advance the cursor to the next row, scrolling the display if necessary.

See Also

Terminal Class | SocketTools Namespace

Terminal.Rows Property

Gets and sets the number of rows in the virtual display.

[Visual Basic]

```
<Description(Description:="Set or return the number of rows in the emulation
   display."), _  Category(Category:="Layout")>
Public Property Rows As Integer
```

[C#]

```
[Description(Description="Set or return the number of rows in the emulation
   display.")]
[Category(Category="Layout")]
public int Rows {get; set;}
```

Property Value

An integer value which specifies the number of rows.

Remarks

The **Rows** property returns the number of rows in the virtual display, or allows the application to change the number of rows. Currently, the number of rows may only be set to 24 or 25. Note that changing the number of rows in the display causes the current display to be invalidated, and the window will be cleared.

See Also

Terminal Class | SocketTools Namespace

Terminal.ScrollBars Property

Gets and sets the scrollbar display mode for the control.

[Visual Basic]

```
<Description(Description:="Returns or sets a value indicating whether the control
   has horizontal or vertical scroll bars."), _  Category(Category:="Design")>
Public Property ScrollBars As TerminalScrollBars
```

[C#]

```
[Description(Description="Returns or sets a value indicating whether the control has
   horizontal or vertical scroll bars.")]
[Category(Category="Design")]
public Terminal.TerminalScrollBars ScrollBars {get; set;}
```

Property Value

A TerminalScrollBars enumeration value which specifies how scrollbars will be displayed.

Remarks

The **ScrollBars** property determines what kind of scroll bars are displayed if the virtual display is larger than the emulation control's window. Scrollbars are only displayed if needed. If the emulation window is large enough to display all of the columns and rows, no scrollbars will be drawn even if they are enabled using this property.

See Also

Terminal Class | SocketTools Namespace

Terminal.SelLength Property

Gets and sets the number of characters selected in the virtual display.

[Visual Basic]

```
<Description(Description:="Set or return the number of characters selected."), _
    Browsable(Browsable:=False)>
Public Property SelLength As Integer
```

[C#]

```
[Description(Description="Set or return the number of characters selected.")]
[Browsable(Browsable=False)]
public int SelLength {get; set;}
```

Property Value

An integer value which specifies the number of selected characters.

Remarks

The **SelLength** property is used to return the number of characters currently selected in the virtual display. When used in conjunction with the **SelStart** property, it can be used to select text from the display.

See Also

Terminal Class | SocketTools Namespace

Terminal.SelStart Property

Gets and sets the starting position of the current text selection.

[Visual Basic]

```
<Description(Description:="Set or return the starting position of the current text
   selection."), _  Browsable(Browsable:=False)>
Public Property SelStart As Integer
```

[C#]

```
[Description(Description="Set or return the starting position of the current text
   selection.")]
[Browsable(Browsable=False)]
public int SelStart {get; set;}
```

Property Value

An integer value which specifies the starting position for the selected text.

Remarks

The **SelStart** property specifies an offset which is the starting position of the selected text. This property can be used in conjunction with the **SelLength** property to select text in the virtual display.

To convert the cursor position to an offset, multiply the y-position by the number of columns and add the x-position. The **SelLength** property determines the number of characters to copy from the starting position. Reading the **SelText** property returns the text displayed at the selected location.

See Also

Terminal Class | SocketTools Namespace

Terminal.SelText Property

Gets the selected text or text from a specific portion of the display.

[Visual Basic]

```
<Browsable(Browsable:=False), _  Description(Description:="Returns the selected text
   or text from a specific portion of the display.")>
Public ReadOnly Property SelText As String
```

[C#]

```
[Browsable(Browsable=False)]
[Description(Description="Returns the selected text or text from a specific portion
   of the display.")]
public string SelText {get;}
```

Property Value

A string which contains the currently selected text.

Remarks

The **SelText** property returns the text which is currently selected in the virtual display. If no text has been selected and the **SelLength** property is greater than zero, then the text starting at the position specified by the **SelStart** property will be returned.

To read a single character a specific location in the display, it is preferable to use the **Cell** property rather than calculating the offset, setting the **SelStart** property and then reading the **SelText** property.

See Also

Terminal Class | SocketTools Namespace

Terminal.Text Property

Gets and sets the text displayed by the control.

[Visual Basic]
```
<Description(Description:="Sets or returns the text displayed by the control."), _
    Category(Category:="Appearance")>
Overrides Public Property Text As String
```

[C#]
```
[Description(Description="Sets or returns the text displayed by the control.")]
[Category(Category="Appearance")]
public override string Text {get; set;}
```

Property Value

A string which contains the current display text.

Remarks

The **Text** property returns the text displayed by the control. The string that is returned contains each row of text in the display, terminated with a carriage-return linefeed. Empty cells at the end of a row are ignored so there are no extraneous spaces in the text. In other words, the value returned by the **Text** property is similar to how text is returned from a multi-line edit control. If you need to access a character at a specific location in the display, use the **Cell** property. If you need to access the text in a specific part of the display, including any empty cells, then use the **SelStart**, **SelLength** and **SelText** properties instead.

Setting the **Text** property will cause the current contents of the display to be replaced by the contents of the specified string. If the string contains escape sequences and/or control characters, they will be processed according to how the **Emulation** property is set.

See Also

Terminal Class | SocketTools Namespace

Terminal.ThrowError Property

Gets and sets a value which specifies if method calls should throw exceptions when an error occurs.

[Visual Basic]

```
<Browsable(Browsable:=False), _  Description(Description:="Set or return if the
   control will throw an exception when an error occurs.")>
Public Property ThrowError As Boolean
```

[C#]

```
[Browsable(Browsable=False)]
[Description(Description="Set or return if the control will throw an exception when
   an error occurs.")]
public bool ThrowError {get; set;}
```

Property Value

Returns **true** if method calls will generate exceptions when an error occurs; otherwise returns **false**. The default value is **false.**

Remarks

Error handling for when calling class methods can be done in either of two different styles, according to the value of this property.

If the **ThrowError** property is set to **false**, the application should check the return value of any method that is used, and report errors based upon the documented value of the return code. It is the responsibility of the application to interpret the error code, if it is desired to explain the error in addition to reporting it. This is the default behavior.

If the **ThrowError** property is set to **true**, then exceptions will be generated whenever a method call fails. The program must be written to catch these exceptions and take the appropriate action when an error occurs. Failure to handle an exception will cause the program to terminate abnormally.

Note that if an error occurs while a property is being read or modified, an exception will be raised regardless of the value of the **ThrowError** property.

Terminal Class | SocketTools Namespace

Terminal.Version Property

Gets a value which returns the current version of the Terminal control.

[Visual Basic]

```
<Description(Description:="Return the current version of the object."), _
    Browsable(Browsable:=False)>
Public ReadOnly Property Version As String
```

[C#]

```
[Description(Description="Return the current version of the object.")]
[Browsable(Browsable=False)]
public string Version {get;}
```

Property Value

A string which specifies the version of the control.

Remarks

The **Version** property returns a string which identifies the current version and build of the Terminal control. This value can be used by an application for validation and debugging purposes.

Terminal Class | SocketTools Namespace

Terminal Methods

The methods of the **Terminal** class are listed below. For a complete list of **Terminal** class members, see the Terminal Members topic.

Public Instance Methods

BeginInvoke (inherited from Control)	Overloaded. Executes the specified delegate asynchronously with the specified arguments, on the thread that the control's underlying handle was created on.
BringToFront (inherited from Control)	Brings the control to the front of the z-order.
Clear	Clear the terminal emulation window.
ClearEol	Erase all characters from the current column to the end of the line.
Contains (inherited from Control)	Retrieves a value indicating whether the specified control is a child of the control.
CreateControl (inherited from Control)	Forces the creation of the control, including the creation of the handle and any child controls.
CreateGraphics (inherited from Control)	Creates the Graphics object for the control.
CreateObjRef (inherited from MarshalByRefObject)	Creates an object that contains all the relevant information required to generate a proxy used to communicate with a remote object.
DelLine	Delete the current line in the terminal emulation display.
Deselect	Deselects any selected text in the display.
Dispose (inherited from Component)	Overloaded. Releases all resources used by the Component.
DoDragDrop (inherited from Control)	Begins a drag-and-drop operation.
EndInvoke (inherited from Control)	Retrieves the return value of the asynchronous operation represented by the IAsyncResult object passed.
Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
FindForm (inherited from Control)	Retrieves the form that the control is on.
Focus (inherited from Control)	Sets input focus to the control.
GetChildAtPoint (inherited from Control)	Retrieves the child control that is located at the specified coordinates.
GetContainerControl (inherited from Control)	Returns the next ContainerControl up the control's chain of parent controls.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.

GetLifetimeService (inherited from MarshalByRefObject)	Retrieves the current lifetime service object that controls the lifetime policy for this instance.
GetNextControl (inherited from Control)	Retrieves the next control forward or back in the tab order of child controls.
GetType (inherited from Object)	Gets the Type of the current instance.
Hide (inherited from Control)	Conceals the control from the user.
Initialize	Overloaded. Initialize an instance of the Terminal control.
InitializeLifetimeService (inherited from MarshalByRefObject)	Obtains a lifetime service object to control the lifetime policy for this instance.
InsLine	Insert an empty line at the current position in the terminal emulation display.
Invalidate (inherited from Control)	Overloaded. Invalidates the specified region of the control (adds it to the control's update region, which is the area that will be repainted at the next paint operation), and causes a paint message to be sent to the control.
Invoke (inherited from Control)	Overloaded. Executes the specified delegate, on the thread that owns the control's underlying window handle, with the specified list of arguments.
PerformLayout (inherited from Control)	Overloaded. Forces the control to apply layout logic to all its child controls.
PointToClient (inherited from Control)	Computes the location of the specified screen point into client coordinates.
PointToScreen (inherited from Control)	Computes the location of the specified client point into screen coordinates.
PreProcessMessage	Preprocesses input messages within the message loop before they are dispatched.
RectangleToClient (inherited from Control)	Computes the size and location of the specified screen rectangle in client coordinates.
RectangleToScreen (inherited from Control)	Computes the size and location of the specified client rectangle in screen coordinates.
Refresh	Forces a complete redraw of the virtual display.
Reset	Reset the internal state of the control, resetting all properties to their default values.
ResetBackColor (inherited from Control)	Resets the BackColor property to its default value.
ResetBindings (inherited from Control)	Resets the DataBindings property to its default value.
ResetCursor (inherited from Control)	Resets the Cursor property to its default value.
ResetFont (inherited from Control)	Resets the Fontproperty to its default value.
ResetForeColor (inherited from Control)	Resets the ForeColor property to its default value.

ResetImeMode (inherited from Control)	Resets the ImeMode property to its default value.
ResetRightToLeft (inherited from Control)	Resets the RightToLeft property to its default value.
ResetText (inherited from Control)	Resets the Text property to its default value.
ResumeLayout (inherited from Control)	Overloaded. Resumes normal layout logic.
Scale (inherited from Control)	Overloaded. Scales the control and any child controls to the specified ratio.
ScrollControlIntoView (inherited from ScrollableControl)	
ScrollDown	Scroll the display down by one line.
ScrollUp	Scroll the display up by one line.
Select (inherited from Control)	Overloaded. Activates the control.
SelectNextControl (inherited from Control)	Activates the next control.
SelectText	Overloaded. Selects a region of the virtual display and returns the selected text.
SendToBack (inherited from Control)	Sends the control to the back of the z-order.
SetAutoScrollMargin (inherited from ScrollableControl)	Sets the size of the auto-scroll margins.
SetBounds (inherited from Control)	Overloaded. Sets the bounds of the control to the specified location and size.
Show (inherited from Control)	Displays the control to the user.
SuspendLayout (inherited from Control)	Temporarily suspends the layout logic for the control.
ToString (inherited from Component)	
Uninitialize	Uninitialize the control and release any resources allocated for the current process.
Update (inherited from Control)	Causes the control to redraw the invalidated regions within its client area.
Validate (inherited from ContainerControl)	Validates the last invalidated control and its ancestors up through, but not including, the current control.
Write	Overloaded. Write the contents of a byte array to the virtual display.

Protected Instance Methods

AccessibilityNotifyClients (inherited from Control)	Notifies the accessibility client applications of the specified AccessibleEvents for the specified child control.
AdjustFormScrollbars (inherited from ContainerControl)	
CreateAccessibilityInstance (inherited from	Creates a new accessibility object for the control.

Control)	
CreateControlsInstance (inherited from Control)	Creates a new instance of the control collection for the control.
CreateHandle (inherited from Control)	Creates a handle for the control.
DefWndProc (inherited from Control)	Sends the specified message to the default window procedure.
DestroyHandle (inherited from Control)	Destroys the handle associated with the control.
Dispose	Overloaded. Releases the unmanaged resources allocated by the Terminal class and optionally releases the managed resources.
Finalize	Destroys an instance of the control, releasing the resources allocated for the virtual display.
GetScrollState (inherited from ScrollableControl)	
GetService (inherited from Component)	Returns an object that represents a service provided by the Component or by its Container.
GetStyle (inherited from Control)	Retrieves the value of the specified control style bit for the control.
GetTopLevel (inherited from Control)	Determines if the control is a top-level control.
InitLayout (inherited from Control)	Called after the control has been added to another container.
InvokeGotFocus (inherited from Control)	Raises the GotFocus event for the specified control.
InvokeLostFocus (inherited from Control)	Raises the LostFocus event for the specified control.
InvokeOnClick (inherited from Control)	Raises the Click event for the specified control.
InvokePaint (inherited from Control)	Raises the Paint event for the specified control.
InvokePaintBackground (inherited from Control)	Raises the PaintBackground event for the specified control.
IsInputChar (inherited from Control)	Determines if a character is an input character that the control recognizes.
IsInputKey (inherited from Control)	Determines whether the specified key is a regular input key or a special key that requires preprocessing.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.
NotifyInvalidate (inherited from Control)	
OnBackColorChanged	Raises the BackColorChanged event.
OnBackgroundImageChanged (inherited from Control)	Raises the BackgroundImageChanged event.
OnBindingContextChanged (inherited from Control)	Raises the BindingContextChangedevent.
OnCausesValidationChanged (inherited from	Raises the CausesValidationChangedevent.

Control)	
OnChangeUICues (inherited from Control)	Raises the ChangeUICues event.
OnClick (inherited from Control)	Raises the Click event.
OnContextMenuChanged (inherited from Control)	Raises the ContextMenuChangedevent.
OnControlAdded (inherited from Control)	Raises the ControlAdded event.
OnControlRemoved (inherited from ContainerControl)	
OnCreateControl (inherited from UserControl)	
OnCursorChanged (inherited from Control)	Raises the CursorChangedevent.
OnDockChanged (inherited from Control)	Raises the DockChangedevent.
OnDoubleClick (inherited from Control)	Raises the DoubleClick event.
OnDragDrop (inherited from Control)	Raises the DragDrop event.
OnDragEnter (inherited from Control)	Raises the DragEnter event.
OnDragLeave (inherited from Control)	Raises the DragLeave event.
OnDragOver (inherited from Control)	Raises the DragOver event.
OnEnabledChanged (inherited from Control)	Raises the EnabledChanged event.
OnEnter (inherited from Control)	Raises the Enter event.
OnFontChanged	Raises the FontChanged event.
OnForeColorChanged	Raises the ForeColorChanged event.
OnGiveFeedback (inherited from Control)	Raises the GiveFeedback event.
OnGotFocus	Raises the GotFocus event.
OnHandleCreated (inherited from Control)	Raises the HandleCreated event.
OnHandleDestroyed (inherited from Control)	Raises the HandleDestroyed event.
OnHelpRequested (inherited from Control)	Raises the HelpRequested event.
OnImeModeChanged (inherited from Control)	Raises the ImeModeChanged event.
OnInvalidated (inherited from Control)	Raises the Invalidated event.
OnKeyDown (inherited from Control)	Raises the KeyDown event.
OnKeyPress (inherited from Control)	Raises the KeyPress event.
OnKeyUp (inherited from Control)	Raises the KeyUp event.
OnLayout (inherited from ScrollableControl)	
OnLeave (inherited from Control)	Raises the Leave event.
OnLoad (inherited from UserControl)	Raises the Load event.
OnLocationChanged (inherited from Control)	Raises the LocationChanged event.
OnLostFocus	Raises the LostFocus event.
OnMouseDown	Raises the MouseDown event.

OnMouseEnter (inherited from Control)	Raises the MouseEnter event.
OnMouseHover (inherited from Control)	Raises the MouseHover event.
OnMouseLeave (inherited from Control)	Raises the MouseLeave event.
OnMouseMove	Raises the MouseMove event.
OnMouseUp	Raises the MouseUp event.
OnMouseWheel (inherited from ScrollableControl)	
OnMove (inherited from Control)	Raises the Move event.
OnNotifyMessage (inherited from Control)	Notifies the control of Windows messages.
OnPaint	Raises the Paint event.
OnPaintBackground (inherited from Control)	Paints the background of the control.
OnParentBackColorChanged (inherited from Control)	Raises the BackColorChanged event when the BackColor property value of the control's container changes.
OnParentBackgroundImageChanged (inherited from Control)	Raises the BackgroundImageChanged event when the BackgroundImage property value of the control's container changes.
OnParentBindingContextChanged (inherited from Control)	Raises the BindingContextChanged event when the BindingContext property value of the control's container changes.
OnParentChanged	Raises the ParentChanged event.
OnParentEnabledChanged (inherited from Control)	Raises the EnabledChanged event when the Enabled property value of the control's container changes.
OnParentFontChanged (inherited from Control)	Raises the FontChanged event when the Font property value of the control's container changes.
OnParentForeColorChanged (inherited from Control)	Raises the ForeColorChanged event when the ForeColor property value of the control's container changes.
OnParentRightToLeftChanged (inherited from Control)	Raises the RightToLeftChanged event when the RightToLeft property value of the control's container changes.
OnParentVisibleChanged (inherited from Control)	Raises the VisibleChanged event when the Visible property value of the control's container changes.
OnQueryContinueDrag (inherited from Control)	Raises the QueryContinueDrag event.
OnResize	Raises the Resize event.
OnRightToLeftChanged (inherited from Control)	Raises the RightToLeftChangedevent.
OnSizeChanged (inherited from Control)	Raises the SizeChanged event.
OnStyleChanged (inherited from Control)	Raises the StyleChanged event.
OnSystemColorsChanged (inherited from Control)	Raises the SystemColorsChanged event.

OnTabIndexChanged (inherited from Control)	Raises the TabIndexChanged event.
OnTabStopChanged (inherited from Control)	Raises the TabStopChanged event.
OnTextChanged (inherited from Control)	Raises the TextChanged event.
OnValidated (inherited from Control)	Raises the Validated event.
OnValidating (inherited from Control)	Raises the Validating event.
OnVisibleChanged (inherited from ScrollableControl)	
ProcessCmdKey (inherited from Control)	Processes a command key.
ProcessDialogChar (inherited from ContainerControl)	
ProcessDialogKey (inherited from ContainerControl)	
ProcessKeyEventArgs (inherited from Control)	Processes a key message and generates the appropriate control events.
ProcessKeyPreview (inherited from Control)	Previews a keyboard message.
ProcessMnemonic (inherited from ContainerControl)	
ProcessTabKey (inherited from ContainerControl)	Selects the next available control and makes it the active control.
RaiseDragEvent (inherited from Control)	
RaiseKeyEvent (inherited from Control)	
RaiseMouseEvent (inherited from Control)	
RaisePaintEvent (inherited from Control)	
RecreateHandle (inherited from Control)	Forces the re-creation of the handle for the control.
ResetMouseEventArgs (inherited from Control)	
RtlTranslateAlignment (inherited from Control)	Overloaded. Converts the specified HorizontalAlignment to the appropriate HorizontalAlignment to support right-to-left text.
RtlTranslateContent (inherited from Control)	Converts the specified ContentAlignment to the appropriate ContentAlignment to support right-to-left text.
RtlTranslateHorizontal (inherited from Control)	Converts the specified HorizontalAlignment to the appropriate HorizontalAlignment to support right-to-left text.
RtlTranslateLeftRight (inherited from Control)	Converts the specified LeftRightAlignment to the appropriate LeftRightAlignment to support right-to-left text.
ScaleCore (inherited from ScrollableControl)	
Select (inherited from ContainerControl)	Overloaded.

SetBoundsCore (inherited from Control)	Performs the work of setting the specified bounds of this control.
SetClientSizeCore (inherited from Control)	Sets the size of the client area of the control.
SetDisplayRectLocation (inherited from ScrollableControl)	
SetScrollState (inherited from ScrollableControl)	
SetStyle (inherited from Control)	Sets the specified style bit to the specified value.
SetTopLevel (inherited from Control)	Sets the control as the top-level control.
SetVisibleCore (inherited from Control)	Sets the control to the specified visible state.
UpdateBounds (inherited from Control)	Overloaded. Updates the bounds of the control with the current size and location.
UpdateDefaultButton (inherited from ContainerControl)	
UpdateStyles (inherited from Control)	Forces the assigned styles to be reapplied to the control.
UpdateZOrder (inherited from Control)	Updates the control in its parent's z-order.
WndProc	Processes Windows messages.

Protected Internal Instance Methods

ProcessKeyMessage (inherited from Control)	Processes a keyboard message.

See Also

Terminal Class | SocketTools Namespace

Terminal.Clear Method

Clear the terminal emulation window.

[Visual Basic]

```
Public Sub Clear()
```

[C#]

```
public void Clear();
```

See Also

Terminal Class | SocketTools Namespace

Terminal.ClearEol Method

Erase all characters from the current column to the end of the line.

[Visual Basic]

```
Public Sub ClearEol()
```

[C#]

```
public void ClearEol();
```

See Also

Terminal Class | SocketTools Namespace

Terminal.DelLine Method

Delete the current line in the terminal emulation display.

[Visual Basic]

```
Public Sub DelLine()
```

[C#]

```
public void DelLine();
```

See Also

Terminal Class | SocketTools Namespace

Terminal.Deselect Method

Deselects any selected text in the display.

[Visual Basic]

```
Public Sub Deselect()
```

[C#]

```
public void Deselect();
```

Remarks

The **Deselect** method deselects any text that has been previously selected using the **Select** method, or by the user using the mouse if the **AutoSelect** property has been set to **true**.

See Also

Terminal Class | SocketTools Namespace

Terminal.Dispose Method

Releases the unmanaged resources allocated by the Terminal class and optionally releases the managed resources.

Overload List

Inherited from Component.

public void Dispose();

Releases the unmanaged resources allocated by the Terminal class and optionally releases the managed resources.

protected override void Dispose(bool);

See Also

Terminal Class | SocketTools Namespace

Terminal.Dispose Method (Boolean)

Releases the unmanaged resources allocated by the Terminal class and optionally releases the managed resources.

[Visual Basic]

```
Overrides Overloads Protected Sub Dispose( _
   ByVal disposing As Boolean _
)
```

[C#]

```
protected override void Dispose(
   bool disposing
);
```

Parameters

disposing

A boolean value which should be specified as **true** to release both managed and unmanaged resources; **false** to release only unmanaged resources.

Remarks

The **Dispose** method releases the resources allocated for this instance of the class. In some cases, better performance can be achieved if the programmer explicitly releases resources when they are no longer being used. The **Dispose** method provides explicit control over these resources.

Unlike the **Uninitialize** method, once the **Dispose** method has been called, that instance of the class cannot be re-initialized and you should not attempt to access class properties or invoke any methods. Note that this method can be called even if other references to the object are active.

You should call **Dispose** in your derived class when you are finished using the derived class. The **Dispose** method leaves the derived class in an unusable state. After calling **Dispose**, you must release all references to the derived class and the **Terminal** class so the memory they were occupying can be reclaimed by garbage collection.

See Also

Terminal Class | SocketTools Namespace | Terminal.Dispose Overload List

Terminal.Finalize Method

Destroys an instance of the control, releasing the resources allocated for the virtual display.

[Visual Basic]

```
Overrides Protected Sub Finalize()
```

[C#]

```
protected override void Finalize();
```

See Also

Terminal Class | SocketTools Namespace

Terminal.Initialize Method

Initialize an instance of the Terminal control.

Overload List

Initialize an instance of the Terminal control.

public bool Initialize();

Initialize an instance of the Terminal control.

public bool Initialize(string);

See Also

Terminal Class | SocketTools Namespace | Uninitialize Method

Terminal.Initialize Method ()

Initialize an instance of the Terminal control.

[Visual Basic]
```
Overloads Public Function Initialize() As Boolean
```

[C#]
```
public bool Initialize();
```

Return Value

A boolean value which specifies if the class was initialized successfully.

Remarks

The **Initialize** method can be used to explicitly initialize an instance of the Terminal control and allocating resources for the current thread. Typically it is not necessary to explicitly call this method because the instance of the class is initialized by the class constructor. However, if the **Uninitialize** method is called, the control must be re-initialized before any other methods are called.

See Also

Terminal Class | SocketTools Namespace | Terminal.Initialize Overload List | Uninitialize Method

Terminal.Initialize Method (String)

Initialize an instance of the Terminal control.

[Visual Basic]

```
Overloads Public Function Initialize( _
   ByVal licenseKey As String _
) As Boolean
```

[C#]

```
public bool Initialize(
   string licenseKey
);
```

Parameters

licenseKey

A string argument which specifies the runtime license key which will be used to initialize the control.

Return Value

A boolean value which specifies if the control was initialized successfully.

Remarks

The **Initialize** method can be used to explicitly initialize an instance of the Terminal control. Typically an application would define the license key as a custom attribute, however this method can be used to initialize the class directly.

The runtime license key for your copy of SocketTools can be generated using the License Manager utility that is included with the product. Note that if you have installed an evaluation license, you will not have a runtime license key and cannot redistribute any applications which use the Terminal control.

See Also

Terminal Class | SocketTools Namespace | Terminal.Initialize Overload List | RuntimeLicenseAttribute Class | Uninitialize Method

Terminal.InsLine Method

Insert an empty line at the current position in the terminal emulation display.

[Visual Basic]

```
Public Sub InsLine()
```

[C#]

```
public void InsLine();
```

See Also

Terminal Class | SocketTools Namespace

Terminal.OnBackColorChanged Method

Raises the BackColorChanged event.

[Visual Basic]
```
<EditorBrowsable(State:=EditorBrowsableState.Advanced)>
Overrides Protected Sub OnBackColorChanged( _
   ByVal e As EventArgs _
)
```

[C#]
```
[EditorBrowsable(State=EditorBrowsableState.Advanced)]
protected override void OnBackColorChanged(
   EventArgs e
);
```

Parameters

e

An EventArgs that contains the event data.

See Also

Terminal Class | SocketTools Namespace

Terminal.OnFontChanged Method

Raises the FontChanged event.

```
[Visual Basic]
<EditorBrowsable(State:=EditorBrowsableState.Advanced)>
Overrides Protected Sub OnFontChanged( _
   ByVal e As EventArgs _
)
```

```
[C#]
[EditorBrowsable(State=EditorBrowsableState.Advanced)]
protected override void OnFontChanged(
   EventArgs e
);
```

Parameters

e

An EventArgs that contains the event data.

See Also

Terminal Class | SocketTools Namespace

Terminal.OnForeColorChanged Method

Raises the ForeColorChanged event.

[Visual Basic]
```
<EditorBrowsable(State:=EditorBrowsableState.Advanced)>
Overrides Protected Sub OnForeColorChanged( _
   ByVal e As EventArgs _
)
```

[C#]
```
[EditorBrowsable(State=EditorBrowsableState.Advanced)]
protected override void OnForeColorChanged(
   EventArgs e
);
```

Parameters

e

An EventArgs that contains the event data.

See Also

Terminal Class | SocketTools Namespace

Terminal.OnGotFocus Method

Raises the GotFocus event.

[Visual Basic]

```
<EditorBrowsable(State:=EditorBrowsableState.Advanced)>
Overrides Protected Sub OnGotFocus( _
   ByVal e As EventArgs _
)
```

[C#]

```
[EditorBrowsable(State=EditorBrowsableState.Advanced)]
protected override void OnGotFocus(
   EventArgs e
);
```

Parameters

e

An EventArgs that contains the event data.

See Also

Terminal Class | SocketTools Namespace

Terminal.OnLostFocus Method

Raises the LostFocus event.

[Visual Basic]
```
<EditorBrowsable(State:=EditorBrowsableState.Advanced)>
Overrides Protected Sub OnLostFocus( _
   ByVal e As EventArgs _
)
```

[C#]
```
[EditorBrowsable(State=EditorBrowsableState.Advanced)]
protected override void OnLostFocus(
   EventArgs e
);
```

Parameters

e

An EventArgs that contains the event data.

See Also

Terminal Class | SocketTools Namespace

Terminal.OnMouseDown Method

Raises the MouseDown event.

[Visual Basic]

```
<EditorBrowsable(State:=EditorBrowsableState.Advanced)>
Overrides Protected Sub OnMouseDown( _
   ByVal e As MouseEventArgs _
)
```

[C#]

```
[EditorBrowsable(State=EditorBrowsableState.Advanced)]
protected override void OnMouseDown(
   MouseEventArgs e
);
```

Parameters

e

A MouseEventArgs that contains the event data.

See Also

Terminal Class | SocketTools Namespace

Terminal.OnMouseMove Method

Raises the MouseMove event.

[Visual Basic]

```
<EditorBrowsable(State:=EditorBrowsableState.Advanced)>
Overrides Protected Sub OnMouseMove( _
   ByVal e As MouseEventArgs _
)
```

[C#]

```
[EditorBrowsable(State=EditorBrowsableState.Advanced)]
protected override void OnMouseMove(
   MouseEventArgs e
);
```

Parameters

e

A MouseEventArgs that contains the event data.

See Also

Terminal Class | SocketTools Namespace

Terminal.OnMouseUp Method

Raises the MouseUp event.

```
[Visual Basic]
<EditorBrowsable(State:=EditorBrowsableState.Advanced)>
Overrides Protected Sub OnMouseUp( _
   ByVal e As MouseEventArgs _
)
```

```
[C#]
[EditorBrowsable(State=EditorBrowsableState.Advanced)]
protected override void OnMouseUp(
   MouseEventArgs e
);
```

Parameters

e

A MouseEventArgs that contains the event data.

See Also

Terminal Class | SocketTools Namespace

Terminal.OnPaint Method

Raises the Paint event.

[Visual Basic]

```
<EditorBrowsable(State:=EditorBrowsableState.Advanced)>
Overrides Protected Sub OnPaint( _
   ByVal e As PaintEventArgs _
)
```

[C#]

```
[EditorBrowsable(State=EditorBrowsableState.Advanced)]
protected override void OnPaint(
   PaintEventArgs e
);
```

Parameters

e

A PaintEventArgs that contains the event data.

See Also

Terminal Class | SocketTools Namespace

Terminal.OnParentChanged Method

Raises the ParentChanged event.

[Visual Basic]

```
<EditorBrowsable(State:=EditorBrowsableState.Advanced)>
Overrides Protected Sub OnParentChanged( _
   ByVal e As EventArgs _
)
```

[C#]

```
[EditorBrowsable(State=EditorBrowsableState.Advanced)]
protected override void OnParentChanged(
   EventArgs e
);
```

Parameters

e

An EventArgs that contains the event data.

See Also

Terminal Class | SocketTools Namespace

Terminal.OnResize Method

Raises the Resize event.

[Visual Basic]
```
<EditorBrowsable(State:=EditorBrowsableState.Advanced)>
Overrides Protected Sub OnResize( _
   ByVal e As EventArgs _
)
```

[C#]
```
[EditorBrowsable(State=EditorBrowsableState.Advanced)]
protected override void OnResize(
   EventArgs e
);
```

Parameters

e

An EventArgs that contains the event data.

See Also

Terminal Class | SocketTools Namespace

Terminal.PreProcessMessage Method

Preprocesses input messages within the message loop before they are dispatched.

[Visual Basic]

```
Overrides Public Function PreProcessMessage( _
   ByRef msg As Message _
) As Boolean
```

[C#]

```
public override bool PreProcessMessage(
   ref Message msg
);
```

Parameters

msg

A Message passed by reference, that represents the message to process.

Return Value

A value of **true** if the message was processed by the control; otherwise, **false**.

Remarks

PreProcessMessage is called by the application's message loop to preprocess input messages before they are dispatched. Possible values for the msg.message field are WM_KEYDOWN, WM_SYSKEYDOWN, WM_CHAR, and WM_SYSCHAR.

When overriding **preProcessMessage()**, a control should return **true** to indicate that it has processed the message. For messages that are not processed by the control, the result of **base.preProcessMessage()** should be returned. Controls will typically override one of the more specialized methods such as **isInputChar()**, **isInputKey()**, **processCmdKey()**, **processDialogChar()**, or **processDialogKey()** instead of overriding **preProcessMessage()**.

See Also

Terminal Class | SocketTools Namespace

Terminal.Refresh Method

Forces a complete redraw of the virtual display.

[Visual Basic]

```
Overrides Public Sub Refresh()
```

[C#]

```
public override void Refresh();
```

Remarks

The **Refresh** method forces the control to redraw the virtual display. Normally, the virtual display is automatically redrawn after the display has been modified and there are no other events being processed. However, there may be situations where you want the display updated immediately.

To prevent the control from automatically redrawing the window when the virtual display has been modified, set the **AutoRefresh** property to **false**. You can then call the **Refresh** method to force the control to be redrawn as needed

See Also

Terminal Class | SocketTools Namespace

Terminal.Reset Method

Reset the internal state of the control, resetting all properties to their default values.

[Visual Basic]
```
Public Sub Reset()
```

[C#]
```
public void Reset();
```

See Also

Terminal Class | SocketTools Namespace

Terminal.ScrollDown Method

Scroll the display down by one line.

[Visual Basic]

```
Public Sub ScrollDown()
```

[C#]

```
public void ScrollDown();
```

See Also

Terminal Class | SocketTools Namespace

Terminal.ScrollUp Method

Scroll the display up by one line.

[Visual Basic]

```
Public Sub ScrollUp()
```

[C#]

```
public void ScrollUp();
```

Terminal Class | SocketTools Namespace

Terminal.SelectText Method

Selects a region of the virtual display and returns the selected text.

Overload List

Selects a region of the virtual display and returns the selected text.

public string SelectText();

Selects a region of the virtual display and returns the selected text.

public string SelectText(int,int);

Selects a region of the virtual display and returns the selected text.

public string SelectText(int,int,int,int);

Selects a region of the virtual display and returns the selected text.

public string SelectText(int,int,int,int,TerminalSelection);

See Also

Terminal Class | SocketTools Namespace

Terminal.SelectText Method ()

Selects a region of the virtual display and returns the selected text.

[Visual Basic]
```
Overloads Public Function SelectText() As String
```

[C#]
```
public string SelectText();
```

Return Value

A string which contains the selected text.

Remarks

The **Select** method selects the entire contents of the virtual display. If the method fails because incorrect row or column values were used, or because an invalid option was specified, it will return an empty string.

See Also

Terminal Class | SocketTools Namespace | Terminal.SelectText Overload List

Terminal.SelectText Method (Int32, Int32)

Selects a region of the virtual display and returns the selected text.

[Visual Basic]

```
Overloads Public Function SelectText( _
   ByVal column As Integer, _
   ByVal row As Integer _
) As String
```

[C#]

```
public string SelectText(
   int column,
   int row
);
```

Parameters

column

An integer value which specifies the starting column for the text selection.

row

An integer value which specifies the starting row for the text selection.

Return Value

A string which contains the selected text.

Remarks

The **Select** method selects a region of the virtual display, from the specified column and row to the end of the virtual display. This enables the application to select text in the same way that a user would by clicking and dragging the mouse over the display window. If the method fails because incorrect row or column values were used, or because an invalid option was specified, it will return an empty string.

See Also

Terminal Class | SocketTools Namespace | Terminal.SelectText Overload List

Terminal.SelectText Method (Int32, Int32, Int32, Int32)

Selects a region of the virtual display and returns the selected text.

[Visual Basic]

```
Overloads Public Function SelectText( _
   ByVal column1 As Integer, _
   ByVal row1 As Integer, _
   ByVal column2 As Integer, _
   ByVal row2 As Integer _
) As String
```

[C#]

```
public string SelectText(
   int column1,
   int row1,
   int column2,
   int row2
);
```

Parameters

column1
An integer value which specifies the starting column for the text selection.

row1
An integer value which specifies the starting row for the text selection.

column2
An integer value which specifies the ending column for the text selection.

row2
An integer value which specifies the ending row for the text selection.

Return Value

A string which contains the selected text.

Remarks

The **Select** method selects a region of the virtual display. This enables the application to select text in the same way that a user would by clicking and dragging the mouse over the display window. If the method fails because incorrect row or column values were used, or because an invalid option was specified, it will return an empty string.

See Also

Terminal Class | SocketTools Namespace | Terminal.SelectText Overload List

Terminal.SelectText Method (Int32, Int32, Int32, Int32, TerminalSelection)

Selects a region of the virtual display and returns the selected text.

[Visual Basic]

```
Overloads Public Function SelectText( _
   ByVal column1 As Integer, _
   ByVal row1 As Integer, _
   ByVal column2 As Integer, _
   ByVal row2 As Integer, _
   ByVal options As TerminalSelection _
) As String
```

[C#]

```
public string SelectText(
   int column1,
   int row1,
   int column2,
   int row2,
   TerminalSelection options
);
```

Parameters

column1

An integer value which specifies the starting column for the text selection.

row1

An integer value which specifies the starting row for the text selection.

column2

An integer value which specifies the ending column for the text selection.

row2

An integer value which specifies the ending row for the text selection.

options

A TerminalSelection enumeration value which specifies one or more selection options.

Return Value

A string which contains the selected text.

Remarks

The **Select** method selects a region of the virtual display. This enables the application to select text in the same way that a user would by clicking and dragging the mouse over the display window. If the method fails because incorrect row or column values were used, or because an invalid option was specified, it will return an empty string.

See Also

Terminal Class | SocketTools Namespace | Terminal.SelectText Overload List

Terminal.Uninitialize Method

Uninitialize the control and release any resources allocated for the current process.

[Visual Basic]

```
Public Sub Uninitialize()
```

[C#]

```
public void Uninitialize();
```

Remarks

The **Uninitialize** destroys the virtual display and releases resources allocated for the current thread. After this method has been called, the control must re-initialized before it can be used.

If the **Initialize** method is explicitly called by the application, it should be matched by a call to the **Uninitialize** method when that instance of the control is no longer needed.

Terminal Class | SocketTools Namespace

Terminal.WndProc Method

Processes Windows messages.

```
[Visual Basic]
<EditorBrowsable(State:=EditorBrowsableState.Advanced)>
Overrides Protected Sub WndProc( _
   ByRef m As Message _
)
```

```
[C#]
[EditorBrowsable(State=EditorBrowsableState.Advanced)]
protected override void WndProc(
   ref Message m
);
```

Parameters

m

The Windows message to process.

Remarks

All messages are sent to the **WndProc** method after getting filtered through the PreProcessMessage method. The **WndProc** method corresponds exactly to the Windows WindowProc function. For more information about processing Windows messages, see the WindowProc function documentation in the Windows Platform SDK reference located in the MSDN Library.

Terminal Class | SocketTools Namespace

Terminal.Write Method

Write the contents of a byte array to the virtual display.

Overload List

Write the contents of a byte array to the virtual display.

public bool Write(byte[]);

Write the contents of a byte array to the virtual display.

public bool Write(byte[],int);

Write a character to the virtual display.

public bool Write(char);

Write one or more characters to the virtual display.

public bool Write(char,int);

Write the contents of a string to the virtual display.

public bool Write(string);

Write the contents of a string to the virtual display.

public bool Write(string,int);

See Also

Terminal Class | SocketTools Namespace

Terminal.Write Method (Byte[])

Write the contents of a byte array to the virtual display.

[Visual Basic]

```
Overloads Public Function Write( _
   ByVal buffer As Byte() _
) As Boolean
```

[C#]

```
public bool Write(
   byte[] buffer
);
```

Parameters

buffer
A byte array which contains the data to be written to the virtual display.

Return Value

A boolean value which specifies if the operation completed successfully. A return value of **false** indicates an error has occurred.

Remarks

The **Write** method writes the data in the specified byte array to the virtual display at the current cursor location. If the data contains control characters or escape sequences, they will be processed according the **Emulation** property setting.

See Also

Terminal Class | SocketTools Namespace | Terminal.Write Overload List

Terminal.Write Method (Byte[], Int32)

Write the contents of a byte array to the virtual display.

[Visual Basic]

```
Overloads Public Function Write( _
   ByVal buffer As Byte(), _
   ByVal length As Integer _
) As Boolean
```

[C#]

```
public bool Write(
   byte[] buffer,
   int length
);
```

Parameters

buffer

A byte array which contains the data to be written to the virtual display.

length

An integer value which specifies the maximum number of bytes of data to write. This value cannot be larger than the size of the buffer specified by the caller.

Return Value

A boolean value which specifies if the operation completed successfully. A return value of **false** indicates an error has occurred.

Remarks

The **Write** method writes the data in the specified byte array to the virtual display at the current cursor location. If the data contains control characters or escape sequences, they will be processed according the **Emulation** property setting.

See Also

Terminal Class | SocketTools Namespace | Terminal.Write Overload List

Terminal.Write Method (Char)

Write a character to the virtual display.

[Visual Basic]

```
Overloads Public Function Write( _
   ByVal character As Char _
) As Boolean
```

[C#]

```
public bool Write(
   char character
);
```

Parameters

character

A character which will be written to the virtual display.

Return Value

A boolean value which specifies if the operation completed successfully. A return value of **false** indicates an error has occurred.

Remarks

The **Write** method writes one character to the virtual display at the current cursor location. If a control characters is specified, it will be processed according the **Emulation** property setting.

See Also

Terminal Class | SocketTools Namespace | Terminal.Write Overload List

Terminal.Write Method (Char, Int32)

Write one or more characters to the virtual display.

[Visual Basic]

```
Overloads Public Function Write( _
   ByVal character As Char, _
   ByVal repeat As Integer _
) As Boolean
```

[C#]

```
public bool Write(
   char character,
   int repeat
);
```

Parameters

character

A character which will be written to the virtual display.

repeat

The number of characters that will be written.

Return Value

A boolean value which specifies if the operation completed successfully. A return value of **false** indicates an error has occurred.

Remarks

The **Write** method writes the specified character to the virtual display at the current cursor location. If one or more control characters are specified, they will be processed according the **Emulation** property setting.

See Also

Terminal Class | SocketTools Namespace | Terminal.Write Overload List

Terminal.Write Method (String)

Write the contents of a string to the virtual display.

[Visual Basic]

```
Overloads Public Function Write( _
   ByVal buffer As String _
) As Boolean
```

[C#]

```
public bool Write(
   string buffer
);
```

Parameters

buffer
A string which contains the data to be written to the virtual display.

Return Value

A boolean value which specifies if the operation completed successfully. A return value of **false** indicates an error has occurred.

Remarks

The **Write** method writes the data in the specified string to the virtual display at the current cursor location. If the data contains control characters or escape sequences, they will be processed according the **Emulation** property setting.

See Also

Terminal Class | SocketTools Namespace | Terminal.Write Overload List

Terminal.Write Method (String, Int32)

Write the contents of a string to the virtual display.

[Visual Basic]

```
Overloads Public Function Write( _
   ByVal buffer As String, _
   ByVal length As Integer _
) As Boolean
```

[C#]

```
public bool Write(
   string buffer,
   int length
);
```

Parameters

buffer

A string which contains the data to be written to the virtual display.

length

An integer value which specifies the maximum number of bytes of data to write. This value cannot be larger than the size of the buffer specified by the caller.

Return Value

A boolean value which specifies if the operation completed successfully. A return value of **false** indicates an error has occurred.

Remarks

The **Write** method writes the data in the specified string to the virtual display at the current cursor location. If the data contains control characters or escape sequences, they will be processed according the **Emulation** property setting.

Terminal Events

The events of the **Terminal** class are listed below. For a complete list of **Terminal** class members, see the Terminal Members topic.

Public Instance Events

BackColorChanged (inherited from Control)	Occurs when the value of the BackColor property changes.
BackgroundImageChanged (inherited from Control)	Occurs when the value of the BackgroundImage property changes.
BindingContextChanged (inherited from Control)	Occurs when the value of the BindingContext property changes.
CausesValidationChanged (inherited from Control)	Occurs when the value of the CausesValidation property changes.
ChangeUICues (inherited from Control)	Occurs when the focus or keyboard user interface (UI) cues change.
Click (inherited from Control)	Occurs when the control is clicked.
ContextMenuChanged (inherited from Control)	Occurs when the value of the ContextMenu property changes.
ControlAdded (inherited from Control)	Occurs when a new control is added to the ControlCollection .
ControlRemoved (inherited from Control)	Occurs when a control is removed from the ControlCollection .
CursorChanged (inherited from Control)	Occurs when the value of the Cursor property changes.
Disposed (inherited from Component)	Adds an event handler to listen to the Disposed event on the component.
DockChanged (inherited from Control)	Occurs when the value of the Dock property changes.
DoubleClick (inherited from Control)	Occurs when the control is double-clicked.
DragDrop (inherited from Control)	Occurs when a drag-and-drop operation is completed.
DragEnter (inherited from Control)	Occurs when an object is dragged into the control's bounds.
DragLeave (inherited from Control)	Occurs when an object is dragged out of the control's bounds.
DragOver (inherited from Control)	Occurs when an object is dragged over the control's bounds.
EnabledChanged (inherited from Control)	Occurs when the Enabled property value has changed.
Enter (inherited from Control)	Occurs when the control is entered.
FontChanged (inherited from Control)	Occurs when the Font property value changes.

⚡ ForeColorChanged (inherited from Control)	Occurs when the ForeColor property value changes.
⚡ GiveFeedback (inherited from Control)	Occurs during a drag operation.
⚡ GotFocus (inherited from Control)	Occurs when the control receives focus.
⚡ HandleCreated (inherited from Control)	Occurs when a handle is created for the control.
⚡ HandleDestroyed (inherited from Control)	Occurs when the control's handle is in the process of being destroyed.
⚡ HelpRequested (inherited from Control)	Occurs when the user requests help for a control.
⚡ ImeModeChanged (inherited from Control)	Occurs when the ImeMode property has changed.
⚡ Invalidated (inherited from Control)	Occurs when a control's display requires redrawing.
⚡ KeyDown (inherited from Control)	Occurs when a key is pressed while the control has focus.
⚡ KeyMapped	Occurs when a mapped key is pressed.
⚡ KeyPress (inherited from Control)	Occurs when a key is pressed while the control has focus.
⚡ KeyUp (inherited from Control)	Occurs when a key is released while the control has focus.
⚡ Layout (inherited from Control)	Occurs when a control should reposition its child controls.
⚡ Leave (inherited from Control)	Occurs when the input focus leaves the control.
⚡ Load (inherited from UserControl)	Occurs before the control becomes visible for the first time.
⚡ LocationChanged (inherited from Control)	Occurs when the Location property value has changed.
⚡ LostFocus (inherited from Control)	Occurs when the control loses focus.
⚡ MouseDown (inherited from Control)	Occurs when the mouse pointer is over the control and a mouse button is pressed.
⚡ MouseEnter (inherited from Control)	Occurs when the mouse pointer enters the control.
⚡ MouseHover (inherited from Control)	Occurs when the mouse pointer hovers over the control.
⚡ MouseLeave (inherited from Control)	Occurs when the mouse pointer leaves the control.
⚡ MouseMove (inherited from Control)	Occurs when the mouse pointer is moved over the control.
⚡ MouseUp (inherited from Control)	Occurs when the mouse pointer is over the control and a mouse button is released.
⚡ MouseWheel (inherited from Control)	Occurs when the mouse wheel moves while the control has focus.
⚡ Move (inherited from Control)	Occurs when the control is moved.
⚡ Paint (inherited from Control)	Occurs when the control is redrawn.

⚡ ParentChanged (inherited from Control)	Occurs when the Parent property value changes.
⚡ QueryAccessibilityHelp (inherited from Control)	Occurs when AccessibleObject is providing help to accessibility applications.
⚡ QueryContinueDrag (inherited from Control)	Occurs during a drag-and-drop operation and allows the drag source to determine whether the drag-and-drop operation should be canceled.
⚡ Resize (inherited from Control)	Occurs when the control is resized.
⚡ RightToLeftChanged (inherited from Control)	Occurs when the RightToLeft property value changes.
⚡ SizeChanged (inherited from Control)	Occurs when the Size property value changes.
⚡ StyleChanged (inherited from Control)	Occurs when the control style changes.
⚡ SystemColorsChanged (inherited from Control)	Occurs when the system colors change.
⚡ TabIndexChanged (inherited from Control)	Occurs when the TabIndex property value changes.
⚡ TabStopChanged (inherited from Control)	Occurs when the TabStop property value changes.
⚡ TextChanged (inherited from UserControl)	
⚡ Validated (inherited from Control)	Occurs when the control is finished validating.
⚡ Validating (inherited from Control)	Occurs when the control is validating.
⚡ VisibleChanged (inherited from Control)	Occurs when the Visible property value changes.

Terminal Class | SocketTools Namespace

Terminal.KeyMapped Event

Occurs when a mapped key is pressed.

[Visual Basic]
```
Public Event KeyMapped As KeyMappedEventHandler
```

[C#]
```
public event KeyMappedEventHandler KeyMapped;
```

Event Data

The event handler receives an argument of type Terminal.KeyMappedEventArgs containing data related to this event. The following **Terminal.KeyMappedEventArgs** properties provide information specific to this event.

Property	Description
Alt	Gets a value indicating whether the ALT key was pressed.
Control	Gets a value indicating whether the CTRL key was pressed.
KeyCode	Gets a value which specifies the key that was pressed.
KeyValue	Gets the escape sequence mapped to the special key.
Shift	Gets a value indicating whether the SHIFT key was pressed.

Remarks

This event is generated when the user presses a special key while the emulation window has focus, and that key is mapped to a string using the KeyMap array.

See Also

Terminal Class | SocketTools Namespace

Terminal.KeyMappedEventArgs Class

Provides data for the KeyMapped event.

For a list of all members of this type, see Terminal.KeyMappedEventArgs Members.

System.Object
  System.EventArgs
    SocketTools.Terminal.KeyMappedEventArgs

[Visual Basic]

```
Public Class Terminal.KeyMappedEventArgs
    Inherits EventArgs
```

[C#]

```
public class Terminal.KeyMappedEventArgs : EventArgs
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

The **KeyMapped** event is generated when the user presses a special key while the emulation window has focus, and that key is mapped to a string using the KeyMap array.

Requirements

Namespace: SocketTools

Assembly: SocketTools.Terminal (in SocketTools.Terminal.dll)

See Also

Terminal.KeyMappedEventArgs Members | SocketTools Namespace

Terminal.KeyMappedEventArgs Members

Terminal.KeyMappedEventArgs overview

Public Instance Constructors

Terminal.KeyMappedEventArgs Constructor	Initializes a new instance of the Terminal.KeyMappedEventArgs class.

Public Instance Properties

Alt	Gets a value indicating whether the ALT key was pressed.
Control	Gets a value indicating whether the CTRL key was pressed.
KeyCode	Gets a value which specifies the key that was pressed.
KeyValue	Gets the escape sequence mapped to the special key.
Shift	Gets a value indicating whether the SHIFT key was pressed.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString (inherited from Object)	Returns a String that represents the current Object.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

Terminal.KeyMappedEventArgs Class | SocketTools Namespace

Terminal.KeyMappedEventArgs Properties

The properties of the **Terminal.KeyMappedEventArgs** class are listed below. For a complete list of **Terminal.KeyMappedEventArgs** class members, see the Terminal.KeyMappedEventArgs Members topic.

Public Instance Properties

Alt	Gets a value indicating whether the ALT key was pressed.
Control	Gets a value indicating whether the CTRL key was pressed.
KeyCode	Gets a value which specifies the key that was pressed.
KeyValue	Gets the escape sequence mapped to the special key.
Shift	Gets a value indicating whether the SHIFT key was pressed.

See Also

Terminal.KeyMappedEventArgs Class | SocketTools Namespace

Terminal.KeyMappedEventArgs.Alt Property

Gets a value indicating whether the ALT key was pressed.

[Visual Basic]

```
Public ReadOnly Property Alt As Boolean
```

[C#]

```
public bool Alt {get;}
```

Property Value

A boolean value that is **true** if the ALT key was pressed; otherwise, **false**.

See Also

Terminal.KeyMappedEventArgs Class | SocketTools Namespace

Terminal.KeyMappedEventArgs.Control Property

Gets a value indicating whether the CTRL key was pressed.

[Visual Basic]

```
Public ReadOnly Property Control As Boolean
```

[C#]

```
public bool Control {get;}
```

Property Value

A boolean value that is **true** if the CTRL key was pressed; otherwise, **false**.

See Also

Terminal.KeyMappedEventArgs Class | SocketTools Namespace

Terminal.KeyMappedEventArgs.KeyCode Property

Gets a value which specifies the key that was pressed.

[Visual Basic]

```
Public ReadOnly Property KeyCode As TerminalKey
```

[C#]

```
public Terminal.TerminalKey KeyCode {get;}
```

Property Value

A TerminalKey enumeration value which specifies the key that was pressed.

See Also

Terminal.KeyMappedEventArgs Class | SocketTools Namespace

Terminal.KeyMappedEventArgs.KeyValue Property

Gets the escape sequence mapped to the special key.

[Visual Basic]

```
Public ReadOnly Property KeyValue As String
```

[C#]

```
public string KeyValue {get;}
```

Property Value

A string which specifies the escape sequence mapped to the key that was pressed.

See Also

Terminal.KeyMappedEventArgs Class | SocketTools Namespace

Terminal.KeyMappedEventArgs.Shift Property

Gets a value indicating whether the SHIFT key was pressed.

[Visual Basic]

```
Public ReadOnly Property Shift As Boolean
```

[C#]

```
public bool Shift {get;}
```

Property Value

A boolean value that is **true** if the SHIFT key was pressed; otherwise, **false**.

Terminal.KeyMappedEventArgs Class | SocketTools Namespace

Terminal.ErrorCode Enumeration

Specifies the error codes returned by the HttpClient class.

[Visual Basic]
```
Public Enum Terminal.ErrorCode
```

[C#]
```
public enum Terminal.ErrorCode
```

Remarks

The HttpClient class uses the **ErrorCode** enumeration to specify what error has occurred when a method fails. The current error code may be determined by checking the value of the **LastError** property.

Note that the last error code is only meaningful if the previous operation has failed.

Members

Member Name	Description
errorNone	No error.
errorNotHandleOwner	Handle not owned by the current thread.
errorOutOfMemory	The specified file or directory does not exist.Out of memory.
errorAccessDenied	Access denied.
errorInvalidParameter	Invalid argument passed to function.
errorClipboardUnavailable	The system clipboard is currently unavailable.
errorClipboardEmpty	The system clipboard is empty or does not contain any text data.
errorInvalidBuffer	Invalid memory address passed to function.
errorBufferTooSmall	The specified buffer is not large enough to contain the data.
errorNoHandles	No more handles are available to this process.
errorInvalidLicense	The license for this product is invalid.
errorProductNotLicensed	This product is not licensed to perform this operation.
errorNotImplemented	This function has not been implemented on this platform.

Requirements

Namespace: SocketTools

Assembly: SocketTools.Terminal (in SocketTools.Terminal.dll)

See Also

SocketTools Namespace

Terminal.TerminalCaret Enumeration

Specifies the caret styles supported by the Terminal control.

[Visual Basic]
```
Public Enum Terminal.TerminalCaret
```

[C#]
```
public enum Terminal.TerminalCaret
```

Members

Member Name	Description
None	No caret is displayed.
Underline	The caret is displayed as an underline.
Block	The caret is displayed as a block that is the full height of the character cell.

Requirements

Namespace: SocketTools

Assembly: SocketTools.Terminal (in SocketTools.Terminal.dll)

See Also

SocketTools Namespace

Terminal.TerminalAttributes Enumeration

Specifies the character cell attributes supported by the Terminal control.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

```
[Visual Basic]
<Flags>
Public Enum Terminal.TerminalAttributes
```

```
[C#]
[Flags]
public enum Terminal.TerminalAttributes
```

Members

Member Name	Description	Value
Normal	Normal, default attributes.	0
Reverse	Foreground and background cell colors are reversed.	1
Bold	The character is displayed using a higher intensity color.	2
Dim	The character is displayed using a lower intensity color.	4
Blink	This attribute is currently not supported.	8
Underline	The character is displayed with an underline.	16
Hidden	The character is stored in display memory, but not shown.	32
Protect	The character is protected and cannot be cleared.	64

Requirements

Namespace: SocketTools

Assembly: SocketTools.Terminal (in SocketTools.Terminal.dll)

See Also

SocketTools Namespace

Terminal.TerminalColor Enumeration

Specifies the colors supported by the Terminal control.

[Visual Basic]
```
Public Enum Terminal.TerminalColor
```

[C#]
```
public enum Terminal.TerminalColor
```

Remarks

A standard ANSI color terminal supports eight standard colors (0-7). To select a foreground color, you add 30 to the color index and pass that value as a parameter to the SGR (select graphic rendition) escape sequence. To select a background color, you add 40 to the color index. For example, to set the current foreground color to white and the background color to blue, you could send the following escape sequence:

```
ESC [ 37;44 m
```

Note that if you wanted to set the foreground color to a bold version of standard yellow, you would first set the bold attribute, and then use the index value of 3, such as:

```
ESC [ 1;33m
```

Changing the value of the ColorMap array allows the application to make selective changes to the actual RGB color value that is used when a color attribute is set. Note that changes to the color map will only affect new characters as they are displayed, not any previously displayed characters

Members

Member Name	Description
Black	Color value RGB(0,0,0)
Red	Color value RGB(160,0,0)
Green	Color value RGB(0,160,0)
Yellow	Color value RGB(160,160,0)
Blue	Color value RGB(0,0,160)
Magenta	Color value RGB(160,0,160)
Cyan	Color value RGB(0,160,160)
White	Color value RGB(224,224,224)
Gray	Color value RGB(192,192,192)
LtRed	Color value RGB(255,128,128)
LtGreen	Color value RGB(144,238,144)
LtYellow	Color value RGB(255,255,192)
LtBlue	Color value RGB(173,216,230)
LtMagenta	Color value RGB(255,192,255)
LtCyan	Color value RGB(224,255,255)

HiWhite	Color value RGB(255,255,255)

Requirements

Namespace: SocketTools

Assembly: SocketTools.Terminal (in SocketTools.Terminal.dll)

SocketTools Namespace

Terminal.TerminalEmulation Enumeration

Specifies the terminal emulation types supported by the Terminal class.

[Visual Basic]
```
Public Enum Terminal.TerminalEmulation
```

[C#]
```
public enum Terminal.TerminalEmulation
```

Members

Member Name	Description
None	The virtual display does not emulate any specific terminal type, and does not process any escape sequences.
ANSI	The virtual display will process ANSI escape sequences. The default keymap for an ANSI console is loaded. This is the default value.
VT100	The virtual display will process DEC VT100 escape sequences. The default keymap for a VT100 terminal is loaded.
VT220	The virtual display will process DEC VT220 escape sequences. The default keymap for a VT220 terminal is loaded.

Requirements

Namespace: SocketTools

Assembly: SocketTools.Terminal (in SocketTools.Terminal.dll)

See Also

SocketTools Namespace

Terminal.TerminalKey Enumeration

Specifies the special function keys which may be mapped by the Terminal control.

[Visual Basic]

```
Public Enum Terminal.TerminalKey
```

[C#]

```
public enum Terminal.TerminalKey
```

Remarks

This **TerminalKey** enumeration lists the constants which can be used as the index value with the KeyMap array to map control or escape sequences to certain keys. These values are also used by the KeyMapped event when the user presses a mapped key.

Members

Terminal.TerminalNewLine Enumeration

Specifies the end-of-line character sequences supported by the Terminal control.

[Visual Basic]
```
Public Enum Terminal.TerminalNewLine
```

[C#]
```
public enum Terminal.TerminalNewLine
```

Members

Member Name	Description
CRLF	A carriage return positions the cursor to the first column, and a linefeed advances the cursor to the next row, scrolling the display if necessary. This is the default value.
CR	A carriage return positions the cursor to the first column and advances to the next row, scrolling the display if necessary.
LF	A linefeed positions the cursor to the first column and advances to the next row, scrolling the display if necessary.

Requirements

Namespace: SocketTools

Assembly: SocketTools.Terminal (in SocketTools.Terminal.dll)

Terminal.TerminalScrollBars Enumeration

Specifies the scrollbar modes supported by the Terminal control.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]
```
<Flags>
Public Enum Terminal.TerminalScrollBars
```

[C#]
```
[Flags]
public enum Terminal.TerminalScrollBars
```

Remarks

Scrollbars are only displayed if needed. If the emulation window is large enough to display all of the columns and rows, no scrollbars will be drawn even if they are enabled.

Members

Member Name	Description	Value
None	Scrollbars are not displayed.	0
Horizontal	A horizontal scrollbar is displayed if necessary.	1
Vertical	A vertical scrollbar is displayed if necessary.	2
Both	Both a horizontal vertical scrollbars are displayed if necessary.	3

Requirements

Namespace: SocketTools

Assembly: SocketTools.Terminal (in SocketTools.Terminal.dll)

See Also

SocketTools Namespace

Terminal.TerminalSelection Enumeration

The selection options supported by the Terminal control.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]
```
<Flags>
Public Enum Terminal.TerminalSelection
```

[C#]
```
[Flags]
public enum Terminal.TerminalSelection
```

Members

Member Name	Description	Value
Default	The default selection option. If there is a region of the display already selected, it will be cleared and the new region is selected. The selected text is buffered and can be accessed using the **SelText** property.	0
Clipboard	Copy the selected text to the clipboard. If this option is not specified, the selected text is buffered and may be accessed using the **SelText** property.	1
NoRefresh	The display is not refreshed when the region is selected. This is useful if the application is going to be selecting multiple regions of the display, or combining more than one region, in order to minimize output to the window.	4096
NoBuffer	Do not buffer the text in the selected region of the display. The display will show any text as being selected, but it will not be available to the application. This can be useful if the application is going to select multiple regions and combine them.	8192
Combine	If there is already a region of the display that has been selected, the new region is combined with the previous region, selecting all of the text.	16384

Requirements

Namespace: SocketTools

Assembly: SocketTools.Terminal (in SocketTools.Terminal.dll)

Terminal.KeyMappedEventHandler Delegate

Represents the method that will handle the KeyMapped event

[Visual Basic]

```
Public Delegate Sub Terminal.KeyMappedEventHandler( _
   ByVal sender As Object, _
   ByVal e As KeyMappedEventArgs _
)
```

[C#]

```
public delegate void Terminal.KeyMappedEventHandler(
      object sender,
      KeyMappedEventArgs e
   );
```

Parameters

sender
: The source of the event.

e
: A KeyMappedEventArgs that contains the event data.

Remarks

When you create an **KeyMappedEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **KeyMappedEventHandler** delegate declaration.

Requirements

Namespace: SocketTools

Assembly: SocketTools.Terminal (in SocketTools.Terminal.dll)

See Also

SocketTools Namespace

Terminal.RuntimeLicenseAttribute Class

Attribute that defines the runtime license key for the class.

For a list of all members of this type, see Terminal.RuntimeLicenseAttribute Members.

System.Object
  System.Attribute
    SocketTools.Terminal.RuntimeLicenseAttribute

[Visual Basic]

```
<AttributeUsage(ValidOn:=AttributeTargets.Assembly, AllowMultiple:=False,
   Inherited:=True)>
Public Class Terminal.RuntimeLicenseAttribute
    Inherits Attribute
```

[C#]

```
[AttributeUsage(ValidOn=AttributeTargets.Assembly, AllowMultiple=False,
   Inherited=True)]
public class Terminal.RuntimeLicenseAttribute : Attribute
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

The RuntimeLicense attribute is used to define the runtime license key that will be used when an instance of the class is created. This attribute is defined in the assembly information module for the language, such as AssemblyInfo.cs when programming C#. The runtime license key must be defined if you wish to redistribute your application.

The runtime license key for your copy of SocketTools can be generated using the License Manager utility that is included with the product. Note that if you have installed an evaluation license, you will not have a runtime license key and cannot redistribute any applications which use the Terminal class.

Example

```
<Assembly: SocketTools.Terminal.RuntimeLicense("abcdefghijklmnop")>
```

```
[assembly: SocketTools.Terminal.RuntimeLicense("abcdefghijklmnop")]
```

Requirements

Namespace: SocketTools

Assembly: SocketTools.Terminal (in SocketTools.Terminal.dll)

See Also

Terminal.RuntimeLicenseAttribute Members | SocketTools Namespace

Terminal.RuntimeLicenseAttribute Members

Terminal.RuntimeLicenseAttribute overview

Public Instance Constructors

Terminal.RuntimeLicenseAttribute Constructor	Constructor for the RuntimeLicense attribute which defines the runtime license key.

Public Instance Properties

LicenseKey	Returns the value of the runtime license key.
TypeId (inherited from Attribute)	When implemented in a derived class, gets a unique identifier for this Attribute.

Public Instance Methods

Equals (inherited from Attribute)	
GetHashCode (inherited from Attribute)	Returns the hash code for this instance.
GetType (inherited from Object)	Gets the Type of the current instance.
IsDefaultAttribute (inherited from Attribute)	When overridden in a derived class, returns an indication whether the value of this instance is the default value for the derived class.
Match (inherited from Attribute)	When overridden in a derived class, returns a value indicating whether this instance equals a specified object.
ToString (inherited from Object)	Returns a String that represents the current Object.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

Terminal.RuntimeLicenseAttribute Class | SocketTools Namespace

Terminal.RuntimeLicenseAttribute Constructor

Constructor for the RuntimeLicense attribute which defines the runtime license key.

[Visual Basic]

```
Public Sub New( _
   ByVal licenseKey As String _
)
```

[C#]

```
public Terminal.RuntimeLicenseAttribute(
   string licenseKey
);
```

Parameters

licenseKey

A string argument which specifies the runtime license key which will be used to initialize the class library.

Remarks

The runtime license key for your copy of SocketTools can be generated using the License Manager utility that is included with the product. Note that if you have installed an evaluation license, you will not have a runtime license key and cannot redistribute any applications which use the Terminal class.

See Also

Terminal.RuntimeLicenseAttribute Class | SocketTools Namespace

Terminal.RuntimeLicenseAttribute Properties

The properties of the **Terminal.RuntimeLicenseAttribute** class are listed below. For a complete list of **Terminal.RuntimeLicenseAttribute** class members, see the Terminal.RuntimeLicenseAttribute Members topic.

Public Instance Properties

LicenseKey	Returns the value of the runtime license key.
TypeId (inherited from Attribute)	When implemented in a derived class, gets a unique identifier for this Attribute.

See Also

Terminal.RuntimeLicenseAttribute Class | SocketTools Namespace

Terminal.RuntimeLicenseAttribute.LicenseKey Property

Returns the value of the runtime license key.

[Visual Basic]

```
Public Property LicenseKey As String
```

[C#]

```
public string LicenseKey {get; set;}
```

Property Value

A string which contains the runtime license key.

See Also

Terminal.RuntimeLicenseAttribute Class | SocketTools Namespace

TerminalEmulationException Class

The exception that is thrown when an error occurs.

For a list of all members of this type, see TerminalEmulationException Members.

System.Object
  System.Exception
    System.ApplicationException
      SocketTools.TerminalEmulationException

[Visual Basic]

```
Public Class TerminalEmulationException
    Inherits ApplicationException
```

[C#]

```
public class TerminalEmulationException : ApplicationException
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

A TerminalEmulationException is thrown by the Terminal control when an error occurs.

The default constructor for the TerminalEmulationException class sets the **ErrorCode** property to the socket error that occurred.

Requirements

Namespace: SocketTools

Assembly: SocketTools.Terminal (in SocketTools.Terminal.dll)

See Also

TerminalEmulationException Members | SocketTools Namespace

TerminalEmulationException Members

TerminalEmulationException overview

Public Instance Constructors

TerminalEmulationException	Overloaded. Initializes a new instance of the TerminalEmulationException class.

Public Instance Properties

ErrorCode	Gets a value which specifies the error that caused the exception.
HelpLink (inherited from Exception)	Gets or sets a link to the help file associated with this exception.
InnerException (inherited from Exception)	Gets the Exception instance that caused the current exception.
Message	Gets a value which describes the error that caused the exception.
Number	Gets a value which specifies the numeric value of the error that caused the exception.
Source (inherited from Exception)	Gets or sets the name of the application or the object that causes the error.
StackTrace (inherited from Exception)	Gets a string representation of the frames on the call stack at the time the current exception was thrown.
TargetSite (inherited from Exception)	Gets the method that throws the current exception.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetBaseException (inherited from Exception)	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetObjectData (inherited from Exception)	When overridden in a derived class, sets the SerializationInfo with information about the exception.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString	Creates and returns a string representation of the current exception.

Protected Instance Properties

HResult (inherited from Exception)	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

TerminalEmulationException Class | SocketTools Namespace

TerminalEmulationException Constructor

Initializes a new instance of the TerminalEmulationException class.

Overload List

Initializes a new instance of the TerminalEmulationException class.

public TerminalEmulationException();

Initializes a new instance of the TerminalEmulationException class with the specified error code.

public TerminalEmulationException(int);

Initializes a new instance of the TerminalEmulationException class with the specified error message.

public TerminalEmulationException(string);

Initializes a new instance of the TerminalEmulationException class with the specified error message and a reference to the inner exception that is the cause of this exception.

public TerminalEmulationException(string,Exception);

See Also

TerminalEmulationException Class | SocketTools Namespace

TerminalEmulationException Constructor ()

Initializes a new instance of the TerminalEmulationException class.

[Visual Basic]

```
Overloads Public Sub New()
```

[C#]

```
public TerminalEmulationException();
```

Return Value

The ctor constructor sets the **ErrorCode** property to the last socket error that occurred. For more information about the errors that may occur, refer to the Terminal.ErrorCode enumeration.

See Also

TerminalEmulationException Class | SocketTools Namespace | TerminalEmulationException Constructor Overload List

TerminalEmulationException Constructor (String)

Initializes a new instance of the TerminalEmulationException class with the specified error message.

[Visual Basic]

```
Overloads Public Sub New( _
   ByVal message As String _
)
```

[C#]

```
public TerminalEmulationException(
   string message
);
```

Parameters

message

The error message that explains the reason for the exception.

Return Value

The content of the ***message*** parameter is intended to be understood by humans. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

See Also

TerminalEmulationException Class | SocketTools Namespace | TerminalEmulationException Constructor Overload List

TerminalEmulationException Constructor (String, Exception)

Initializes a new instance of the TerminalEmulationException class with the specified error message and a reference to the inner exception that is the cause of this exception.

[Visual Basic]

```
Overloads Public Sub New( _
   ByVal message As String, _
   ByVal innerException As Exception _
)
```

[C#]

```
public TerminalEmulationException(
   string message,
   Exception innerException
);
```

Parameters

message

The error message that explains the reason for the exception.

innerException

The exception that is the cause of the current exception. If the ***innerException*** parameter is not a null reference, the current exception is raised in a **catch** block that handles the inner exception.

Remarks

The content of the message parameter is intended to be understood by humans. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

An exception that is thrown as a direct result of a previous exception should include a reference to the previous exception in the **InnerException** property. The **InnerException** property returns the same value that is passed into the constructor, or a null reference if the **InnerException** property does not supply the inner exception value to the constructor.

TerminalEmulationException Class | SocketTools Namespace | TerminalEmulationException Constructor Overload List

TerminalEmulationException Constructor (Int32)

Initializes a new instance of the TerminalEmulationException class with the specified error code.

[Visual Basic]

```
Overloads Public Sub New( _
   ByVal code As Integer _
)
```

[C#]

```
public TerminalEmulationException(
   int code
);
```

Parameters

code

An integer value which specifies an error code.

Return Value

This constructor sets the **ErrorCode** property to the specified error code. For more information about the errors that may occur, refer to the Terminal.ErrorCode enumeration.

See Also

TerminalEmulationException Class | SocketTools Namespace | TerminalEmulationException Constructor Overload List

TerminalEmulationException Properties

The properties of the **TerminalEmulationException** class are listed below. For a complete list of **TerminalEmulationException** class members, see the TerminalEmulationException Members topic.

Public Instance Properties

ErrorCode	Gets a value which specifies the error that caused the exception.
HelpLink (inherited from Exception)	Gets or sets a link to the help file associated with this exception.
InnerException (inherited from Exception)	Gets the Exception instance that caused the current exception.
Message	Gets a value which describes the error that caused the exception.
Number	Gets a value which specifies the numeric value of the error that caused the exception.
Source (inherited from Exception)	Gets or sets the name of the application or the object that causes the error.
StackTrace (inherited from Exception)	Gets a string representation of the frames on the call stack at the time the current exception was thrown.
TargetSite (inherited from Exception)	Gets the method that throws the current exception.

Protected Instance Properties

HResult (inherited from Exception)	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception.

See Also

TerminalEmulationException Class | SocketTools Namespace

TerminalEmulationException.ErrorCode Property

Gets a value which specifies the error that caused the exception.

[Visual Basic]

```
Public ReadOnly Property ErrorCode As ErrorCode
```

[C#]

```
public Terminal.ErrorCode ErrorCode {get;}
```

Property Value

Returns a Terminal.ErrorCode enumeration value which specifies the error code

Remarks

The **ErrorCode** property returns the error code that specifies the cause of the exception.

The default constructor for the TerminalEmulationException class sets the error code to the last network error that occurred. For more information about the errors that may occur, refer to the Terminal.ErrorCode enumeration.

See Also

TerminalEmulationException Class | SocketTools Namespace

TerminalEmulationException.Message Property

Gets a value which describes the error that caused the exception.

[Visual Basic]
```
Overrides Public ReadOnly Property Message As String
```

[C#]
```
public override string Message {get;}
```

Property Value

A string which describes the error that caused the exception.

Remarks

The **Message** property returns a string which describes the error that caused the exception.

See Also

TerminalEmulationException Class | SocketTools Namespace

TerminalEmulationException.Number Property

Gets a value which specifies the numeric value of the error that caused the exception.

[Visual Basic]

```
Public ReadOnly Property Number As Integer
```

[C#]

```
public int Number {get;}
```

Property Value

An integer value that specifies the error that caused the exception.

Remarks

The **Number** property returns an integer value which specifies the numeric value of the error that caused the exception.

See Also

TerminalEmulationException Class | SocketTools Namespace

TerminalEmulationException Methods

The methods of the **TerminalEmulationException** class are listed below. For a complete list of **TerminalEmulationException** class members, see the TerminalEmulationException Members topic.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetBaseException (inherited from Exception)	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetObjectData (inherited from Exception)	When overridden in a derived class, sets the SerializationInfo with information about the exception.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString	Creates and returns a string representation of the current exception.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

TerminalEmulationException Class | SocketTools Namespace

TerminalEmulationException.ToString Method

Creates and returns a string representation of the current exception.

[Visual Basic]

```
Overrides Public Function ToString() As String
```

[C#]

```
public override string ToString();
```

Return Value

A string representation of the current exception.

Remarks

The **ToString** method returns a representation of the current exception that is intended to be understood by humans. Where the exception contains culture-sensitive data, the string representation returned by **ToString** is required to take into account the current system culture. Although there are no exact requirements for the format of the returned string, it should attempt to reflect the value of the object as perceived by the user.

This implementation of **ToString** obtains the numeric error code value and a description of the error that caused the current exception. If there is no error message or it is an empty string, then no error message is returned.

This method overrides **ApplicationException.ToString**.

See Also

TerminalEmulationException Class | SocketTools Namespace

TextMessage Class

Send text messages to a mobile communications device using a gateway service.

For a list of all members of this type, see TextMessage Members.

System.Object
 SocketTools.TextMessage

[Visual Basic]

```
Public Class TextMessage
    Implements IDisposable
```

[C#]

```
public class TextMessage : IDisposable
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

Short Message Service (SMS) is a text messaging service used by mobile communication devices to exchange brief text messages. Most service providers also provide gateway servers that can be used to send messages to a wireless device on their network using standard email protocols. The **SocketTools.TextMessage** class provides methods that can be used to determine the provider associated with a specific telephone number and send a text message to the device using the provider's mail gateway.

This class has been designed to assist developers in sending text message notifications as part of their application. For example, it can be used to enable your software to automatically send notifications when a specific event occurs, such as an error condition. This class is not designed to be used with software that will send out a large number of text messages to many users, and there are limitations on the number of messages that may be sent to different phone numbers over a short period of time. Because many recipients must pay a fee for each text message they receive, text messages should only be sent to those who explicitly request them.

Note: This component only supports service providers in North America and cannot be used to send text messages to mobile devices that use providers outside of the United States and Canada. Some service providers may prevent messages from being sent through their gateway to a user that does not have unlimited text messaging as part of their service agreement.

Requirements

Namespace: SocketTools

Assembly: SocketTools.TextMessage (in SocketTools.TextMessage.dll)

TextMessage overview

Public Instance Constructors

TextMessage Constructor	Initializes a new instance of the TextMessage class.

Public Instance Properties

Account	Gets and sets a value which specifies an account name used to authenticate a client session.
AuthType	Gets and sets the type of client authentication that should be used.
IsInitialized	Gets a value which indicates if the current instance of the class has been initialized successfully.
LastError	Gets and sets a value which specifies the last error that has occurred.
LastErrorString	Gets a value which describes the last error that has occurred.
Message	Gets and sets the current message text.
Password	Gets and sets the password used to authenticate the session.
PhoneNumber	Gets and sets the phone number for the mobile device.
Provider	Gets and sets the name of the preferred wireless service provider.
Providers	Gets a collection of known wireless service providers.
Relay	Enable or disable the use of an intermediate relay server to send messages.
Secure	Enable or disable secure connections to the server.
Sender	Gets and sets the value that identifies the sender of the message.
ServerName	Gets and sets the name of the server that is used to send messages.
ServerPort	Gets and sets the port number used to establish a connection.
ServiceType	Gets and sets the type of service used to send messages.
ThrowError	Gets and sets a value which specifies if method calls should throw exceptions when an error occurs.
Timeout	Gets and sets a value which specifies a timeout

	period in seconds.
Trace	Gets and sets a value which indicates if network function logging is enabled.
TraceFile	Gets and sets a value which specifies the name of the logfile.
TraceFlags	Gets and sets a value which specifies the client function tracing flags.
Urgent	Enable or disable the option that flags a message as urgent.
UserName	Gets and sets the user name or ID used to authenticate the session.
Version	Gets a value which returns the current version of the TextMessage class library.

Public Instance Methods

Dispose	Overloaded. Releases all resources used by TextMessage.
Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetAddress	Get the email address associated with the specified phone number.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetProvider	Get the name of the wireless service provider associated with a phone number.
GetType (inherited from Object)	Gets the Type of the current instance.
Initialize	Overloaded. Initialize an instance of the TextMessage class.
Reset	Reset the internal state of the object, resetting all properties to their default values.
SendMessage	Overloaded. Send a text message to the specified mobile device.
ToString (inherited from Object)	Returns a String that represents the current Object.
Uninitialize	Uninitialize the class library and release any resources allocated for the current thread.

Public Instance Events

OnError	Occurs when an client operation fails.

Protected Instance Methods

Dispose	Overloaded. Releases the unmanaged resources allocated by the TextMessage class and optionally

	releases the managed resources.
Finalize	Destroys an instance of the class, releasing the resources allocated for the session and unloading the networking library.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

TextMessage Properties

The properties of the **TextMessage** class are listed below. For a complete list of **TextMessage** class members, see the TextMessage Members topic.

Public Instance Properties

Account	Gets and sets a value which specifies an account name used to authenticate a client session.
AuthType	Gets and sets the type of client authentication that should be used.
IsInitialized	Gets a value which indicates if the current instance of the class has been initialized successfully.
LastError	Gets and sets a value which specifies the last error that has occurred.
LastErrorString	Gets a value which describes the last error that has occurred.
Message	Gets and sets the current message text.
Password	Gets and sets the password used to authenticate the session.
PhoneNumber	Gets and sets the phone number for the mobile device.
Provider	Gets and sets the name of the preferred wireless service provider.
Providers	Gets a collection of known wireless service providers.
Relay	Enable or disable the use of an intermediate relay server to send messages.
Secure	Enable or disable secure connections to the server.
Sender	Gets and sets the value that identifies the sender of the message.
ServerName	Gets and sets the name of the server that is used to send messages.
ServerPort	Gets and sets the port number used to establish a connection.
ServiceType	Gets and sets the type of service used to send messages.
ThrowError	Gets and sets a value which specifies if method calls should throw exceptions when an error occurs.
Timeout	Gets and sets a value which specifies a timeout period in seconds.
Trace	Gets and sets a value which indicates if network

	function logging is enabled.
TraceFile	Gets and sets a value which specifies the name of the logfile.
TraceFlags	Gets and sets a value which specifies the client function tracing flags.
Urgent	Enable or disable the option that flags a message as urgent.
UserName	Gets and sets the user name or ID used to authenticate the session.
Version	Gets a value which returns the current version of the TextMessage class library.

See Also

TextMessage Class | SocketTools Namespace

TextMessage.Account Property

Gets and sets a value which specifies an account name used to authenticate a client session.

[Visual Basic]

```
Public Property Account As String
```

[C#]

```
public string Account {get; set;}
```

Property Value

A string which specifies the account name.

Remarks

This property is provided for future expansion when additional gateway service types and authentication methods are added to this component. This **Account** property is not used when a message is sent using an SMTP gateway.

See Also

TextMessage Class | SocketTools Namespace

TextMessage.AuthType Property

Gets and sets the type of client authentication that should be used.

[Visual Basic]

```
Public Property AuthType As AuthTypes
```

[C#]

```
public TextMessage.AuthTypes AuthType {get; set;}
```

Property Value

A TextMessage.AuthTypes enumeration that specifies the authentication method.

Remarks

This property is provided for future expansion when additional gateway service types and authentication methods are added to this component. Applications should not change the value of the **AuthType** property.

See Also

TextMessage Class | SocketTools Namespace | TextMessage.AuthTypes

TextMessage.ErrorEventArgs.Description Property

Gets a value which describes the last error that has occurred.

[Visual Basic]

```
Public ReadOnly Property Description As String
```

[C#]

```
public string Description {get;}
```

Property Value

A string which describes the last error that has occurred.

See Also

TextMessage.ErrorEventArgs Class | SocketTools Namespace | Error Property

TextMessage.LastError Property

Gets and sets a value which specifies the last error that has occurred.

[Visual Basic]

```
Public Property LastError As ErrorCode
```

[C#]

```
public TextMessage.ErrorCode LastError {get; set;}
```

Property Value

Returns an ErrorCode enumeration value which specifies the last error code.

Remarks

The **LastError** property returns the error code associated with the last error that occurred for the current instance of the class. It is important to note that this value only has meaning if the previous method indicates that an error has actually occurred.

It is possible to explicitly clear the last error code by assigning the property to the value **ErrorCode.errorNone**.

The error code value can be cast to an integer value for display purposes if required. For a description of the error that can be displayed using a message box or some other similar mechanism, get the value of the **LastErrorString** property.

See Also

TextMessage Class | SocketTools Namespace

TextMessage.LastErrorString Property

Gets a value which describes the last error that has occurred.

[Visual Basic]

```
Public ReadOnly Property LastErrorString As String
```

[C#]

```
public string LastErrorString {get;}
```

Property Value

A string which describes the last error that has occurred.

Remarks

The **LastErrorString** property can be used to obtain a description of the last error that occurred for the current instance of the class. It is important to note that this value only has meaning if the previous method indicates that an error has actually occurred.

See Also

TextMessage Class | SocketTools Namespace

TextMessage.Message Property

Gets and sets the current message text.

[Visual Basic]

```
Public Property Message As String
```

[C#]

```
public string Message {get; set;}
```

Property Value

A string that contains the current text message.

Remarks

This property returns the current message text. Changing the value of this property will change the message text sent by the **SendMessage** method if no message is explicitly specified. In most cases, a message should not exceed 160 characters in length, although some service providers may accept longer messages. If a message exceeds the maximum number of characters accepted by a service provider, the message may be ignored or it may be split into multiple messages.

See Also

TextMessage Class | SocketTools Namespace | PhoneNumber Property | Sender Property | SendMessage Method

TextMessage.Password Property

Gets and sets the password used to authenticate the session.

[Visual Basic]

```
Public Property Password As String
```

[C#]

```
public string Password {get; set;}
```

Property Value

A string that specifies the current password used to authenticate the client session.

Remarks

This property is used to authenticate the current client session. If the message is being sent using SMTP, this value is used to specify a password when connecting to the mail server . If no authentication is required, this property may be an empty string. Note that some service providers may use terminology other than "password" with their documentation; in that case, this property will always specify the second of a pair of authentication tokens sent to the server to identify the client.

See Also

TextMessage Class | SocketTools Namespace | Relay Property | ServerName Property | ServerPort Property | UserName Property

TextMessage.PhoneNumber Property

Gets and sets the phone number for the mobile device.

[Visual Basic]

```
Public Property PhoneNumber As String
```

[C#]

```
public string PhoneNumber {get; set;}
```

Property Value

A string which specifies the phone number for the mobile device.

Remarks

The **PhoneNumber** property returns the current phone number. Changing the value of this property will change the default phone number the **SendMessage** method will use when sending a message. This can be a standard E.164 formatted phone number or an unformatted number. Any extraneous whitespace, punctuation or other non-numeric characters in the string will be ignored.

TextMessage Class | SocketTools Namespace | Message Property | Relay Property | Sender Property | SendMessage Method

TextMessage.Provider Property

Gets and sets the name of the preferred wireless service provider.

[Visual Basic]

```
Public Property Provider As String
```

[C#]

```
public string Provider {get; set;}
```

Property Value

A string which specifies the preferred wireless service provider associated with the mobile device.

Remarks

This property returns the preferred wireless service provider associated with the current phone number. Changing the value of this property will change the preferred wireless service provider. If this property is an empty string, the default provider assigned to the recipient's phone number will be used. This property is only used with messages sent using SMTP and is ignored for other message services.

In the United States and Canada, most wireless common carriers are required to provide wireless number portability (WNP) which allows a customer to continue to use their current phone number even if they switch to another service provider. This can result in a situation where a specific phone number is shown as allocated to one provider, but in actuality that user has switched to a different provider. For example, a user may have originally purchased a phone and service with AT&T and then later switched to Verizon, but decided to keep their phone number. In this case, if Verizon was not specified as the preferred provider, the library would attempt to send the message to the AT&T gateway, since that was the original provider who allocated the phone number.

For most applications, the correct way to handle the situation in which a user may have switched to a different service provider is to allow them to select a preferred provider in your user interface. For example, you could display a drop-down list of available providers for them to select from, populated using the **Providers** property. If they select a preferred provider, then you would assign that value to this property. If they choose to use the default provider, set this property to an empty string.

See Also

TextMessage Class | SocketTools Namespace | Providers Property | SendMessage Method

TextMessage.Providers Property

Gets a collection of known wireless service providers.

[Visual Basic]

```
Public Property Providers As ArrayList
```

[C#]

```
public System.Collections.ArrayList Providers {get; set;}
```

Property Value

A collection of strings that specify the names of known wireless service providers.

Remarks

This property will return a read-only collection of known wireless service providers in the United States and Canada. Typically this collection would be used to populate a UI control such as a ListBox or ComboBox to provide the user with a list of service providers to choose from.

Attempting to assign a value to this property will cause a **System.NotSupportedException** exception to be raised.

See Also

TextMessage Class | SocketTools Namespace | Provider Property | GetProvider Method

TextMessage.Relay Property

Enable or disable the use of an intermediate relay server to send messages.

[Visual Basic]

```
Public Property Relay As Boolean
```

[C#]

```
public bool Relay {get; set;}
```

Property Value

A boolean value which specifies if a relay mail server will be used to send the text message. A value of **true** specifies that a relay server will be used, while a value of **false** specifies that the message will be sent directly to the wireless service provider's gateway.

Remarks

The **Relay** property is used to determine if the class will send the message directly to the wireless service provider's gateway server, or if the message will be relayed through another mail server. The default value for this property is **false**. Setting this property to **true** will cause the control to connect to the mail server specified by the **ServerName** property, authenticate the client session if necessary and then submit the message.

When a text message is sent using the SMTP service, the default action is to attempt to connect directly to the wireless service provider's gateway server. However, many residential Internet service providers (ISPs) do not permit their customers to connect to third-party mail servers and will block the outbound connection. Some wireless service providers may also reject messages that originate from residential IP addresses.

To resolve this issue, the developer should allow the user to specify an alternate mail server that will relay the message to the wireless service provider. For residential users, this will typically be the mail server provided by their ISP. For business users, this will usually be their corporate mail server. The **ServerName** and **ServerPort** properties are used to identify the relay server, and the **UserName** and **Password** properties provide the credentials to authenticate the client session.

See Also

TextMessage Class | SocketTools Namespace | Password Property | ServerName Property | ServerPort Property | UserName Property

TextMessage.Secure Property

Enable or disable secure connections to the server.

[Visual Basic]

```
Public Property Secure As Boolean
```

[C#]

```
public bool Secure {get; set;}
```

Property Value

A boolean value which specifies if a secure connection should be established.

Remarks

The **Secure** property determines if a secure connection is established to the server. The default value for this property is **false**, which specifies that a standard connection to the server is used. To establish a secure connection, the application must set this property value to **true** prior to calling the **SendMessage** method.

This property is only used when sending a message through a relay server using the SMTP service. Messages that are sent directly to the wireless service provider's gateway do not use authentication and are not secure, regardless of the value of this property.

See Also

TextMessage Class | SocketTools Namespace | Relay Property | SendMessage Method

TextMessage.Sender Property

Gets and sets the value that identifies the sender of the message.

[Visual Basic]

```
Public Property Sender As String
```

[C#]

```
public string Sender {get; set;}
```

Property Value

A string value that identifies the person sending the text message.

Remarks

The **Sender** property returns the email address of the sender when the SMTP service is used to send the message. For other service types, this property typically specifies the phone number or shortcode associated with the sender. Assigning a value to this property will set the default sender when the **SendMessage** method is called.

See Also

TextMessage Class | SocketTools Namespace | PhoneNumber Property | SendMessage Method

TextMessage.ServerName Property

Gets and sets the name of the server that is used to send messages.

[Visual Basic]

```
Public Property ServerName As String
```

[C#]

```
public string ServerName {get; set;}
```

Property Value

A string that specifies the host name or IP address of a mail server.

Remarks

The **ServerName** property is used to specify an alternate server that is used to deliver messages. When the SMTP service is used, this property is used in conjunction with the **Relay** property to enable the relaying of messages through another mail server.

By default, the phone number is used to automatically determine the host name of the gateway server that is responsible for accepting messages for the mobile device. However, under some circumstances it may not be possible to send messages directly to the wireless service provider's gateway. For example, many Internet service providers (ISPs) require that customers relay all messages through their servers and block any attempt to establish a direct connection with another mail server. This property can be used to specify an alternate server that will be responsible for sending the message.

See Also

TextMessage Class | SocketTools Namespace | Relay Property | ServerPort Property | SendMessage Method

TextMessage.ServerPort Property

Gets and sets the port number used to establish a connection.

[Visual Basic]

```
Public Property ServerPort As Integer
```

[C#]

```
public int ServerPort {get; set;}
```

Property Value

An integer value that specifies the mail server port number.

Remarks

The **ServerPort** property defines the port number which is used to establish a connection with the server. This property is used in conjunction with the **ServerName** property to specify an alternate server which is responsible for delivering messages.

See Also

TextMessage Class | SocketTools Namespace | Relay Property | ServerName Property | SendMessage Method

TextMessage.ServiceType Property

Gets and sets the type of service used to send messages.

[Visual Basic]
```
Public Property ServiceType As ServiceTypes
```

[C#]
```
public TextMessage.ServiceTypes ServiceType {get; set;}
```

Property Value

A SocketTools.ServiceTypes enumeration that specifies the type of service.

Remarks

This property is provided for future expansion when additional gateway service types and authentication methods are added to this component. Applications should not change the value of the **ServiceType** property.

See Also

TextMessage Class | SocketTools Namespace | TextMessage.ServiceTypes

TextMessage.ThrowError Property

Gets and sets a value which specifies if method calls should throw exceptions when an error occurs.

[Visual Basic]

```
Public Property ThrowError As Boolean
```

[C#]

```
public bool ThrowError {get; set;}
```

Property Value

Returns **true** if method calls will generate exceptions when an error occurs; otherwise returns **false**. The default value is **false**.

Remarks

Error handling for when calling class methods can be done in either of two different styles, according to the value of this property.

If the **ThrowError** property is set to **false**, the application should check the return value of any method that is used, and report errors based upon the documented value of the return code. It is the responsibility of the application to interpret the error code, if it is desired to explain the error in addition to reporting it. This is the default behavior.

If the **ThrowError** property is set to **true**, then exceptions will be generated whenever a method call fails. The program must be written to catch these exceptions and take the appropriate action when an error occurs. Failure to handle an exception will cause the program to terminate abnormally.

Note that if an error occurs while a property is being read or modified, an exception will be raised regardless of the value of the **ThrowError** property.

See Also

TextMessage Class | SocketTools Namespace

TextMessage.Timeout Property

Gets and sets a value which specifies a timeout period in seconds.

[Visual Basic]

```
Public Property Timeout As Integer
```

[C#]

```
public int Timeout {get; set;}
```

Property Value

An integer value which specifies a timeout period in seconds.

Remarks

Setting the **Timeout** property specifies the number of seconds until a blocking operation fails and the method returns to the caller. This includes the amount of time the control will spend attempting to connect to a remote host, and if the connection is not established within the given time period, the connection attempt will fail.

See Also

TextMessage Class | SocketTools Namespace

TextMessage.Trace Property

Gets and sets a value which indicates if network function logging is enabled.

[Visual Basic]

```
Public Property Trace As Boolean
```

[C#]

```
public bool Trace {get; set;}
```

Property Value

Returns **true** if network function tracing is enabled; otherwise returns **false**. The default value is **false**.

Remarks

The **Trace** property is used to enable (or disable) the tracing of network function calls. When enabled, each function call is logged to a file, including the function parameters, return value and error code if applicable. This facility can be enabled and disabled at run time, and the trace log file can be specified by setting the **TraceFile** property. All function calls that are being logged are appended to the trace file, if it exists. If no trace file exists when tracing is enabled, the trace file is created.

The tracing facility is available in all of the SocketTools networking classes and is enabled or disabled for an entire process. This means that once trace logging is enabled for a given component, all of the function calls made by the process using any of the SocketTools classes will be logged. For example, if you have an application using both the File Transfer Protocol and Post Office Protocol classes, and you set the **Trace** property to **true**, function calls made by both classes will be logged. Additionally, enabling a trace is cumulative, and tracing is not stopped until it is disabled for all classes used by the process.

If trace logging is not enabled, there is no negative impact on performance or throughput. Once enabled, application performance can degrade, especially in those situations in which multiple processes are being traced or the logfile is fairly large. Since logfiles can grow very quickly, even with modest applications, it is recommended that you delete the file when it is no longer needed.

When redistributing your application, make sure that you include the **SocketTools10.TraceLog.dll** module with your installation. If this library is not present, then no trace output will be generated and the value of the **Trace** property will be ignored. Only those function calls made by the SocketTools networking classes will be logged. Calls made directly to the Windows Sockets API, or calls made by other classes, will not be logged.

See Also

TextMessage Class | SocketTools Namespace

TextMessage.TraceFile Property

Gets and sets a value which specifies the name of the logfile.

[Visual Basic]

```
Public Property TraceFile As String
```

[C#]

```
public string TraceFile {get; set;}
```

Property Value

A string which specifies the name of the file.

Remarks

The **TraceFile** property is used to specify the name of the trace file that is created when network function tracing is enabled. If this property is set to an empty string (the default value), then a file named **SocketTools.log** is created in the system's temporary directory. If no temporary directory exists, then the file is created in the current working directory.

If the file exists, the trace output is appended to the file, otherwise the file is created. Since network function tracing is enabled per-process, the trace file is shared by all instances of the class being used. If multiple class instances have tracing enabled, the **TraceFile** property should be set to the same value for each instance. Since trace files can grow very quickly, even with modest applications, it is recommended that you delete the file when it is no longer needed.

The trace file has the following format:

```
 MyApp INF: WSAAsyncSelect(46, 0xcc4, 0x7e9, 0x27) returned 0 MyApp WRN:
connect(46, 192.0.0.1:1234, 16) returned -1 [10035] MyApp ERR: accept(46,
NULL, 0x0) returned -1 [10038]
```

The first column contains the name of the process that is being traced. The second column identifies if the trace record is reporting information, a warning, or an error. What follows is the name of the function being called, the arguments passed to the function and the function's return value. If a warning or error is reported, the error code is appended to the record (the value is placed inside brackets).

If parameters are passed as integer values, they are recorded in decimal. If the parameter or return value is a pointer (a memory address), it is recorded as a hexadecimal value preceded with "0x". A special type of pointer, called a null pointer, is recorded as NULL. Those functions which expect socket addresses are displayed in the following format:

```
aa.bb.cc.dd:nnnn
```

The first four numbers separated by periods represent the IP address, and the number following the colon represents the port number in host byte order. Note that in the second line of the above example, the control is attempting to connect to a system with the IP address 192.0.0.1 on port 1234.

Note that if the specified file cannot be created, or the user does not have permission to modify an existing file, the error is silently ignored and no trace output will be generated.

See Also

TextMessage Class | SocketTools Namespace

TextMessage.TraceFlags Property

Gets and sets a value which specifies the client function tracing flags.

[Visual Basic]
```
Public Property TraceFlags As TraceOptions
```

[C#]
```
public TextMessage.TraceOptions TraceFlags {get; set;}
```

Property Value

A TraceOptions enumeration which specifies the amount of detail written to the trace logfile.

Remarks

The **TraceFlags** property is used to specify the type of information written to the trace file when network function tracing is enabled.

Because network function tracing is enabled per-process, the trace flags are shared by all instances of the class being used. If multiple class instances have tracing enabled, the **TraceFlags** property should be set to the same value for each instance. Changing the trace flags for any one instance of the class will affect the logging performed for all SocketTools classes used by the application.

Warnings are generated when a non-fatal error is returned by a network function. For example, if data is being written and the error **errorOperationWouldBlock** occurs, a warning is generated because the application simply needs to attempt to write the data at a later time.

See Also

TextMessage Class | SocketTools Namespace

TextMessage.Urgent Property

Enable or disable the option that flags a message as urgent.

[Visual Basic]

```
Public Property Urgent As Boolean
```

[C#]

```
public bool Urgent {get; set;}
```

Property Value

A boolean value which specifies if the message should be flagged as urgent.

Remarks

The **Urgent** property specifies whether a message will be flagged as urgent or not. If this property is set to **true**, the message will sent with a high priority. Note that this does not guarantee the message will be received any differently than a standard text message. Each wireless service provider may handle urgent messages differently, and some providers may simply ignore the message priority. By default, this property is **false**.

See Also

TextMessage Class | SocketTools Namespace

TextMessage.UserName Property

Gets and sets the user name or ID used to authenticate the session.

[Visual Basic]

```
Public Property UserName As String
```

[C#]

```
public string UserName {get; set;}
```

Property Value

A string that specifies the current username used to authenticate the client session.

Remarks

The **UserName** property is used to authenticate the current session. If the message is being sent using SMTP, this property is used to specify a user name when connecting to the mail server . If no authentication is required, this property may be an empty string. Note that some service providers may use terminology other than "username" with their documentation; in that case, this property will always specify the first of a pair of authentication tokens sent to the server to identify the client.

See Also

TextMessage Class | SocketTools Namespace | Password Property

TextMessage.Version Property

Gets a value which returns the current version of the TextMessage class library.

[Visual Basic]
```
Public ReadOnly Property Version As String
```

[C#]
```
public string Version {get;}
```

Property Value

A string which specifies the version of the class library.

Remarks

The **Version** property returns a string which identifies the current version and build of the TextMessage class library. This value can be used by an application for validation and debugging purposes.

TextMessage Class | SocketTools Namespace

TextMessage Methods

The methods of the **TextMessage** class are listed below. For a complete list of **TextMessage** class members, see the TextMessage Members topic.

Public Instance Methods

Dispose	Overloaded. Releases all resources used by TextMessage.
Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetAddress	Get the email address associated with the specified phone number.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetProvider	Get the name of the wireless service provider associated with a phone number.
GetType (inherited from Object)	Gets the Type of the current instance.
Initialize	Overloaded. Initialize an instance of the TextMessage class.
Reset	Reset the internal state of the object, resetting all properties to their default values.
SendMessage	Overloaded. Send a text message to the specified mobile device.
ToString (inherited from Object)	Returns a String that represents the current Object.
Uninitialize	Uninitialize the class library and release any resources allocated for the current thread.

Protected Instance Methods

Dispose	Overloaded. Releases the unmanaged resources allocated by the TextMessage class and optionally releases the managed resources.
Finalize	Destroys an instance of the class, releasing the resources allocated for the session and unloading the networking library.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

TextMessage Class | SocketTools Namespace

TextMessage.Dispose Method

Releases all resources used by TextMessage.

Overload List

Releases all resources used by TextMessage.

public void Dispose();

Releases the unmanaged resources allocated by the TextMessage class and optionally releases the managed resources.

protected virtual void Dispose(bool);

See Also

TextMessage Class | SocketTools Namespace

TextMessage.Dispose Method ()

Releases all resources used by TextMessage.

[Visual Basic]
```
NotOverridable Overloads Public Sub Dispose() _
    Implements IDisposable.Dispose
```

[C#]
```
public void Dispose();
```

Implements

IDisposable.Dispose

Remarks

The **Dispose** method terminates any active connection and explicitly releases the resources allocated for this instance of the class. In some cases, better performance can be achieved if the programmer explicitly releases resources when they are no longer being used. The **Dispose** method provides explicit control over these resources.

Unlike the **Uninitialize** method, once the **Dispose** method has been called, that instance of the class cannot be re-initialized and you should not attempt to access class properties or invoke any methods. Note that this method can be called even if other references to the object are active.

See Also

TextMessage Class | SocketTools Namespace | TextMessage.Dispose Overload List

TextMessage.Dispose Method (Boolean)

Releases the unmanaged resources allocated by the TextMessage class and optionally releases the managed resources.

[Visual Basic]

```
Overridable Overloads Protected Sub Dispose( _
   ByVal disposing As Boolean _
)
```

[C#]

```
protected virtual void Dispose(
   bool disposing
);
```

Parameters

disposing

A boolean value which should be specified as **true** to release both managed and unmanaged resources; **false** to release only unmanaged resources.

Remarks

The **Dispose** method terminates any active connection and explicitly releases the resources allocated for this instance of the class. In some cases, better performance can be achieved if the programmer explicitly releases resources when they are no longer being used. The **Dispose** method provides explicit control over these resources.

Unlike the **Uninitialize** method, once the **Dispose** method has been called, that instance of the class cannot be re-initialized and you should not attempt to access class properties or invoke any methods. Note that this method can be called even if other references to the object are active.

You should call **Dispose** in your derived class when you are finished using the derived class. The **Dispose** method leaves the derived class in an unusable state. After calling **Dispose**, you must release all references to the derived class and the **TextMessage** class so the memory they were occupying can be reclaimed by garbage collection.

See Also

TextMessage Class | SocketTools Namespace | TextMessage.Dispose Overload List

TextMessage.Finalize Method

Destroys an instance of the class, releasing the resources allocated for the session and unloading the networking library.

[Visual Basic]

```
Overrides Protected Sub Finalize()
```

[C#]

```
protected override void Finalize();
```

See Also

TextMessage Class | SocketTools Namespace

TextMessage.GetAddress Method

Get the email address associated with the specified phone number.

[Visual Basic]

```
Public Function GetAddress( _
   ByVal phoneNumber As String, _
   ByRef mailAddress As String _
) As Boolean
```

[C#]

```
public bool GetAddress(
   string phoneNumber,
   ref string mailAddress
);
```

Parameters

phoneNumber

A string value which specifies the phone number of the mobile device. This can be a standard E.164 formatted number or an unformatted number. Any extraneous whitespace, punctuation or other non-numeric characters in the string will be ignored.

mailAddress

A string that will contain the email address associated with the specified phone number when the method returns. A mail message sent to this address will be forwarded to the mobile device as a text message. This parameter must be passed by reference.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetAddress** method can be used to determine if a phone number is associated with a mobile device and obtain the email address for the wireless service provider's gateway. This is done by sending an query to a server that will check the phone number against a database of known providers and the phone numbers that have been allocated for wireless devices.

This method sends an HTTP query to the server **api.sockettools.com** to obtain information about the phone number and wireless service provider. This requires that the local system can establish a standard network connection over port 80. If the client cannot connect to the server, the method will fail and an appropriate error will be returned. The server imposes a limit on the maximum number of connections that can be established and the maximum number of requests that can be issued per minute. If this method is called multiple times over a short period, the control may also force the application to block briefly. Server responses are cached per session, so calling this method multiple times using the same phone number will not increase the request count.

See Also

TextMessage Class | SocketTools Namespace | Provider Property | Providers Property | GetProvider Method | SendMessage Method

TextMessage.GetProvider Method

Get the name of the wireless service provider associated with a phone number.

[Visual Basic]

```
Public Function GetProvider( _
   ByVal phoneNumber As String, _
   ByRef providerName As String _
) As Boolean
```

[C#]

```
public bool GetProvider(
   string phoneNumber,
   ref string providerName
);
```

Parameters

phoneNumber
A string value which specifies the phone number of the mobile device. This can be a standard E.164 formatted number or an unformatted number. Any extraneous whitespace, punctuation or other non-numeric characters in the string will be ignored.

providerName
A string that will contain the name of the wireless service provider associated with the specified phone number when the method returns. This parameter must be passed by reference.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetProvider** method can be used to determine if a phone number is associated with a mobile device and obtain the name of the service provider associated with the number. This is done by sending an query to a server that will check the phone number against a database of known providers and the phone numbers that have been allocated for wireless devices.

This method sends an HTTP query to the server **api.sockettools.com** to obtain information about the phone number and wireless service provider. This requires that the local system can establish a standard network connection over port 80. If the client cannot connect to the server, the method will fail and an appropriate error will be returned. The server imposes a limit on the maximum number of connections that can be established and the maximum number of requests that can be issued per minute. If this method is called multiple times over a short period, the control may also force the application to block briefly. Server responses are cached per session, so calling this method multiple times using the same phone number will not increase the request count.

See Also

TextMessage Class | SocketTools Namespace | Provider Property | Providers Property | GetAddress Method | SendMessage Method

TextMessage.Initialize Method

Initialize an instance of the TextMessage class.

Overload List

Initialize an instance of the TextMessage class.

public bool Initialize();

Initialize an instance of the TextMessage class.

public bool Initialize(string);

See Also

TextMessage Class | SocketTools Namespace | Uninitialize Method

TextMessage.Initialize Method ()

Initialize an instance of the TextMessage class.

[Visual Basic]
```
Overloads Public Function Initialize() As Boolean
```

[C#]
```
public bool Initialize();
```

Return Value

A boolean value which specifies if the class was initialized successfully.

Remarks

The **Initialize** method can be used to explicitly initialize an instance of the **TextMessage** class, loading the networking library and allocating resources for the current thread. This must be the first method that is called before you attempt to modify any property values or invoke other methods in this instance. Failure to initialize the class may result in in subsequent errors and/or cause an exception to be raised.

Each time the **Initialize** method is invoked, it increments an internal counter that keeps track of the number of times that it has been called by any thread in the current process. The **Uninitialize** method decrements this counter, and when the usage count drops to zero, the class will automatically unload the system libraries that it has dynamically loaded and will destroy the process heap that was allocated when the first instance of the class was created.

See Also

TextMessage Class | SocketTools Namespace | TextMessage.Initialize Overload List | Uninitialize Method

TextMessage.Initialize Method (String)

Initialize an instance of the TextMessage class.

[Visual Basic]

```
Overloads Public Function Initialize( _
   ByVal licenseKey As String _
) As Boolean
```

[C#]

```
public bool Initialize(
   string licenseKey
);
```

Return Value

A boolean value which specifies if the class was initialized successfully.

Remarks

The **Initialize** method can be used to explicitly initialize an instance of the **TextMessage** class, loading the networking library and allocating resources for the current thread. This must be the first method that is called before you attempt to modify any property values or invoke other methods in this instance. Failure to initialize the class may result in in subsequent errors and/or cause an exception to be raised.

Each time the **Initialize** method is invoked, it increments an internal counter that keeps track of the number of times that it has been called by any thread in the current process. The **Uninitialize** method decrements this counter, and when the usage count drops to zero, the class will automatically unload the system libraries that it has dynamically loaded and will destroy the process heap that was allocated when the first instance of the class was created.

Example

The following example shows how to use the Initialize method to initialize an instance of the class. This example assumes that the license key string has been defined in code.

```
SocketTools.TextMessage txtMessage = new SocketTools.TextMessage();

if (txtMessage.Initialize(strLicenseKey) == false)
{
 MessageBox.Show(txtMessage.LastErrorString, "Error",
 MessageBoxButtons.OK, MessageBoxIcon.Exclamation);
 return;
}
```

```
Dim txtMessage As New SocketTools.TextMessage

If txtMessage.Initialize(strLicenseKey) = False Then
    MsgBox(txtMessage.LastErrorString, vbIconExclamation)
    Exit Sub
End If
```

See Also

TextMessage Class | SocketTools Namespace | TextMessage.Initialize Overload List | RuntimeLicenseAttribute Class | Uninitialize Method

TextMessage.Reset Method

Reset the internal state of the object, resetting all properties to their default values.

[Visual Basic]
```
Public Sub Reset()
```

[C#]
```
public void Reset();
```

Remarks

The **Reset** method returns the object to its default state. If a socket has been allocated, it will be released and any active connections will be terminated. All properties will be reset to their default values.

See Also

TextMessage Class | SocketTools Namespace

TextMessage.SendMessage Method

Send a text message to the specified mobile device.

Overload List

Send a text message to the specified mobile device.

public bool SendMessage();

Send a text message to the specified mobile device.

public bool SendMessage(string);

Send a text message to the specified mobile device.

public bool SendMessage(string,string,string);

See Also

TextMessage Class | SocketTools Namespace | Message Property | PhoneNumber Property | Relay Property | Sender Property | ServiceType Property

TextMessage.SendMessage Method ()

Send a text message to the specified mobile device.

[Visual Basic]

```
Overloads Public Function SendMessage() As Boolean
```

[C#]

```
public bool SendMessage();
```

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **SendMessage** method is used to send a text message to a mobile device. This class is designed to support multiple methods of sending text messages, with the **ServiceType** property determining how the message is sent.

The value of the **PhoneNumber** property is used to determine the phone number of the mobile device that the message will be sent to. The value of the **Sender** property is used to specify the sender of the message. The value of the **Message** property specifies the content of the message that is sent.

For more information, refer to the SendMessage method.

See Also

TextMessage Class | SocketTools Namespace | TextMessage.SendMessage Overload List | Message Property | PhoneNumber Property | Relay Property | Sender Property | ServiceType Property

TextMessage.SendMessage Method (String)

Send a text message to the specified mobile device.

[Visual Basic]

```
Overloads Public Function SendMessage( _
   ByVal phoneNumber As String _
) As Boolean
```

[C#]

```
public bool SendMessage(
   string phoneNumber
);
```

Parameters

phoneNumber

An string value which specifies the phone number of the mobile device. This can be a standard E.164 formatted number or an unformatted number. Any extraneous whitespace, punctuation or other non-numeric characters in the string will be ignored.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **SendMessage** method is used to send a text message to a mobile device. This class is designed to support multiple methods of sending text messages, with the **ServiceType** property determining how the message is sent.

The value of the **Sender** property is used to specify the sender of the message. The value of the **Message** property specifies the content of the message that is sent.

For more information, refer to the SendMessage method.

See Also

TextMessage Class | SocketTools Namespace | TextMessage.SendMessage Overload List | Message Property | Relay Property | Sender Property | ServiceType Property

TextMessage.SendMessage Method (String, String, String)

Send a text message to the specified mobile device.

[Visual Basic]

```
Overloads Public Function SendMessage( _
   ByVal phoneNumber As String, _
   ByVal sender As String, _
   ByVal message As String _
) As Boolean
```

[C#]

```
public bool SendMessage(
   string phoneNumber,
   string sender,
   string message
);
```

Parameters

phoneNumber
An string value which specifies the phone number of the mobile device. This can be a standard E.164 formatted number or an unformatted number. Any extraneous whitespace, punctuation or other non-numeric characters in the string will be ignored.

sender
A string value that identifies the sender of the message. For messages being sent using SMTP, this should be a valid email address.

message
A string value that contains the text message that will be sent.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **SendMessage** method is used to send a text message to a mobile device. This control is designed to support multiple methods of sending text messages, with the **ServiceType** property determining how the message is sent:

ServiceTypes.serviceSmtp
This message service sends the message through the wireless service provider's mail gateway using the SMTP protocol. However, it is important to note that many of these gateways will not accept messages from a client that is connected to them using a residential Internet service provider. If the application is being run on a system that uses a residential provider, that service provider may also block outbound connections to all mail servers other than their own. These anti-spam measures typically require that most end-user applications specify a relay mail server rather than submitting the message directly to the wireless provider's gateway.

Because most wireless carriers in the United States and Canada must provide for wireless number portability, there is the possibility that the provider information returned may no longer correspond to the telephone number. It is recommended that you provide your end-user with the ability to specify an alternate preferred provider to use when sending the text message. For more information, refer to **Providers** properties.

This method sends an HTTP query to the server **api.sockettools.com** to obtain information about the phone number and wireless service provider. This requires that the local system can establish a standard network connection over port 80. If the client cannot connect to the server, the method will fail and an appropriate error will be returned. The server imposes a limit on the maximum number of connections that can be established and the maximum number of requests that can be issued per minute. If this method is called multiple times over a short period, the control may also force the application to block briefly. Server responses are cached per session, so calling this method multiple times using the same phone number will not increase the request count.

TextMessage Class | SocketTools Namespace | TextMessage.SendMessage Overload List | Providers Property | Relay Property | ServiceType Property

TextMessage.Uninitialize Method

Uninitialize the class library and release any resources allocated for the current thread.

[Visual Basic]

```
Public Sub Uninitialize()
```

[C#]

```
public void Uninitialize();
```

Remarks

The **Uninitialize** method terminates any connection established by the control and resets the internal state of the class. This method is not typically used because any resources that have been allocated by an instance of the class will automatically be released when it is destroyed.

Each time the **Initialize** method is invoked, it increments an internal counter that keeps track of the number of times that it has been called by any thread in the current process. The **Uninitialize** method decrements this counter, and when the usage count drops to zero, the class will automatically unload the system libraries that it has dynamically loaded and will destroy the process heap that was allocated when the first instance of the class was created.

TextMessage Class | SocketTools Namespace | Initialize Method

TextMessage Events

The events of the **TextMessage** class are listed below. For a complete list of **TextMessage** class members, see the TextMessage Members topic.

Public Instance Events

⚡ OnError	Occurs when an client operation fails.

See Also

TextMessage Class | SocketTools Namespace

TextMessage.OnError Event

Occurs when an client operation fails.

[Visual Basic]

```
Public Event OnError As OnErrorEventHandler
```

[C#]

```
public event OnErrorEventHandler OnError;
```

Event Data

The event handler receives an argument of type TextMessage.ErrorEventArgs containing data related to this event. The following **TextMessage.ErrorEventArgs** properties provide information specific to this event.

Property	Description
Description	Gets a value which describes the last error that has occurred.
Error	Gets a value which specifies the last error that has occurred.

Remarks

The **OnError** event occurs when a client operation fails.

See Also

TextMessage Class | SocketTools Namespace | ErrorCode Enumeration | LastError Property | LastErrorString Property

TextMessage.ErrorEventArgs Class

Provides data for the OnError event.

For a list of all members of this type, see TextMessage.ErrorEventArgs Members.

System.Object
  System.EventArgs
    SocketTools.TextMessage.ErrorEventArgs

[Visual Basic]

```
Public Class TextMessage.ErrorEventArgs
    Inherits EventArgs
```

[C#]

```
public class TextMessage.ErrorEventArgs : EventArgs
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

ErrorEventArgs specifies the numeric error code and a description of the error that has occurred.

An OnError event occurs when a method fails.

Requirements

Namespace: SocketTools

Assembly: SocketTools.TextMessage (in SocketTools.TextMessage.dll)

See Also

TextMessage.ErrorEventArgs Members | SocketTools Namespace

TextMessage.ErrorEventArgs Members

TextMessage.ErrorEventArgs overview

Public Instance Constructors

TextMessage.ErrorEventArgs Constructor	Initializes a new instance of the TextMessage.ErrorEventArgs class.

Public Instance Properties

Description	Gets a value which describes the last error that has occurred.
Error	Gets a value which specifies the last error that has occurred.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString (inherited from Object)	Returns a String that represents the current Object.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

TextMessage.ErrorEventArgs Class | SocketTools Namespace

TextMessage.ErrorEventArgs Constructor

Initializes a new instance of the TextMessage.ErrorEventArgs class.

[Visual Basic]
```
Public Sub New()
```

[C#]
```
public TextMessage.ErrorEventArgs();
```

See Also

TextMessage.ErrorEventArgs Class | SocketTools Namespace

TextMessage.ErrorEventArgs Properties

The properties of the **TextMessage.ErrorEventArgs** class are listed below. For a complete list of **TextMessage.ErrorEventArgs** class members, see the TextMessage.ErrorEventArgs Members topic.

Public Instance Properties

Description	Gets a value which describes the last error that has occurred.
Error	Gets a value which specifies the last error that has occurred.

See Also

TextMessage.ErrorEventArgs Class | SocketTools Namespace

TextMessage.ErrorEventArgs.Error Property

Gets a value which specifies the last error that has occurred.

[Visual Basic]

```
Public ReadOnly Property Error As ErrorCode
```

[C#]

```
public TextMessage.ErrorCode Error {get;}
```

Property Value

ErrorCode enumeration which specifies the error.

See Also

TextMessage.ErrorEventArgs Class | SocketTools Namespace | Description Property

TextMessage.AuthTypes Enumeration

Specifies the authentication methods that the TextMessage class supports.

[Visual Basic]

```
Public Enum TextMessage.AuthTypes
```

[C#]

```
public enum TextMessage.AuthTypes
```

Members

Member Name	Description
authDefault	The default authentication method for this service type should be used. Most applications should use this value unless a service type provides multiple authentication methods.
authUserName	The service requires authentication using a username and password. This value can be used with an SMTP service that requires user authentication and is typically needed when using a mail server relay. For the **serviceSmtp** service, this is the default authentication method.

Requirements

Namespace: SocketTools

Assembly: SocketTools.TextMessage (in SocketTools.TextMessage.dll)

See Also

SocketTools Namespace | ServiceTypes Enumeration | AuthType Property (SocketTools.TextMessage)

TextMessage.ErrorCode Enumeration

Specifies the error codes returned by the TextMessage class.

[Visual Basic]
```
Public Enum TextMessage.ErrorCode
```

[C#]
```
public enum TextMessage.ErrorCode
```

Remarks

The TextMessage class uses the **ErrorCode** enumeration to specify what error has occurred when a method fails. The current error code may be determined by checking the value of the **LastError** property.

Note that the last error code is only meaningful if the previous operation has failed.

Members

Member Name	Description
errorNone	No error.
errorNotHandleOwner	Handle not owned by the current thread.
errorFileNotFound	The specified file or directory does not exist.
errorFileNotCreated	The specified file could not be created.
errorOperationCanceled	The blocking operation has been canceled.
errorInvalidFileType	The specified file is a block or character device, not a regular file.
errorInvalidDevice	The specified file type is invalid or not a regular file.
errorTooManyParameters	The maximum number of function parameters has been exceeded.
errorInvalidFileName	The specified file name contains invalid characters or is too long.
errorInvalidFileHandle	Invalid file handle passed to function.
errorFileReadFailed	Unable to read data from the specified file.
errorFileWriteFailed	Unable to write data to the specified file.
errorOutOfMemory	Out of memory.
errorAccessDenied	Access denied.
errorInvalidParameter	Invalid argument passed to function.
errorClipboardUnavailable	The system clipboard is currently unavailable.
errorClipboardEmpty	The system clipboard is empty or does not contain any text data.
errorFileEmpty	The specified file does not contain any data.
errorFileExists	The specified file already exists.

errorEndOfFile	End of file.
errorDeviceNotFound	The specified device could not be found.
errorDirectoryNotFound	The specified directory could not be found.
errorInvalidbuffer	Invalid memory address passed to function.
errorBufferTooSmall	The specified buffer is not large enough to contain the data.
errorNoHandles	No more handles are available to this process.
errorOperationWouldBlock	The specified operation would block the current thread.
errorOperationInProgress	A blocking operation is currently in progress.
errorAlreadyInProgress	The specified operation is already in progress.
errorInvalidHandle	Invalid handle passed to function.
errorInvalidAddress	Invalid network address specified.
errorInvalidSize	Datagram is too large to fit in specified buffer.
errorInvalidProtocol	Invalid network protocol specified.
errorProtocolNotAvailable	The specified network protocol is not available.
errorProtocolNotSupported	The specified protocol is not supported.
errorSocketNotSupported	The specified socket type is not supported.
errorInvalidOption	The specified option is invalid.
errorProtocolFamily	Specified protocol family is not supported.
errorProtocolAddress	The specified address is invalid for this protocol family.
errorAddressInUse	The specified address is in use by another process.
errorAddressUnavailable	The specified address cannot be assigned.
errorNetworkUnavailable	The networking subsystem is unavailable.
errorNetworkUnreachable	The specified network is unreachable.
errorNetworkReset	Network dropped connection on remote reset.
errorConnectionAborted	Connection was aborted due to timeout or other failure.
errorConnectionReset	Connection was reset by remote network.
errorOutOfBuffers	No buffer space is available.
errorAlreadyConnected	Connection already established with remote host.
errorNotConnected	No connection established with remote host.
errorConnectionShutdown	Unable to send or receive data after connection shutdown.
errorOperationTimeout	The specified operation has timed out.
errorConnectionRefused	The connection has been refused by the remote host.

errorHostUnavailable	The specified host is unavailable.
errorHostUnreachable	Remote host is unreachable.
errorTooManyProcesses	Too many processes are using the networking subsystem.
errorTooManyThreads	Too many threads have been created by the current process.
errorTooManySessions	Too many client sessions have been created by the current process.
errorInternalFailure	An unexpected internal error has occurred.
errorNetworkNotReady	Network subsystem is not ready for communication.
errorInvalidVersion	This version of the operating system is not supported.
errorNetworkNotInitialized	The networking subsystem has not been initialized.
errorRemoteShutdown	The remote host has initiated a graceful shutdown sequence.
errorInvalidHostName	The specified hostname is invalid or could not be resolved.
errorHostNameNotFound	The specified hostname could not be found.
errorHostNameRefused	Unable to resolve hostname, request refused.
errorHostNameNotResolved	Unable to resolve hostname, no address for specified host.
errorInvalidLicense	The license for this product is invalid.
errorProductNotLicensed	This product is not licensed to perform this operation.
errorNotImplemented	This function has not been implemented on this platform.
errorUnknownLocalhost	Unable to determine local host name.
errorInvalidHostAddress	Invalid host address specified.
errorInvalidServicePort	Invalid service port number specified.
errorInvalidServiceName	Invalid or unknown service name specified.
errorInvalidEventId	Invalid event identifier specified.
errorOperationNotBlocking	No blocking operation in progress on this socket.
errorSecurityNotInitialized	Unable to initialize security interface for this process.
errorSecurityContext	Unable to establish security context for this session.
errorSecurityCredentials	Unable to open certificate store or establish security credentials.
errorSecurityCertificate	Unable to validate the certificate chain for this

	session.
errorSecurityDecryption	Unable to decrypt data stream.
errorSecurityEncryption	Unable to encrypt data stream.
errorOperationNotSupported	The specified operation is not supported.
errorInvalidProtocolVersion	Invalid application protocol version specified.
errorNoServerResponse	No data returned from server.
errorInvalidServerResponse	Invalid data returned from server.
errorUnexpectedServerResponse	Unexpected response code returned from server.
errorServerTransactionFailed	Server transaction failed.
errorServiceUnavailable	The service is currently unavailable.
errorServiceNotReady	The service is not ready, try again later.
errorServerResyncFailed	Unable to resynchronize with server.
errorInvalidProxyType	Invalid proxy server type specified.
errorProxyRequired	Resource must be accessed through specified proxy.
errorInvalidProxyLogin	Unable to login to proxy server using specified credentials.
errorProxyResyncFailed	Unable to resynchronize with proxy server.
errorInvalidCommand	Invalid command specified.
errorInvalidCommandParameter	Invalid command parameter specified.
errorInvalidCommandSequence	Invalid command sequence specified.
errorCommandNotImplemented	Specified command not implemented on this server.
errorCommandNotAuthorized	Specified command not authorized for the current user.
errorCommandAborted	Specified command was aborted by the remote host.
errorOptionNotSupported	The specified option is not supported on this server.
errorRequestNotCompleted	The current client request has not been completed.
errorInvalidUserName	The specified username is invalid.
errorInvalidPassword	The specified password is invalid.
errorInvalidAccount	The specified account name is invalid.
errorAccountRequired	Account name has not been specified.
errorInvalidAuthenticationType	Invalid authentication protocol specified.
errorAuthenticationRequired	User authentication is required.
errorProxyAuthenticationRequired	Proxy authentication required.

errorAlreadyAuthenticated	User has already been authenticated.
errorAuthenticationFailed	Unable to authenticate the specified user.
errorNetworkAdapter	Unable to determine network adapter configuration.
errorInvalidRecordType	Invalid record type specified.
errorInvalidRecordName	Invalid record name specified.
errorInvalidRecordData	Invalid record data specified.
errorConnectionOpen	Data connection already established.
errorConnectionClosed	Server closed data connection.
errorConnectionPassive	Data connection is passive.
errorConnectionFailed	Unable to open data connection to server.
errorInvalidSecurityLevel	Data connection cannot be opened with this security setting.
errorCachedTLSRequired	Data connection requires cached TLS session.
errorDataReadOnly	Data connection is read-only.
errorDataWriteOnly	Data connection is write-only.
errorEndOfData	End of data.
errorRemoteFileUnavailable	Remote file is unavailable.
errorInsufficientStorage	Insufficient storage on server.
errorStorageallocation	File exceeded storage allocation on server.
errorDirectoryExists	The specified directory already exists.
errorDirectoryEmpty	No files returned by the server for the specified directory.
errorEndOfDirectory	End of directory listing.
errorUnknownDirectoryFormat	Unknown directory format.
errorInvalidResource	Invalid resource name specified.
errorResourceRedirected	The specified resource has been redirected.
errorResourceRestricted	Access to this resource has been restricted.
errorResourceNotModified	The specified resource has not been modified.
errorResourceNotFound	The specified resource cannot be found.
errorResourceConflict	Request could not be completed due to the current state of the resource.
errorResourceRemoved	The specified resource has been permanently removed from this server.
errorContentLengthRequired	Request must include the content length.
errorRequestPrecondition	Request could not be completed due to server precondition.
errorUnsupportedMediaType	Request specified an unsupported media type.

errorInvalidContentRange	Content range specified for this resource is invalid.
errorInvalidMessagePart	Message is not multipart or an invalid message part was specified.
errorInvalidMessageHeader	The specified message header is invalid or has not been defined.
errorInvalidMessageBoundary	The multipart message boundary has not been defined.
errorNoFileAttachment	The current message part does not contain a file attachment.
errorUnknownFileType	The specified file type could not be determined.
errorDataNotEncoded	The specified data block could not be encoded.
errorDataNotDecoded	The specified data block could not be decoded.
errorFileNotEncoded	The specified file could not be encoded.
errorFileNotDecoded	The specified file could not be decoded.
errorNoMessageText	No message text.
errorInvalidCharacterSet	Invalid character set specified.
errorInvalidEncodingType	Invalid encoding type specified.
errorInvalidMessageNumber	Invalid message number specified.
errorNoReturnAddress	No valid return address specified.
errorNoValidRecipients	No valid recipients specified.
errorInvalidRecipient	The specified recipient address is invalid.
errorRelayNotAuthorized	The specified domain is invalid or server will not relay messages.
errorMailboxUnavailable	Specified mailbox is currently unavailable.
errorMailboxReadOnly	The selected mailbox cannot be modified.
errorMailboxNotSelected	No mailbox has been selected.
errorInvalidMailbox	Specified mailbox is invalid.
errorInvalidDomain	The specified domain name is invalid or not recognized.
errorInvalidSender	The specified sender address is invalid or not recognized.
errorMessageNotDelivered	Message not delivered to any of the specified recipients.
errorEndOfMessageData	No more message data available to be read
errorInvalidmessageSize	The specified message size is invalid.
errorMessageNotCreated	The message could not be created in the specified mailbox.
errorNoMoreMailboxes	No more mailboxes exist on this server.

errorInvalidEmulationType	The specified terminal emulation type is invalid.
errorInvalidFontHandle	The specified font handle is invalid.
errorInvalidFontName	The specified font name is invalid or unavailable.
errorInvalidPacketSize	The specified packet size is invalid.
errorInvalidPacketData	The specified packet data is invalid.
errorInvalidPacketId	The unique packet identifier is invalid.
errorPacketTTLExpired	The specified packet time-to-live period has expired.
errorInvalidNewsGroup	Invalid newsgroup specified.
errorNoNewsgroupSelected	No newsgroup selected.
errorEmptyNewsgroup	No articles in specified newsgroup.
errorInvalidArticle	Invalid article number specified.
errorNoArticleSelected	No article selected in the current newsgroup.
errorFirstArticle	First article in current newsgroup.
errorLastArticle	Last article in current newsgroup.
errorArticleExists	Unable to transfer article, article already exists.
errorArticleRejected	Unable to transfer article, article rejected.
errorArticleTransferFailed	Article transfer failed.
errorArticlePostingDenied	Posting is not permitted on this server.
errorArticlePostingFailed	Unable to post article on this server.
errorInvalidDateFormat	The specified date format is not recognized.
errorFeatureNotSupported	The specified feature is not supported on this server.
errorInvalidFormHandle	The specified form handle is invalid or a form has not been created.
errorInvalidFormAction	The specified form action is invalid or has not been specified.
errorInvalidFormMethod	The specified form method is invalid or not supported.
errorInvalidFormType	The specified form type is invalid or not supported.
errorInvalidFormField	The specified form field name is invalid or does not exist.
errorEmptyForm	The specified form does not contain any field values.
errorMaximumConnections	The maximum number of client connections exceeded.
errorThreadCreationFailed	Unable to create a new thread for the current process.
errorInvalidThreadHandle	The specified thread handle is no longer valid.

errorThreadTerminated	The specified thread has been terminated.
errorThreadDeadlock	The operation would result in the current thread becoming deadlocked.
errorInvalidClientMoniker	The specified moniker is not associated with any client session.
errorClientMonikerExists	The specified moniker has been assigned to another client session.
errorServerInactive	The specified server is not listening for client connections.
errorServerSuspended	The specified server is suspended and not accepting client connections.
errorNoMessageStore	No message store has been specified.
errorMessageStoreChanged	The message store has changed since it was last accessed.
errorMessageNotFound	No message was found that matches the specified criteria.
errorMessageDeleted	The specified message has been deleted.
errorFileChecksumMismatch	The local and remote file checksums do not match.
errorFileSizeMismatch	The local and remote file sizes do not match.
errorInvalidFeedUrl	The news feed URL is invalid or specifies an unsupported protocol.
errorInvalidFeedFormat	The internal format of the news feed is invalid.
errorInvalidFeedVersion	This version of the news feed is not supported.
errorChannelEmpty	There are no valid items found in this news feed.
errorInvalidItemNumber	The specified channel item identifier is invalid.
errorItemNotFound	The specified channel item could not be found.
errorItemEmpty	The specified channel item does not contain any data.
errorInvalidItemProperty	The specified item property name is invalid.
errorItemPropertyNotFound	The specified item property has not been defined.
errorInvalidChannelTitle	The channel title is invalid or has not been defined.
errorInvalidChannelLink	The channel hyperlink is invalid or has not been defined.
errorInvalidChannelDescription	The channel description is invalid or has not been defined.
errorInvalidItemText	The description for an item is invalid or has not been defined.
errorInvalidItemLink	The hyperlink for an item is invalid or has not been defined.

errorInvalidServiceType	The specified service type is invalid.
errorServiceSuspended	Access to the specified service has been suspended.
errorServiceRestricted	Access to the specified service has been restricted.
errorInvalidProviderName	The specified provider name is invalid or unknown.
errorInvalidPhoneNumber	The specified phone number is invalid or not supported in this region.
errorGatewayNotFound	A message gateway cannot be found for the specified provider.
errorMessageTooLong	The message exceeds the maximum number of characters permitted.
errorInvalidProviderData	The request returned invalid or incomplete service provider data.
errorInvalidGatewayData	The request returned invalid or incomplete message gateway data.
errorMultipleProviders	The request has returned multiple service providers.
errorProviderNotFound	The specified service provider could not be found.
errorInvalidMessageService	The specified message is not supported with this service type.
errorInvalidMessageFormat	The specified message format is invalid.
errorInvalidConfiguration	The specified configuration options are invalid.
errorServerActive	The requested action is not permitted while the server is active.
errorServerPortBound	Unable to obtain exclusive use of the specified local port.
errorInvalidClientSession	The specified client identifier is invalid for this session.
errorClientNotIdentified	The specified client has not provided user credentials.
errorInvalidClientState	The requested action cannot be performed at this time.
errorInvalidResultCode	The specified result code is not valid for this protocol
errorCommandRequired	The specified command is required and cannot be disabled.
errorCommandDisabled	The specified command has been disabled.
errorCommandSequence	The command cannot be processed at this time.
errorCommandCompleted	The previous command has completed.
errorInvalidProgramName	The specified program name is invalid or unrecognized.

errorInvalidRequestHeader	The request header contains one or more invalid values.
errorInvalidVirtualHost	The specified virtual host name is invalid.
errorVirtualHostNotFound	The specified virtual host does not exist.
errorTooManyVirtualHosts	Too many virtual hosts created for this server.
errorInvalidVirtualPath	The specified virtual path name is invalid.
errorVirtualPathNotFound	The specified virtual path does not exist.
errorTooManyVirtualPaths	Too many virtual paths created for this server.
errorInvalidTask	The asynchronous task identifier is invalid.
errorTaskActive	The asynchronous task has not finished.
errorTaskQueued	The asynchronous task has been queued.
errorTaskSuspended	The asynchronous task has been suspended.
errorTaskFinished	The asynchronous task has finished.

Requirements

Namespace: SocketTools

Assembly: SocketTools.TextMessage (in SocketTools.TextMessage.dll)

See Also

SocketTools Namespace | LastError Property | LastErrorString Property | OnError Event

TextMessage.ServiceTypes Enumeration

Specifies the gateway services that the TextMessage class supports.

[Visual Basic]
```
Public Enum TextMessage.ServiceTypes
```

[C#]
```
public enum TextMessage.ServiceTypes
```

Members

Member Name	Description
serviceSmtp	The text message will be sent through the mail gateway for the specified service provider. This service uses SMTP to submit the message for delivery, either directly to the server provider's mail gateway server or through a relay server. This is the default service type.

Requirements

Namespace: SocketTools

Assembly: SocketTools.TextMessage (in SocketTools.TextMessage.dll)

See Also

SocketTools Namespace | AuthTypes Enumeration | ServiceType Property (SocketTools.TextMessage)

TextMessage.TraceOptions Enumeration

Specifies the logging options that the TextMessage class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]

```
<Flags>
Public Enum TextMessage.TraceOptions
```

[C#]

```
[Flags]
public enum TextMessage.TraceOptions
```

Remarks

The TextMessage class uses the **TraceOptions** enumeration to specify what kind of debugging information is written to the trace logfile. These options are only meaningful when trace logging is enabled by setting the **Trace** property to **true**.

Members

Member Name	Description	Value
traceDefault	The default trace logging option. This is the same as specifying the **traceInfo** option.	0
traceInfo	All network function calls are written to the trace file. This is the default value.	0
traceError	Only those network function calls which fail are recorded in the trace file.	1
traceWarning	Only those network function calls which fail, or return values which indicate a warning, are recorded in the trace file.	2
traceHexDump	All network function calls are written to the trace file, plus all the data that is sent or received is displayed, in both ASCII and hexadecimal format.	4

Requirements

Namespace: SocketTools

Assembly: SocketTools.TextMessage (in SocketTools.TextMessage.dll)

See Also

SocketTools Namespace | Trace Property (SocketTools.TextMessage) | TraceFile Property (SocketTools.TextMessage) | TraceFlags Property (SocketTools.TextMessage)

TextMessage.OnErrorEventHandler Delegate

Represents the method that will handle the OnError event.

[Visual Basic]

```
Public Delegate Sub TextMessage.OnErrorEventHandler( _
   ByVal sender As Object, _
   ByVal e As ErrorEventArgs _
)
```

[C#]

```
public delegate void TextMessage.OnErrorEventHandler(
      object sender,
      ErrorEventArgs e
   );
```

Parameters

sender

The source of the event.

e

An ErrorEventArgs that contains the event data.

Remarks

When you create an **OnErrorEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnErrorEventHandler** delegate declaration.

Requirements

Namespace: SocketTools

Assembly: SocketTools.TextMessage (in SocketTools.TextMessage.dll)

See Also

SocketTools Namespace

TextMessage.RuntimeLicenseAttribute Class

Attribute that defines the runtime license key for the class.

For a list of all members of this type, see TextMessage.RuntimeLicenseAttribute Members.

System.Object
  System.Attribute
    SocketTools.TextMessage.RuntimeLicenseAttribute

[Visual Basic]

```
<AttributeUsage(ValidOn:=AttributeTargets.Assembly, AllowMultiple:=False,
   Inherited:=True)>
Public Class TextMessage.RuntimeLicenseAttribute
    Inherits Attribute
```

[C#]

```
[AttributeUsage(ValidOn=AttributeTargets.Assembly, AllowMultiple=False,
   Inherited=True)]
public class TextMessage.RuntimeLicenseAttribute : Attribute
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

The RuntimeLicense attribute is used to define the runtime license key that will be used when an instance of the class is created. This attribute is defined in the assembly information module for the language, such as AssemblyInfo.cs when programming C#. The runtime license key must be defined if you wish to redistribute your application.

The runtime license key for your copy of SocketTools can be generated using the License Manager utility that is included with the product. Note that if you have installed an evaluation license, you will not have a runtime license key and cannot redistribute any applications which use the TextMessage class.

Example

```
<Assembly: SocketTools.TextMessage.RuntimeLicense("abcdefghijklmnop")>
```

```
[assembly: SocketTools.TextMessage.RuntimeLicense("abcdefghijklmnop")]
```

Requirements

Namespace: SocketTools

Assembly: SocketTools.TextMessage (in SocketTools.TextMessage.dll)

See Also

TextMessage.RuntimeLicenseAttribute Members | SocketTools Namespace

TextMessage.RuntimeLicenseAttribute Members

TextMessage.RuntimeLicenseAttribute overview

Public Instance Constructors

TextMessage.RuntimeLicenseAttribute Constructor	Constructor for the RuntimeLicense attribute which defines the runtime license key.

Public Instance Properties

LicenseKey	Returns the value of the runtime license key.
TypeId (inherited from Attribute)	When implemented in a derived class, gets a unique identifier for this Attribute.

Public Instance Methods

Equals (inherited from Attribute)	
GetHashCode (inherited from Attribute)	Returns the hash code for this instance.
GetType (inherited from Object)	Gets the Type of the current instance.
IsDefaultAttribute (inherited from Attribute)	When overridden in a derived class, returns an indication whether the value of this instance is the default value for the derived class.
Match (inherited from Attribute)	When overridden in a derived class, returns a value indicating whether this instance equals a specified object.
ToString (inherited from Object)	Returns a String that represents the current Object.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

TextMessage.RuntimeLicenseAttribute Class | SocketTools Namespace

TextMessage.RuntimeLicenseAttribute Constructor

Constructor for the RuntimeLicense attribute which defines the runtime license key.

[Visual Basic]

```
Public Sub New( _
   ByVal licenseKey As String _
)
```

[C#]

```
public TextMessage.RuntimeLicenseAttribute(
   string licenseKey
);
```

Parameters

licenseKey

A string argument which specifies the runtime license key which will be used to initialize the class library.

Remarks

The runtime license key for your copy of SocketTools can be generated using the License Manager utility that is included with the product. Note that if you have installed an evaluation license, you will not have a runtime license key and cannot redistribute any applications which use the TextMessage class.

TextMessage.RuntimeLicenseAttribute Class | SocketTools Namespace

TextMessage.RuntimeLicenseAttribute Properties

The properties of the **TextMessage.RuntimeLicenseAttribute** class are listed below. For a complete list of **TextMessage.RuntimeLicenseAttribute** class members, see the TextMessage.RuntimeLicenseAttribute Members topic.

Public Instance Properties

LicenseKey	Returns the value of the runtime license key.
TypeId (inherited from Attribute)	When implemented in a derived class, gets a unique identifier for this Attribute.

See Also

TextMessage.RuntimeLicenseAttribute Class | SocketTools Namespace

TextMessage.RuntimeLicenseAttribute.LicenseKey Property

Returns the value of the runtime license key.

[Visual Basic]

```
Public Property LicenseKey As String
```

[C#]

```
public string LicenseKey {get; set;}
```

Property Value

A string which contains the runtime license key.

See Also

TextMessage.RuntimeLicenseAttribute Class | SocketTools Namespace

TextMessageException Class

The exception that is thrown when a client error occurs.

For a list of all members of this type, see TextMessageException Members.

System.Object
  System.Exception
    System.ApplicationException
      SocketTools.TextMessageException

[Visual Basic]
```
Public Class TextMessageException
    Inherits ApplicationException
```

[C#]
```
public class TextMessageException : ApplicationException
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

A TextMessageException is thrown by the TextMessage class when an error occurs.

The default constructor for the TextMessageException class sets the **ErrorCode** property to the last client error that occurred.

Requirements

Namespace: SocketTools

Assembly: SocketTools.TextMessage (in SocketTools.TextMessage.dll)

See Also

TextMessageException Members | SocketTools Namespace

TextMessageException Members

TextMessageException overview

Public Instance Constructors

TextMessageException	Overloaded. Initializes a new instance of the TextMessageException class.

Public Instance Properties

ErrorCode	Gets a value which specifies the error that caused the exception.
HelpLink (inherited from Exception)	Gets or sets a link to the help file associated with this exception.
InnerException (inherited from Exception)	Gets the Exception instance that caused the current exception.
Message	Gets a value which describes the error that caused the exception.
Number	Gets a value which specifies the numeric value of the error that caused the exception.
Source (inherited from Exception)	Gets or sets the name of the application or the object that causes the error.
StackTrace (inherited from Exception)	Gets a string representation of the frames on the call stack at the time the current exception was thrown.
TargetSite (inherited from Exception)	Gets the method that throws the current exception.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetBaseException (inherited from Exception)	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetObjectData (inherited from Exception)	When overridden in a derived class, sets the SerializationInfo with information about the exception.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString	Creates and returns a string representation of the current exception.

Protected Instance Properties

HResult (inherited from Exception)	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

TextMessageException Class | SocketTools Namespace

TextMessageException Constructor

Initializes a new instance of the TextMessageException class with the last network error code.

Overload List

Initializes a new instance of the TextMessageException class with the last network error code.

public TextMessageException();

Initializes a new instance of the TextMessageException class with a specified error number.

public TextMessageException(int);

Initializes a new instance of the TextMessageException class with a specified error message.

public TextMessageException(string);

Initializes a new instance of the TextMessageException class with a specified error message and a reference to the inner exception that is the cause of this exception.

public TextMessageException(string,Exception);

See Also

TextMessageException Class | SocketTools Namespace

TextMessageException Constructor ()

Initializes a new instance of the TextMessageException class with the last network error code.

[Visual Basic]

```
Overloads Public Sub New()
```

[C#]

```
public TextMessageException();
```

Remarks

The ctor constructor sets the **ErrorCode** property to the last client error that occurred. For more information about the errors that may occur, refer to the TextMessage.ErrorCode enumeration.

See Also

TextMessageException Class | SocketTools Namespace | TextMessageException Constructor Overload List

TextMessageException Constructor (Int32)

Initializes a new instance of the TextMessageException class with a specified error number.

[Visual Basic]

```
Overloads Public Sub New( _
   ByVal code As Integer _
)
```

[C#]

```
public TextMessageException(
   int code
);
```

Parameters

code

An integer value which specifies an error code.

Remarks

This constructor sets the **ErrorCode** property to the specified error code. For more information about the errors that may occur, refer to the TextMessage.ErrorCode enumeration.

See Also

TextMessageException Class | SocketTools Namespace | TextMessageException Constructor Overload List

TextMessageException Constructor (String)

Initializes a new instance of the TextMessageException class with a specified error message.

[Visual Basic]

```
Overloads Public Sub New( _
   ByVal message As String _
)
```

[C#]

```
public TextMessageException(
   string message
);
```

Parameters

message

The error message that explains the reason for the exception.

Remarks

The content of the ***message*** parameter is intended to be understood by humans. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

See Also

TextMessageException Class | SocketTools Namespace | TextMessageException Constructor Overload List

TextMessageException Constructor (String, Exception)

Initializes a new instance of the TextMessageException class with a specified error message and a reference to the inner exception that is the cause of this exception.

[Visual Basic]

```
Overloads Public Sub New( _
   ByVal message As String, _
   ByVal innerException As Exception _
)
```

[C#]

```
public TextMessageException(
   string message,
   Exception innerException
);
```

Parameters

message
The error message that explains the reason for the exception.

innerException
The exception that is the cause of the current exception. If the *innerException* parameter is not a null reference, the current exception is raised in a **catch** block that handles the inner exception.

Remarks

The content of the message parameter is intended to be understood by humans. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

An exception that is thrown as a direct result of a previous exception should include a reference to the previous exception in the **InnerException** property. The **InnerException** property returns the same value that is passed into the constructor, or a null reference if the **InnerException** property does not supply the inner exception value to the constructor.

TextMessageException Class | SocketTools Namespace | TextMessageException Constructor Overload List

TextMessageException Properties

The properties of the **TextMessageException** class are listed below. For a complete list of **TextMessageException** class members, see the TextMessageException Members topic.

Public Instance Properties

ErrorCode	Gets a value which specifies the error that caused the exception.
HelpLink (inherited from Exception)	Gets or sets a link to the help file associated with this exception.
InnerException (inherited from Exception)	Gets the Exception instance that caused the current exception.
Message	Gets a value which describes the error that caused the exception.
Number	Gets a value which specifies the numeric value of the error that caused the exception.
Source (inherited from Exception)	Gets or sets the name of the application or the object that causes the error.
StackTrace (inherited from Exception)	Gets a string representation of the frames on the call stack at the time the current exception was thrown.
TargetSite (inherited from Exception)	Gets the method that throws the current exception.

Protected Instance Properties

HResult (inherited from Exception)	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception.

See Also

TextMessageException Class | SocketTools Namespace

TextMessageException.ErrorCode Property

Gets a value which specifies the error that caused the exception.

[Visual Basic]

```
Public ReadOnly Property ErrorCode As ErrorCode
```

[C#]

```
public TextMessage.ErrorCode ErrorCode {get;}
```

Property Value

Returns a TextMessage.ErrorCode enumeration value which specifies the error code.

Remarks

The **ErrorCode** property returns the error code that specifies the cause of the exception.

The default constructor for the TextMessageException class sets the error code to the last network error that occurred. For more information about the errors that may occur, refer to the TextMessage.ErrorCode enumeration.

See Also

TextMessageException Class | SocketTools Namespace

TextMessageException.Message Property

Gets a value which describes the error that caused the exception.

[Visual Basic]

```
Overrides Public ReadOnly Property Message As String
```

[C#]

```
public override string Message {get;}
```

Property Value

A string which describes the error that caused the exception.

Remarks

The **Message** property returns a string which describes the error that caused the exception.

See Also

TextMessageException Class | SocketTools Namespace

TextMessageException.Number Property

Gets a value which specifies the numeric value of the error that caused the exception.

[Visual Basic]

```
Public ReadOnly Property Number As Integer
```

[C#]

```
public int Number {get;}
```

Property Value

An integer value that specifies the error that caused the exception.

Remarks

The **Number** property returns an integer value which specifies the numeric value of the error that caused the exception. For network related errors, this value is the same as the values returned by the Windows Sockets API. For more information about socket error codes, see the Windows Socket Version 2 API error code documentation in MSDN.

See Also

TextMessageException Class | SocketTools Namespace

TextMessageException Methods

The methods of the **TextMessageException** class are listed below. For a complete list of **TextMessageException** class members, see the TextMessageException Members topic.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetBaseException (inherited from Exception)	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetObjectData (inherited from Exception)	When overridden in a derived class, sets the SerializationInfo with information about the exception.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString	Creates and returns a string representation of the current exception.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

TextMessageException Class | SocketTools Namespace

TextMessageException.ToString Method

Creates and returns a string representation of the current exception.

[Visual Basic]
```
Overrides Public Function ToString() As String
```

[C#]
```
public override string ToString();
```

Return Value

A string representation of the current exception.

Remarks

The **ToString** method returns a representation of the current exception that is intended to be understood by humans. Where the exception contains culture-sensitive data, the string representation returned by **ToString** is required to take into account the current system culture. Although there are no exact requirements for the format of the returned string, it should attempt to reflect the value of the object as perceived by the user.

This implementation of **ToString** obtains the numeric error code value and a description of the error that caused the current exception. If there is no error message or it is an empty string, then no error message is returned.

This method overrides **ApplicationException.ToString**.

See Also

TextMessageException Class | SocketTools Namespace

WebLocation Class

Get physical location information for the local computer system.

For a list of all members of this type, see WebLocation Members.

System.Object
  SocketTools.WebLocation

[Visual Basic]

```
Public Class WebLocation
    Implements IDisposable
```

[C#]

```
public class WebLocation : IDisposable
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

The **SocketTools.WebLocation** class returns information about the location associated with the with the external IP address of the local system. The accuracy of this information can vary depending on the location, with the most detailed information being available for North America. The country and time zone information for all locations is generally accurate. However, as the location information becomes more precise, details such as city names, postal codes and specific geographic locations (e.g.: longitude and latitude) may have reduced accuracy.

This location information should not be used by applications which require extremely accurate map coordinates, such as navigation software. The location information in North America should be generally accurate within a 25 mile (40km) radius. However, given the nature of how IP address location works, there is no guarantee that location information for any specific IP address or network will be accurate.

Software that is designed to protect the privacy of users, such as those which route all Internet traffic through proxy servers or VPNs, can significantly impact the accuracy of this information. In this case, the data returned by this class may reflect the location of the network or proxy server, and not the location of the person using your application. It is recommended that you always request permission from the user before acquiring their location, have them confirm that the location is correct and provide a mechanism for them to update that information.

This component uses SocketTools Web Services and will only function if there is an active Internet connection and the local system is capable of establishing a secure connection to the location service.

Requirements

Namespace: SocketTools

Assembly: SocketTools.WebLocation (in SocketTools.WebLocation.dll)

See Also

WebLocation Members | SocketTools Namespace

WebLocation Members

WebLocation overview

Public Instance Constructors

WebLocation Constructor	Initializes a new instance of the WebLocation class.

Public Instance Properties

ASNumber	Gets the autonomous system number for the network.
CityName	Gets the city name for the current location.
Coordinates	Gets the GPS coordinates for the current location.
CountryAlpha	Gets the ISO code for the country at the current location.
CountryCode	Gets the numeric code for the country at the current location.
CountryName	Gets the name of the country for the current location.
IPAddress	Gets the external IP address for the local system.
IsInitialized	Determine if the class instance has been initialized.
LastError	Gets and sets a value which specifies the last error that has occurred.
LastErrorString	Gets a value which describes the last error that has occurred.
LastUpdate	Gets the number of seconds since the last location update.
Latitude	Gets the latitude for the current location.
LocalTime	Gets the local time adjusted for the location's time zone.
LocationId	Gets a unique identifier for the current location.
Longitude	Gets the longitude for the current location
Organization	Gets the name of the organization that owns the network.
PostalCode	Gets the postal code for the current location.
RegionCode	Gets the numeric region code for the current location.
RegionName	Gets the region name for the current location
Subdivision	Gets the subdivision name for the current location.
SubdivisionCode	Gets the alphanumeric code for the current subdivision.
ThrowError	Gets and sets a value which specifies if method

	calls should throw exceptions when an error occurs.
Timeout	Gets and sets the number of seconds to wait until a location query fails.
Timezone	Gets the time zone for the current location.
Trace	Gets and sets a value which indicates if network function logging is enabled.
TraceFile	Gets and sets a value which specifies the name of the logfile.
TraceFlags	Gets and sets a value which specifies the client function tracing flags.
TzOffset	Gets the time zone offset in seconds for the current location.
TzShortName	Gets an abbreviated time zone name for the current location.
Version	Gets a value which returns the current version of the WebLocation class library.

Public Instance Methods

Dispose	Overloaded. Releases all resources used by WebLocation.
Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from Object)	Gets the Type of the current instance.
Initialize	Overloaded. Initialize an instance of the WebLocation class.
Reset	Reset the internal state of the object, resetting all properties to their default values.
ToString (inherited from Object)	Returns a String that represents the current Object.
Uninitialize	Uninitialize the class library and release any resources allocated for the current thread.
Update	Update the current location information for the local system.

Public Instance Events

OnError	Occurs when an client operation fails.

Protected Instance Methods

Dispose	Overloaded. Releases the unmanaged resources allocated by the WebLocation class and optionally

	releases the managed resources.
Finalize	Destroys an instance of the class, releasing the resources allocated for the session and unloading the networking library.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

WebLocation Properties

The properties of the **WebLocation** class are listed below. For a complete list of **WebLocation** class members, see the WebLocation Members topic.

Public Instance Properties

ASNumber	Gets the autonomous system number for the network.
CityName	Gets the city name for the current location.
Coordinates	Gets the GPS coordinates for the current location.
CountryAlpha	Gets the ISO code for the country at the current location.
CountryCode	Gets the numeric code for the country at the current location.
CountryName	Gets the name of the country for the current location.
IPAddress	Gets the external IP address for the local system.
IsInitialized	Determine if the class instance has been initialized.
LastError	Gets and sets a value which specifies the last error that has occurred.
LastErrorString	Gets a value which describes the last error that has occurred.
LastUpdate	Gets the number of seconds since the last location update.
Latitude	Gets the latitude for the current location.
LocalTime	Gets the local time adjusted for the location's time zone.
LocationId	Gets a unique identifier for the current location.
Longitude	Gets the longitude for the current location
Organization	Gets the name of the organization that owns the network.
PostalCode	Gets the postal code for the current location.
RegionCode	Gets the numeric region code for the current location.
RegionName	Gets the region name for the current location
Subdivision	Gets the subdivision name for the current location.
SubdivisionCode	Gets the alphanumeric code for the current subdivision.
ThrowError	Gets and sets a value which specifies if method calls should throw exceptions when an error occurs.

Timeout	Gets and sets the number of seconds to wait until a location query fails.
Timezone	Gets the time zone for the current location.
Trace	Gets and sets a value which indicates if network function logging is enabled.
TraceFile	Gets and sets a value which specifies the name of the logfile.
TraceFlags	Gets and sets a value which specifies the client function tracing flags.
TzOffset	Gets the time zone offset in seconds for the current location.
TzShortName	Gets an abbreviated time zone name for the current location.
Version	Gets a value which returns the current version of the WebLocation class library.

See Also

WebLocation Class | SocketTools Namespace

WebLocation.ASNumber Property

Gets the autonomous system number for the network.

[Visual Basic]

```
Public ReadOnly Property ASNumber As Integer
```

[C#]

```
public int ASNumber {get;}
```

Property Value

An integer value which uniquely identifies a global network.

Remarks

This property returns an integer value which is used to uniquely identify a global network (autonomous system) that is connected to the Internet. This number is assigned by regional registries and used by large networks, such as Internet Service Providers, for exchanging routing information with one another. This value can be used to determine the ownership of a particular network.

See Also

WebLocation Class | SocketTools Namespace | IPAddress Property | LocationId Property | Organization Property

WebLocation.CityName Property

Gets the city name for the current location.

[Visual Basic]

```
Public ReadOnly Property CityName As String
```

[C#]

```
public string CityName {get;}
```

Property Value

A string which identifies the city in which the external IP address is located.

Remarks

This property returns a string which identifies the city in which the external IP address is located. These names will always be in English, regardless of the current system locale. If the city name cannot be determined, this property may return an empty string.

See Also

WebLocation Class | SocketTools Namespace | CountryName Property | PostalCode Property | RegionName Property | Subdivision Property

WebLocation.Coordinates Property

Gets the GPS coordinates for the current location.

[Visual Basic]

```
Public ReadOnly Property Coordinates As String
```

[C#]

```
public string Coordinates {get;}
```

Property Value

A string which specifies the location coordinates.

Remarks

This property returns a string which specifies the location expressed using the Universal Transverse Mercator (UTM) coordinate system with the WGS-84 ellipsoid. UTM coordinates are commonly used with the Global Positioning System (GPS) and are comprised of three parts: the zone, the easting (the eastward-measured distance or x-coordinate) and the northing (the northward-measured distance or y-coordinate). An example of a string value returned by this property would be "14S 702089E 3646476N".

See Also

WebLocation Class | SocketTools Namespace | Latitude Property | Longitude Property

WebLocation.CountryAlpha Property

Gets the ISO code for the country at the current location.

[Visual Basic]

```
Public ReadOnly Property CountryAlpha As String
```

[C#]

```
public string CountryAlpha {get;}
```

Property Value

A string which contains the ISO 3166-1 alpha-2 code for the country.

Remarks

This property returns a string which contains the ISO 3166-1 alpha-2 code for the country the external IP address is located in. This is a two-letter country code established by the International Organization for Standardization (ISO).

The SubdivisionCode property can be used to determine the standard ISO standard code for a regional subdivision (such as a state, province or territory). For example, if the IP address is located in Los Angeles, California the CountryAlpha property would return "US" and the SubdivisionCode property would return "CA".

See Also

WebLocation Class | SocketTools Namespace | CountryCode Property | CountryName Property | RegionName Property | Subdivision Property | SubdivisionCode Property

WebLocation.CountryCode Property

Gets the numeric code for the country at the current location.

[Visual Basic]
```
Public ReadOnly Property CountryCode As Integer
```

[C#]
```
public int CountryCode {get;}
```

Property Value

An integer value which identifies the country where the external IP address is located.

Remarks

This property returns an integer value which identifies the country where the external IP address is located. These codes can be up to three digits (usually displayed with leading zeros as necessary) and correspond to the country codes assigned by the United Nations. For example, the code for the United States is 840. It is important to note that these are not international dialing codes and should not be used with telephony applications.

See Also

WebLocation Class | SocketTools Namespace | CountryAlpha Property | CountryName Property | RegionName Property | Subdivision Property

WebLocation.CountryName Property

Gets the name of the country for the current location.

[Visual Basic]

```
Public ReadOnly Property CountryName As String
```

[C#]

```
public string CountryName {get;}
```

Property Value

A string which contains the full name of the country.

Remarks

This property returns a string which contains the full name of the country in which the external IP address is located. These names will always be in English, regardless of the current system locale.

See Also

WebLocation Class | SocketTools Namespace | CountryAlpha Property | CountryCode Property | RegionName Property | Subdivision Property

WebLocation.ErrorEventArgs.Description Property

Gets a value which describes the last error that has occurred.

[Visual Basic]

```
Public ReadOnly Property Description As String
```

[C#]

```
public string Description {get;}
```

Property Value

A string which describes the last error that has occurred.

See Also

WebLocation.ErrorEventArgs Class | SocketTools Namespace | Error Property

WebLocation.IPAddress Property

Gets the external IP address for the local system.

[Visual Basic]

```
Public ReadOnly Property IPAddress As String
```

[C#]

```
public string IPAddress {get;}
```

Property Value

a string which specifies the external IP address for the local system.

Remarks

This property returns a string which specifies the external IP address for the local system. If the system has been assigned multiple IP addresses, it reflects the address of the interface that was used to establish a connection with the SocketTools server. If the connection is made through a Virtual Private Network (VPN) it will use that assigned IP address. If a connection is made through a proxy server, the IP address may be address of the proxy rather than the local host, depending on how the connection is made.

This property cannot be assigned a value to query the location of different IP addresses. If the external IP address of the local system cannot be determined, this property will return an empty string.

See Also

WebLocation Class | SocketTools Namespace | ASNumber Property | LocationId Property | Organization Property

WebLocation.IsInitialized Property

Determine if the class instance has been initialized.

[Visual Basic]

```
Public ReadOnly Property IsInitialized As Boolean
```

[C#]

```
public bool IsInitialized {get;}
```

Property Value

A boolean value which specifies if the class instance has been initialized.

Remarks

This property is used to determine if the current instance of the class has been initialized properly. Normally this is done by calling the **Initialize** method after the class has been instantiated. If this property returns **false**, the application must call the **Initialize** method with a valid runtime license key before performing any other operation.

The most common reason that the class instance may not initialize correctly is that no valid development or runtime license key can be found or the license key that was provided is invalid. It may also indicate a problem with the system configuration or user access rights, such as not being able to load the required networking libraries or not being able to access the system registry

See Also

WebLocation Class | SocketTools Namespace | Initialize Method

WebLocation.LastError Property

Gets and sets a value which specifies the last error that has occurred.

[Visual Basic]

```
Public Property LastError As ErrorCode
```

[C#]

```
public WebLocation.ErrorCode LastError {get; set;}
```

Property Value

Returns an ErrorCode enumeration value which specifies the last error code.

Remarks

The **LastError** property returns the error code associated with the last error that occurred for the current instance of the class. It is important to note that this value only has meaning if the previous method indicates that an error has actually occurred.

It is possible to explicitly clear the last error code by assigning the property to the value **ErrorCode.errorNone**.

The error code value can be cast to an integer value for display purposes if required. For a description of the error that can be displayed using a message box or some other similar mechanism, get the value of the **LastErrorString** property.

See Also

WebLocation Class | SocketTools Namespace

WebLocation.LastErrorString Property

Gets a value which describes the last error that has occurred.

[Visual Basic]

```
Public ReadOnly Property LastErrorString As String
```

[C#]

```
public string LastErrorString {get;}
```

Property Value

A string which describes the last error that has occurred.

Remarks

The **LastErrorString** property can be used to obtain a description of the last error that occurred for the current instance of the class. It is important to note that this value only has meaning if the previous method indicates that an error has actually occurred.

See Also

WebLocation Class | SocketTools Namespace

WebLocation.LastUpdate Property

Gets the number of seconds since the last location update.

[Visual Basic]

```
Public ReadOnly Property LastUpdate As Integer
```

[C#]

```
public int LastUpdate {get;}
```

Property Value

An integer value which specifies the number of seconds since the last location query was performed.

Remarks

This property returns an integer value which specifies the number of seconds since the last location query was performed. A return value of zero indicates that the current location has not been updated.

See Also

WebLocation Class | SocketTools Namespace | Reset Method | Update Method

WebLocation.Latitude Property

Gets the latitude for the current location.

[Visual Basic]

```
Public ReadOnly Property Latitude As Double
```

[C#]

```
public double Latitude {get;}
```

Property Value

A numeric value which specifies the latitude of the current location in decimal format

Remarks

This property returns a value which specifies the latitude of the current location in decimal format. A positive value indicates a location that is north of the equator, while a negative value is a location that is south of the equator.

See Also

WebLocation Class | SocketTools Namespace | Coordinates Property | Longitude Property

WebLocation.LocalTime Property

Gets the local time adjusted for the location's time zone.

[Visual Basic]

```
Public ReadOnly Property LocalTime As Date
```

[C#]

```
public System.DateTime LocalTime {get;}
```

Property Value

A **DateTime** value which contains the date and time at the current location.

Remarks

This property returns the current date and time at the location, adjusted for its time zone and whether or not it's in daylight savings time.

If the current location cannot be determined, this property will return **DateTime.MinValue**.

See Also

WebLocation Class | SocketTools Namespace | Timezone Property | TzOffset Property | TzShortName Property

WebLocation.LocationId Property

Gets a unique identifier for the current location.

[Visual Basic]

```
Public ReadOnly Property LocationId As String
```

[C#]

```
public string LocationId {get;}
```

Property Value

A string of hexadecimal characters which uniquely identifies the location for this computer system

Remarks

This property returns a string of hexadecimal characters which uniquely identifies the location for this computer system. This value is used internally by the location service, and may also be used by the application for its own purposes. If this value changes in subsequent queries, it indicates the external IP address for the local system has changed.

See Also

WebLocation Class | SocketTools Namespace | ASNumber Property | IPAddress Property | Organization Property

WebLocation.Longitude Property

Gets the longitude for the current location

[Visual Basic]

```
Public ReadOnly Property Longitude As Double
```

[C#]

```
public double Longitude {get;}
```

Property Value

A numeric value which specifies the longitude of the current location in decimal format

Remarks

This property returns a value which specifies the longitude of the current location in decimal format. A positive value indicates a location that is east of the prime meridian, while a negative value is a location that is west of the prime meridian.

See Also

WebLocation Class | SocketTools Namespace | Coordinates Property | Latitude Property

WebLocation.Organization Property

Gets the name of the organization that owns the network.

[Visual Basic]

```
Public ReadOnly Property Organization As String
```

[C#]

```
public string Organization {get;}
```

Property Value

A string which identifies the organization associated with the local system's external IP address.

Remarks

This property returns a string which identifies the organization associated with the local system's external IP address. For residential end-users this is typically the name of their Internet Service provider, however it may also identify a private company such as Microsoft, Google or Amazon. Because of the nature of how this information is updated, the organization names can change over time due to acquisitions or changes of ownership. If the owner of the network cannot be determined, this property may return an empty string.

WebLocation Class | SocketTools Namespace | ASNumber Property | IPAddress Property | LocationId Property

WebLocation.PostalCode Property

Gets the postal code for the current location.

[Visual Basic]
```
Public ReadOnly Property PostalCode As String
```

[C#]
```
public string PostalCode {get;}
```

Property Value

A string which specifies the postal code for the current location.

Remarks

This property returns a string which contains the postal code associated with the area where the IP address is located. In the United States, this is a 5-digit numeric code. In Canada, this will contain the forward sortation area (the first three characters of the six character postal code). Local delivery portions of a postal code (such as the ZIP+4 code in the United States, or the local delivery unit in Canada) are not included.

This information will be most accurate within the geographic region of North America. Postal codes are locale specific, and this property may return an empty string if the postal code for the location cannot be determined.

WebLocation Class | SocketTools Namespace | CityName Property | CountryName Property | RegionName Property | Subdivision Property

WebLocation.RegionCode Property

Gets the numeric region code for the current location.

[Visual Basic]

```
Public ReadOnly Property RegionCode As Integer
```

[C#]

```
public int RegionCode {get;}
```

Property Value

An integer value which identifies the geographical region in which the external IP address is located.

Remarks

This property returns an integer value which identifies the geographical region in which the external IP address is located. This value corresponds to the name returned by the **RegionName** property. The numeric values use the UN M49 standard established by the United Nations Statistics Division.

See Also

WebLocation Class | SocketTools Namespace | CityName Property | CountryName Property | RegionName Property | Subdivision Property

WebLocation.RegionName Property

Gets the region name for the current location

[Visual Basic]

```
Public ReadOnly Property RegionName As String
```

[C#]

```
public string RegionName {get;}
```

Property Value

A string which identifies the region in which the external IP address is located.

Remarks

This property returns a string which identifies the region in which the external IP address is located. This refers to a broad geographical area, such as "North America" or "Southeast Asia" and uses the conventions for supranational regions as defined by UN M49 codes. These names will always be in English, regardless of the current system locale.

See Also

WebLocation Class | SocketTools Namespace | CityName Property | CountryName Property | RegionCode Property | Subdivision Property

WebLocation.Subdivision Property

Gets the subdivision name for the current location.

[Visual Basic]

```
Public ReadOnly Property Subdivision As String
```

[C#]

```
public string Subdivision {get;}
```

Property Value

A string which identifies the geopolitical subdivision within a country where the external IP address is located.

Remarks

This property returns a string which identifies the geopolitical subdivision within a country where the external IP address is located. In the United States, this will contain the full name of the state or commonwealth. In Canada, this will contain the name of the province or territory. These names will always be in English, regardless of the current system locale.

If a subdivision name does not exist for the location, this property will return an empty string.

The **SubdivisionCode** property will return a standardized abbreviation for the area. For example, in the United States it would return the two-character code for the state.

See Also

WebLocation Class | SocketTools Namespace | CityName Property | CountryName Property | RegionName Property | SubdivisionCode Property

WebLocation.SubdivisionCode Property

Gets the alphanumeric code for the current subdivision.

[Visual Basic]

```
Public ReadOnly Property SubdivisionCode As String
```

[C#]

```
public string SubdivisionCode {get;}
```

Property Value

A string which is either a two- or three-letter code which identifies a geopolitical subdivision within the country.

Remarks

This property returns a string string which is either a two- or three-letter code which identifies a geopolitical subdivision within the country where the external IP address is located. These codes are defined by the ISO 3166-2 standard. For example, the code for the state of California in the United States is "CA".

For international specificity, these subdivision codes are often combined with the value of the ISO alpha-2 code returned by the **CountryAlpha** property. For example, to identify the state of California, you could combine with the alpha-2 code for the United States, creating "US-CA" as an identifier.

If a subdivision code does not exist for the location, this property will return an empty string.

See Also

WebLocation Class | SocketTools Namespace | CityName Property | CountryName Property | RegionName Property | Subdivision Property

WebLocation.ThrowError Property

Gets and sets a value which specifies if method calls should throw exceptions when an error occurs.

[Visual Basic]

```
Public Property ThrowError As Boolean
```

[C#]

```
public bool ThrowError {get; set;}
```

Property Value

Returns **true** if method calls will generate exceptions when an error occurs; otherwise returns **false**. The default value is **false**.

Remarks

Error handling for when calling class methods can be done in either of two different styles, according to the value of this property.

If the **ThrowError** property is set to **false**, the application should check the return value of any method that is used, and report errors based upon the documented value of the return code. It is the responsibility of the application to interpret the error code, if it is desired to explain the error in addition to reporting it. This is the default behavior.

If the **ThrowError** property is set to **true**, then exceptions will be generated whenever a method call fails. The program must be written to catch these exceptions and take the appropriate action when an error occurs. Failure to handle an exception will cause the program to terminate abnormally.

Note that if an error occurs while a property is being read or modified, an exception will be raised regardless of the value of the **ThrowError** property.

See Also

WebLocation Class | SocketTools Namespace | LastError Property | LastErrorString Property

WebLocation.Timeout Property

Gets and sets the number of seconds to wait until a location query fails.

[Visual Basic]

```
Public Property Timeout As Integer
```

[C#]

```
public int Timeout {get; set;}
```

Property Value

An integer value which specifies a timeout period in seconds.

Remarks

Setting this property specifies the number of seconds until a request for location information fails and returns an error. This includes the amount of time spent attempting to connect to the location service. If a connection cannot be established within the given time period, the operation will fail.

See Also

WebLocation Class | SocketTools Namespace | Update Method

WebLocation.Timezone Property

Gets the time zone for the current location.

[Visual Basic]

```
Public ReadOnly Property Timezone As String
```

[C#]

```
public string Timezone {get;}
```

Property Value

A string which specifies the full time zone name in which the external IP address is located.

Remarks

This property returns a string which specifies the full time zone name in which the external IP address is located. These names are defined by the Internet Assigned Numbers Authority (IANA) and have values like "America/Los_Angeles" and "Europe/London". These time zones may also be defined as "Etc/GMT+10" if there is not a regional name associated with the time zone.

The **TzShortName** property will return an abbreviated time zone name, such as "PST".

See Also

WebLocation Class | SocketTools Namespace | LocalTime Property | TzOffset Property | TzShortName Property

WebLocation.Trace Property

Gets and sets a value which indicates if network function logging is enabled.

[Visual Basic]

```
Public Property Trace As Boolean
```

[C#]

```
public bool Trace {get; set;}
```

Property Value

Returns **true** if network function tracing is enabled; otherwise returns **false**. The default value is **false**.

Remarks

The **Trace** property is used to enable (or disable) the tracing of network function calls. When enabled, each function call is logged to a file, including the function parameters, return value and error code if applicable. This facility can be enabled and disabled at run time, and the trace log file can be specified by setting the **TraceFile** property. All function calls that are being logged are appended to the trace file, if it exists. If no trace file exists when tracing is enabled, the trace file is created.

The tracing facility is available in all of the SocketTools networking classes and is enabled or disabled for an entire process. This means that once trace logging is enabled for a given component, all of the function calls made by the process using any of the SocketTools classes will be logged. For example, if you have an application using both the File Transfer Protocol and Post Office Protocol classes, and you set the **Trace** property to **true**, function calls made by both classes will be logged. Additionally, enabling a trace is cumulative, and tracing is not stopped until it is disabled for all classes used by the process.

If trace logging is not enabled, there is no negative impact on performance or throughput. Once enabled, application performance can degrade, especially in those situations in which multiple processes are being traced or the logfile is fairly large. Since logfiles can grow very quickly, even with modest applications, it is recommended that you delete the file when it is no longer needed.

When redistributing your application, make sure that you include the **SocketTools10.TraceLog.dll** module with your installation. If this library is not present, then no trace output will be generated and the value of the **Trace** property will be ignored. Only those function calls made by the SocketTools networking classes will be logged. Calls made directly to the Windows Sockets API, or calls made by other classes, will not be logged.

See Also

WebLocation Class | SocketTools Namespace

WebLocation.TraceFile Property

Gets and sets a value which specifies the name of the logfile.

[Visual Basic]

```
Public Property TraceFile As String
```

[C#]

```
public string TraceFile {get; set;}
```

Property Value

A string which specifies the name of the file.

Remarks

The **TraceFile** property is used to specify the name of the trace file that is created when network function tracing is enabled. If this property is set to an empty string (the default value), then a file named **SocketTools.log** is created in the system's temporary directory. If no temporary directory exists, then the file is created in the current working directory.

If the file exists, the trace output is appended to the file, otherwise the file is created. Since network function tracing is enabled per-process, the trace file is shared by all instances of the class being used. If multiple class instances have tracing enabled, the **TraceFile** property should be set to the same value for each instance. Since trace files can grow very quickly, even with modest applications, it is recommended that you delete the file when it is no longer needed.

The trace file has the following format:

```
 MyApp INF: WSAAsyncSelect(46, 0xcc4, 0x7e9, 0x27) returned 0 MyApp WRN:
connect(46, 192.0.0.1:1234, 16) returned -1 [10035] MyApp ERR: accept(46,
NULL, 0x0) returned -1 [10038]
```

The first column contains the name of the process that is being traced. The second column identifies if the trace record is reporting information, a warning, or an error. What follows is the name of the function being called, the arguments passed to the function and the function's return value. If a warning or error is reported, the error code is appended to the record (the value is placed inside brackets).

If parameters are passed as integer values, they are recorded in decimal. If the parameter or return value is a pointer (a memory address), it is recorded as a hexadecimal value preceded with "0x". A special type of pointer, called a null pointer, is recorded as NULL. Those functions which expect socket addresses are displayed in the following format:

```
aa.bb.cc.dd:nnnn
```

The first four numbers separated by periods represent the IP address, and the number following the colon represents the port number in host byte order. Note that in the second line of the above example, the component is attempting to connect to a system with the IP address 192.0.0.1 on port 1234.

Note that if the specified file cannot be created, or the user does not have permission to modify an existing file, the error is silently ignored and no trace output will be generated.

See Also

WebLocation Class | SocketTools Namespace

WebLocation.TraceFlags Property

Gets and sets a value which specifies the client function tracing flags.

[Visual Basic]

```
Public Property TraceFlags As TraceOptions
```

[C#]

```
public WebLocation.TraceOptions TraceFlags {get; set;}
```

Property Value

A TraceOptions enumeration which specifies the amount of detail written to the trace logfile.

Remarks

The **TraceFlags** property is used to specify the type of information written to the trace file when network function tracing is enabled.

Because network function tracing is enabled per-process, the trace flags are shared by all instances of the class being used. If multiple class instances have tracing enabled, the **TraceFlags** property should be set to the same value for each instance. Changing the trace flags for any one instance of the class will affect the logging performed for all SocketTools classes used by the application.

Warnings are generated when a non-fatal error is returned by a network function. For example, if data is being written and the error **errorOperationWouldBlock** occurs, a warning is generated because the application simply needs to attempt to write the data at a later time.

See Also

WebLocation Class | SocketTools Namespace

WebLocation.TzOffset Property

Gets the time zone offset in seconds for the current location.

[Visual Basic]
```
Public ReadOnly Property TzOffset As Integer
```

[C#]
```
public int TzOffset {get;}
```

Property Value

An integer which specifies the number of seconds east or west of the prime meridian (UTC).

Remarks

This property returns an integer which specifies the number of seconds east or west of the prime meridian (UTC). A positive value indicates a time zone that is east of the prime meridian and a negative value indicates a time zone that is west of the prime meridian. For example, the Pacific time zone in the western United States during daylight savings time would have a value of -25200 (7 hours).

See Also

WebLocation Class | SocketTools Namespace | LocalTime Property | Timezone Property | TzShortName Property

WebLocation.TzShortName Property

Gets an abbreviated time zone name for the current location.

[Visual Basic]

```
Public ReadOnly Property TzShortName As String
```

[C#]

```
public string TzShortName {get;}
```

Property Value

A string which specifies the abbreviated time zone code for the current location.

Remarks

This property returns a string which specifies the abbreviated time zone code in which the external IP address is located. If daylight savings time is used within the time zone, then this value can change based on whether or not daylight savings is in effect. For example, if the IP address is located within the Pacific time zone in the United States, this will return "PDT" when daylight savings is in effect and "PST" when it is not.

If the time zone code cannot be determined for this location, a value such as "UTC+9" may be returned, indicating the number of hours ahead or behind UTC.

See Also

WebLocation Class | SocketTools Namespace | LocalTime Property | Timezone Property | TzOffset Property

WebLocation.Version Property

Gets a value which returns the current version of the WebLocation class library.

[Visual Basic]

```
Public ReadOnly Property Version As String
```

[C#]

```
public string Version {get;}
```

Property Value

A string which specifies the version of the class library.

Remarks

The **Version** property returns a string which identifies the current version and build of the WebLocation class library. This value can be used by an application for validation and debugging purposes.

See Also

WebLocation Class | SocketTools Namespace

WebLocation Methods

The methods of the **WebLocation** class are listed below. For a complete list of **WebLocation** class members, see the WebLocation Members topic.

Public Instance Methods

Dispose	Overloaded. Releases all resources used by WebLocation.
Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from Object)	Gets the Type of the current instance.
Initialize	Overloaded. Initialize an instance of the WebLocation class.
Reset	Reset the internal state of the object, resetting all properties to their default values.
ToString (inherited from Object)	Returns a String that represents the current Object.
Uninitialize	Uninitialize the class library and release any resources allocated for the current thread.
Update	Update the current location information for the local system.

Protected Instance Methods

Dispose	Overloaded. Releases the unmanaged resources allocated by the WebLocation class and optionally releases the managed resources.
Finalize	Destroys an instance of the class, releasing the resources allocated for the session and unloading the networking library.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

WebLocation Class | SocketTools Namespace

WebLocation.Dispose Method

Releases all resources used by WebLocation.

Overload List

Releases all resources used by WebLocation.

public void Dispose();

Releases the unmanaged resources allocated by the WebLocation class and optionally releases the managed resources.

protected virtual void Dispose(bool);

See Also

WebLocation Class | SocketTools Namespace

WebLocation.Dispose Method ()

Releases all resources used by WebLocation.

[Visual Basic]

```
NotOverridable Overloads Public Sub Dispose() _
    Implements IDisposable.Dispose
```

[C#]

```
public void Dispose();
```

Implements

IDisposable.Dispose

Remarks

The **Dispose** method terminates any active connection and explicitly releases the resources allocated for this instance of the class. In some cases, better performance can be achieved if the programmer explicitly releases resources when they are no longer being used. The **Dispose** method provides explicit control over these resources.

Unlike the **Uninitialize** method, once the **Dispose** method has been called, that instance of the class cannot be re-initialized and you should not attempt to access class properties or invoke any methods. Note that this method can be called even if other references to the object are active.

See Also

WebLocation Class | SocketTools Namespace | WebLocation.Dispose Overload List

WebLocation.Dispose Method (Boolean)

Releases the unmanaged resources allocated by the WebLocation class and optionally releases the managed resources.

[Visual Basic]

```
Overridable Overloads Protected Sub Dispose( _
   ByVal disposing As Boolean _
)
```

[C#]

```
protected virtual void Dispose(
   bool disposing
);
```

Parameters

disposing

A boolean value which should be specified as **true** to release both managed and unmanaged resources; **false** to release only unmanaged resources.

Remarks

The **Dispose** method terminates any active connection and explicitly releases the resources allocated for this instance of the class. In some cases, better performance can be achieved if the programmer explicitly releases resources when they are no longer being used. The **Dispose** method provides explicit control over these resources.

Unlike the **Uninitialize** method, once the **Dispose** method has been called, that instance of the class cannot be re-initialized and you should not attempt to access class properties or invoke any methods. Note that this method can be called even if other references to the object are active.

You should call **Dispose** in your derived class when you are finished using the derived class. The **Dispose** method leaves the derived class in an unusable state. After calling **Dispose**, you must release all references to the derived class and the **WebLocation** class so the memory they were occupying can be reclaimed by garbage collection.

See Also

WebLocation Class | SocketTools Namespace | WebLocation.Dispose Overload List

WebLocation.Initialize Method

Initialize an instance of the WebLocation class.

Overload List

Initialize an instance of the WebLocation class.

public bool Initialize();

Initialize an instance of the WebLocation class.

public bool Initialize(string);

See Also

WebLocation Class | SocketTools Namespace | Uninitialize Method | RuntimeLicenseAttribute Class

WebLocation.Initialize Method ()

Initialize an instance of the WebLocation class.

[Visual Basic]

```
Overloads Public Function Initialize() As Boolean
```

[C#]

```
public bool Initialize();
```

Return Value

A boolean value which specifies if the class was initialized successfully.

Remarks

The **Initialize** method can be used to explicitly initialize an instance of the **WebLocation** class, loading the networking library and allocating resources for the current thread. This must be the first method that is called before you attempt invoke other methods. Failure to initialize the class may result in subsequent errors and/or cause an exception to be raised.

Each time the **Initialize** method is invoked, it increments an internal counter that keeps track of the number of times that it has been called by any thread in the current process. The **Uninitialize** method decrements this counter, and when the usage count drops to zero, the class will automatically unload the system libraries that it has dynamically loaded and will destroy the process heap that was allocated when the first instance of the class was created.

See Also

WebLocation Class | SocketTools Namespace | WebLocation.Initialize Overload List | Uninitialize Method | RuntimeLicenseAttribute Class

WebLocation.Initialize Method (String)

Initialize an instance of the WebLocation class.

[Visual Basic]

```
Overloads Public Function Initialize( _
   ByVal licenseKey As String _
) As Boolean
```

[C#]

```
public bool Initialize(
   string licenseKey
);
```

Return Value

A boolean value which specifies if the class was initialized successfully.

Remarks

The **Initialize** method can be used to explicitly initialize an instance of the **WebLocation** class, loading the networking library and allocating resources for the current thread. This must be the first method that is called before you attempt invoke other methods. Failure to initialize the class may result in subsequent errors and/or cause an exception to be raised.

Each time the **Initialize** method is invoked, it increments an internal counter that keeps track of the number of times that it has been called by any thread in the current process. The **Uninitialize** method decrements this counter, and when the usage count drops to zero, the class will automatically unload the system libraries that it has dynamically loaded and will destroy the process heap that was allocated when the first instance of the class was created.

Example

The following example shows how to use the Initialize method to initialize an instance of the class. This example assumes that the license key string has been defined in code.

```
SocketTools.WebLocation myLocation = new SocketTools.WebLocation();

if (txtMessage.Initialize(strLicenseKey) == false)
{
 MessageBox.Show(myLocation.LastErrorString, "Error",
 MessageBoxButtons.OK, MessageBoxIcon.Exclamation);
 return;
}
```

```
Dim myLocation As New SocketTools.WebLocation

If myLocation.Initialize(strLicenseKey) = False Then
    MsgBox(myLocation.LastErrorString, vbIconExclamation)
    Exit Sub
End If
```

See Also

WebLocation Class | SocketTools Namespace | WebLocation.Initialize Overload List | Uninitialize Method | RuntimeLicenseAttribute Class

WebLocation.Reset Method

Reset the internal state of the object, resetting all properties to their default values.

[Visual Basic]

```
Public Sub Reset()
```

[C#]

```
public void Reset();
```

Remarks

The **Reset** method returns the object to its default state. If a socket has been allocated, it will be released and any active connections will be terminated. All properties will be reset to their default values.

See Also

WebLocation Class | SocketTools Namespace

WebLocation.Uninitialize Method

Uninitialize the class library and release any resources allocated for the current thread.

[Visual Basic]

```
Public Sub Uninitialize()
```

[C#]

```
public void Uninitialize();
```

Remarks

The **Uninitialize** method resets the internal state of the class instance and releases the system resources it has allocated. This method is not typically used because any resources that have been allocated by an instance of the class will automatically be released when it is destroyed.

Each time the **Initialize** method is invoked, it increments an internal counter that keeps track of the number of times that it has been called by any thread in the current process. The **Uninitialize** method decrements this counter, and when the usage count drops to zero, the class will automatically unload the system libraries that it has dynamically loaded and will destroy the process heap that was allocated when the first instance of the class was created.

See Also

WebLocation Class | SocketTools Namespace | Initialize Method

WebLocation.Update Method

Update the current location information for the local system.

[Visual Basic]

```
Public Function Update() As Boolean
```

[C#]

```
public bool Update();
```

Return Value

A boolean value which indicates if the location information was updated for the local system.

Remarks

This method causes the component to query the location service to obtain current information about the physical location of the computer system based on its external IP address. The location data is cached and additional queries are only performed if it detects the external IP address for the local system has changed.

A return value of **true** means the current location was updated successfully. A return value of **false** indicates that the current location could not be determined. The **LastError** property can be used to identify the specific cause of the failure.

See Also

WebLocation Class | SocketTools Namespace | LastError Property | LastUpdate Property

WebLocation Events

The events of the **WebLocation** class are listed below. For a complete list of **WebLocation** class members, see the WebLocation Members topic.

Public Instance Events

⚡ OnError	Occurs when an client operation fails.

See Also

WebLocation Class | SocketTools Namespace

WebLocation.OnError Event

Occurs when an client operation fails.

[Visual Basic]

```
Public Event OnError As OnErrorEventHandler
```

[C#]

```
public event OnErrorEventHandler OnError;
```

Event Data

The event handler receives an argument of type WebLocation.ErrorEventArgs containing data related to this event. The following **WebLocation.ErrorEventArgs** properties provide information specific to this event.

Property	Description
Description	Gets a value which describes the last error that has occurred.
Error	Gets a value which specifies the last error that has occurred.

Remarks

The **OnError** event occurs when a client operation fails.

See Also

WebLocation Class | SocketTools Namespace | ErrorCode Enumeration | LastError Property | LastErrorString Property

WebLocation.ErrorEventArgs Class

Provides data for the OnError event.

For a list of all members of this type, see WebLocation.ErrorEventArgs Members.

System.Object
  System.EventArgs
    SocketTools.WebLocation.ErrorEventArgs

[Visual Basic]
```
Public Class WebLocation.ErrorEventArgs
    Inherits EventArgs
```

[C#]
```
public class WebLocation.ErrorEventArgs : EventArgs
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

ErrorEventArgs specifies the numeric error code and a description of the error that has occurred.

An OnError event occurs when a method fails.

Requirements

Namespace: SocketTools

Assembly: SocketTools.WebLocation (in SocketTools.WebLocation.dll)

See Also

WebLocation.ErrorEventArgs Members | SocketTools Namespace

WebLocation.ErrorEventArgs Members

WebLocation.ErrorEventArgs overview

Public Instance Constructors

WebLocation.ErrorEventArgs Constructor	Initializes a new instance of the WebLocation.ErrorEventArgs class.

Public Instance Properties

Description	Gets a value which describes the last error that has occurred.
Error	Gets a value which specifies the last error that has occurred.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString (inherited from Object)	Returns a String that represents the current Object.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

WebLocation.ErrorEventArgs Class | SocketTools Namespace

WebLocation.ErrorEventArgs Constructor

Initializes a new instance of the WebLocation.ErrorEventArgs class.

[Visual Basic]

```
Public Sub New()
```

[C#]

```
public WebLocation.ErrorEventArgs();
```

See Also

WebLocation.ErrorEventArgs Class | SocketTools Namespace

WebLocation.ErrorEventArgs Properties

The properties of the **WebLocation.ErrorEventArgs** class are listed below. For a complete list of **WebLocation.ErrorEventArgs** class members, see the WebLocation.ErrorEventArgs Members topic.

Public Instance Properties

Description	Gets a value which describes the last error that has occurred.
Error	Gets a value which specifies the last error that has occurred.

See Also

WebLocation.ErrorEventArgs Class | SocketTools Namespace

WebLocation.ErrorEventArgs.Error Property

Gets a value which specifies the last error that has occurred.

[Visual Basic]

```
Public ReadOnly Property Error As ErrorCode
```

[C#]

```
public WebLocation.ErrorCode Error {get;}
```

Property Value

ErrorCode enumeration which specifies the error.

See Also

WebLocation.ErrorEventArgs Class | SocketTools Namespace | Description Property

WebLocation.ErrorCode Enumeration

Specifies the error codes returned by the WebLocation class.

[Visual Basic]
```
Public Enum WebLocation.ErrorCode
```

[C#]
```
public enum WebLocation.ErrorCode
```

Remarks

The WebLocation class uses the **ErrorCode** enumeration to specify what error has occurred when a method fails. The current error code may be determined by checking the value of the **LastError** property.

Note that the last error code is only meaningful if the previous operation has failed.

Members

Member Name	Description
errorNone	No error.
errorNotHandleOwner	Handle not owned by the current thread.
errorFileNotFound	The specified file or directory does not exist.
errorFileNotCreated	The specified file could not be created.
errorOperationCanceled	The blocking operation has been canceled.
errorInvalidFileType	The specified file is a block or character device, not a regular file.
errorInvalidDevice	The specified file type is invalid or not a regular file.
errorTooManyParameters	The maximum number of function parameters has been exceeded.
errorInvalidFileName	The specified file name contains invalid characters or is too long.
errorInvalidFileHandle	Invalid file handle passed to function.
errorFileReadFailed	Unable to read data from the specified file.
errorFileWriteFailed	Unable to write data to the specified file.
errorOutOfMemory	Out of memory.
errorAccessDenied	Access denied.
errorInvalidParameter	Invalid argument passed to function.
errorClipboardUnavailable	The system clipboard is currently unavailable.
errorClipboardEmpty	The system clipboard is empty or does not contain any text data.
errorFileEmpty	The specified file does not contain any data.
errorFileExists	The specified file already exists.

errorEndOfFile	End of file.
errorDeviceNotFound	The specified device could not be found.
errorDirectoryNotFound	The specified directory could not be found.
errorInvalidbuffer	Invalid memory address passed to function.
errorBufferTooSmall	The specified buffer is not large enough to contain the data.
errorNoHandles	No more handles are available to this process.
errorOperationWouldBlock	The specified operation would block the current thread.
errorOperationInProgress	A blocking operation is currently in progress.
errorAlreadyInProgress	The specified operation is already in progress.
errorInvalidHandle	Invalid handle passed to function.
errorInvalidAddress	Invalid network address specified.
errorInvalidSize	Datagram is too large to fit in specified buffer.
errorInvalidProtocol	Invalid network protocol specified.
errorProtocolNotAvailable	The specified network protocol is not available.
errorProtocolNotSupported	The specified protocol is not supported.
errorSocketNotSupported	The specified socket type is not supported.
errorInvalidOption	The specified option is invalid.
errorProtocolFamily	Specified protocol family is not supported.
errorProtocolAddress	The specified address is invalid for this protocol family.
errorAddressInUse	The specified address is in use by another process.
errorAddressUnavailable	The specified address cannot be assigned.
errorNetworkUnavailable	The networking subsystem is unavailable.
errorNetworkUnreachable	The specified network is unreachable.
errorNetworkReset	Network dropped connection on remote reset.
errorConnectionAborted	Connection was aborted due to timeout or other failure.
errorConnectionReset	Connection was reset by remote network.
errorOutOfBuffers	No buffer space is available.
errorAlreadyConnected	Connection already established with remote host.
errorNotConnected	No connection established with remote host.
errorConnectionShutdown	Unable to send or receive data after connection shutdown.
errorOperationTimeout	The specified operation has timed out.
errorConnectionRefused	The connection has been refused by the remote host.

errorHostUnavailable	The specified host is unavailable.
errorHostUnreachable	Remote host is unreachable.
errorTooManyProcesses	Too many processes are using the networking subsystem.
errorTooManyThreads	Too many threads have been created by the current process.
errorTooManySessions	Too many client sessions have been created by the current process.
errorInternalFailure	An unexpected internal error has occurred.
errorNetworkNotReady	Network subsystem is not ready for communication.
errorInvalidVersion	This version of the operating system is not supported.
errorNetworkNotInitialized	The networking subsystem has not been initialized.
errorRemoteShutdown	The remote host has initiated a graceful shutdown sequence.
errorInvalidHostName	The specified hostname is invalid or could not be resolved.
errorHostNameNotFound	The specified hostname could not be found.
errorHostNameRefused	Unable to resolve hostname, request refused.
errorHostNameNotResolved	Unable to resolve hostname, no address for specified host.
errorInvalidLicense	The license for this product is invalid.
errorProductNotLicensed	This product is not licensed to perform this operation.
errorNotImplemented	This function has not been implemented on this platform.
errorUnknownLocalhost	Unable to determine local host name.
errorInvalidHostAddress	Invalid host address specified.
errorInvalidServicePort	Invalid service port number specified.
errorInvalidServiceName	Invalid or unknown service name specified.
errorInvalidEventId	Invalid event identifier specified.
errorOperationNotBlocking	No blocking operation in progress on this socket.
errorSecurityNotInitialized	Unable to initialize security interface for this process.
errorSecurityContext	Unable to establish security context for this session.
errorSecurityCredentials	Unable to open certificate store or establish security credentials.
errorSecurityCertificate	Unable to validate the certificate chain for this

	session.
errorSecurityDecryption	Unable to decrypt data stream.
errorSecurityEncryption	Unable to encrypt data stream.
errorOperationNotSupported	The specified operation is not supported.
errorInvalidProtocolVersion	Invalid application protocol version specified.
errorNoServerResponse	No data returned from server.
errorInvalidServerResponse	Invalid data returned from server.
errorUnexpectedServerResponse	Unexpected response code returned from server.
errorServerTransactionFailed	Server transaction failed.
errorServiceUnavailable	The service is currently unavailable.
errorServiceNotReady	The service is not ready, try again later.
errorServerResyncFailed	Unable to resynchronize with server.
errorInvalidProxyType	Invalid proxy server type specified.
errorProxyRequired	Resource must be accessed through specified proxy.
errorInvalidProxyLogin	Unable to login to proxy server using specified credentials.
errorProxyResyncFailed	Unable to resynchronize with proxy server.
errorInvalidCommand	Invalid command specified.
errorInvalidCommandParameter	Invalid command parameter specified.
errorInvalidCommandSequence	Invalid command sequence specified.
errorCommandNotImplemented	Specified command not implemented on this server.
errorCommandNotAuthorized	Specified command not authorized for the current user.
errorCommandAborted	Specified command was aborted by the remote host.
errorOptionNotSupported	The specified option is not supported on this server.
errorRequestNotCompleted	The current client request has not been completed.
errorInvalidUserName	The specified username is invalid.
errorInvalidPassword	The specified password is invalid.
errorInvalidAccount	The specified account name is invalid.
errorAccountRequired	Account name has not been specified.
errorInvalidAuthenticationType	Invalid authentication protocol specified.
errorAuthenticationRequired	User authentication is required.
errorProxyAuthenticationRequired	Proxy authentication required.

errorAlreadyAuthenticated	User has already been authenticated.
errorAuthenticationFailed	Unable to authenticate the specified user.
errorNetworkAdapter	Unable to determine network adapter configuration.
errorInvalidRecordType	Invalid record type specified.
errorInvalidRecordName	Invalid record name specified.
errorInvalidRecordData	Invalid record data specified.
errorConnectionOpen	Data connection already established.
errorConnectionClosed	Server closed data connection.
errorConnectionPassive	Data connection is passive.
errorConnectionFailed	Unable to open data connection to server.
errorInvalidSecurityLevel	Data connection cannot be opened with this security setting.
errorCachedTLSRequired	Data connection requires cached TLS session.
errorDataReadOnly	Data connection is read-only.
errorDataWriteOnly	Data connection is write-only.
errorEndOfData	End of data.
errorRemoteFileUnavailable	Remote file is unavailable.
errorInsufficientStorage	Insufficient storage on server.
errorStorageallocation	File exceeded storage allocation on server.
errorDirectoryExists	The specified directory already exists.
errorDirectoryEmpty	No files returned by the server for the specified directory.
errorEndOfDirectory	End of directory listing.
errorUnknownDirectoryFormat	Unknown directory format.
errorInvalidResource	Invalid resource name specified.
errorResourceRedirected	The specified resource has been redirected.
errorResourceRestricted	Access to this resource has been restricted.
errorResourceNotModified	The specified resource has not been modified.
errorResourceNotFound	The specified resource cannot be found.
errorResourceConflict	Request could not be completed due to the current state of the resource.
errorResourceRemoved	The specified resource has been permanently removed from this server.
errorContentLengthRequired	Request must include the content length.
errorRequestPrecondition	Request could not be completed due to server precondition.
errorUnsupportedMediaType	Request specified an unsupported media type.

errorInvalidContentRange	Content range specified for this resource is invalid.
errorInvalidMessagePart	Message is not multipart or an invalid message part was specified.
errorInvalidMessageHeader	The specified message header is invalid or has not been defined.
errorInvalidMessageBoundary	The multipart message boundary has not been defined.
errorNoFileAttachment	The current message part does not contain a file attachment.
errorUnknownFileType	The specified file type could not be determined.
errorDataNotEncoded	The specified data block could not be encoded.
errorDataNotDecoded	The specified data block could not be decoded.
errorFileNotEncoded	The specified file could not be encoded.
errorFileNotDecoded	The specified file could not be decoded.
errorNoMessageText	No message text.
errorInvalidCharacterSet	Invalid character set specified.
errorInvalidEncodingType	Invalid encoding type specified.
errorInvalidMessageNumber	Invalid message number specified.
errorNoReturnAddress	No valid return address specified.
errorNoValidRecipients	No valid recipients specified.
errorInvalidRecipient	The specified recipient address is invalid.
errorRelayNotAuthorized	The specified domain is invalid or server will not relay messages.
errorMailboxUnavailable	Specified mailbox is currently unavailable.
errorMailboxReadOnly	The selected mailbox cannot be modified.
errorMailboxNotSelected	No mailbox has been selected.
errorInvalidMailbox	Specified mailbox is invalid.
errorInvalidDomain	The specified domain name is invalid or not recognized.
errorInvalidSender	The specified sender address is invalid or not recognized.
errorMessageNotDelivered	Message not delivered to any of the specified recipients.
errorEndOfMessageData	No more message data available to be read
errorInvalidmessageSize	The specified message size is invalid.
errorMessageNotCreated	The message could not be created in the specified mailbox.
errorNoMoreMailboxes	No more mailboxes exist on this server.

errorInvalidEmulationType	The specified terminal emulation type is invalid.
errorInvalidFontHandle	The specified font handle is invalid.
errorInvalidFontName	The specified font name is invalid or unavailable.
errorInvalidPacketSize	The specified packet size is invalid.
errorInvalidPacketData	The specified packet data is invalid.
errorInvalidPacketId	The unique packet identifier is invalid.
errorPacketTTLExpired	The specified packet time-to-live period has expired.
errorInvalidNewsGroup	Invalid newsgroup specified.
errorNoNewsgroupSelected	No newsgroup selected.
errorEmptyNewsgroup	No articles in specified newsgroup.
errorInvalidArticle	Invalid article number specified.
errorNoArticleSelected	No article selected in the current newsgroup.
errorFirstArticle	First article in current newsgroup.
errorLastArticle	Last article in current newsgroup.
errorArticleExists	Unable to transfer article, article already exists.
errorArticleRejected	Unable to transfer article, article rejected.
errorArticleTransferFailed	Article transfer failed.
errorArticlePostingDenied	Posting is not permitted on this server.
errorArticlePostingFailed	Unable to post article on this server.
errorInvalidDateFormat	The specified date format is not recognized.
errorFeatureNotSupported	The specified feature is not supported on this server.
errorInvalidFormHandle	The specified form handle is invalid or a form has not been created.
errorInvalidFormAction	The specified form action is invalid or has not been specified.
errorInvalidFormMethod	The specified form method is invalid or not supported.
errorInvalidFormType	The specified form type is invalid or not supported.
errorInvalidFormField	The specified form field name is invalid or does not exist.
errorEmptyForm	The specified form does not contain any field values.
errorMaximumConnections	The maximum number of client connections exceeded.
errorThreadCreationFailed	Unable to create a new thread for the current process.
errorInvalidThreadHandle	The specified thread handle is no longer valid.

errorThreadTerminated	The specified thread has been terminated.
errorThreadDeadlock	The operation would result in the current thread becoming deadlocked.
errorInvalidClientMoniker	The specified moniker is not associated with any client session.
errorClientMonikerExists	The specified moniker has been assigned to another client session.
errorServerInactive	The specified server is not listening for client connections.
errorServerSuspended	The specified server is suspended and not accepting client connections.
errorNoMessageStore	No message store has been specified.
errorMessageStoreChanged	The message store has changed since it was last accessed.
errorMessageNotFound	No message was found that matches the specified criteria.
errorMessageDeleted	The specified message has been deleted.
errorFileChecksumMismatch	The local and remote file checksums do not match.
errorFileSizeMismatch	The local and remote file sizes do not match.
errorInvalidFeedUrl	The news feed URL is invalid or specifies an unsupported protocol.
errorInvalidFeedFormat	The internal format of the news feed is invalid.
errorInvalidFeedVersion	This version of the news feed is not supported.
errorChannelEmpty	There are no valid items found in this news feed.
errorInvalidItemNumber	The specified channel item identifier is invalid.
errorItemNotFound	The specified channel item could not be found.
errorItemEmpty	The specified channel item does not contain any data.
errorInvalidItemProperty	The specified item property name is invalid.
errorItemPropertyNotFound	The specified item property has not been defined.
errorInvalidChannelTitle	The channel title is invalid or has not been defined.
errorInvalidChannelLink	The channel hyperlink is invalid or has not been defined.
errorInvalidChannelDescription	The channel description is invalid or has not been defined.
errorInvalidItemText	The description for an item is invalid or has not been defined.
errorInvalidItemLink	The hyperlink for an item is invalid or has not been defined.

errorInvalidServiceType	The specified service type is invalid.
errorServiceSuspended	Access to the specified service has been suspended.
errorServiceRestricted	Access to the specified service has been restricted.
errorInvalidProviderName	The specified provider name is invalid or unknown.
errorInvalidPhoneNumber	The specified phone number is invalid or not supported in this region.
errorGatewayNotFound	A message gateway cannot be found for the specified provider.
errorMessageTooLong	The message exceeds the maximum number of characters permitted.
errorInvalidProviderData	The request returned invalid or incomplete service provider data.
errorInvalidGatewayData	The request returned invalid or incomplete message gateway data.
errorMultipleProviders	The request has returned multiple service providers.
errorProviderNotFound	The specified service provider could not be found.
errorInvalidMessageService	The specified message is not supported with this service type.
errorInvalidMessageFormat	The specified message format is invalid.
errorInvalidConfiguration	The specified configuration options are invalid.
errorServerActive	The requested action is not permitted while the server is active.
errorServerPortBound	Unable to obtain exclusive use of the specified local port.
errorInvalidClientSession	The specified client identifier is invalid for this session.
errorClientNotIdentified	The specified client has not provided user credentials.
errorInvalidClientState	The requested action cannot be performed at this time.
errorInvalidResultCode	The specified result code is not valid for this protocol
errorCommandRequired	The specified command is required and cannot be disabled.
errorCommandDisabled	The specified command has been disabled.
errorCommandSequence	The command cannot be processed at this time.
errorCommandCompleted	The previous command has completed.
errorInvalidProgramName	The specified program name is invalid or unrecognized.

errorInvalidRequestHeader	The request header contains one or more invalid values.
errorInvalidVirtualHost	The specified virtual host name is invalid.
errorVirtualHostNotFound	The specified virtual host does not exist.
errorTooManyVirtualHosts	Too many virtual hosts created for this server.
errorInvalidVirtualPath	The specified virtual path name is invalid.
errorVirtualPathNotFound	The specified virtual path does not exist.
errorTooManyVirtualPaths	Too many virtual paths created for this server.
errorInvalidTask	The asynchronous task identifier is invalid.
errorTaskActive	The asynchronous task has not finished.
errorTaskQueued	The asynchronous task has been queued.
errorTaskSuspended	The asynchronous task has been suspended.
errorTaskFinished	The asynchronous task has finished.

Requirements

Namespace: SocketTools

Assembly: SocketTools.WebLocation (in SocketTools.WebLocation.dll)

See Also

SocketTools Namespace | LastError Property | LastErrorString Property | OnError Event

WebLocation.OnErrorEventHandler Delegate

Represents the method that will handle the OnError event.

[Visual Basic]

```
Public Delegate Sub WebLocation.OnErrorEventHandler( _
   ByVal sender As Object, _
   ByVal e As ErrorEventArgs _
)
```

[C#]

```
public delegate void WebLocation.OnErrorEventHandler(
      object sender,
      ErrorEventArgs e
   );
```

Parameters

sender

The source of the event.

e

An ErrorEventArgs that contains the event data.

Remarks

When you create an **OnErrorEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnErrorEventHandler** delegate declaration.

Requirements

Namespace: SocketTools

Assembly: SocketTools.WebLocation (in SocketTools.WebLocation.dll)

See Also

SocketTools Namespace

WebLocation.RuntimeLicenseAttribute Class

Attribute that defines the runtime license key for the class.

For a list of all members of this type, see WebLocation.RuntimeLicenseAttribute Members.

System.Object
  System.Attribute
    SocketTools.WebLocation.RuntimeLicenseAttribute

[Visual Basic]

```
<AttributeUsage(ValidOn:=AttributeTargets.Assembly, AllowMultiple:=False,
   Inherited:=True)>
Public Class WebLocation.RuntimeLicenseAttribute
    Inherits Attribute
```

[C#]

```
[AttributeUsage(ValidOn=AttributeTargets.Assembly, AllowMultiple=False,
   Inherited=True)]
public class WebLocation.RuntimeLicenseAttribute : Attribute
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

The RuntimeLicense attribute is used to define the runtime license key that will be used when an instance of the class is created. This attribute is defined in the assembly information module for the language, such as AssemblyInfo.cs when programming C#. The runtime license key must be defined if you wish to redistribute your application.

The runtime license key for your copy of SocketTools can be generated using the License Manager utility that is included with the product. Note that if you have installed an evaluation license, you will not have a runtime license key and cannot redistribute any applications which use the WebLocation class.

Example

```
<Assembly: SocketTools.WebLocation.RuntimeLicense("abcdefghijklmnop")>
```

```
[assembly: SocketTools.WebLocation.RuntimeLicense("abcdefghijklmnop")]
```

Requirements

Namespace: SocketTools

Assembly: SocketTools.WebLocation (in SocketTools.WebLocation.dll)

WebLocation.RuntimeLicenseAttribute Members

WebLocation.RuntimeLicenseAttribute overview

Public Instance Constructors

WebLocation.RuntimeLicenseAttribute Constructor	Constructor for the RuntimeLicense attribute which defines the runtime license key.

Public Instance Properties

LicenseKey	Returns the value of the runtime license key.
TypeId (inherited from Attribute)	When implemented in a derived class, gets a unique identifier for this Attribute.

Public Instance Methods

Equals (inherited from Attribute)	
GetHashCode (inherited from Attribute)	Returns the hash code for this instance.
GetType (inherited from Object)	Gets the Type of the current instance.
IsDefaultAttribute (inherited from Attribute)	When overridden in a derived class, returns an indication whether the value of this instance is the default value for the derived class.
Match (inherited from Attribute)	When overridden in a derived class, returns a value indicating whether this instance equals a specified object.
ToString (inherited from Object)	Returns a String that represents the current Object.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

WebLocation.RuntimeLicenseAttribute Class | SocketTools Namespace

WebLocation.RuntimeLicenseAttribute Constructor

Constructor for the RuntimeLicense attribute which defines the runtime license key.

[Visual Basic]

```
Public Sub New( _
   ByVal licenseKey As String _
)
```

[C#]

```
public WebLocation.RuntimeLicenseAttribute(
   string licenseKey
);
```

Parameters

licenseKey

A string argument which specifies the runtime license key which will be used to initialize the class library.

Remarks

The runtime license key for your copy of SocketTools can be generated using the License Manager utility that is included with the product. Note that if you have installed an evaluation license, you will not have a runtime license key and cannot redistribute any applications which use the WebLocation class.

See Also

WebLocation.RuntimeLicenseAttribute Class | SocketTools Namespace

WebLocation.RuntimeLicenseAttribute Properties

The properties of the **WebLocation.RuntimeLicenseAttribute** class are listed below. For a complete list of **WebLocation.RuntimeLicenseAttribute** class members, see the WebLocation.RuntimeLicenseAttribute Members topic.

Public Instance Properties

LicenseKey	Returns the value of the runtime license key.
TypeId (inherited from Attribute)	When implemented in a derived class, gets a unique identifier for this Attribute.

See Also

WebLocation.RuntimeLicenseAttribute Class | SocketTools Namespace

WebLocation.RuntimeLicenseAttribute.LicenseKey Property

Returns the value of the runtime license key.

[Visual Basic]

```
Public Property LicenseKey As String
```

[C#]

```
public string LicenseKey {get; set;}
```

Property Value

A string which contains the runtime license key.

See Also

WebLocation.RuntimeLicenseAttribute Class | SocketTools Namespace

WebLocationException Class

The exception that is thrown when a client error occurs.

For a list of all members of this type, see WebLocationException Members.

System.Object
  System.Exception
    System.ApplicationException
      SocketTools.WebLocationException

[Visual Basic]

```
Public Class WebLocationException
    Inherits ApplicationException
```

[C#]

```
public class WebLocationException : ApplicationException
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

A WebLocationException is thrown by the WebLocation class when an error occurs.

The default constructor for the WebLocationException class sets the **ErrorCode** property to the last client error that occurred.

Requirements

Namespace: SocketTools

Assembly: SocketTools.WebLocation (in SocketTools.WebLocation.dll)

See Also

WebLocationException Members | SocketTools Namespace

WebLocationException Members

WebLocationException overview

Public Instance Constructors

WebLocationException	Overloaded. Initializes a new instance of the WebLocationException class.

Public Instance Properties

ErrorCode	Gets a value which specifies the error that caused the exception.
HelpLink (inherited from Exception)	Gets or sets a link to the help file associated with this exception.
InnerException (inherited from Exception)	Gets the Exception instance that caused the current exception.
Message	Gets a value which describes the error that caused the exception.
Number	Gets a value which specifies the numeric value of the error that caused the exception.
Source (inherited from Exception)	Gets or sets the name of the application or the object that causes the error.
StackTrace (inherited from Exception)	Gets a string representation of the frames on the call stack at the time the current exception was thrown.
TargetSite (inherited from Exception)	Gets the method that throws the current exception.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetBaseException (inherited from Exception)	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetObjectData (inherited from Exception)	When overridden in a derived class, sets the SerializationInfo with information about the exception.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString	Creates and returns a string representation of the current exception.

Protected Instance Properties

HResult (inherited from Exception)	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

WebLocationException Class | SocketTools Namespace

WebLocationException Constructor

Initializes a new instance of the WebLocationException class with the last network error code.

Overload List

Initializes a new instance of the WebLocationException class with the last network error code.

public WebLocationException();

Initializes a new instance of the WebLocationException class with a specified error number.

public WebLocationException(int);

Initializes a new instance of the WebLocationException class with a specified error message.

public WebLocationException(string);

Initializes a new instance of the WebLocationException class with a specified error message and a reference to the inner exception that is the cause of this exception.

public WebLocationException(string,Exception);

See Also

WebLocationException Class | SocketTools Namespace

WebLocationException Constructor ()

Initializes a new instance of the WebLocationException class with the last network error code.

[Visual Basic]

```
Overloads Public Sub New()
```

[C#]

```
public WebLocationException();
```

Remarks

The ctor constructor sets the **ErrorCode** property to the last client error that occurred. For more information about the errors that may occur, refer to the WebLocation.ErrorCode enumeration.

See Also

WebLocationException Class | SocketTools Namespace | WebLocationException Constructor Overload List

WebLocationException Constructor (String)

Initializes a new instance of the WebLocationException class with a specified error message.

[Visual Basic]

```
Overloads Public Sub New( _
   ByVal message As String _
)
```

[C#]

```
public WebLocationException(
   string message
);
```

Parameters

message

The error message that explains the reason for the exception.

Remarks

The content of the ***message*** parameter is intended to be understood by humans. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

See Also

WebLocationException Class | SocketTools Namespace | WebLocationException Constructor Overload List

WebLocationException Constructor (String, Exception)

Initializes a new instance of the WebLocationException class with a specified error message and a reference to the inner exception that is the cause of this exception.

[Visual Basic]

```
Overloads Public Sub New( _
   ByVal message As String, _
   ByVal innerException As Exception _
)
```

[C#]

```
public WebLocationException(
   string message,
   Exception innerException
);
```

Parameters

message

The error message that explains the reason for the exception.

innerException

The exception that is the cause of the current exception. If the ***innerException*** parameter is not a null reference, the current exception is raised in a **catch** block that handles the inner exception.

Remarks

The content of the message parameter is intended to be understood by humans. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

An exception that is thrown as a direct result of a previous exception should include a reference to the previous exception in the **InnerException** property. The **InnerException** property returns the same value that is passed into the constructor, or a null reference if the **InnerException** property does not supply the inner exception value to the constructor.

WebLocationException Class | SocketTools Namespace | WebLocationException Constructor Overload List

WebLocationException Constructor (Int32)

Initializes a new instance of the WebLocationException class with a specified error number.

```
[Visual Basic]
Overloads Public Sub New( _
   ByVal code As Integer _
)
```

```
[C#]
public WebLocationException(
   int code
);
```

Parameters

code

An integer value which specifies an error code.

Remarks

This constructor sets the **ErrorCode** property to the specified error code. For more information about the errors that may occur, refer to the WebLocation.ErrorCode enumeration.

See Also

WebLocationException Class | SocketTools Namespace | WebLocationException Constructor Overload List

WebLocationException Properties

The properties of the **WebLocationException** class are listed below. For a complete list of **WebLocationException** class members, see the WebLocationException Members topic.

Public Instance Properties

ErrorCode	Gets a value which specifies the error that caused the exception.
HelpLink (inherited from Exception)	Gets or sets a link to the help file associated with this exception.
InnerException (inherited from Exception)	Gets the Exception instance that caused the current exception.
Message	Gets a value which describes the error that caused the exception.
Number	Gets a value which specifies the numeric value of the error that caused the exception.
Source (inherited from Exception)	Gets or sets the name of the application or the object that causes the error.
StackTrace (inherited from Exception)	Gets a string representation of the frames on the call stack at the time the current exception was thrown.
TargetSite (inherited from Exception)	Gets the method that throws the current exception.

Protected Instance Properties

HResult (inherited from Exception)	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception.

See Also

WebLocationException Class | SocketTools Namespace

WebLocationException.ErrorCode Property

Gets a value which specifies the error that caused the exception.

[Visual Basic]

```
Public ReadOnly Property ErrorCode As ErrorCode
```

[C#]

```
public WebLocation.ErrorCode ErrorCode {get;}
```

Property Value

Returns a WebLocation.ErrorCode enumeration value which specifies the error code.

Remarks

The **ErrorCode** property returns the error code that specifies the cause of the exception.

The default constructor for the WebLocationException class sets the error code to the last network error that occurred. For more information about the errors that may occur, refer to the WebLocation.ErrorCode enumeration.

See Also

WebLocationException Class | SocketTools Namespace

WebLocationException.Message Property

Gets a value which describes the error that caused the exception.

[Visual Basic]

```
Overrides Public ReadOnly Property Message As String
```

[C#]

```
public override string Message {get;}
```

Property Value

A string which describes the error that caused the exception.

Remarks

The **Message** property returns a string which describes the error that caused the exception.

See Also

WebLocationException Class | SocketTools Namespace

WebLocationException.Number Property

Gets a value which specifies the numeric value of the error that caused the exception.

[Visual Basic]

```
Public ReadOnly Property Number As Integer
```

[C#]

```
public int Number {get;}
```

Property Value

An integer value that specifies the error that caused the exception.

Remarks

The **Number** property returns an integer value which specifies the numeric value of the error that caused the exception. For network related errors, this value is the same as the values returned by the Windows Sockets API. For more information about socket error codes, see the Windows Socket Version 2 API error code documentation in MSDN.

See Also

WebLocationException Class | SocketTools Namespace

WebLocationException Methods

The methods of the **WebLocationException** class are listed below. For a complete list of **WebLocationException** class members, see the WebLocationException Members topic.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetBaseException (inherited from Exception)	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetObjectData (inherited from Exception)	When overridden in a derived class, sets the SerializationInfo with information about the exception.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString	Creates and returns a string representation of the current exception.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

WebLocationException Class | SocketTools Namespace

WebLocationException.ToString Method

Creates and returns a string representation of the current exception.

[Visual Basic]

```
Overrides Public Function ToString() As String
```

[C#]

```
public override string ToString();
```

Return Value

A string representation of the current exception.

Remarks

The **ToString** method returns a representation of the current exception that is intended to be understood by humans. Where the exception contains culture-sensitive data, the string representation returned by **ToString** is required to take into account the current system culture. Although there are no exact requirements for the format of the returned string, it should attempt to reflect the value of the object as perceived by the user.

This implementation of **ToString** obtains the numeric error code value and a description of the error that caused the current exception. If there is no error message or it is an empty string, then no error message is returned.

This method overrides **ApplicationException.ToString**.

WebLocationException Class | SocketTools Namespace

WebStorage Class

Application storage and data management services.

For a list of all members of this type, see WebStorage Members.

System.Object
  SocketTools.WebStorage

[Visual Basic]
```
Public Class WebStorage
    Implements IDisposable
```

[C#]
```
public class WebStorage : IDisposable
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Example

The WebStorage class enables an application to securely store and manage data remotely.

This class uses SocketTools Web Services. It will only function if there is an active Internet connection and the local system is capable of establishing a secure connection to the storage servers.

Requirements

Namespace: SocketTools

Assembly: SocketTools.WebStorage (in SocketTools.WebStorage.dll)

See Also

WebStorage Members | SocketTools Namespace

WebStorage Members

WebStorage overview

Public Static (Shared) Fields

webTimeout	A constant value which specifies the default timeout period.

Public Static (Shared) Methods

ErrorText	Returns the description of an error code.

Public Instance Constructors

WebStorage Constructor	Initializes a new instance of the WebStorage class.

Public Instance Properties

AccountId	Gets a value that specifies the storage account ID associated with the development license.
AppId	Gets and sets the application identifier associated with the storage container.
Handle	Gets a value that specifies the storage handle allocated for the current session.
IsBlocked	Gets a value which indicates if the current thread is performing a blocking storage operation.
IsConnected	Gets a value which indicates if a connection to the storage server has been established.
IsInitialized	Gets a value which indicates if the current instance of the class has been initialized successfully.
IsOpened	Gets a value which indicates if a storage container has been opened.
LastError	Gets and sets a value which specifies the last error that has occurred.
LastErrorString	Gets a value which describes the last error that has occurred.
ObjectAttributes	Gets the attributes for the current object.
ObjectContent	Gets the content type for the current object.
ObjectCreated	Gets the date and time the current object was created.
ObjectDigest	Gets the SHA-256 digest value for the current object.
ObjectId	Gets the unique identifier for the current object.
ObjectLabel	Gets the label for the current object.
ObjectLimit	Gets the maximum number of objects that may be

	created.
ObjectModified	Gets the date and time the current object was last modified.
ObjectSize	Gets the size of the current object in bytes
StorageFree	Gets the total number of bytes available to store new objects.
StorageId	Gets a unique identifier for the current storage container.
StorageLimit	Gets the maximum number of bytes of storage available.
StorageObjects	Gets the current number of objects stored for your account.
StorageType	Gets the current storage container type identifier.
StorageUsed	Gets the current number of bytes of storage used for your account.
ThrowError	Gets and sets a value which specifies if method calls should throw exceptions when an error occurs.
Timeout	Gets and sets a value which specifies a timeout period in seconds.
Trace	Gets and sets a value which indicates if network function logging is enabled.
TraceFile	Gets and sets a value which specifies the name of the logfile.
TraceFlags	Gets and sets a value which specifies the client function tracing flags.
TransferBytes	Gets a value which specifies the number of bytes transferred to or from the server.
TransferRate	Gets a value which specifies the data transfer rate in bytes per second.
TransferTime	Gets a value which specifies the number of seconds elapsed during a data transfer.
Version	Gets a value which returns the current version of the WebStorage class library.

Public Instance Methods

Cancel	Cancel the current storage operation.
Close	Close the storage container.
CompareData	Overloaded. Compare the data in a byte buffer with a stored object.
CompareFile	Compare the data in a file with a stored object.
Copy	Overloaded. Copy the contents of a stored object

	to another container.
Delete	Delete a stored object from the container.
DeleteAll	Delete all stored objects in the container.
Dispose	Overloaded. Releases all resources used by WebStorage.
Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
Exists	Determine if a stored object exists in the container.
FindFirst	Overloaded. Find the first stored object that matches a label or content type.
FindNext	Find the next stored object that matches a label or content type.
GetData	Overloaded. Download the data in a stored object to a byte array buffer
GetFile	Download the data in a stored object to a local file.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from Object)	Gets the Type of the current instance.
Initialize	Overloaded. Initialize an instance of the WebStorage class.
Move	Move the contents of a stored object to another container.
Open	Overloaded. Open a storage container for the specified application.
PutData	Overloaded. Upload the data in a byte array buffer to the storage container.
PutFile	Overloaded. Upload a local file to the current storage container.
RegisterId	Register a new application identifier with the storage service.
Rename	Change the label of an existing storage object.
Reset	Reset the internal state of the class instance, resetting all properties to their default values.
ToString (inherited from Object)	Returns a String that represents the current Object.
Uninitialize	Uninitialize the class library and release any resources allocated for the current thread.
UnregisterId	Unregister a previously registered application identifier.
ValidateId	Check an application identifier to ensure it is valid

	and exists.
ValidateLabel	Validate an object label to ensure it uses allowed characters.

Public Instance Events

OnCancel	Occurs when a storage operation is canceled.
OnDownload	Occurs when a storage object has been downloaded.
OnError	Occurs when an storage operation fails.
OnProgress	Occurs as a data stream is being read or written to the client.
OnTimeout	Occurs when a blocking operation fails to complete before the timeout period elapses.
OnUpload	Occurs when a storage object has been uploaded.

Protected Instance Methods

Dispose	Overloaded. Releases the unmanaged resources allocated by the WebStorage class and optionally releases the managed resources.
Finalize	Destroys an instance of the class, releasing the resources allocated for the session and unloading the networking library.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

WebStorage Properties

The properties of the **WebStorage** class are listed below. For a complete list of **WebStorage** class members, see the WebStorage Members topic.

Public Instance Properties

AccountId	Gets a value that specifies the storage account ID associated with the development license.
AppId	Gets and sets the application identifier associated with the storage container.
Handle	Gets a value that specifies the storage handle allocated for the current session.
IsBlocked	Gets a value which indicates if the current thread is performing a blocking storage operation.
IsConnected	Gets a value which indicates if a connection to the storage server has been established.
IsInitialized	Gets a value which indicates if the current instance of the class has been initialized successfully.
IsOpened	Gets a value which indicates if a storage container has been opened.
LastError	Gets and sets a value which specifies the last error that has occurred.
LastErrorString	Gets a value which describes the last error that has occurred.
ObjectAttributes	Gets the attributes for the current object.
ObjectContent	Gets the content type for the current object.
ObjectCreated	Gets the date and time the current object was created.
ObjectDigest	Gets the SHA-256 digest value for the current object.
ObjectId	Gets the unique identifier for the current object.
ObjectLabel	Gets the label for the current object.
ObjectLimit	Gets the maximum number of objects that may be created.
ObjectModified	Gets the date and time the current object was last modified.
ObjectSize	Gets the size of the current object in bytes
StorageFree	Gets the total number of bytes available to store new objects.
StorageId	Gets a unique identifier for the current storage container.

StorageLimit	Gets the maximum number of bytes of storage available.
StorageObjects	Gets the current number of objects stored for your account.
StorageType	Gets the current storage container type identifier.
StorageUsed	Gets the current number of bytes of storage used for your account.
ThrowError	Gets and sets a value which specifies if method calls should throw exceptions when an error occurs.
Timeout	Gets and sets a value which specifies a timeout period in seconds.
Trace	Gets and sets a value which indicates if network function logging is enabled.
TraceFile	Gets and sets a value which specifies the name of the logfile.
TraceFlags	Gets and sets a value which specifies the client function tracing flags.
TransferBytes	Gets a value which specifies the number of bytes transferred to or from the server.
TransferRate	Gets a value which specifies the data transfer rate in bytes per second.
TransferTime	Gets a value which specifies the number of seconds elapsed during a data transfer.
Version	Gets a value which returns the current version of the WebStorage class library.

WebStorage Class | SocketTools Namespace

WebStorage.AccountId Property

Gets a value that specifies the storage account ID associated with the development license.

[Visual Basic]

```
Public ReadOnly Property AccountId As String
```

[C#]

```
public string AccountId {get;}
```

Property Value

A string which contains the account ID.

Remarks

The account ID is a string that uniquely identifies the web services account that is associated with the session. The account ID corresponds with your product serial number and runtime license key, but it is not identical to either of those values.

If you are using an evaluation license, the account ID is temporary and only valid during the evaluation period. After the evaluation period has expired, the account ID is revoked and objects stored using this ID will be deleted. It is not recommended that you store critical application data using an evaluation license.

See Also

WebStorage Class | SocketTools Namespace | AppId Property | StorageId Property

WebStorage.AppId Property

Gets and sets the application identifier associated with the storage container.

[Visual Basic]
```
Public Property AppId As String
```

[C#]
```
public string AppId {get; set;}
```

Property Value

A string which contains the application identifier.

Remarks

This property returns the current application ID. The application ID is a string that uniquely identifies the application and can only contain letters, numbers, the period and the underscore character. The default value for this property is SocketTools.Storage.Default.

You can register a unique identifier for your application using the **RegisterId** method

See Also

WebStorage Class | SocketTools Namespace | AccountId Property | StorageId Property

WebStorage.Handle Property

Gets a value that specifies the storage handle allocated for the current session.

[Visual Basic]

```
Public ReadOnly Property Handle As Integer
```

[C#]

```
public int Handle {get;}
```

Property Value

An integer which represents a client handle. If there is no active connection, a value of -1 is returned.

Remarks

The **Handle** property specifies the numeric descriptor of the current storage session.

See Also

WebStorage Class | SocketTools Namespace

WebStorage.IsBlocked Property

Gets a value which indicates if the current thread is performing a blocking storage operation.

[Visual Basic]

```
Public ReadOnly Property IsBlocked As Boolean
```

[C#]

```
public bool IsBlocked {get;}
```

Property Value

Returns **true** if the current thread is blocking, otherwise returns **false**.

Remarks

The **IsBlocked** property returns **true** if the current thread is blocked performing a storage operation. Because the Windows Sockets API only permits one blocking operation per thread of execution, this property should be checked before performing a storage operation in response to an event.

If the **IsBlocked** property returns **false**, this means there are no blocking operations on the current thread at that time. However, this does not guarantee that the next storage request will not fail. An application should always check the return value from a method and check the value of the **LastError** property if an error occurs.

Note that this property will return **true** if there is any blocking operation being performed by the current thread, regardless of whether this specific instance of the class is responsible for the blocking operation or not.

See Also

WebStorage Class | SocketTools Namespace | IsConnected Property

WebStorage.IsConnected Property

Gets a value which indicates if a connection to the storage server has been established.

[Visual Basic]

```
Public ReadOnly Property IsConnected As Boolean
```

[C#]

```
public bool IsConnected {get;}
```

Property Value

Returns **true** if the connection has been established; otherwise returns **false**.

Remarks

This property will return **false** if the **Open** method has not been called to open a storage container, or if the connection to the server has been terminated. A value of **true** indicates that the storage container has been opened and there is a valid connection to the server.

The client does not maintain a continuous, persistent connection with the storage server. The connection may be closed and reopened internally as needed. If the client session has been idle for a period of time, this property can return **false**. If the **LastError** property returns **errorNotConnected** it means the client session is valid, however it not currently connected to the storage server. The next call to store or retrieve an object will the cause the client to reconnect automatically.

See Also

WebStorage Class | SocketTools Namespace | IsBlocked Property | LastError Property | Close Method | Open Method

WebStorage.IsInitialized Property

Gets a value which indicates if the current instance of the class has been initialized successfully.

[Visual Basic]

```
Public ReadOnly Property IsInitialized As Boolean
```

[C#]

```
public bool IsInitialized {get;}
```

Property Value

Returns **true** if the class instance has been initialized; otherwise returns **false**.

Remarks

The **IsInitialized** property is used to determine if the current instance of the class has been initialized properly. Normally this is done automatically by the class constructor, however there are circumstances where the class may not be able to initialize itself.

The most common reasons that a class instance may not initialize correctly is that no runtime license key has been defined in the assembly or the license key provided is invalid. It may also indicate a problem with the system configuration or user access rights, such as not being able to load the required networking libraries or not being able to access the system registry.

See Also

WebStorage Class | SocketTools Namespace

WebStorage.LastError Property

Gets and sets a value which specifies the last error that has occurred.

[Visual Basic]

```
Public Property LastError As ErrorCode
```

[C#]

```
public WebStorage.ErrorCode LastError {get; set;}
```

Property Value

Returns an ErrorCode enumeration value which specifies the last error code.

Remarks

The **LastError** property returns the error code associated with the last error that occurred for the current instance of the class. It is important to note that this value only has meaning if the previous method indicates that an error has actually occurred.

It is possible to explicitly clear the last error code by assigning the property to the value **ErrorCode.errorNone**.

The error code value can be cast to an integer value for display purposes if required. For a description of the error that can be displayed using a message box or some other similar mechanism, get the value of the **LastErrorString** property.

See Also

WebStorage Class | SocketTools Namespace

WebStorage.LastErrorString Property

Gets a value which describes the last error that has occurred.

[Visual Basic]

```
Public ReadOnly Property LastErrorString As String
```

[C#]

```
public string LastErrorString {get;}
```

Property Value

A string which describes the last error that has occurred.

Remarks

The **LastErrorString** property can be used to obtain a description of the last error that occurred for the current instance of the class. It is important to note that this value only has meaning if the previous method indicates that an error has actually occurred.

WebStorage Class | SocketTools Namespace

WebStorage.ObjectAttributes Property

Gets the attributes for the current object.

[Visual Basic]

```
Public ReadOnly Property ObjectAttributes As Attributes
```

[C#]

```
public WebStorage.Attributes ObjectAttributes {get;}
```

Property Value

Returns an Attributes enumeration value which specifies one or more attribute flags for the current storage object.

See Also

WebStorage Class | SocketTools Namespace | Exists Method | FindFirst Method | FindNext Method

WebStorage.ObjectContent Property

Gets the content type for the current object.

[Visual Basic]
```
Public ReadOnly Property ObjectContent As String
```

[C#]
```
public string ObjectContent {get;}
```

Property Value

A string which specifies the MIME content type for the current storage object.

Remarks

This property returns a string which specifies the MIME content type for the current storage object. The content type is typically determined by the object label and evaluating the contents of the object. It is also possible for the application to explicitly specify the content type of the object when it is created.

The object content type will always be in the format **type/subtype** where the type specifies a common media type (e.g.: text, audio, video, etc.) and subtype specifies the specific content. The most common content type for text files is **text/plain**. If the content type is unknown, the default content type is **application/octet-stream**.

Text objects may also optionally include the character encoding as part of the content type. For example, if an object contains UTF-8 encoded text, the content type may be returned as text/plain; charset=utf-8. If your application is parsing the content types, you must check if a character encoding was also included in the value. Text objects that do not specify an encoding either contain ASCII or text which uses the system code page. Unicode text will always be stored using UTF-8 encoding.

See Also

WebStorage Class | SocketTools Namespace | Exists Method | PutData Method | PutFile Method

WebStorage.ObjectCreated Property

Gets the date and time the current object was created.

[Visual Basic]

```
Public ReadOnly Property ObjectCreated As Date
```

[C#]

```
public System.DateTime ObjectCreated {get;}
```

Property Value

A **DateTime** value which contains the date and time when the current object was created.

Remarks

This property returns object creation date and time using Coordinated Universal Time (UTC) and is not adjusted for the local timezone.

If there is no current object, this property will return a value of **DateTime.MinValue**.

See Also

WebStorage Class | SocketTools Namespace | ObjectModified Property | Exists Method | GetData Method | GetFile Method

WebStorage.ObjectDigest Property

Gets the SHA-256 digest value for the current object.

[Visual Basic]
```
Public ReadOnly Property ObjectDigest As String
```

[C#]
```
public string ObjectDigest {get;}
```

Property Value

A string value which specifies the digest of the object contents, computed using an SHA-256 hash.

Remarks

This property returns a string value which specifies the digest of the object contents, computed using an SHA-256 hash. The digest value is always represented as a string of hexadecimal numbers that is exactly 64 characters long. It is important to note that even a zero-length object will have a digest, which is the standard SHA-256 NULL hash value.

See Also

WebStorage Class | SocketTools Namespace | ObjectContent Property | ObjectId Property | ObjectSize Property | Exists Method

WebStorage.ObjectId Property

Gets the unique identifier for the current object.

[Visual Basic]

```
Public ReadOnly Property ObjectId As String
```

[C#]

```
public string ObjectId {get;}
```

Property Value

A string value which uniquely identifies the current object.

Remarks

This property returns a unique identifier associated with the current object. Object IDs are guaranteed to be unique for each storage object that is created by the application.

See Also

WebStorage Class | SocketTools Namespace | ObjectContent Property | ObjectLabel Property | ObjectSize Property | Exists Method

WebStorage.ObjectLabel Property

Gets the label for the current object.

[Visual Basic]
```
Public Property ObjectLabel As String
```

[C#]
```
public string ObjectLabel {get; set;}
```

Property Value

A string value which contains the label assigned to the object.

Remarks

This property returns a string which specifies the label assigned to the current object by the application. Object labels are case-sensitive and must be unique for each object. An application uses labels to reference an object with a human-recognizable name, rather than referencing them by their object ID.

Object labels are similar to Windows file names, except they are case-sensitive. The maximum length of a label string is 511 characters. Leading and trailing whitespace (spaces, tabs, linebreaks, etc.) are ignored in label names.

Illegal characters include ASCII and Unicode control characters 0 through 31, single quotes (39), double quotes (34), less than symbol (60), greater than symbol (62), pipe (124), asterisk (42) and question mark (63). It is not possible to embed null characters in the label name.

Labels can contain Unicode characters which are internally encoded as UTF-8.

WebStorage Class | SocketTools Namespace | ObjectContent Property | ObjectDigest Property | ObjectId Property | ObjectSize Property | Exists Method

WebStorage.ObjectLimit Property

Gets the maximum number of objects that may be created.

[Visual Basic]

```
Public ReadOnly Property ObjectLimit As Long
```

[C#]

```
public long ObjectLimit {get;}
```

Property Value

An integer value which specifies the maximum number of storage objects that may be created.

Remarks

This property returns an integer value which specifies the maximum number of storage objects that may be created. In addition to the limit on the total amount of storage that may be used, there is a limit on the total number of objects that may be created by all applications.

See Also

WebStorage Class | SocketTools Namespace | StorageFree Property | StorageLimit Property | StorageObjects Property | StorageUsed Property

WebStorage.ObjectModified Property

Gets the date and time the current object was last modified.

[Visual Basic]

```
Public ReadOnly Property ObjectModified As Date
```

[C#]

```
public System.DateTime ObjectModified {get;}
```

Property Value

A **DateTime** value which contains the date and time when the current object was last modified.

Remarks

This property returns object creation date and time using Coordinated Universal Time (UTC) and is not adjusted for the local timezone.

If there is no current object, this property will return a value of **DateTime.MinValue**.

See Also

WebStorage Class | SocketTools Namespace | ObjectCreated Property | Exists Method | GetData Method | GetFile Method

WebStorage.ObjectSize Property

Gets the size of the current object in bytes

[Visual Basic]

```
Public ReadOnly Property ObjectSize As Long
```

[C#]

```
public long ObjectSize {get;}
```

Property Value

An integer value that specifies the size of the current storage object in bytes.

Remarks

This property returns a value that specifies the size of the current storage object in bytes. If there is no current object, this property will return a value of zero.

See Also

WebStorage Class | SocketTools Namespace | StorageFree Property | StorageLimit Property | StorageObjects Property | StorageUsed Property

WebStorage.StorageFree Property

Gets the total number of bytes available to store new objects.

[Visual Basic]
```
Public ReadOnly Property StorageFree As Long
```

[C#]
```
public long StorageFree {get;}
```

Property Value

An integer value which specifies the number of bytes available for the storage of new objects.

Remarks

This property returns a value which specifies the number of bytes available for the storage of new objects. This value reflects the total amount of available storage across all applications registered with the development account. If this value is zero, your storage account has reached its storage limit.

If your storage quota has been exceeded, either because the total number of objects or the total bytes of storage has reached their limit, your applications will be unable to create new objects. Your application can continue to access existing objects, regardless of your current quota limits.

To free storage space, use the **Delete** method to delete individual storage objects that are no longer needed by your application, or use the **DeleteAll** method to delete all objects in the current container.

See Also

WebStorage Class | SocketTools Namespace | StorageLimit Property | StorageUsed Property | Delete Method | DeleteAll Method

WebStorage.StorageId Property

Gets a unique identifier for the current storage container.

[Visual Basic]

```
Public ReadOnly Property StorageId As String
```

[C#]

```
public string StorageId {get;}
```

Property Value

A string value which identifies the current storage container.

Remarks

This property returns a string which identifies the current storage container opened with the **Open** method. The storage ID is associated with your development license and is guaranteed to be a unique value. If no storage container has been opened, this property will return an empty string.

See Also

WebStorage Class | SocketTools Namespace

WebStorage.StorageLimit Property

Gets the maximum number of bytes of storage available.

[Visual Basic]

```
Public ReadOnly Property StorageLimit As Long
```

[C#]

```
public long StorageLimit {get;}
```

Property Value

An integer value which specifies the maximum number of bytes of data storage available.

Remarks

This property returns a value which specifies the maximum number of bytes of data storage available. This limit applies to all applications registered with the development account. In addition to limits on the total number of bytes that can be stored, there are also limits on the total number objects which may be created, and the individual size of each object.

Storage quota limits are assigned for each SocketTools development account. Accounts that are created with an evaluation license have much lower quota limits than a standard account and should be used for testing purposes only. After the evaluation period has ended, all objects stored using the evaluation license will be deleted.

This value does not represent limits on the storage used by a specific application. Quotas limits apply to all applications that are registered with the development account, which is identified with the runtime license key passed to the **Initialize** method.

If your storage quota has been exceeded, either because the total number of objects or the total bytes of storage has reached their limit, your applications will be unable to create new objects. Your application can continue to access existing objects, regardless of your current quota limits.

To free storage space, use the **Delete** method to delete individual storage objects that are no longer needed by your application, or use the **DeleteAll** method to delete all objects in the current container.

See Also

WebStorage Class | SocketTools Namespace | ObjectLimit Property | StorageFree Property | StorageObjects Property | StorageUsed Property | Delete Method | DeleteAll Method

WebStorage.StorageObjects Property

Gets the current number of objects stored for your account.

[Visual Basic]

```
Public ReadOnly Property StorageObjects As Long
```

[C#]

```
public long StorageObjects {get;}
```

Property Value

An integer value which specifies the number of storage objects allocated for the account.

Remarks

This property returns an integer value which specifies the number of storage objects allocated for the account. This value may not exceed the total number of objects specified by the **ObjectLimit** property.

See Also

WebStorage Class | SocketTools Namespace | ObjectLimit Property | StorageFree Property | StorageUsed Property

WebStorage.StorageType Property

Gets the current storage container type identifier.

[Visual Basic]

```
Public ReadOnly Property StorageType As Container
```

[C#]

```
public WebStorage.Container StorageType {get;}
```

Property Value

A Container enumeration which identifies the current storage container type

Remarks

The storage type specifies the type of container that objects will be stored in. You can think of the storage containers as special folders which store individual objects. In most cases, we recommend using **Container.storageGlobal** which means that stored objects will be accessible to all users of your application. However, you can limit access to the stored objects based on the local domain, local machine ID or the current user SID.

If you specify anything other than global storage, objects can be orphaned if the system configuration changes. For example, if **Container.storageMachine** is specified, the objects that are stored there can only be accessed from that computer system. If the system is reconfigured (for example, the boot volume formatted and Windows is reinstalled) the unique identifier for that system will change and the previous objects that were stored by your application can no longer be accessed.

It is advisable is to store critical application data and configuration information using **Container.storageGlobal** and use other non-global storage containers for configuration information that is unique to that system and/or user which is not critical and can be easily recreated.

See Also

WebStorage Class | SocketTools Namespace | StorageId Property | Open Method

WebStorage.StorageUsed Property

Gets the current number of bytes of storage used for your account.

[Visual Basic]

```
Public ReadOnly Property StorageUsed As Long
```

[C#]

```
public long StorageUsed {get;}
```

Property Value

An integer value which specifies the total number of bytes of data allocated for all storage objects.

Remarks

This property returns a value which specifies the total number of bytes of data allocated for all storage objects. This value may not exceed the total number of bytes of storage available, which is returned by the **StorageLimit** property.

This value does not represent the storage used by a specific application. This property returns the amount of storage used by all applications that are registered with the development account, which is identified with the runtime license key passed to the **Initialize** method.

See Also

WebStorage Class | SocketTools Namespace | ObjectLimit Property | StorageFree Property | StorageLimit Property

WebStorage.ThrowError Property

Gets and sets a value which specifies if method calls should throw exceptions when an error occurs.

[Visual Basic]

```
Public Property ThrowError As Boolean
```

[C#]

```
public bool ThrowError {get; set;}
```

Property Value

Returns **true** if method calls will generate exceptions when an error occurs; otherwise returns **false**. The default value is **false**.

Remarks

Error handling for when calling class methods can be done in either of two different styles, according to the value of this property.

If the **ThrowError** property is set to **false**, the application should check the return value of any method that is used, and report errors based upon the documented value of the return code. It is the responsibility of the application to interpret the error code, if it is desired to explain the error in addition to reporting it. This is the default behavior.

If the **ThrowError** property is set to **true**, then exceptions will be generated whenever a method call fails. The program must be written to catch these exceptions and take the appropriate action when an error occurs. Failure to handle an exception will cause the program to terminate abnormally.

Note that if an error occurs while a property is being read or modified, an exception will be raised regardless of the value of the **ThrowError** property.

See Also

WebStorage Class | SocketTools Namespace

WebStorage.Timeout Property

Gets and sets a value which specifies a timeout period in seconds.

[Visual Basic]

```
Public Property Timeout As Integer
```

[C#]

```
public int Timeout {get; set;}
```

Property Value

An integer value which specifies a timeout period in seconds.

Remarks

Setting the **Timeout** property specifies the number of seconds until a storage operation fails and returns an error. For most applications it is recommended the timeout period be set between 10 and 20 seconds.

See Also

WebStorage Class | SocketTools Namespace

WebStorage.Trace Property

Gets and sets a value which indicates if network function logging is enabled.

[Visual Basic]
```
Public Property Trace As Boolean
```

[C#]
```
public bool Trace {get; set;}
```

Property Value

Returns **true** if network function tracing is enabled; otherwise returns **false**. The default value is **false**.

Remarks

The **Trace** property is used to enable (or disable) the tracing of network function calls. When enabled, each function call is logged to a file, including the function parameters, return value and error code if applicable. This facility can be enabled and disabled at run time, and the trace log file can be specified by setting the **TraceFile** property. All function calls that are being logged are appended to the trace file, if it exists. If no trace file exists when tracing is enabled, the trace file is created.

The tracing facility is available in all of the SocketTools networking classes and is enabled or disabled for an entire process. This means that once trace logging is enabled for a given component, all of the function calls made by the process using any of the SocketTools classes will be logged. For example, if you have an application using both the File Transfer Protocol and Post Office Protocol classes, and you set the **Trace** property to **true**, function calls made by both classes will be logged. Additionally, enabling a trace is cumulative, and tracing is not stopped until it is disabled for all classes used by the process.

If trace logging is not enabled, there is no negative impact on performance or throughput. Once enabled, application performance can degrade, especially in those situations in which multiple processes are being traced or the logfile is fairly large. Since logfiles can grow very quickly, even with modest applications, it is recommended that you delete the file when it is no longer needed.

When redistributing your application, make sure that you include the **SocketTools10.TraceLog.dll** module with your installation. If this library is not present, then no trace output will be generated and the value of the **Trace** property will be ignored. Only those function calls made by the SocketTools networking classes will be logged. Calls made directly to the Windows Sockets API, or calls made by other classes, will not be logged.

See Also

WebStorage Class | SocketTools Namespace

WebStorage.TraceFile Property

Gets and sets a value which specifies the name of the logfile.

```
[Visual Basic]
Public Property TraceFile As String
```

```
[C#]
public string TraceFile {get; set;}
```

Property Value

A string which specifies the name of the file.

Remarks

The **TraceFile** property is used to specify the name of the trace file that is created when network function tracing is enabled. If this property is set to an empty string (the default value), then a file named **SocketTools.log** is created in the system's temporary directory. If no temporary directory exists, then the file is created in the current working directory.

If the file exists, the trace output is appended to the file, otherwise the file is created. Since network function tracing is enabled per-process, the trace file is shared by all instances of the class being used. If multiple class instances have tracing enabled, the **TraceFile** property should be set to the same value for each instance. Since trace files can grow very quickly, even with modest applications, it is recommended that you delete the file when it is no longer needed.

The trace file has the following format:

```
 MyApp INF: WSAAsyncSelect(46, 0xcc4, 0x7e9, 0x27) returned 0 MyApp WRN:
connect(46, 192.0.0.1:1234, 16) returned -1 [10035] MyApp ERR: accept(46,
NULL, 0x0) returned -1 [10038]
```

The first column contains the name of the process that is being traced. The second column identifies if the trace record is reporting information, a warning, or an error. What follows is the name of the function being called, the arguments passed to the function and the function's return value. If a warning or error is reported, the error code is appended to the record (the value is placed inside brackets).

If parameters are passed as integer values, they are recorded in decimal. If the parameter or return value is a pointer (a memory address), it is recorded as a hexadecimal value preceded with "0x". A special type of pointer, called a null pointer, is recorded as NULL. Those functions which expect socket addresses are displayed in the following format:

```
aa.bb.cc.dd:nnnn
```

The first four numbers separated by periods represent the IP address, and the number following the colon represents the port number in host byte order. Note that in the second line of the above example, the control is attempting to connect to a system with the IP address 192.0.0.1 on port 1234.

Note that if the specified file cannot be created, or the user does not have permission to modify an existing file, the error is silently ignored and no trace output will be generated.

See Also

WebStorage Class | SocketTools Namespace

WebStorage.TraceFlags Property

Gets and sets a value which specifies the client function tracing flags.

[Visual Basic]
```
Public Property TraceFlags As TraceOptions
```

[C#]
```
public WebStorage.TraceOptions TraceFlags {get; set;}
```

Property Value

A TraceOptions enumeration which specifies the amount of detail written to the trace logfile.

Remarks

The **TraceFlags** property is used to specify the type of information written to the trace file when network function tracing is enabled.

Because network function tracing is enabled per-process, the trace flags are shared by all instances of the class being used. If multiple class instances have tracing enabled, the **TraceFlags** property should be set to the same value for each instance. Changing the trace flags for any one instance of the class will affect the logging performed for all SocketTools classes used by the application.

Warnings are generated when a non-fatal error is returned by a network function. For example, if data is being written and the error **errorOperationWouldBlock** occurs, a warning is generated because the application simply needs to attempt to write the data at a later time.

See Also

WebStorage Class | SocketTools Namespace

WebStorage.TransferBytes Property

Gets a value which specifies the number of bytes transferred to or from the server.

[Visual Basic]

```
Public ReadOnly Property TransferBytes As Long
```

[C#]

```
public long TransferBytes {get;}
```

Property Value

An integer value which specifies the number of bytes of data transferred to or from the server.

Remarks

The **TransferBytes** property returns the number of bytes that have been copied to or from the server. If this property is read while a transfer is ongoing, the property returns the number of bytes that have been copied up to that point. If read after a transfer has completed, the total number of bytes copied is returned. This property value is reset with every data transfer.

See Also

WebStorage Class | SocketTools Namespace

WebStorage.TransferRate Property

Gets a value which specifies the data transfer rate in bytes per second.

[Visual Basic]

```
Public ReadOnly Property TransferRate As Integer
```

[C#]

```
public int TransferRate {get;}
```

Property Value

An integer value which specifies the transfer rate in bytes per second.

Remarks

The **TransferRate** property returns the rate at which the file data is being transferred, expressed in bytes per second. If this property is read while a transfer is ongoing, it returns the current average transfer rate.

If this property is read after the transfer has completed, it returns the final transfer rate which is calculated as the total number of bytes transferred divided by the number of seconds to complete the transfer.

This property value is reset with every data transfer.

See Also

WebStorage Class | SocketTools Namespace

WebStorage.TransferTime Property

Gets a value which specifies the number of seconds elapsed during a data transfer.

[Visual Basic]

```
Public ReadOnly Property TransferTime As Integer
```

[C#]

```
public int TransferTime {get;}
```

Property Value

An integer value which specifies the transfer time in seconds.

Remarks

The **TransferTime** property returns the number of seconds that have elapsed since the data transfer began. If the property is read while a transfer is ongoing, it returns the elapsed time. If the property is read after the transfer is complete, it returns the total number of seconds it took to transfer the data.

This property value is reset with every data transfer.

See Also

WebStorage Class | SocketTools Namespace

WebStorage.Version Property

Gets a value which returns the current version of the WebStorage class library.

[Visual Basic]

```
Public ReadOnly Property Version As String
```

[C#]

```
public string Version {get;}
```

Property Value

A string which specifies the version of the class library.

Remarks

The **Version** property returns a string which identifies the current version and build of the WebStorage class library. This value can be used by an application for validation and debugging purposes.

See Also

WebStorage Class | SocketTools Namespace

WebStorage Methods

The methods of the **WebStorage** class are listed below. For a complete list of **WebStorage** class members, see the WebStorage Members topic.

Public Static (Shared) Methods

ErrorText	Returns the description of an error code.

Public Instance Methods

Cancel	Cancel the current storage operation.
Close	Close the storage container.
CompareData	Overloaded. Compare the data in a byte buffer with a stored object.
CompareFile	Compare the data in a file with a stored object.
Copy	Overloaded. Copy the contents of a stored object to another container.
Delete	Delete a stored object from the container.
DeleteAll	Delete all stored objects in the container.
Dispose	Overloaded. Releases all resources used by WebStorage.
Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
Exists	Determine if a stored object exists in the container.
FindFirst	Overloaded. Find the first stored object that matches a label or content type.
FindNext	Find the next stored object that matches a label or content type.
GetData	Overloaded. Download the data in a stored object to a byte array buffer
GetFile	Download the data in a stored object to a local file.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from Object)	Gets the Type of the current instance.
Initialize	Overloaded. Initialize an instance of the WebStorage class.
Move	Move the contents of a stored object to another container.
Open	Overloaded. Open a storage container for the specified application.

PutData	Overloaded. Upload the data in a byte array buffer to the storage container.
PutFile	Overloaded. Upload a local file to the current storage container.
RegisterId	Register a new application identifier with the storage service.
Rename	Change the label of an existing storage object.
Reset	Reset the internal state of the class instance, resetting all properties to their default values.
ToString (inherited from Object)	Returns a String that represents the current Object.
Uninitialize	Uninitialize the class library and release any resources allocated for the current thread.
UnregisterId	Unregister a previously registered application identifier.
ValidateId	Check an application identifier to ensure it is valid and exists.
ValidateLabel	Validate an object label to ensure it uses allowed characters.

Protected Instance Methods

Dispose	Overloaded. Releases the unmanaged resources allocated by the WebStorage class and optionally releases the managed resources.
Finalize	Destroys an instance of the class, releasing the resources allocated for the session and unloading the networking library.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

WebStorage Class | SocketTools Namespace

WebStorage.Cancel Method

Cancel the current storage operation.

[Visual Basic]

```
Public Function Cancel() As Boolean
```

[C#]

```
public bool Cancel();
```

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If no storage container is currently open, or the current operation cannot be canceled, the return value will be **false**.

Remarks

When the **Cancel** method is called, the current storage operation will not immediately fail. An internal flag is set which causes the blocking operation to exit with an error. This means that the application cannot cancel a data transfer and immediately issue a request for another storage object. Instead it must allow the calling stack to unwind, returning back to the blocking operation before making any further method calls.

See Also

WebStorage Class | SocketTools Namespace

WebStorage.Close Method

Close the storage container.

[Visual Basic]

```
Public Function Close() As Boolean
```

[C#]

```
public bool Close();
```

Return Value

This method returns a Boolean value. If the storage container is closed, the return value is **true**. If no storage container is currently open, or the container cannot be closed, the return value will be **false**.

Remarks

The **Close** method should be called after all operations using the storage container have completed. The access token granted to the application will be released and the memory allocated for the session cache will be freed.

This method is automatically invoked when the object is disposed or the **Reset** method is called.

See Also

WebStorage Class | SocketTools Namespace

WebStorage.CompareData Method

Compare the data in a byte buffer with a stored object.

Overload List

Compare the data in a byte buffer with a stored object.

public bool CompareData(string,byte[],int);

Compare the data in a MemoryStream object with a stored object.

public bool CompareData(string,MemoryStream);

Compare the text in a string with a stored object.

public bool CompareData(string,string);

See Also

WebStorage Class | SocketTools Namespace | CompareFile Method

WebStorage.CompareData Method (String, Byte[], Int32)

Compare the data in a byte buffer with a stored object.

[Visual Basic]

```
Overloads Public Function CompareData( _
   ByVal labelName As String, _
   ByVal byteBuffer As Byte(), _
   ByVal length As Integer _
) As Boolean
```

[C#]

```
public bool CompareData(
   string labelName,
   byte[] byteBuffer,
   int length
);
```

Parameters

labelName
A string which specifies the label of the object that should be compared against the contents of the byte array buffer.

byteBuffer
A byte array which contains the data that should be compared against the contents. of the object.

length
An integer value which specifies the number of bytes to compare with the contents of the stored object. This value must match the size of the object exactly.

Return Value

This method returns a Boolean value. If the data matches the contents of the stored object exactly, it will return **true**, otherwise it will return **false**.

Remarks

The **CompareData** method performs a binary comparison of the data in the specified byte array with the contents of the storage object on the server. The amount of data in the buffer must match the size of the stored object exactly, or this method will fail. Partial comparisons are not supported by this method.

If you need to compare the contents of a file with a stored object, use the **CompareFile** method.

See Also

WebStorage Class | SocketTools Namespace | WebStorage.CompareData Overload List | CompareFile Method

WebStorage.CompareData Method (String, MemoryStream)

Compare the data in a MemoryStream object with a stored object.

[Visual Basic]

```
Overloads Public Function CompareData( _
   ByVal labelName As String, _
   ByVal memStream As MemoryStream _
) As Boolean
```

[C#]

```
public bool CompareData(
   string labelName,
   MemoryStream memStream
);
```

Parameters

labelName

A string which specifies the label of the object that should be compared against the contents of the MemoryStream.

memStream

A **MemoryStream** object which contains the data that should be compared against the contents of the stored object.

Return Value

This method returns a Boolean value. If the data matches the contents of the stored object exactly, it will return **true**, otherwise it will return **false**.

Remarks

The **CompareData** method performs a binary comparison of the data in the **MemoryStream** object with the contents of the storage object on the server. The amount of data in the MemoryStream must match the size of the stored object exactly, or this method will fail. Partial comparisons are not supported by this method.

If you need to compare the contents of a file with a stored object, use the **CompareFile** method.

See Also

WebStorage Class | SocketTools Namespace | WebStorage.CompareData Overload List | CompareFile Method

WebStorage.CompareData Method (String, String)

Compare the text in a string with a stored object.

[Visual Basic]

```
Overloads Public Function CompareData( _
   ByVal labelName As String, _
   ByVal textBuffer As String _
) As Boolean
```

[C#]

```
public bool CompareData(
   string labelName,
   string textBuffer
);
```

Parameters

labelName

A string which specifies the label of the object that should be compared against the contents of the text buffer.

textBuffer

A string which contains the text that should be compared against the contents of the stored object.

Return Value

This method returns a Boolean value. If the data matches the contents of the stored object exactly, it will return **true**, otherwise it will return **false**.

Remarks

The **CompareData** method performs a comparison of the text in the string buffer with the contents of the storage object on the server. The amount of text in the string buffer must match the size of the stored object exactly, or this method will fail. Partial comparisons are not supported by this method.

All text objects are stored using UTF-8 encoding and the contents of the **textBuffer** parameter will be encoded as UTF-8 prior to being compared with the contents of the stored object. If you need to perform a binary comparison of the data, use the version of this method that accepts a byte array or **MemoryStream** object.

If you need to compare the contents of a file with a stored object, use the **CompareFile** method.

See Also

WebStorage Class | SocketTools Namespace | WebStorage.CompareData Overload List | CompareFile Method

WebStorage.CompareFile Method

Compare the data in a file with a stored object.

[Visual Basic]

```
Public Function CompareFile( _
   ByVal labelName As String, _
   ByVal localFile As String _
) As Boolean
```

[C#]

```
public bool CompareFile(
   string labelName,
   string localFile
);
```

Parameters

labelName

A string which specifies the label of the object that should be compared against the contents of the local file.

localFile

A string which specifies the name of the file to compare against the contents of the stored object. If no path is specified in the file name, the current working directory will be used.

Return Value

This method returns a Boolean value. If the contents of the file matches the contents of the stored object exactly, it will return **true**, otherwise it will return **false**.

Remarks

The **CompareFile** method performs a binary comparison of the data in the file with the contents of the storage object on the server. The contents of the file must be identical to the contents of the stored object or the method will fail.

If you need to compare the contents of a file with a string or byte array, use the **CompareData** method.

See Also

WebStorage Class | SocketTools Namespace | CompareData Method

WebStorage.Copy Method

Copy the contents of a stored object within the current container.

Overload List

Copy the contents of a stored object within the current container.

public bool Copy(string,string);

Copy the contents of a stored object to another container.

public bool Copy(string,string,Container);

See Also

WebStorage Class | SocketTools Namespace

WebStorage.Copy Method (String, String)

Copy the contents of a stored object within the current container.

[Visual Basic]

```
Overloads Public Function Copy( _
   ByVal oldLabel As String, _
   ByVal newLabel As String _
) As Boolean
```

[C#]

```
public bool Copy(
   string oldLabel,
   string newLabel
);
```

Parameters

oldLabel
A string which specifies the label of the object that should be copied.

newLabel
A string which specifies the new label for the copied object.

Return Value

This method returns a Boolean value. If the stored object was copied, it will return **true**, otherwise it will return **false**.

Remarks

The **Copy** method is used to create a copy of an existing storage object. It may be used to duplicate an object with a different label, or it may be used to copy the object to a new storage container type.

Copied objects are assigned their own unique ID and are not linked to one another. Any subsequent changes made to the original object will not affect the copied object. Attempting to copy an object to itself or another existing object will result in an error.

This method updates the current object. Various properties such as **ObjectId** and **ObjectLabel** will reflect the values associated with the new, copied object and not the original object it was copied from.

See Also

WebStorage Class | SocketTools Namespace | WebStorage.Copy Overload List

WebStorage.Copy Method (String, String, Container)

Copy the contents of a stored object to another container.

[Visual Basic]

```
Overloads Public Function Copy( _
   ByVal oldLabel As String, _
   ByVal newLabel As String, _
   ByVal storageType As Container _
) As Boolean
```

[C#]

```
public bool Copy(
   string oldLabel,
   string newLabel,
   Container storageType
);
```

Parameters

oldLabel

A string which specifies the label of the object that should be copied.

newLabel

A string which specifies the new label for the copied object.

storageType

A Container enumeration which specifies the storage container that the stored object should be copied to.

Return Value

This method returns a Boolean value. If the stored object was copied to the container, it will return **true**, otherwise it will return **false**.

Remarks

The **Copy** method is used to create a copy of an existing storage object. It may be used to duplicate an object with a different label, or it may be used to copy the object to a new storage container type. For example, it can copy an object originally created in the **Container.storageUser** container to a new object stored in the **Container.storageMachine** container.

Copied objects are assigned their own unique ID and are not linked to one another. Any subsequent changes made to the original object will not affect the copied object. Attempting to copy an object to itself or another existing object will result in an error.

This method updates the current object. Various properties such as **ObjectId** and **ObjectLabel** will reflect the values associated with the new, copied object and not the original object it was copied from.

See Also

WebStorage Class | SocketTools Namespace | WebStorage.Copy Overload List

WebStorage.Delete Method

Delete a stored object from the container.

```
[Visual Basic]
Public Function Delete( _
   ByVal labelName As String _
) As Boolean
```

```
[C#]
public bool Delete(
   string labelName
);
```

Parameters

labelName
A string which specifies the label of the object that should be deleted.

Return Value

This method returns a Boolean value. If the stored object was deleted, it will return **true**, otherwise it will return **false**.

Remarks

The **Delete** method is used to delete a stored object from the container. This method permanently deletes the storage object and its associated data from the server. Deleted objects cannot be recovered by the application. To remove all objects stored in the container, use the **DeleteAll** method.

See Also

WebStorage Class | SocketTools Namespace | DeleteAll Method

WebStorage.DeleteAll Method

Delete all stored objects in the container.

[Visual Basic]

```
Public Function DeleteAll() As Boolean
```

[C#]

```
public bool DeleteAll();
```

Return Value

This method returns a Boolean value. If all stored objects in the container have been deleted, it will return **true**, otherwise it will return **false**.

Remarks

The storage container contains information for each of the objects that have been stored by the application. Each of these objects are associated with the application ID and the storage type that was specified when calling the **Open** method. The **DeleteAll** method instructs the server to remove all objects in the continer, resetting it back to its initial state.

Exercise caution when using this method. The operation is immediate and the objects that are stored in the container are permanently deleted. They cannot be recovered by your application.

See Also

WebStorage Class | SocketTools Namespace | Delete Method

WebStorage.Exists Method

Determine if a stored object exists in the container.

[Visual Basic]

```
Public Function Exists( _
   ByVal labelName As String _
) As Boolean
```

[C#]

```
public bool Exists(
   string labelName
);
```

Parameters

labelName
A string which specifies the label of the object.

Return Value

This method returns a Boolean value. If an object exists in the current container with the specified label, it will return **true**, other, otherwise it will return **false**.

Remarks

The **Exists** method is used to check for the existence of a stored object in the current container. If the object exists, various properties that return information about the current object, such as **ObjectId** and **ObjectSize** will be updated to return the metadata associated with the object.

Although storage object labels are similar to Windows file names, they are case-sensitive. When requesting information about an object, your application must specify the label name exactly as it was created. The object label cannot contain wildcard characters.

To obtain information about how much storage your applications are using and the total number of stored objects, use the **StorageUsed** and **StorageObjects** properties.

If you wish to enumerate all of the stored objects within the container, use the **FindFirst** and **FindNext** methods.

See Also

WebStorage Class | SocketTools Namespace | ObjectId Property | ObjectModified Property | StorageObjects Property | FindFirst Method | FindNext Method

WebStorage.FindFirst Method

Find the first stored object in the storage container.

Overload List

Find the first stored object in the storage container.

public bool FindFirst();

Find the first stored object that matches a label.

public bool FindFirst(string);

Find the first stored object that matches a label or content type.

public bool FindFirst(string,string);

See Also

WebStorage Class | SocketTools Namespace | Exists Method | FindNext Method

WebStorage.FindFirst Method ()

Find the first stored object in the storage container.

[Visual Basic]

```
Overloads Public Function FindFirst() As Boolean
```

[C#]

```
public bool FindFirst();
```

Return Value

This method returns a Boolean value. If a storage obgject is found in the container, this method will return **true**, otherwise it will return **false**.

Remarks

The **FindFirst** method returns information about the first object in the current storage container. It is used in conjunction with the **FindNext** method to enumerate all of the objects in the container.

If an object exists, various properties that return information about the current object, such as **ObjectId** and **ObjectSize** will be updated to return the metadata associated with the object.

See Also

WebStorage Class | SocketTools Namespace | WebStorage.FindFirst Overload List | Exists Method | FindNext Method

WebStorage.FindFirst Method (String)

Find the first stored object that matches a label.

[Visual Basic]

```
Overloads Public Function FindFirst( _
   ByVal matchLabel As String _
) As Boolean
```

[C#]

```
public bool FindFirst(
   string matchLabel
);
```

Parameters

matchLabel

A string which specifies the value to match against the object labels in the container. The string may contain wildcard characters similar to those use with the Windows filesystem. A "?" character matches any single character, and "*" matches any number of characters in the label. If this parameter is an empty string, all objects in the container will be matched.

Return Value

This method returns a Boolean value. If a matching object label is found in the current storage container, this method will return **true**, otherwise it will return **false**.

Remarks

The **FindFirst** method returns information about the first object that matches a given label. It is used in conjunction with the **FindNext** method to enumerate all of the matching objects in the storage container.

If a matching object exists, various properties that return information about the current object, such as **ObjectId** and **ObjectSize** will be updated to return the metadata associated with the object.

See Also

WebStorage Class | SocketTools Namespace | WebStorage.FindFirst Overload List | Exists Method | FindNext Method

WebStorage.FindFirst Method (String, String)

Find the first stored object that matches a label or content type.

[Visual Basic]

```
Overloads Public Function FindFirst( _
   ByVal matchLabel As String, _
   ByVal contentType As String _
) As Boolean
```

[C#]

```
public bool FindFirst(
   string matchLabel,
   string contentType
);
```

Parameters

matchLabel

A string which specifies the value to match against the object labels in the container. The string may contain wildcard characters similar to those use with the Windows filesystem. A "?" character matches any single character, and "*" matches any number of characters in the label. If this parameter is an empty string, all objects in the container will be matched.

contentType

A string which specifies the content type of the objects to be enumerated. If this parameter is an empty string, the content type is ignored and all matching objects are returned. If a content type is specified, it must be a valid MIME media content type designated using the standard **type/subtype** nomenclature.

Return Value

This method returns a Boolean value. If a matching object label or content type is found in the current storage container, this method will return **true**, otherwise it will return **false**.

Remarks

The **FindFirst** method returns information about the first object that matches a given label, content type or both. It is used in conjunction with the **FindNext** method to enumerate all of the matching objects in the storage container.

If a matching object exists, various properties that return information about the current object, such as **ObjectId** and **ObjectSize** will be updated to return the metadata associated with the object.

See Also

WebStorage Class | SocketTools Namespace | WebStorage.FindFirst Overload List | Exists Method | FindNext Method

WebStorage.FindNext Method

Find the next stored object that matches a label or content type.

[Visual Basic]

```
Public Function FindNext() As Boolean
```

[C#]

```
public bool FindNext();
```

Return Value

This method returns a Boolean value. If the next matching object label or content type is found, this method will return **true**, otherwise it will return **false**.

Remarks

The **FindNext** method returns information about the next object that matches a given label, content type or both. This method may only be called after the FindFirst method is called, otherwise it will fail.

If a matching object exists, various properties that return information about the current object, such as **ObjectId** and **ObjectSize** will be updated to return the metadata associated with the object.

See Also

WebStorage Class | SocketTools Namespace | Exists Method | FindFirst Method

WebStorage.GetData Method

Download the data in a stored object to a byte array buffer

Overload List

Download the data in a stored object to a byte array buffer

public bool GetData(string,byte[],ref int);

Download the data in a stored object to a byte array buffer

public bool GetData(string,ref byte[]);

Download the data in a stored object to a MemoryStream.

public bool GetData(string,MemoryStream);

Download the data in a stored object to a MemoryStream.

public bool GetData(string,ref string);

See Also

WebStorage Class | SocketTools Namespace

WebStorage.GetData Method (String, Byte[], Int32)

Download the data in a stored object to a byte array buffer

[Visual Basic]

```
Overloads Public Function GetData( _
   ByVal labelName As String, _
   ByVal byteBuffer As Byte(), _
   ByRef length As Integer _
) As Boolean
```

[C#]

```
public bool GetData(
   string labelName,
   byte[] byteBuffer,
   ref int length
);
```

Parameters

labelName
A string which specifies the label of the object that should be retrieved from the server.

byteBuffer
A byte array that will contain the object data when the method returns.

length
An integer variable passed by reference that will contain the number of bytes of data copied into the buffer. If the variable is initialized to a non-zero value prior to calling this method, this specifies the maximum number of bytes of data that may be copied into the buffer.

Return Value

This method returns a Boolean value. If the object exists and could be retrieved from the server, this method will return **true**, otherwise it will return **false**.

Remarks

The **GetData** method transfers data from a stored object to the specified buffer. This method will cause the current thread to block until the data transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

When this method returns, various properties that contain information about the current object, such as **ObjectId** and **ObjectSize**, will be updated to return the metadata associated with the object which was downloaded.

See Also

WebStorage Class | SocketTools Namespace | WebStorage.GetData Overload List

WebStorage.GetData Method (String, Byte[])

Download the data in a stored object to a byte array buffer

[Visual Basic]

```
Overloads Public Function GetData( _
   ByVal labelName As String, _
   ByRef byteBuffer As Byte() _
) As Boolean
```

[C#]

```
public bool GetData(
   string labelName,
   ref byte[] byteBuffer
);
```

Parameters

labelName

A string which specifies the label of the object that should be retrieved from the server.

byteBuffer

A byte array variable passed by reference that will contain the object data when the method returns.

Return Value

This method returns a Boolean value. If the object exists and could be retrieved from the server, this method will return **true**, otherwise it will return **false**.

Remarks

The **GetData** method transfers data from a stored object to the specified buffer. This method will cause the current thread to block until the data transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

When this method returns, various properties that contain information about the current object, such as **ObjectId** and **ObjectSize**, will be updated to return the metadata associated with the object which was downloaded.

See Also

WebStorage Class | SocketTools Namespace | WebStorage.GetData Overload List

WebStorage.GetData Method (String, MemoryStream)

Download the data in a stored object to a MemoryStream.

[Visual Basic]

```
Overloads Public Function GetData( _
   ByVal labelName As String, _
   ByVal memStream As MemoryStream _
) As Boolean
```

[C#]

```
public bool GetData(
   string labelName,
   MemoryStream memStream
);
```

Parameters

labelName

A string which specifies the label of the object that should be retrieved from the server.

memStream

A System.IO.MemoryStream object that will contain the object data when the method returns. This stream must be open and writable.

Return Value

This method returns a Boolean value. If the object exists and could be retrieved from the server, this method will return **true**, otherwise it will return **false**.

Remarks

The **GetData** method transfers data from a stored object to the specified buffer. This method will cause the current thread to block until the data transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

When this method returns, various properties that contain information about the current object, such as **ObjectId** and **ObjectSize**, will be updated to return the metadata associated with the object which was downloaded.

See Also

WebStorage Class | SocketTools Namespace | WebStorage.GetData Overload List

WebStorage.GetData Method (String, String)

Download the data in a stored object to a MemoryStream.

[Visual Basic]

```
Overloads Public Function GetData( _
   ByVal labelName As String, _
   ByRef textBuffer As String _
) As Boolean
```

[C#]

```
public bool GetData(
   string labelName,
   ref string textBuffer
);
```

Parameters

labelName

A string which specifies the label of the object that should be retrieved from the server.

textBuffer

A string variable passed by reference which will contain the the contents of the stored object when the method returns.

Return Value

This method returns a Boolean value. If the object exists and could be retrieved from the server, this method will return **true**, otherwise it will return **false**.

Remarks

The **GetData** method transfers data from a stored object to the specified string. This method will cause the current thread to block until the data transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

This version of the method should only be used with objects which only contain text. It should never be used to retrieve the contents of a stored object which contains binary data.

When this method returns, various properties that contain information about the current object, such as **ObjectId** and **ObjectSize**, will be updated to return the metadata associated with the object which was downloaded.

WebStorage Class | SocketTools Namespace | WebStorage.GetData Overload List

WebStorage.GetFile Method

Download the data in a stored object to a local file.

[Visual Basic]

```
Public Function GetFile( _
   ByVal localFile As String, _
   ByVal labelName As String _
) As Boolean
```

[C#]

```
public bool GetFile(
   string localFile,
   string labelName
);
```

Parameters

localFile

A string which specifies the name of the local file that will be created or overwritten with the contents of the storage object. If a path is not specified, the file will be created in the current working directory.

labelName

A string which specifies specifies the label of the object that should be retrieved from the server.

Return Value

This method returns a Boolean value. If the object exists and could be retrieved from the server, this method will return **true**, otherwise it will return **false**.

Remarks

The **GetFile** method downloads data from a stored object to a local file. This method will cause the current thread to block until the data transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

When this method returns, various properties that contain information about the current object, such as **ObjectId** and **ObjectSize**, will be updated to return the metadata associated with the object which was downloaded.

WebStorage.Initialize Method

Initialize an instance of the WebStorage class.

Overload List

Initialize an instance of the WebStorage class.

public bool Initialize();

Initialize an instance of the WebStorage class.

public bool Initialize(string);

See Also

WebStorage Class | SocketTools Namespace | Uninitialize Method

WebStorage.Initialize Method ()

Initialize an instance of the WebStorage class.

[Visual Basic]

```
Overloads Public Function Initialize() As Boolean
```

[C#]

```
public bool Initialize();
```

Return Value

A boolean value which specifies if the class was initialized successfully.

Remarks

The **Initialize** method can be used to explicitly initialize an instance of the WebStorage class, loading the networking library and allocating resources for the current thread. Typically it is not necessary to explicitly call this method because the instance of the class is initialized by the class constructor. However, if the **Uninitialize** method is called, the class must be re-initialized before any other methods are called.

See Also

WebStorage Class | SocketTools Namespace | WebStorage.Initialize Overload List | Uninitialize Method

WebStorage.Initialize Method (String)

Initialize an instance of the WebStorage class.

[Visual Basic]

```
Overloads Public Function Initialize( _
   ByVal licenseKey As String _
) As Boolean
```

[C#]

```
public bool Initialize(
   string licenseKey
);
```

Return Value

A boolean value which specifies if the class was initialized successfully.

Remarks

The **Initialize** method can be used to explicitly initialize an instance of the WebStorage class, loading the networking library and allocating resources for the current thread. Typically an application would define the license key as a custom attribute, however this method can be used to initialize the class directly.

The runtime license key for your copy of SocketTools can be generated using the License Manager utility that is included with the product. Note that if you have installed an evaluation license, you will not have a runtime license key and cannot redistribute any applications which use the WebStorage class.

Example

The following example shows how to use the Initialize method to initialize an instance of the class. This example assumes that the license key string has been defined in code.

```
SocketTools.WebStorage webClient = new SocketTools.WebStorage();

if (webClient.Initialize(strLicenseKey) == false)
{
    MessageBox.Show(webClient.LastErrorString, "Error",
                    MessageBoxButtons.OK, MessageBoxIcon.Exclamation);
    return;
}
```

```
Dim webClient As New SocketTools.WebStorage

If webClient.Initialize(strLicenseKey) = False Then
    MsgBox(httpClient.LastErrorString, vbIconExclamation)
    Exit Sub
End If
```

WebStorage Class | SocketTools Namespace | WebStorage.Initialize Overload List | RuntimeLicenseAttribute Class | Uninitialize Method

WebStorage.Move Method

Move the contents of a stored object to another container.

[Visual Basic]

```
Public Function Move( _
   ByVal oldLabel As String, _
   ByVal newLabel As String, _
   ByVal storageType As Container _
) As Boolean
```

[C#]

```
public bool Move(
   string oldLabel,
   string newLabel,
   Container storageType
);
```

Parameters

oldLabel

A string which specifies the label of the object that should be moved.

newLabel

A string which specifies the new label for the object being moved.

storageType

A Container enumeration which specifies the storage container that the stored object should be moved to.

Return Value

This method returns a Boolean value. If the stored object was moved to the container, it will return **true**, otherwise it will return **false**.

Remarks

The **Move** method is used to move an existing storage object to a new container. For example, it can move an object originally created in the **Container.storageUser** container to the **Container.storageMachine** container. Using this method to move an object within the same container is effectively the same as calling the **Rename** method.

This method updates the current object. Various properties such as **ObjectId** and **ObjectLabel** will reflect the values associated with the object which has been moved.

WebStorage.Open Method

Open the global storage container for the current application.

Overload List

Open the global storage container for the current application.

public bool Open();

Open a storage container for the current application.

public bool Open(Container);

Open the global storage container for the specified application.

public bool Open(string);

Open a storage container for the specified application.

public bool Open(string,Container);

Open a storage container for the specified application.

public bool Open(string,Container,int);

See Also

WebStorage Class | SocketTools Namespace | Close Method | Container Enumeration

WebStorage.Open Method ()

Open the global storage container for the current application.

[Visual Basic]

```
Overloads Public Function Open() As Boolean
```

[C#]

```
public bool Open();
```

Return Value

This method returns a Boolean value. If the container was opened, it will return **true**, otherwise it will return **false**.

Remarks

The **Open** method opens the global storage container and requests an access token for the application. This method that must be called prior to accessing any stored objects.

It is advisable is to store critical application data and configuration information in the global storage container and use other non-global storage containers for configuration information that is unique to that system and/or user which is not critical and can be easily recreated.

If a storage container was opened prior to calling this method, the current container will be closed and the new container opened.

See Also

WebStorage Class | SocketTools Namespace | WebStorage.Open Overload List | Close Method | Container Enumeration

WebStorage.Open Method (Container)

Open a storage container for the current application.

[Visual Basic]

```
Overloads Public Function Open( _
   ByVal storageType As Container _
) As Boolean
```

[C#]

```
public bool Open(
   Container storageType
);
```

Parameters

storageType

A Container enumeration which specifies the storage container.

Return Value

This method returns a Boolean value. If the container was opened, it will return **true**, otherwise it will return **false**.

Remarks

The **Open** method opens the specified storage container using the current application ID and requests an access token for the application. This method that must be called prior to accessing any stored objects.

The ***storageType*** parameter specifies the type of container that objects will be stored in. In most cases, we recommend using **Container.storageGlobal** which means that stored objects will be accessible to all users of your application. However, you can limit access to the stored objects based on the local domain, local machine ID or the current user SID.

If you specify anything other than global storage, objects can be orphaned if the system configuration changes. For example, if **Container.storageMachine** is specified, the objects that are stored there can only be accessed from that computer system. If the system is reconfigured (for example, the boot volume formatted and Windows is reinstalled) the unique identifier for that system will change and the previous objects that were stored by your application wil no longer be accessible.

It is advisable is to store critical application data and configuration information in the **Container.storageGlobal** container and use other non-global storage containers for configuration information that is unique to that system and/or user which is not critical and can be easily recreated.

If a storage container was opened prior to calling this method, the current container will be closed and the new container opened.

WebStorage.Open Method (String)

Open the global storage container for the specified application.

[Visual Basic]

```
Overloads Public Function Open( _
   ByVal appId As String _
) As Boolean
```

[C#]

```
public bool Open(
   string appId
);
```

Parameters

appId

A string which specifies the application ID for the storage container. The application ID is a string that uniquely identifies the application and can only contain letters, numbers, the period and the underscore character. will be used.

Return Value

This method returns a Boolean value. If the container was opened, it will return **true**, otherwise it will return **false**.

Remarks

The **Open** method opens the specified storage container and requests an access token for the application. This method that must be called prior to accessing any stored objects.

The application ID is a string that uniquely identifies the application requesting the access and must have been previously registered with the server by calling the **RegisterId** method. If the ***appId*** parameter is an empty string, the a default internal ID will be used which is allocated for each storage account. You can use this default ID if you wish to share data between all of the applications you create.

The ***storageType*** parameter specifies the type of container that objects will be stored in. In most cases, we recommend using **Container.storageGlobal** which means that stored objects will be accessible to all users of your application. However, you can limit access to the stored objects based on the local domain, local machine ID or the current user SID.

If you specify anything other than global storage, objects can be orphaned if the system configuration changes. For example, if **Container.storageMachine** is specified, the objects that are stored there can only be accessed from that computer system. If the system is reconfigured (for example, the boot volume formatted and Windows is reinstalled) the unique identifier for that system will change and the previous objects that were stored by your application wil no longer be accessible.

It is advisable is to store critical application data and configuration information in the **Container.storageGlobal** container and use other non-global storage containers for configuration information that is unique to that system and/or user which is not critical and can be easily recreated.

If a storage container was opened prior to calling this method, the current container will be closed and the new container opened.

WebStorage.Open Method (String, Container)

Open a storage container for the specified application.

[Visual Basic]

```
Overloads Public Function Open( _
   ByVal appId As String, _
   ByVal storageType As Container _
) As Boolean
```

[C#]

```
public bool Open(
   string appId,
   Container storageType
);
```

Parameters

appId

A string which specifies the application ID for the storage container. The application ID is a string that uniquely identifies the application and can only contain letters, numbers, the period and the underscore character. will be used.

storageType

A Container enumeration which specifies the storage container. The default container is **Container.storageGlobal**.

Return Value

This method returns a Boolean value. If the container was opened, it will return **true**, otherwise it will return **false**.

Remarks

The **Open** method opens the specified storage container and requests an access token for the application. This method that must be called prior to accessing any stored objects.

The application ID is a string that uniquely identifies the application requesting the access and must have been previously registered with the server by calling the **RegisterId** method. If the ***appId*** parameter is an empty string, the a default internal ID will be used which is allocated for each storage account. You can use this default ID if you wish to share data between all of the applications you create.

The ***storageType*** parameter specifies the type of container that objects will be stored in. In most cases, we recommend using **Container.storageGlobal** which means that stored objects will be accessible to all users of your application. However, you can limit access to the stored objects based on the local domain, local machine ID or the current user SID.

If you specify anything other than global storage, objects can be orphaned if the system configuration changes. WebStorage.Open Method (String, Container, Int32)

Open a storage container for the specified application.

[Visual Basic]

```
Overloads Public Function Open( _
   ByVal appId As String, _
   ByVal storageType As Container, _
   ByVal timeout As Integer _
) As Boolean
```

[C#]

```
public bool Open(
   string appId,
   Container storageType,
   int timeout
);
```

Parameters

appId

A string which specifies the application ID for the storage container. The application ID is a string that uniquely identifies the application and can only contain letters, numbers, the period and the underscore character. will be used.

storageType

A Container enumeration which specifies the storage container. The default container is **Container.storageGlobal**.

timeout

Return Value

This method returns a Boolean value. If the container was opened, it will return **true**, otherwise it will return **false**.

Remarks

The **Open** method opens the specified storage container and requests an access token for the application. This method that must be called prior to accessing any stored objects.

The application ID is a string that uniquely identifies the application requesting the access and must have been previously registered with the server by calling the **RegisterId** method. If the ***appId*** parameter is an empty string, the a default internal ID will be used which is allocated for each storage account. You can use this default ID if you wish to share data between all of the applications you create.

The ***storageType*** parameter specifies the type of container that objects will be stored in. In most cases, we recommend using **Container.storageGlobal** which means that stored objects will be accessible to all users of your application. However, you can limit access to the stored objects based on the local domain, local machine ID or the current user SID.

If you specify anything other than global storage, objects can be orphaned if the system configuration changes. For example, if **Container.storageMachine** is specified, the objects that are stored there can only be accessed from that computer system. If the system is reconfigured (for example, the boot volume formatted and Windows is reinstalled) the unique identifier for that system will change and the previous objects that were stored by your application wil no longer be accessible.

It is advisable is to store critical application data and configuration information in the **Container.storageGlobal** container and use other non-global storage containers for configuration information that is unique to that system and/or user which is not critical and can be easily recreated.

If a storage container was opened prior to calling this method, the current container will be closed and the new container opened.

WebStorage.PutData Method

Upload the data in a byte array buffer to the storage container.

Overload List

Upload the data in a byte array buffer to the storage container.

public bool PutData(string,Attributes,byte[],int);

Upload the data in a MemoryStream object to the storage container.

public bool PutData(string,Attributes,MemoryStream);

Upload the text in a string to the storage container.

public bool PutData(string,Attributes,string);

Upload the data in a byte array buffer to the storage container.

public bool PutData(string,byte[]);

Upload the data in a byte array buffer to the storage container.

public bool PutData(string,byte[],int);

Upload the data in a MemoryStream object to the storage container.

public bool PutData(string,MemoryStream);

Upload the text in a string to the storage container.

public bool PutData(string,string);

Upload the data in a byte array buffer to the storage container.

public bool PutData(string,string,Attributes,byte[],int);

Upload the data in a MemoryStream object to the storage container.

public bool PutData(string,string,Attributes,MemoryStream);

Upload the text in a string to the storage container.

public bool PutData(string,string,Attributes,string);

Upload the data in a byte array buffer to the storage container.

public bool PutData(string,string,byte[],int);

Upload the data in a MemoryStream object to the storage container.

public bool PutData(string,string,MemoryStream);

Upload the text in a string to the storage container.

public bool PutData(string,string,string);

See Also

WebStorage Class | SocketTools Namespace | Close Method | GetData Method | Open Method | Attributes Enumeration

WebStorage.PutData Method (String, String, Attributes, Byte[], Int32)

Upload the data in a byte array buffer to the storage container.

[Visual Basic]

```
Overloads Public Function PutData( _
   ByVal labelName As String, _
   ByVal contentType As String, _
   ByVal objAttributes As Attributes, _
   ByVal byteBuffer As Byte(), _
   ByVal length As Integer _
) As Boolean
```

[C#]

```
public bool PutData(
   string labelName,
   string contentType,
   Attributes objAttributes,
   byte[] byteBuffer,
   int length
);
```

Parameters

labelName
: A string which specifies the label of the object that should be uploaded to the server. If an object with the same label already exists, it will be replaced with the contents of the buffer

contentType
: An string which identifies the contents of the buffer being stored. If this parameter is an empty string, the method will attempt to automatically determine the content type based on the object label and the contents of the buffer

objAttributes
: An Attributes enumeration which specifies the attributes for the object being stored.

byteBuffer
: A byte array which contains the data to be stored.

length
: An integer value which specifies the number of bytes of data to be stored. This value cannot exceed the size of the byte array.

Return Value

This method returns a Boolean value. If the data has been uploaded to the storage server, it will return **true**, otherwise it will return **false**.

Remarks

The **PutData** method uploads the contents of a byte array to the current storage container. If an object exists with the same label, it will be replaced. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

Although storage object labels are similar to Windows file names, they are case-sensitive. When requesting information about an object, your application must specify the label name exactly as it was created using this method. The object label cannot contain wildcard characters.

If the label identifies an object that already exists in the container, and that object was created with the

Attributes.objectReadOnly attribute, this method will fail. To replace a read-only object, the application must explicitly move, rename or delete the existing object.

If a content type is provided, it must specify a valid MIME media type and subtype. For example, normal text has a content type of **text/plain** while XML-formatted text would have a content type of **text/xml**. Data that contains unstructured binary data is typically identified as **application/octet-stream.**. If you do not specify a content type, an appropriate content type will be determined automatically based on the label and the contents of the buffer.

If you wish to upload the contents of a file, use the **PutFile** method.

When this method returns, various properties such as **ObjectId** and **ObjectLabel** will be updated to reflect the values associated with the object that was created or replaced on the server.

WebStorage Class | SocketTools Namespace | WebStorage.PutData Overload List | Close Method | GetData Method | Open Method | Attributes Enumeration

WebStorage.PutData Method (String, String, Byte[], Int32)

Upload the data in a byte array buffer to the storage container.

[Visual Basic]

```
Overloads Public Function PutData( _
   ByVal labelName As String, _
   ByVal contentType As String, _
   ByVal byteBuffer As Byte(), _
   ByVal length As Integer _
) As Boolean
```

[C#]

```
public bool PutData(
   string labelName,
   string contentType,
   byte[] byteBuffer,
   int length
);
```

Parameters

labelName
A string which specifies the label of the object that should be uploaded to the server. If an object with the same label already exists, it will be replaced with the contents of the buffer

contentType
An string which identifies the contents of the buffer being stored. If this parameter is an empty string, the method will attempt to automatically determine the content type based on the object label and the contents of the buffer

byteBuffer
A byte array which contains the data to be stored.

length
An integer value which specifies the number of bytes of data to be stored. This value cannot exceed the size of the byte array.

Return Value

This method returns a Boolean value. If the data has been uploaded to the storage server, it will return **true**, otherwise it will return **false**.

Remarks

The **PutData** method uploads the contents of a byte array to the current storage container with default attributes. If an object exists with the same label, it will be replaced. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

Although storage object labels are similar to Windows file names, they are case-sensitive. When requesting information about an object, your application must specify the label name exactly as it was created using this method. The object label cannot contain wildcard characters.

If the label identifies an object that already exists in the container, and that object was created with the **Attributes.objectReadOnly** attribute, this method will fail. To replace a read-only object, the application must explicitly move, rename or delete the existing object.

If a content type is provided, it must specify a valid MIME media type and subtype. For example, normal text has a content type of **text/plain** while XML-formatted text would have a content type of **text/xml**. Data that contains unstructured binary data is typically identified as **application/octet-stream.**. If you do not specify a content type, an appropriate content type will be determined automatically based on the label and the contents of the buffer.

If you wish to upload the contents of a file, use the **PutFile** method.

When this method returns, various properties such as **ObjectId** and **ObjectLabel** will be updated to reflect the values associated with the object that was created or replaced on the server.

WebStorage.PutData Method (String, Byte[])

Upload the data in a byte array buffer to the storage container.

[Visual Basic]

```
Overloads Public Function PutData( _
   ByVal labelName As String, _
   ByVal byteBuffer As Byte() _
) As Boolean
```

[C#]

```
public bool PutData(
   string labelName,
   byte[] byteBuffer
);
```

Parameters

labelName

A string which specifies the label of the object that should be uploaded to the server. If an object with the same label already exists, it will be replaced with the contents of the buffer

byteBuffer

A byte array which contains the data to be stored.

Return Value

This method returns a Boolean value. If the data has been uploaded to the storage server, it will return **true**, otherwise it will return **false**.

Remarks

The **PutData** method uploads the contents of a byte array to the current storage container with default attributes and a default content type. If an object exists with the same label, it will be replaced. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

Although storage object labels are similar to Windows file names, they are case-sensitive. When requesting information about an object, your application must specify the label name exactly as it was created using this method. The object label cannot contain wildcard characters.

If the label identifies an object that already exists in the container, and that object was created with the **Attributes.objectReadOnly** attribute, this method will fail. To replace a read-only object, the application must explicitly move, rename or delete the existing object.

An appropriate content type for the data will be determined automatically based on the label and the contents of the buffer.

If you wish to upload the contents of a file, use the **PutFile** method.

When this method returns, various properties such as **ObjectId** and **ObjectLabel** will be updated to reflect the values associated with the object that was created or replaced on the server.

See Also

WebStorage Class | SocketTools Namespace | WebStorage.PutData Overload List | Close Method | GetData Method | Open Method

WebStorage.PutData Method (String, String, Attributes, MemoryStream)

Upload the data in a MemoryStream object to the storage container.

[Visual Basic]

```
Overloads Public Function PutData( _
   ByVal labelName As String, _
   ByVal contentType As String, _
   ByVal objAttributes As Attributes, _
   ByVal memStream As MemoryStream _
) As Boolean
```

[C#]

```
public bool PutData(
   string labelName,
   string contentType,
   Attributes objAttributes,
   MemoryStream memStream
);
```

Parameters

labelName
A string which specifies the label of the object that should be uploaded to the server. If an object with the same label already exists, it will be replaced with the contents of the buffer

contentType
An string which identifies the contents of the buffer being stored. If this parameter is an empty string, the method will attempt to automatically determine the content type based on the object label and the contents of the buffer

objAttributes
An Attributes enumeration which specifies the attributes for the object being stored.

memStream
A MemoryStream object which contains the data to be stored. The stream must be open and readable.

Return Value

This method returns a Boolean value. If the data has been uploaded to the storage server, it will return **true**, otherwise it will return **false**.

Remarks

The **PutData** method uploads the contents of a **MemoryStream** object to the current storage container. If a storage object exists with the same label, it will be replaced. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

Although storage object labels are similar to Windows file names, they are case-sensitive. When requesting information about an object, your application must specify the label name exactly as it was created using this method. The object label cannot contain wildcard characters.

If the label identifies an object that already exists in the container, and that object was created with the **Attributes.objectReadOnly** attribute, this method will fail. To replace a read-only object, the application must explicitly move, rename or delete the existing object.

If a content type is provided, it must specify a valid MIME media type and subtype. For example, normal text has a content type of **text/plain** while XML-formatted text would have a content type of **text/xml**. Data that contains unstructured binary data is typically identified as **application/octet-stream.**. If you do not specify a content type, an appropriate content type will be determined automatically based on the label and the contents of the buffer.

If you wish to upload the contents of a file, use the **PutFile** method.

When this method returns, various properties such as **ObjectId** and **ObjectLabel** will be updated to reflect the values associated with the object that was created or replaced on the server.

WebStorage.PutData Method (String, String, MemoryStream)

Upload the data in a MemoryStream object to the storage container.

[Visual Basic]

```
Overloads Public Function PutData( _
   ByVal labelName As String, _
   ByVal contentType As String, _
   ByVal memStream As MemoryStream _
) As Boolean
```

[C#]

```
public bool PutData(
   string labelName,
   string contentType,
   MemoryStream memStream
);
```

Parameters

labelName

A string which specifies the label of the object that should be uploaded to the server. If an object with the same label already exists, it will be replaced with the contents of the buffer

contentType

An string which identifies the contents of the buffer being stored. If this parameter is an empty string, the method will attempt to automatically determine the content type based on the object label and the contents of the buffer

memStream

A MemoryStream object which contains the data to be stored. The stream must be open and readable.

Return Value

This method returns a Boolean value. If the data has been uploaded to the storage server, it will return **true**, otherwise it will return **false**.

Remarks

The **PutData** method uploads the contents of a **MemoryStream** object to the current storage container using default attributes. If a storage object exists with the same label, it will be replaced. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

Although storage object labels are similar to Windows file names, they are case-sensitive. When requesting information about an object, your application must specify the label name exactly as it was created using this method. The object label cannot contain wildcard characters.

If the label identifies an object that already exists in the container, and that object was created with the **Attributes.objectReadOnly** attribute, this method will fail. To replace a read-only object, the application must explicitly move, rename or delete the existing object.

If a content type is provided, it must specify a valid MIME media type and subtype. For example, normal text has a content type of **text/plain** while XML-formatted text would have a content type of **text/xml**. Data that contains unstructured binary data is typically identified as **application/octet-stream.**. If you do not specify a content type, an appropriate content type will be determined automatically based on the label and the contents of the buffer.

If you wish to upload the contents of a file, use the **PutFile** method.

When this method returns, various properties such as **ObjectId** and **ObjectLabel** will be updated to reflect the values associated with the object that was created or replaced on the server.

WebStorage.PutData Method (String, Attributes, MemoryStream)

Upload the data in a MemoryStream object to the storage container.

[Visual Basic]

```
Overloads Public Function PutData( _
   ByVal labelName As String, _
   ByVal objAttributes As Attributes, _
   ByVal memStream As MemoryStream _
) As Boolean
```

[C#]

```
public bool PutData(
   string labelName,
   Attributes objAttributes,
   MemoryStream memStream
);
```

Parameters

labelName

A string which specifies the label of the object that should be uploaded to the server. If an object with the same label already exists, it will be replaced with the contents of the buffer

objAttributes

An Attributes enumeration which specifies the attributes for the object being stored.

memStream

A MemoryStream object which contains the data to be stored. The stream must be open and readable.

Return Value

This method returns a Boolean value. If the data has been uploaded to the storage server, it will return **true**, otherwise it will return **false**.

Remarks

The **PutData** method uploads the contents of a **MemoryStream** object to the current storage container using the default content type for the data being stored. If a storage object exists with the same label, it will be replaced. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

Although storage object labels are similar to Windows file names, they are case-sensitive. When requesting information about an object, your application must specify the label name exactly as it was created using this method. The object label cannot contain wildcard characters.

If the label identifies an object that already exists in the container, and that object was created with the **Attributes.objectReadOnly** attribute, this method will fail. To replace a read-only object, the application must explicitly move, rename or delete the existing object.

An appropriate content type is be determined automatically based on the label and the contents of the buffer.

If you wish to upload the contents of a file, use the **PutFile** method.

When this method returns, various properties such as **ObjectId** and **ObjectLabel** will be updated to reflect the values associated with the object that was created or replaced on the server.

WebStorage.PutData Method (String, MemoryStream)

Upload the data in a MemoryStream object to the storage container.

[Visual Basic]

```
Overloads Public Function PutData( _
   ByVal labelName As String, _
   ByVal memStream As MemoryStream _
) As Boolean
```

[C#]

```
public bool PutData(
   string labelName,
   MemoryStream memStream
);
```

Parameters

labelName

A string which specifies the label of the object that should be uploaded to the server. If an object with the same label already exists, it will be replaced with the contents of the buffer

memStream

A MemoryStream object which contains the data to be stored. The stream must be open and readable.

Return Value

This method returns a Boolean value. If the data has been uploaded to the storage server, it will return **true**, otherwise it will return **false**.

Remarks

The **PutData** method uploads the contents of a **MemoryStream** object to the current storage container using the default attributes and content type for the data being stored. If a storage object exists with the same label, it will be replaced. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

Although storage object labels are similar to Windows file names, they are case-sensitive. When requesting information about an object, your application must specify the label name exactly as it was created using this method. The object label cannot contain wildcard characters.

If the label identifies an object that already exists in the container, and that object was created with the **Attributes.objectReadOnly** attribute, this method will fail. To replace a read-only object, the application must explicitly move, rename or delete the existing object.

An appropriate content type is be determined automatically based on the label and the contents of the buffer.

If you wish to upload the contents of a file, use the **PutFile** method.

When this method returns, various properties such as **ObjectId** and **ObjectLabel** will be updated to reflect the values associated with the object that was created or replaced on the server.

WebStorage Class | SocketTools Namespace | WebStorage.PutData Overload List | Close Method | GetData Method | Open Method

WebStorage.PutData Method (String, String, Attributes, String)

Upload the text in a string to the storage container.

[Visual Basic]

```
Overloads Public Function PutData( _
   ByVal labelName As String, _
   ByVal contentType As String, _
   ByVal objAttributes As Attributes, _
   ByVal textBuffer As String _
) As Boolean
```

[C#]

```
public bool PutData(
   string labelName,
   string contentType,
   Attributes objAttributes,
   string textBuffer
);
```

Parameters

labelName
: A string which specifies the label of the object that should be uploaded to the server. If an object with the same label already exists, it will be replaced with the contents of the buffer

contentType
: An string which identifies the contents of the buffer being stored. If this parameter is an empty string, the method will attempt to automatically determine the content type based on the object label and the contents of the buffer

objAttributes
: An Attributes enumeration which specifies the attributes for the object being stored.

textBuffer
: A string which contains the text to be stored.

Return Value

This method returns a Boolean value. If the data has been uploaded to the storage server, it will return **true**, otherwise it will return **false**.

Remarks

The **PutData** method uploads the contents of a string to the current storage container. If the string contains non-ASCII characters, they will automatically converted to use UTF-8 encoding prior to being stored on the server. If a storage object exists with the same label, it will be replaced. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

Although storage object labels are similar to Windows file names, they are case-sensitive. When requesting information about an object, your application must specify the label name exactly as it was created using this method. The object label cannot contain wildcard characters.

If the label identifies an object that already exists in the container, and that object was created with the **Attributes.objectReadOnly** attribute, this method will fail. To replace a read-only object, the application must explicitly move, rename or delete the existing object.

If a content type is provided, it must specify a valid MIME media type and subtype. For example, normal text has a content type of **text/plain** while XML-formatted text would have a content type of **text/xml**. If you do not specify a content type, an appropriate content type will be determined automatically based on the label and the contents of the string. In most cases, the content type will default to **text/plain**.

This version of the **PutData** method should never be used to store binary data, particularly data that contains embedded null bytes. You should only use this method to store plain text. If you need to store binary data, use the version of **PutData** which accepts either a byte array or **MemoryStream** object.

If you wish to upload the contents of a file, use the **PutFile** method.

When this method returns, various properties such as **ObjectId** and **ObjectLabel** will be updated to reflect the values associated with the object that was created or replaced on the server.

WebStorage.PutFile Method (String, String)

Upload a local file to the current storage container.

[Visual Basic]

```
Overloads Public Function PutFile( _
   ByVal localFile As String, _
   ByVal labelName As String _
) As Boolean
```

[C#]

```
public bool PutFile(
   string localFile,
   string labelName
);
```

Parameters

localFile
: A string which specifies the name of the local file that will be uploaded to the current storage container. If a path is not specified, the file will be opened in the current working directory.

labelName
: A string which specifies the label of the object that should be created. If an object with the same label already exists, it will be replaced with the contents of the file.

Return Value

This method returns a Boolean value. If the data has been uploaded to the storage server, it will return **true**, otherwise it will return **false**.

Remarks

The **PutFile** method uploads the contents of a file to the current storage container. If an object exists with the same label, it will be replaced. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

Although storage object labels are similar to Windows file names, they are case-sensitive. When requesting information about an object, your application must specify the label name exactly as it was created using this method. The object label cannot contain wildcard characters.

WebStorage.PutFile Method (String, String, String)

Upload a local file to the current storage container.

[Visual Basic]

```
Overloads Public Function PutFile( _
   ByVal localFile As String, _
   ByVal labelName As String, _
   ByVal contentType As String _
) As Boolean
```

[C#]

```
public bool PutFile(
   string localFile,
   string labelName,
   string contentType
);
```

Parameters

localFile
A string which specifies the name of the local file that will be uploaded to the current storage container. If a path is not specified, the file will be opened in the current working directory.

labelName
A string which specifies the label of the object that should be created. If an object with the same label already exists, it will be replaced with the contents of the file.

contentType
An string which identifies the contents of the file being uploaded. If this parameter is an empty string, the method will attempt to automatically determine the content type based on the object label and the contents of the file.

Return Value

This method returns a Boolean value. If the data has been uploaded to the storage server, it will return **true**, otherwise it will return **false**.

Remarks

The **PutFile** method uploads the contents of a file to the current storage container. If an object exists with the same label, it will be replaced. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

Although storage object labels are similar to Windows file names, they are case-sensitive. When requesting information about an object, your application must specify the label name exactly as it was created using this method. The object label cannot contain wildcard characters.

If the label identifies an object that already exists in the container, and that object was created with the **Attributes.objectReadOnly** attribute, this method will fail. To replace a read-only object, the application must explicitly move, rename or delete the existing object.

If a content type is provided, it must specify a valid MIME media type and subtype. For example, normal text has a content type of **text/plain** while XML-formatted text would have a content type of **text/xml**. Data that contains unstructured binary data is typically identified as **application/octet-stream**. If you do not specify a content type, an appropriate content type will be determined automatically based on the file name and contents.

If you wish to upload the contents of a string or byte array, use the **PutData** method.

When this method returns, various properties such as **ObjectId** and **ObjectLabel** will be updated to reflect the values associated with the object that was created or replaced on the server.

WebStorage.PutFile Method (String, String, String, Attributes)

Upload a local file to the current storage container.

[Visual Basic]

```
Overloads Public Function PutFile( _
   ByVal localFile As String, _
   ByVal labelName As String, _
   ByVal contentType As String, _
   ByVal objAttributes As Attributes _
) As Boolean
```

[C#]

```
public bool PutFile(
   string localFile,
   string labelName,
   string contentType,
   Attributes objAttributes
);
```

Parameters

localFile
A string which specifies the name of the local file that will be uploaded to the current storage container. If a path is not specified, the file will be opened in the current working directory.

labelName
A string which specifies the label of the object that should be created. If an object with the same label already exists, it will be replaced with the contents of the file.

contentType
An string which identifies the contents of the file being uploaded. If this parameter is an empty string, the method will attempt to automatically determine the content type based on the object label and the contents of the file.

objAttributes
An Attributes enumeration which specifies the attributes for the object being created or replaced.

Return Value

This method returns a Boolean value. If the data has been uploaded to the storage server, it will return **true**, otherwise it will return **false**.

Remarks

The **PutFile** method uploads the contents of a file to the current storage container. If an object exists with the same label, it will be replaced. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

Although storage object labels are similar to Windows file names, they are case-sensitive. When requesting information about an object, your application must specify the label name exactly as it was created using this method. The object label cannot contain wildcard characters.

If the label identifies an object that already exists in the container, and that object was created with the **Attributes.objectReadOnly** attribute, this method will fail. To replace a read-only object, the application must explicitly move, rename or delete the existing object.

If a content type is provided, it must specify a valid MIME media type and subtype. For example, normal text has a content type of **text/plain** while XML-formatted text would have a content type of **text/xml**.

Data that contains unstructured binary data is typically identified as **application/octet-stream**. If you do not specify a content type, an appropriate content type will be determined automatically based on the file name and contents.

If you wish to upload the contents of a string or byte array, use the **PutData** method.

When this method returns, various properties such as **ObjectId** and **ObjectLabel** will be updated to reflect the values associated with the object that was created or replaced on the server.

WebStorage.RegisterId Method

Register a new application identifier with the storage service.

```
[Visual Basic]
Public Function RegisterId( _
   ByVal appId As String _
) As Boolean
```

```
[C#]
public bool RegisterId(
   string appId
);
```

Parameters

appId

A string which identifies the application requesting access. If the application ID contains illegal characters, the method will fail. See the remarks below on the recommended practice for identifying your application.

Return Value

This method returns a Boolean value. If the application ID has been registered, it will return **true**, otherwise it will return **false**.

Remarks

The **RegisterId** method registers an application ID with the server which uniquely identifies the application that is requesting access to the storage container. The ID must only consist of ASCII letters, numbers, the period and underscore character. Whitespace characters and non-ASCII Unicode characters are not permitted. The maximum length of an application ID string is 63 characters.

It is recommended that you use a standard format for the application ID that consists of your company name, application name and optionally a version number. For example:

- MyCompany.MyApplication
- MyCompany.MyApplication.1

It is important to note that with these two example IDs, although they are similar, they reference two different applications. Objects stored using the first ID will not be accessible using the second ID. If you want to store objects that should be shared between all versions of the application, it is recommended that you use the first form, without the version number. If you want to store objects that should only be accessible to a specific version of your application, then it is recommended that you use the second form that includes the version number.

It is safe to call this method with an application ID that was previously registered. If the provided application ID has already been registered, this method will succeed.

If you no longer wish to use an application ID you have previously registered, you can call the **UnregisterId** method. Exercise caution when unregistering an application. This will cause all objects stored using that ID to be deleted by the storage server. Once an application ID has been unregistered, the operation is permanent. Calling **UnregisterId** and then **RegisterId** again using the same ID will force the system to create new access tokens for your application. You will not be able to regain access to the objects that were previously stored using that application ID.

The application ID is intended to be an application defined human-readable string that uniquely identifies your application. If you want to obtain the internal storage ID associated with your application, get the value of the **StorageId** property. The storage ID is a fixed-length string of letters and numbers guaranteed to be unique across all applications that you register.

It is not required for your application to create a unique application ID. Each storage account has a default internal application ID named **SocketTools.Storage.Default**. This default ID is used if an application-defined ID is not provided to the **Open** method. It is intended to identify storage available to all applications that you create.

WebStorage Class | SocketTools Namespace

WebStorage.Rename Method

Change the label of an existing storage object.

[Visual Basic]

```
Public Function Rename( _
   ByVal oldLabel As String, _
   ByVal newLabel As String _
) As Boolean
```

[C#]

```
public bool Rename(
   string oldLabel,
   string newLabel
);
```

Parameters

oldLabel
A string which specifies the label of the object that should be renamed.

newLabel
A string which specifies the new label for the object being renamed.

Return Value

This method returns a Boolean value. If the stored object was renamed, it will return **true**, otherwise it will return **false**.

Remarks

The **Rename** method is used to change the label of an existing storage object within the current container. If you wish to move an object to a different, use the **Move** method.

This method updates the current object. Various properties such as **ObjectId** and **ObjectLabel** will reflect the values associated with the object which has been renamed.

See Also

WebStorage Class | SocketTools Namespace

WebStorage.Reset Method

Reset the internal state of the class instance, resetting all properties to their default values.

[Visual Basic]

```
Public Sub Reset()
```

[C#]

```
public void Reset();
```

Remarks

The **Reset** method returns the class instance to its defaults. Property values are initialized to their internal defaults, the current storage container is closed and any handles allocated by the class will be released.

See Also

WebStorage Class | SocketTools Namespace

WebStorage.Uninitialize Method

Uninitialize the class library and release any resources allocated for the current thread.

[Visual Basic]

```
Public Sub Uninitialize()
```

[C#]

```
public void Uninitialize();
```

Remarks

The **Uninitialize** method terminates any active connection, releases resources allocated for the current thread and unloads the networking library. After this method has been called, no further client operations may be performed until the class instance has been re-initialized.

If the **Initialize** method is explicitly called by the application, it should be matched by a call to the **Uninitialize** method when that instance of the class is no longer needed.

See Also

WebStorage Class | SocketTools Namespace | Initialize Method

WebStorage.UnregisterId Method

Unregister a previously registered application identifier.

[Visual Basic]

```
Public Function UnregisterId( _
   ByVal appId As String _
) As Boolean
```

[C#]

```
public bool UnregisterId(
   string appId
);
```

Parameters

appId

A string which specifies the application ID to be deleted. If the application ID is a zero-length string or contains illegal characters, the method will fail.

Return Value

This method returns a Boolean value. If the application ID was deleted, it will return **true**, otherwise it will return **false**.

Remarks

The **UnregisterId** method deletes the internal storage identifier associated with the application ID and revokes all access tokens that were granted for the application. This operation is immediate and permanent.

Exercise caution when using this method. This will permanently delete all objects that were stored for the specified application. Calling **UnregisterId** and then **RegisterId** again using the same ID will force the system to create new access tokens for your application. You will not be able to regain access to the objects that were previously stored using that ID.

This method cannot be used to unregister the default storage application identifier **SocketTools.Storage.Default**. If this ID is specified, the method will fail with an error indicating that the ID is invalid.

See Also

WebStorage Class | SocketTools Namespace

WebStorage.ValidateId Method

Check an application identifier to ensure it is valid and exists.

[Visual Basic]

```
Public Function ValidateId( _
   ByVal appId As String _
) As Boolean
```

[C#]

```
public bool ValidateId(
   string appId
);
```

Parameters

appId

A string which specifies the application ID to be validated. If the application ID is a zero-length string or contains illegal characters, the method will fail.

Return Value

This method returns a Boolean value. If the application ID is valid and exists, it will return **true**, otherwise it will return **false**.

Remarks

The **ValidateId** method is used to determine if the specified application identifier is valid and has been previously registered using the **RegisterId** method. The ID must only consist of ASCII letters, numbers, the period and underscore character. Whitespace characters and non-ASCII Unicode characters are not permitted. The maximum length of an application ID string is 63 characters.

See Also

WebStorage Class | SocketTools Namespace

WebStorage.ValidateLabel Method

Validate an object label to ensure it uses allowed characters.

```
[Visual Basic]
Public Function ValidateLabel( _
   ByVal labelName As String _
) As Boolean
```

```
[C#]
public bool ValidateLabel(
   string labelName
);
```

Parameters

labelName

A string which specifies the object label to be validated. This parameter cannot be an empty string.

Return Value

This method returns a Boolean value. If the object label is valid, it will return **true**, otherwise it will return **false**.

Remarks

Object labels are similar to Windows file names, except they are case-sensitive. The maximum length of a label string is 511 characters. Leading and trailing whitespace (spaces, tabs, linebreaks, etc.) are ignored in label names.

Illegal characters include ASCII and Unicode control characters 0 through 31, single quotes (39), double quotes (34), less than symbol (60), greater than symbol (62), pipe (124), asterisk (42) and question mark (63). It is not possible to embed null characters in the label name.

Label names may contain forward slash (47) characters and backslash (92) characters, however it is important to note that objects are not stored in a hierarchical structure. An application can create its own folder-like structure to the labels it creates, but this structure is not imposed or enforced by the class.

Labels can contain Unicode characters which are internally encoded as UTF-8.

WebStorage Events

The events of the **WebStorage** class are listed below. For a complete list of **WebStorage** class members, see the WebStorage Members topic.

Public Instance Events

OnCancel	Occurs when a storage operation is canceled.
OnDownload	Occurs when a storage object has been downloaded.
OnError	Occurs when an storage operation fails.
OnProgress	Occurs as a data stream is being read or written to the client.
OnTimeout	Occurs when a blocking operation fails to complete before the timeout period elapses.
OnUpload	Occurs when a storage object has been uploaded.

See Also

WebStorage Class | SocketTools Namespace

WebStorage.OnCancel Event

Occurs when a storage operation is canceled.

[Visual Basic]
```
Public Event OnCancel As EventHandler
```

[C#]
```
public event EventHandler OnCancel;
```

Remarks

The **OnCancel** event is generated when a storage operation, such as uploading or download data, is canceled with the **Cancel** method.

See Also

WebStorage Class | SocketTools Namespace

WebStorage.OnDownload Event

Occurs when a storage object has been downloaded.

[Visual Basic]
```
Public Event OnDownload As OnDownloadEventHandler
```

[C#]
```
public event OnDownloadEventHandler OnDownload;
```

Event Data

The event handler receives an argument of type WebStorage.DownloadEventArgs containing data related to this event. The following **WebStorage.DownloadEventArgs** properties provide information specific to this event.

Property	Description
ObjectLabel	Gets a value which specifies the object label.
ObjectSize	Get a value which specifies the size of the object.

Remarks

The **OnDownload** event is generated when a stored object has been successfully uploaded using either the **GetData** or **GetFile** methods.

When this event occurs, the transfer has completed successfully and the downloaded object becomes the current object for the session. Prior to this event, the **OnProgress** event will occur periodically which provides information about the progress of the data transfer.

See Also

WebStorage Class | SocketTools Namespace

WebStorage.DownloadEventArgs Class

Provides data for the OnDownload event.

For a list of all members of this type, see WebStorage.DownloadEventArgs Members.

System.Object
  System.EventArgs
    SocketTools.WebStorage.DownloadEventArgs

[Visual Basic]
```
Public Class WebStorage.DownloadEventArgs
    Inherits EventArgs
```

[C#]
```
public class WebStorage.DownloadEventArgs : EventArgs
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

DownloadEventArgs specifies the label and size for for the object that has been downloaded.

The OnDownload event occurs whenever a storage object has been successfully downloaded.

Requirements

Namespace: SocketTools

Assembly: SocketTools.WebStorage (in SocketTools.WebStorage.dll)

WebStorage.DownloadEventArgs overview

Public Instance Constructors

WebStorage.DownloadEventArgs Constructor	Initializes a new instance of the WebStorage.DownloadEventArgs class.

Public Instance Properties

ObjectLabel	Gets a value which specifies the object label.
ObjectSize	Get a value which specifies the size of the object.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString (inherited from Object)	Returns a String that represents the current Object.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

WebStorage.DownloadEventArgs Properties

The properties of the **WebStorage.DownloadEventArgs** class are listed below. For a complete list of **WebStorage.DownloadEventArgs** class members, see the WebStorage.DownloadEventArgs Members topic.

Public Instance Properties

ObjectLabel	Gets a value which specifies the object label.
ObjectSize	Get a value which specifies the size of the object.

See Also

WebStorage.DownloadEventArgs Class | SocketTools Namespace

WebStorage.DownloadEventArgs.ObjectLabel Property

Gets a value which specifies the object label.

[Visual Basic]
```
Public ReadOnly Property ObjectLabel As String
```

[C#]
```
public string ObjectLabel {get;}
```

Property Value

A string value which contains the object label.

Remarks

This string contains the label of the stored object that was downloaded.

See Also

WebStorage.DownloadEventArgs Class | SocketTools Namespace

WebStorage.DownloadEventArgs.ObjectSize Property

Get a value which specifies the size of the object.

[Visual Basic]

```
Public ReadOnly Property ObjectSize As Long
```

[C#]

```
public long ObjectSize {get;}
```

Property Value

A long integer value which contains the object size in bytes.

Remarks

This integer contains the size of the downloaded object in bytes.

WebStorage.OnError Event

Occurs when an storage operation fails.

[Visual Basic]
```
Public Event OnError As OnErrorEventHandler
```

[C#]
```
public event OnErrorEventHandler OnError;
```

Event Data

The event handler receives an argument of type WebStorage.ErrorEventArgs containing data related to this event. The following **WebStorage.ErrorEventArgs** properties provide information specific to this event.

Property	Description
Description	Gets a value which describes the last error that has occurred.
Error	Gets a value which specifies the last error that has occurred.

Remarks

The **OnError** event occurs when a storage operation fails.

See Also

WebStorage Class | SocketTools Namespace

WebStorage.ErrorEventArgs Class

Provides data for the OnError event.

For a list of all members of this type, see WebStorage.ErrorEventArgs Members.

System.Object
  System.EventArgs
    SocketTools.WebStorage.ErrorEventArgs

[Visual Basic]

```
Public Class WebStorage.ErrorEventArgs
    Inherits EventArgs
```

[C#]

```
public class WebStorage.ErrorEventArgs : EventArgs
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

ErrorEventArgs specifies the numeric error code and a description of the error that has occurred.

An OnError event occurs when a method fails.

Requirements

Namespace: SocketTools

Assembly: SocketTools.WebStorage (in SocketTools.WebStorage.dll)

The properties of the **WebStorage.ErrorEventArgs** class are listed below. For a complete list of **WebStorage.ErrorEventArgs** class members, see the WebStorage.ErrorEventArgs Members topic.

Public Instance Properties

Description	Gets a value which describes the last error that has occurred.
Error	Gets a value which specifies the last error that has occurred.

See Also

WebStorage.ErrorEventArgs Class | SocketTools Namespace

WebStorage.ErrorEventArgs.Description Property

Gets a value which describes the last error that has occurred.

[Visual Basic]

```
Public ReadOnly Property Description As String
```

[C#]

```
public string Description {get;}
```

Property Value

A string which describes the last error that has occurred.

See Also

WebStorage.ErrorEventArgs Class | SocketTools Namespace | Error Property

WebStorage.ErrorEventArgs.Error Property

Gets a value which specifies the last error that has occurred.

[Visual Basic]

```
Public ReadOnly Property Error As ErrorCode
```

[C#]

```
public WebStorage.ErrorCode Error {get;}
```

Property Value

ErrorCode enumeration which specifies the error.

See Also

WebStorage.ErrorEventArgs Class | SocketTools Namespace | Description Property

WebStorage.OnProgress Event

Occurs as a data stream is being read or written to the client.

[Visual Basic]
```
Public Event OnProgress As OnProgressEventHandler
```

[C#]
```
public event OnProgressEventHandler OnProgress;
```

Event Data

The event handler receives an argument of type WebStorage.ProgressEventArgs containing data related to this event. The following **WebStorage.ProgressEventArgs** properties provide information specific to this event.

Property	Description
BytesCopied	Gets a value which specifies the number of bytes of data that has been sent or received.
BytesTotal	Gets a value which specifies the size of object being transferred.
ObjectLabel	Gets a value which specifies the object label.
Percent	Gets a value which specifies the percentage of data that has been sent or received.

Remarks

The **OnProgress** event occurs as a data stream is being read or written to the client. If large amounts of data are being read or written, this event can be used to update a progress bar or other user-interface component to provide the user with some visual feedback on the progress of the operation.

See Also

WebStorage Class | SocketTools Namespace

WebStorage.ProgressEventArgs Class

Provides data for the OnProgress event.

For a list of all members of this type, see WebStorage.ProgressEventArgs Members.

System.Object
  System.EventArgs
    SocketTools.WebStorage.ProgressEventArgs

[Visual Basic]

```
Public Class WebStorage.ProgressEventArgs
    Inherits EventArgs
```

[C#]

```
public class WebStorage.ProgressEventArgs : EventArgs
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

ProgressEventArgs specifies the number of bytes copied from the data stream, the total number of bytes in the data stream and a completion percentage.

The OnProgress event occurs as a data stream is being read or written to the client. This event only occurs when the **GetData, GetFile**, **PostData, PostFile, PutData, PutFile** or **SubmitForm** methods are called.

Requirements

Namespace: SocketTools

Assembly: SocketTools.WebStorage (in SocketTools.WebStorage.dll)

See Also

The properties of the **WebStorage.ProgressEventArgs** class are listed below. For a complete list of **WebStorage.ProgressEventArgs** class members, see the WebStorage.ProgressEventArgs Members topic.

Public Instance Properties

BytesCopied	Gets a value which specifies the number of bytes of data that has been sent or received.
BytesTotal	Gets a value which specifies the size of object being transferred.
ObjectLabel	Gets a value which specifies the object label.
Percent	Gets a value which specifies the percentage of data that has been sent or received.

See Also

WebStorage.ProgressEventArgs Class | SocketTools Namespace

WebStorage.ProgressEventArgs.BytesCopied Property

Gets a value which specifies the number of bytes of data that has been sent or received.

[Visual Basic]

```
Public ReadOnly Property BytesCopied As Long
```

[C#]

```
public long BytesCopied {get;}
```

Property Value

An integer value which specifies the number of bytes of data.

Remarks

The **BytesCopied** property specifies the number of bytes that have been read from the client and stored in the local stream buffer, or written from the stream buffer to the client.

See Also

WebStorage.ProgressEventArgs Class | SocketTools Namespace | BytesTotal Property | Percent Property

WebStorage.ProgressEventArgs.BytesTotal Property

Gets a value which specifies the size of object being transferred.

[Visual Basic]
```
Public ReadOnly Property BytesTotal As Long
```

[C#]
```
public long BytesTotal {get;}
```

Property Value

An integer value which specifies the number of bytes of data.

Remarks

The **BytesTotal** property specifies the total amount of data being exchanged with the storage server.

See Also

WebStorage.ProgressEventArgs Class | SocketTools Namespace | BytesCopied Property | Percent Property

WebStorage.ProgressEventArgs.ObjectLabel Property

Gets a value which specifies the object label.

[Visual Basic]

```
Public ReadOnly Property ObjectLabel As String
```

[C#]

```
public string ObjectLabel {get;}
```

Property Value

A string value which specifies the label for the object being transferred.

See Also

WebStorage.ProgressEventArgs Class | SocketTools Namespace

WebStorage.ProgressEventArgs.Percent Property

Gets a value which specifies the percentage of data that has been sent or received.

[Visual Basic]

```
Public ReadOnly Property Percent As Integer
```

[C#]

```
public int Percent {get;}
```

Property Value

An integer value which specifies a percentage.

Remarks

The **Percent** property specifies the percentage of data that has been transmitted, expressed as an integer value between 0 and 100, inclusive.

See Also

WebStorage.ProgressEventArgs Class | SocketTools Namespace | BytesCopied Property | BytesTotal Property

WebStorage.OnTimeout Event

Occurs when a blocking operation fails to complete before the timeout period elapses.

[Visual Basic]

```
Public Event OnTimeout As EventHandler
```

[C#]

```
public event EventHandler OnTimeout;
```

Remarks

The **OnTimeout** event occurs when a blocking operation, such as sending or receiving data on the client, fails to complete before the specified timeout period elapses. The timeout period for a blocking operation can be adjusted by setting the **Timeout** property.

This event is only generated if the client is in blocking mode.

See Also

WebStorage Class | SocketTools Namespace

WebStorage.OnUpload Event

Occurs when a storage object has been uploaded.

[Visual Basic]
```
Public Event OnUpload As OnUploadEventHandler
```

[C#]
```
public event OnUploadEventHandler OnUpload;
```

Event Data

The event handler receives an argument of type WebStorage.UploadEventArgs containing data related to this event. The following **WebStorage.UploadEventArgs** properties provide information specific to this event.

Property	Description
ObjectLabel	Gets a value which specifies the object label.
ObjectSize	Get a value which specifies the size of the object.

Remarks

The **OnUpload** event is generated when a stored object has been successfully uploaded using either the **PutData** or **PutFile** methods.

When this event occurs, the transfer has completed successfully and the uploaded object becomes the current object for the session. Prior to this event, the **OnProgress** event will occur periodically which provides information about the progress of the data transfer.

The properties of the **WebStorage.UploadEventArgs** class are listed below. For a complete list of **WebStorage.UploadEventArgs** class members, see the WebStorage.UploadEventArgs Members topic.

Public Instance Properties

ObjectLabel	Gets a value which specifies the object label.
ObjectSize	Get a value which specifies the size of the object.

See Also

WebStorage.UploadEventArgs Class | SocketTools Namespace

WebStorage.UploadEventArgs.ObjectLabel Property

Gets a value which specifies the object label.

[Visual Basic]

```
Public ReadOnly Property ObjectLabel As String
```

[C#]

```
public string ObjectLabel {get;}
```

Property Value

A string value which contains the object label.

Remarks

This string contains the label of the stored object that was uploaded.

See Also

WebStorage.UploadEventArgs Class | SocketTools Namespace

WebStorage.UploadEventArgs.ObjectSize Property

Get a value which specifies the size of the object.

[Visual Basic]

```
Public ReadOnly Property ObjectSize As Long
```

[C#]

```
public long ObjectSize {get;}
```

Property Value

A long integer value which contains the object size in bytes.

Remarks

This integer contains the size of the uploaded object in bytes.

WebStorage.UploadEventArgs Class | SocketTools Namespace

WebStorage.Attributes Enumeration

The attributes for stored objects.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]
```
<Flags>
Public Enum WebStorage.Attributes
```

[C#]
```
[Flags]
public enum WebStorage.Attributes
```

Remarks

This identifies the attributes that can be specified for stored objects.

Members

Member Name	Description	Value
objectDefault	Default object attributes. This value is used to indicate the object can be modified, or that the attributes for a previously existing object should not be changed.	0
objectNormal	A normal object that that can be read and modified by the application. This is the default attribute for new objects that are created by the application.	1
objectReadOnly	A read-only object that can only be read by the application. Attempts to modify or replace the contents of the object will fail. Read-only objects can be deleted.	2
objectHidden	A hidden object. Objects with this attribute are not returned when enumerated using the FindFirst and FindNext methods. The object can only be accessed directly when specifying its label.	3

Requirements

Namespace: SocketTools

Assembly: SocketTools.WebStorage (in SocketTools.WebStorage.dll)

See Also

SocketTools Namespace

WebStorage.Container Enumeration

Identifies the storage container type.

[Visual Basic]
```
Public Enum WebStorage.Container
```

[C#]
```
public enum WebStorage.Container
```

Remarks

This enumeration identifies the storage containers that are available to the application. You can think of the storage containers as special folders which store individual objects. In most cases, we recommend using **storageGlobal** which means that stored objects will be accessible to all users of your application.

Members

Member Name	Description
storageDefault	The default storage type. If a storage container has been opened, this value specifies that the current storage type for the container should be used. Otherwise, this value will default to using global storage.
storageGlobal	Global storage. Objects stored using this storage type are available to all users. Any changes made to objects using this storage type will affect all users of the application. Unless there is a specific need to limit access to the objects stored by the application to specific domains, local machines or users, it is recommended that you use this storage type when creating new objects.
storageDomain	Local domain storage. Objects stored using this storage type are only available to users in the same local domain, as defined by the domain name or workgroup name assigned to the local system. If the domain or workgroup name changes, objects previously stored using this storage type will not be available to the application.
storageMachine	Local machine storage. Objects stored using this storage type are only available to users on the same local machine. The local machine is identified by unique characteristics of the system, including the boot volume GUID. Objects previously stored using this storage type will not be available on that system if the boot disk is reformatted.
storageUser	Current user storage. Objects stored using this storage type are only available to the current user logged in on the local machine. The user identifier

	is based on the Windows user SID that is assigned when the user account is created. If the user account is deleted, the objects previously stored using this storage type will not be available to the application.

Requirements

Namespace: SocketTools

Assembly: SocketTools.WebStorage (in SocketTools.WebStorage.dll)

See Also

SocketTools Namespace

WebStorage.ErrorCode Enumeration

Specifies the error codes returned by the WebStorage class.

[Visual Basic]
```
Public Enum WebStorage.ErrorCode
```

[C#]
```
public enum WebStorage.ErrorCode
```

Remarks

The WebStorage class uses the **ErrorCode** enumeration to specify what error has occurred when a method fails. The current error code may be determined by checking the value of the **LastError** property.

Note that the last error code is only meaningful if the previous operation has failed.

Members

Member Name	Description
errorNone	No error.
errorNotHandleOwner	Handle not owned by the current thread.
errorFileNotFound	The specified file or directory does not exist.
errorFileNotCreated	The specified file could not be created.
errorOperationCanceled	The blocking operation has been canceled.
errorInvalidFileType	The specified file is a block or character device, not a regular file.
errorInvalidDevice	The specified file type is invalid or not a regular file.
errorTooManyParameters	The maximum number of function parameters has been exceeded.
errorInvalidFileName	The specified file name contains invalid characters or is too long.
errorInvalidFileHandle	Invalid file handle passed to function.
errorFileReadFailed	Unable to read data from the specified file.
errorFileWriteFailed	Unable to write data to the specified file.
errorOutOfMemory	Out of memory.
errorAccessDenied	Access denied.
errorInvalidParameter	Invalid argument passed to function.
errorClipboardUnavailable	The system clipboard is currently unavailable.
errorClipboardEmpty	The system clipboard is empty or does not contain any text data.
errorFileEmpty	The specified file does not contain any data.
errorFileExists	The specified file already exists.

errorEndOfFile	End of file.
errorDeviceNotFound	The specified device could not be found.
errorDirectoryNotFound	The specified directory could not be found.
errorInvalidbuffer	Invalid memory address passed to function.
errorBufferTooSmall	The specified buffer is not large enough to contain the data.
errorNoHandles	No more handles are available to this process.
errorOperationWouldBlock	The specified operation would block the current thread.
errorOperationInProgress	A blocking operation is currently in progress.
errorAlreadyInProgress	The specified operation is already in progress.
errorInvalidHandle	Invalid handle passed to function.
errorInvalidAddress	Invalid network address specified.
errorInvalidSize	Datagram is too large to fit in specified buffer.
errorInvalidProtocol	Invalid network protocol specified.
errorProtocolNotAvailable	The specified network protocol is not available.
errorProtocolNotSupported	The specified protocol is not supported.
errorSocketNotSupported	The specified socket type is not supported.
errorInvalidOption	The specified option is invalid.
errorProtocolFamily	Specified protocol family is not supported.
errorProtocolAddress	The specified address is invalid for this protocol family.
errorAddressInUse	The specified address is in use by another process.
errorAddressUnavailable	The specified address cannot be assigned.
errorNetworkUnavailable	The networking subsystem is unavailable.
errorNetworkUnreachable	The specified network is unreachable.
errorNetworkReset	Network dropped connection on remote reset.
errorConnectionAborted	Connection was aborted due to timeout or other failure.
errorConnectionReset	Connection was reset by remote network.
errorOutOfBuffers	No buffer space is available.
errorAlreadyConnected	Connection already established with remote host.
errorNotConnected	No connection established with remote host.
errorConnectionShutdown	Unable to send or receive data after connection shutdown.
errorOperationTimeout	The specified operation has timed out.
errorConnectionRefused	The connection has been refused by the remote host.

errorHostUnavailable	The specified host is unavailable.
errorHostUnreachable	Remote host is unreachable.
errorTooManyProcesses	Too many processes are using the networking subsystem.
errorTooManyThreads	Too many threads have been created by the current process.
errorTooManySessions	Too many client sessions have been created by the current process.
errorInternalFailure	An unexpected internal error has occurred.
errorNetworkNotReady	Network subsystem is not ready for communication.
errorInvalidVersion	This version of the operating system is not supported.
errorNetworkNotInitialized	The networking subsystem has not been initialized.
errorRemoteShutdown	The remote host has initiated a graceful shutdown sequence.
errorInvalidHostName	The specified hostname is invalid or could not be resolved.
errorHostNameNotFound	The specified hostname could not be found.
errorHostNameRefused	Unable to resolve hostname, request refused.
errorHostNameNotResolved	Unable to resolve hostname, no address for specified host.
errorInvalidLicense	The license for this product is invalid.
errorProductNotLicensed	This product is not licensed to perform this operation.
errorNotImplemented	This function has not been implemented on this platform.
errorUnknownLocalhost	Unable to determine local host name.
errorInvalidHostAddress	Invalid host address specified.
errorInvalidServicePort	Invalid service port number specified.
errorInvalidServiceName	Invalid or unknown service name specified.
errorInvalidEventId	Invalid event identifier specified.
errorOperationNotBlocking	No blocking operation in progress on this socket.
errorSecurityNotInitialized	Unable to initialize security interface for this process.
errorSecurityContext	Unable to establish security context for this session.
errorSecurityCredentials	Unable to open certificate store or establish security credentials.
errorSecurityCertificate	Unable to validate the certificate chain for this

	session.
errorSecurityDecryption	Unable to decrypt data stream.
errorSecurityEncryption	Unable to encrypt data stream.
errorOperationNotSupported	The specified operation is not supported.
errorInvalidProtocolVersion	Invalid application protocol version specified.
errorNoServerResponse	No data returned from server.
errorInvalidServerResponse	Invalid data returned from server.
errorUnexpectedServerResponse	Unexpected response code returned from server.
errorServerTransactionFailed	Server transaction failed.
errorServiceUnavailable	The service is currently unavailable.
errorServiceNotReady	The service is not ready, try again later.
errorServerResyncFailed	Unable to resynchronize with server.
errorInvalidProxyType	Invalid proxy server type specified.
errorProxyRequired	Resource must be accessed through specified proxy.
errorInvalidProxyLogin	Unable to login to proxy server using specified credentials.
errorProxyResyncFailed	Unable to resynchronize with proxy server.
errorInvalidCommand	Invalid command specified.
errorInvalidCommandParameter	Invalid command parameter specified.
errorInvalidCommandSequence	Invalid command sequence specified.
errorCommandNotImplemented	Specified command not implemented on this server.
errorCommandNotAuthorized	Specified command not authorized for the current user.
errorCommandAborted	Specified command was aborted by the remote host.
errorOptionNotSupported	The specified option is not supported on this server.
errorRequestNotCompleted	The current client request has not been completed.
errorInvalidUserName	The specified username is invalid.
errorInvalidPassword	The specified password is invalid.
errorInvalidAccount	The specified account name is invalid.
errorAccountRequired	Account name has not been specified.
errorInvalidAuthenticationType	Invalid authentication protocol specified.
errorAuthenticationRequired	User authentication is required.
errorProxyAuthenticationRequired	Proxy authentication required.

errorAlreadyAuthenticated	User has already been authenticated.
errorAuthenticationFailed	Unable to authenticate the specified user.
errorNetworkAdapter	Unable to determine network adapter configuration.
errorInvalidRecordType	Invalid record type specified.
errorInvalidRecordName	Invalid record name specified.
errorInvalidRecordData	Invalid record data specified.
errorConnectionOpen	Data connection already established.
errorConnectionClosed	Server closed data connection.
errorConnectionPassive	Data connection is passive.
errorConnectionFailed	Unable to open data connection to server.
errorInvalidSecurityLevel	Data connection cannot be opened with this security setting.
errorCachedTLSRequired	Data connection requires cached TLS session.
errorDataReadOnly	Data connection is read-only.
errorDataWriteOnly	Data connection is write-only.
errorEndOfData	End of data.
errorRemoteFileUnavailable	Remote file is unavailable.
errorInsufficientStorage	Insufficient storage on server.
errorStorageallocation	File exceeded storage allocation on server.
errorDirectoryExists	The specified directory already exists.
errorDirectoryEmpty	No files returned by the server for the specified directory.
errorEndOfDirectory	End of directory listing.
errorUnknownDirectoryFormat	Unknown directory format.
errorInvalidResource	Invalid resource name specified.
errorResourceRedirected	The specified resource has been redirected.
errorResourceRestricted	Access to this resource has been restricted.
errorResourceNotModified	The specified resource has not been modified.
errorResourceNotFound	The specified resource cannot be found.
errorResourceConflict	Request could not be completed due to the current state of the resource.
errorResourceRemoved	The specified resource has been permanently removed from this server.
errorContentLengthRequired	Request must include the content length.
errorRequestPrecondition	Request could not be completed due to server precondition.
errorUnsupportedMediaType	Request specified an unsupported media type.

errorInvalidContentRange	Content range specified for this resource is invalid.
errorInvalidMessagePart	Message is not multipart or an invalid message part was specified.
errorInvalidMessageHeader	The specified message header is invalid or has not been defined.
errorInvalidMessageBoundary	The multipart message boundary has not been defined.
errorNoFileAttachment	The current message part does not contain a file attachment.
errorUnknownFileType	The specified file type could not be determined.
errorDataNotEncoded	The specified data block could not be encoded.
errorDataNotDecoded	The specified data block could not be decoded.
errorFileNotEncoded	The specified file could not be encoded.
errorFileNotDecoded	The specified file could not be decoded.
errorNoMessageText	No message text.
errorInvalidCharacterSet	Invalid character set specified.
errorInvalidEncodingType	Invalid encoding type specified.
errorInvalidMessageNumber	Invalid message number specified.
errorNoReturnAddress	No valid return address specified.
errorNoValidRecipients	No valid recipients specified.
errorInvalidRecipient	The specified recipient address is invalid.
errorRelayNotAuthorized	The specified domain is invalid or server will not relay messages.
errorMailboxUnavailable	Specified mailbox is currently unavailable.
errorMailboxReadOnly	The selected mailbox cannot be modified.
errorMailboxNotSelected	No mailbox has been selected.
errorInvalidMailbox	Specified mailbox is invalid.
errorInvalidDomain	The specified domain name is invalid or not recognized.
errorInvalidSender	The specified sender address is invalid or not recognized.
errorMessageNotDelivered	Message not delivered to any of the specified recipients.
errorEndOfMessageData	No more message data available to be read
errorInvalidmessageSize	The specified message size is invalid.
errorMessageNotCreated	The message could not be created in the specified mailbox.
errorNoMoreMailboxes	No more mailboxes exist on this server.

errorInvalidEmulationType	The specified terminal emulation type is invalid.
errorInvalidFontHandle	The specified font handle is invalid.
errorInvalidFontName	The specified font name is invalid or unavailable.
errorInvalidPacketSize	The specified packet size is invalid.
errorInvalidPacketData	The specified packet data is invalid.
errorInvalidPacketId	The unique packet identifier is invalid.
errorPacketTTLExpired	The specified packet time-to-live period has expired.
errorInvalidNewsGroup	Invalid newsgroup specified.
errorNoNewsgroupSelected	No newsgroup selected.
errorEmptyNewsgroup	No articles in specified newsgroup.
errorInvalidArticle	Invalid article number specified.
errorNoArticleSelected	No article selected in the current newsgroup.
errorFirstArticle	First article in current newsgroup.
errorLastArticle	Last article in current newsgroup.
errorArticleExists	Unable to transfer article, article already exists.
errorArticleRejected	Unable to transfer article, article rejected.
errorArticleTransferFailed	Article transfer failed.
errorArticlePostingDenied	Posting is not permitted on this server.
errorArticlePostingFailed	Unable to post article on this server.
errorInvalidDateFormat	The specified date format is not recognized.
errorFeatureNotSupported	The specified feature is not supported on this server.
errorInvalidFormHandle	The specified form handle is invalid or a form has not been created.
errorInvalidFormAction	The specified form action is invalid or has not been specified.
errorInvalidFormMethod	The specified form method is invalid or not supported.
errorInvalidFormType	The specified form type is invalid or not supported.
errorInvalidFormField	The specified form field name is invalid or does not exist.
errorEmptyForm	The specified form does not contain any field values.
errorMaximumConnections	The maximum number of client connections exceeded.
errorThreadCreationFailed	Unable to create a new thread for the current process.
errorInvalidThreadHandle	The specified thread handle is no longer valid.

errorThreadTerminated	The specified thread has been terminated.
errorThreadDeadlock	The operation would result in the current thread becoming deadlocked.
errorInvalidClientMoniker	The specified moniker is not associated with any client session.
errorClientMonikerExists	The specified moniker has been assigned to another client session.
errorServerInactive	The specified server is not listening for client connections.
errorServerSuspended	The specified server is suspended and not accepting client connections.
errorNoMessageStore	No message store has been specified.
errorMessageStoreChanged	The message store has changed since it was last accessed.
errorMessageNotFound	No message was found that matches the specified criteria.
errorMessageDeleted	The specified message has been deleted.
errorFileChecksumMismatch	The local and remote file checksums do not match.
errorFileSizeMismatch	The local and remote file sizes do not match.
errorInvalidFeedUrl	The news feed URL is invalid or specifies an unsupported protocol.
errorInvalidFeedFormat	The internal format of the news feed is invalid.
errorInvalidFeedVersion	This version of the news feed is not supported.
errorChannelEmpty	There are no valid items found in this news feed.
errorInvalidItemNumber	The specified channel item identifier is invalid.
errorItemNotFound	The specified channel item could not be found.
errorItemEmpty	The specified channel item does not contain any data.
errorInvalidItemProperty	The specified item property name is invalid.
errorItemPropertyNotFound	The specified item property has not been defined.
errorInvalidChannelTitle	The channel title is invalid or has not been defined.
errorInvalidChannelLink	The channel hyperlink is invalid or has not been defined.
errorInvalidChannelDescription	The channel description is invalid or has not been defined.
errorInvalidItemText	The description for an item is invalid or has not been defined.
errorInvalidItemLink	The hyperlink for an item is invalid or has not been defined.

errorInvalidServiceType	The specified service type is invalid.
errorServiceSuspended	Access to the specified service has been suspended.
errorServiceRestricted	Access to the specified service has been restricted.
errorInvalidProviderName	The specified provider name is invalid or unknown.
errorInvalidPhoneNumber	The specified phone number is invalid or not supported in this region.
errorGatewayNotFound	A message gateway cannot be found for the specified provider.
errorMessageTooLong	The message exceeds the maximum number of characters permitted.
errorInvalidProviderData	The request returned invalid or incomplete service provider data.
errorInvalidGatewayData	The request returned invalid or incomplete message gateway data.
errorMultipleProviders	The request has returned multiple service providers.
errorProviderNotFound	The specified service provider could not be found.
errorInvalidMessageService	The specified message is not supported with this service type.
errorInvalidMessageFormat	The specified message format is invalid.
errorInvalidConfiguration	The specified configuration options are invalid.
errorServerActive	The requested action is not permitted while the server is active.
errorServerPortBound	Unable to obtain exclusive use of the specified local port.
errorInvalidClientSession	The specified client identifier is invalid for this session.
errorClientNotIdentified	The specified client has not provided user credentials.
errorInvalidClientState	The requested action cannot be performed at this time.
errorInvalidResultCode	The specified result code is not valid for this protocol
errorCommandRequired	The specified command is required and cannot be disabled.
errorCommandDisabled	The specified command has been disabled.
errorCommandSequence	The command cannot be processed at this time.
errorCommandCompleted	The previous command has completed.
errorInvalidProgramName	The specified program name is invalid or unrecognized.

errorInvalidRequestHeader	The request header contains one or more invalid values.
errorInvalidVirtualHost	The specified virtual host name is invalid.
errorVirtualHostNotFound	The specified virtual host does not exist.
errorTooManyVirtualHosts	Too many virtual hosts created for this server.
errorInvalidVirtualPath	The specified virtual path name is invalid.
errorVirtualPathNotFound	The specified virtual path does not exist.
errorTooManyVirtualPaths	Too many virtual paths created for this server.
errorInvalidTask	The asynchronous task identifier is invalid.
errorTaskActive	The asynchronous task has not finished.
errorTaskQueued	The asynchronous task has been queued.
errorTaskSuspended	The asynchronous task has been suspended.
errorTaskFinished	The asynchronous task has finished.
errorInvalidAccountUuid	The account unique identifier is invalid
errorInvalidAccountId	The application account identifier is invalid
errorInvalidProductId	The product identifier identifier is invalid
errorInvalidSerialNumber	The product serial number is invalid
errorInvalidAppId	The application identifier is invalid
errorInvalidApiKey	The application key is invalid
errorAccountExists	The application account identifier already exists
errorAccountNotCreated	The application account identifier was not created
errorAccountNotFound	The application account identifier was not found
errorAccountNotExpired	access to this account has not expired
errorAccountNotUpdated	The application account could not be updated
errorAccountExpired	access to this account has expired
errorAccountRevoked	access to this account has been revoked
errorApiKeyNotCreated	The application key could not be created
errorApiKeyNotFound	The application key could not be found
errorApiKeyNotExpired	The application key has not expired
errorApiKeyNotUnique	The application key identifier is not unique
errorApiKeyNotUpdated	They application key could not be updated
errorApiKeyNotDeleted	The application key could not be deleted
errorApiKeyExists	The application key already exists
errorApiKeyExpired	The application key has expired and must be refreshed
errorApiKeyRevoked	The application key has been revoked

errorApiKeyAppId	The application was not found or was not specified
errorInvalidToken	The access token is invalid or was not specified
errorTokenNotCreated	The access token could not be created
errorTokenNotFound	The access token could not be found
errorTokenNotExpired	The access token has not expired
errorTokenNotUpdated	The access token was not updated
errorTokenNotDeleted	The access token could not be deleted
errorTokenExpired	The access token has expired and must be refreshed
errorTokenRevoked	The access token has been revoked
errorNoApiKeysFound	no application keys found for this account
errorNoTokensFound	no access tokens found for this application key
errorNoTokensRevoked	no access tokens have been revoked
errorInvalidStorageObject	invalid storage object identifier
errorStorageObjectReadOnly	The storage object is read-only
errorStorageObjectExpired	access to the storage object has expired
errorStorageObjectSize	The storage object size exceeds storage limits
errorStorageObjectDigest	The storage object digest is invalid or cannot be computed
errorStorageObjectExists	a storage object with this label already exists
errorStorageObjectModified	a storage object with this label has been modified
errorStorageObjectNotOwner	The current user is not the storage object owner
errorStorageObjectNotFound	The specified storage object does not exist
errorStorageObjectNotCreated	The storage object was not created
errorStorageObjectNotModified	The storage object was not modified
errorStorageObjectNotRenamed	The storage object was not renamed
errorStorageFolderEmpty	The storage folder does not contain any objects
errorStorageAccountQuota	The storage account has exceeded its quota
errorStorageAccountLimit	The storage account has exceeded its object limit
errorInvalidStorageType	The specified storage type is invalid
errorInvalidStorageProvider	The specified storage provider is not available
errorInvalidStorageRegion	The specified storage region is not available
errorInvalidStorageContainer	The storage container does not exist or cannot be accessed
errorInvalidStorageLabel	The storage object label is invalid or undefined

Requirements

Namespace: SocketTools

Assembly: SocketTools.WebStorage (in SocketTools.WebStorage.dll)

SocketTools Namespace | LastError Property | LastErrorString Property | OnError Event

WebStorage.TraceOptions Enumeration

Specifies the logging options that the WebStorage class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

```
[Visual Basic]
<Flags>
Public Enum WebStorage.TraceOptions
```

```
[C#]
[Flags]
public enum WebStorage.TraceOptions
```

Remarks

The WebStorage class uses the **TraceOptions** enumeration to specify what kind of debugging information is written to the trace logfile. These options are only meaningful when trace logging is enabled by setting the **Trace** property to **true**.

Members

Member Name	Description	Value
traceDefault	The default trace logging option. This is the same as specifying the **traceInfo** option.	0
traceInfo	All network function calls are written to the trace file. This is the default value.	0
traceError	Only those network function calls which fail are recorded in the trace file.	1
traceWarning	Only those network function calls which fail, or return values which indicate a warning, are recorded in the trace file.	2
traceHexDump	All network function calls are written to the trace file, plus all the data that is sent or received is displayed, in both ASCII and hexadecimal format.	4
traceProcess	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for multithreaded applications that are using worker threads.	4096

WebStorage.OnDownloadEventHandler Delegate

Represents the method that will handle the OnDownload event.

[Visual Basic]

```
Public Delegate Sub WebStorage.OnDownloadEventHandler( _
   ByVal sender As Object, _
   ByVal e As DownloadEventArgs _
)
```

[C#]

```
public delegate void WebStorage.OnDownloadEventHandler(
      object sender,
      DownloadEventArgs e
   );
```

Parameters

sender

The source of the event.

e

A DownloadEventArgs object that contains the event data.

Remarks

When you create an **OnDownloadEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnDownloadEventHandler** delegate declaration.

Requirements

Namespace: SocketTools

Assembly: SocketTools.WebStorage (in SocketTools.WebStorage.dll)

SocketTools Namespace

WebStorage.OnErrorEventHandler Delegate

Represents the method that will handle the OnError event.

[Visual Basic]

```
Public Delegate Sub WebStorage.OnErrorEventHandler( _
   ByVal sender As Object, _
   ByVal e As ErrorEventArgs _
)
```

[C#]

```
public delegate void WebStorage.OnErrorEventHandler(
      object sender,
      ErrorEventArgs e
   );
```

Parameters

sender

The source of the event.

e

An ErrorEventArgs that contains the event data.

Remarks

When you create an **OnErrorEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnErrorEventHandler** delegate declaration.

Requirements

Namespace: SocketTools

Assembly: SocketTools.WebStorage (in SocketTools.WebStorage.dll)

WebStorage.OnProgressEventHandler Delegate

Represents the method that will handle the OnProgress event.

[Visual Basic]

```
Public Delegate Sub WebStorage.OnProgressEventHandler( _
   ByVal sender As Object, _
   ByVal e As ProgressEventArgs _
)
```

[C#]

```
public delegate void WebStorage.OnProgressEventHandler(
      object sender,
      ProgressEventArgs e
   );
```

Parameters

sender

The source of the event.

e

A ProgressEventArgs that contains the event data.

Remarks

When you create an **OnProgressEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnProgressEventHandler** delegate declaration.

Requirements

Namespace: SocketTools

Assembly: SocketTools.WebStorage (in SocketTools.WebStorage.dll)

SocketTools Namespace

WebStorage.OnUploadEventHandler Delegate

Represents the method that will handle the OnUpload event.

[Visual Basic]

```
Public Delegate Sub WebStorage.OnUploadEventHandler( _
   ByVal sender As Object, _
   ByVal e As UploadEventArgs _
)
```

[C#]

```
public delegate void WebStorage.OnUploadEventHandler(
      object sender,
      UploadEventArgs e
   );
```

Parameters

sender

The source of the event.

e

A UploadEventArgs object that contains the event data.

Remarks

When you create an **OnUploadEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnUploadEventHandler** delegate declaration.

Requirements

Namespace: SocketTools

Assembly: SocketTools.WebStorage (in SocketTools.WebStorage.dll)

SocketTools Namespace

WebStorage.RuntimeLicenseAttribute Class

Attribute that defines the runtime license key for the class.

For a list of all members of this type, see WebStorage.RuntimeLicenseAttribute Members.

System.Object
  System.Attribute
    SocketTools.WebStorage.RuntimeLicenseAttribute

[Visual Basic]

```
<AttributeUsage(ValidOn:=AttributeTargets.Assembly, AllowMultiple:=False,
   Inherited:=True)>
Public Class WebStorage.RuntimeLicenseAttribute
    Inherits Attribute
```

[C#]

```
[AttributeUsage(ValidOn=AttributeTargets.Assembly, AllowMultiple=False,
   Inherited=True)]
public class WebStorage.RuntimeLicenseAttribute : Attribute
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

The RuntimeLicense attribute is used to define the runtime license key that will be used when an instance of the class is created. This attribute is defined in the assembly information module for the language, such as AssemblyInfo.cs when programming C#. The runtime license key must be defined if you wish to redistribute your application.

The runtime license key for your copy of SocketTools can be generated using the License Manager utility that is included with the product. Note that if you have installed an evaluation license, you will not have a runtime license key and cannot redistribute any applications which use the WebStorage class.

Example

```
<Assembly: SocketTools.WebStorage.RuntimeLicense("abcdefghijklmnop")>
```

```
[assembly: SocketTools.WebStorage.RuntimeLicense("abcdefghijklmnop")]
```

Requirements

Namespace: SocketTools

Assembly: SocketTools.WebStorage (in SocketTools.WebStorage.dll)

WebStorage.RuntimeLicenseAttribute Members

WebStorage.RuntimeLicenseAttribute overview

Public Instance Constructors

WebStorage.RuntimeLicenseAttribute Constructor	Constructor for the RuntimeLicense attribute which defines the runtime license key.

Public Instance Properties

LicenseKey	Returns the value of the runtime license key.
TypeId (inherited from Attribute)	When implemented in a derived class, gets a unique identifier for this Attribute.

Public Instance Methods

Equals (inherited from Attribute)	
GetHashCode (inherited from Attribute)	Returns the hash code for this instance.
GetType (inherited from Object)	Gets the Type of the current instance.
IsDefaultAttribute (inherited from Attribute)	When overridden in a derived class, returns an indication whether the value of this instance is the default value for the derived class.
Match (inherited from Attribute)	When overridden in a derived class, returns a value indicating whether this instance equals a specified object.
ToString (inherited from Object)	Returns a String that represents the current Object.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

WebStorage.RuntimeLicenseAttribute Class | SocketTools Namespace

WebStorage.RuntimeLicenseAttribute Constructor

Constructor for the RuntimeLicense attribute which defines the runtime license key.

[Visual Basic]

```
Public Sub New( _
   ByVal licenseKey As String _
)
```

[C#]

```
public WebStorage.RuntimeLicenseAttribute(
   string licenseKey
);
```

Parameters

licenseKey

A string argument which specifies the runtime license key which will be used to initialize the class library.

Remarks

The runtime license key for your copy of SocketTools can be generated using the License Manager utility that is included with the product. Note that if you have installed an evaluation license, you will not have a runtime license key and cannot redistribute any applications which use the WebStorage class.

See Also

WebStorage.RuntimeLicenseAttribute Class | SocketTools Namespace

WebStorage.RuntimeLicenseAttribute Properties

The properties of the **WebStorage.RuntimeLicenseAttribute** class are listed below. For a complete list of **WebStorage.RuntimeLicenseAttribute** class members, see the WebStorage.RuntimeLicenseAttribute Members topic.

Public Instance Properties

LicenseKey	Returns the value of the runtime license key.
TypeId (inherited from Attribute)	When implemented in a derived class, gets a unique identifier for this Attribute.

See Also

WebStorage.RuntimeLicenseAttribute Class | SocketTools Namespace

WebStorage.RuntimeLicenseAttribute.LicenseKey Property

Returns the value of the runtime license key.

[Visual Basic]

```
Public Property LicenseKey As String
```

[C#]

```
public string LicenseKey {get; set;}
```

Property Value

A string which contains the runtime license key.

See Also

WebStorage.RuntimeLicenseAttribute Class | SocketTools Namespace

WebStorageException Class

The exception that is thrown when a client error occurs.

For a list of all members of this type, see WebStorageException Members.

System.Object
  System.Exception
    System.ApplicationException
      SocketTools.WebStorageException

[Visual Basic]

```
Public Class WebStorageException
    Inherits ApplicationException
```

[C#]

```
public class WebStorageException : ApplicationException
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

A WebStorageException is thrown by the WebStorage class when an error occurs.

The default constructor for the WebStorageException class sets the **ErrorCode** property to the last client error that occurred.

Requirements

Namespace: SocketTools

Assembly: SocketTools.WebStorage (in SocketTools.WebStorage.dll)

WebStorageException Members | SocketTools Namespace

WebStorageException Members

WebStorageException overview

Public Instance Constructors

WebStorageException	Overloaded. Initializes a new instance of the WebStorageException class.

Public Instance Properties

ErrorCode	Gets a value which specifies the error that caused the exception.
HelpLink (inherited from Exception)	Gets or sets a link to the help file associated with this exception.
InnerException (inherited from Exception)	Gets the Exception instance that caused the current exception.
Message	Gets a value which describes the error that caused the exception.
Number	Gets a value which specifies the numeric value of the error that caused the exception.
Source (inherited from Exception)	Gets or sets the name of the application or the object that causes the error.
StackTrace (inherited from Exception)	Gets a string representation of the frames on the call stack at the time the current exception was thrown.
TargetSite (inherited from Exception)	Gets the method that throws the current exception.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetBaseException (inherited from Exception)	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetObjectData (inherited from Exception)	When overridden in a derived class, sets the SerializationInfo with information about the exception.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString	Creates and returns a string representation of the current exception.

Protected Instance Properties

HResult (inherited from Exception)	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

WebStorageException Class | SocketTools Namespace

WebStorageException Constructor

Initializes a new instance of the WebStorageException class with the last network error code.

Overload List

Initializes a new instance of the WebStorageException class with the last network error code.

public WebStorageException();

Initializes a new instance of the WebStorageException class with a specified error number.

public WebStorageException(int);

Initializes a new instance of the WebStorageException class with a specified error message.

public WebStorageException(string);

Initializes a new instance of the WebStorageException class with a specified error message and a reference to the inner exception that is the cause of this exception.

public WebStorageException(string,Exception);

See Also

WebStorageException Class | SocketTools Namespace

WebStorageException Constructor ()

Initializes a new instance of the WebStorageException class with the last network error code.

[Visual Basic]

```
Overloads Public Sub New()
```

[C#]

```
public WebStorageException();
```

Remarks

The ctor constructor sets the **ErrorCode** property to the last client error that occurred. For more information about the errors that may occur, refer to the WebStorage.ErrorCode enumeration.

WebStorageException Class | SocketTools Namespace | WebStorageException Constructor Overload List

WebStorageException Constructor (String)

Initializes a new instance of the WebStorageException class with a specified error message.

[Visual Basic]
```
Overloads Public Sub New( _
   ByVal message As String _
)
```

[C#]
```
public WebStorageException(
   string message
);
```

Parameters

message
The error message that explains the reason for the exception.

Remarks

The content of the ***message*** parameter is intended to be understood by humans. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

See Also

WebStorageException Class | SocketTools Namespace | WebStorageException Constructor Overload List

WebStorageException Constructor (String, Exception)

Initializes a new instance of the WebStorageException class with a specified error message and a reference to the inner exception that is the cause of this exception.

[Visual Basic]

```
Overloads Public Sub New( _
   ByVal message As String, _
   ByVal innerException As Exception _
)
```

[C#]

```
public WebStorageException(
   string message,
   Exception innerException
);
```

Parameters

message

The error message that explains the reason for the exception.

innerException

The exception that is the cause of the current exception. If the *innerException* parameter is not a null reference, the current exception is raised in a **catch** block that handles the inner exception.

Remarks

The content of the message parameter is intended to be understood by humans. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

An exception that is thrown as a direct result of a previous exception should include a reference to the previous exception in the **InnerException** property. The **InnerException** property returns the same value that is passed into the constructor, or a null reference if the **InnerException** property does not supply the inner exception value to the constructor.

See Also

WebStorageException Class | SocketTools Namespace | WebStorageException Constructor Overload List

WebStorageException Constructor (Int32)

Initializes a new instance of the WebStorageException class with a specified error number.

[Visual Basic]

```
Overloads Public Sub New( _
   ByVal code As Integer _
)
```

[C#]

```
public WebStorageException(
   int code
);
```

Parameters

code

An integer value which specifies an error code.

Remarks

This constructor sets the **ErrorCode** property to the specified error code. For more information about the errors that may occur, refer to the WebStorage.ErrorCode enumeration.

See Also

WebStorageException Class | SocketTools Namespace | WebStorageException Constructor Overload List

WebStorageException Properties

The properties of the **WebStorageException** class are listed below. For a complete list of **WebStorageException** class members, see the WebStorageException Members topic.

Public Instance Properties

ErrorCode	Gets a value which specifies the error that caused the exception.
HelpLink (inherited from Exception)	Gets or sets a link to the help file associated with this exception.
InnerException (inherited from Exception)	Gets the Exception instance that caused the current exception.
Message	Gets a value which describes the error that caused the exception.
Number	Gets a value which specifies the numeric value of the error that caused the exception.
Source (inherited from Exception)	Gets or sets the name of the application or the object that causes the error.
StackTrace (inherited from Exception)	Gets a string representation of the frames on the call stack at the time the current exception was thrown.
TargetSite (inherited from Exception)	Gets the method that throws the current exception.

Protected Instance Properties

HResult (inherited from Exception)	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception.

See Also

WebStorageException Class | SocketTools Namespace

WebStorageException.ErrorCode Property

Gets a value which specifies the error that caused the exception.

[Visual Basic]

```
Public ReadOnly Property ErrorCode As ErrorCode
```

[C#]

```
public WebStorage.ErrorCode ErrorCode {get;}
```

Property Value

Returns a WebStorage.ErrorCode enumeration value which specifies the error code.

Remarks

The **ErrorCode** property returns the error code that specifies the cause of the exception.

The default constructor for the WebStorageException class sets the error code to the last network error that occurred. For more information about the errors that may occur, refer to the WebStorage.ErrorCode enumeration.

See Also

WebStorageException Class | SocketTools Namespace

WebStorageException.Message Property

Gets a value which describes the error that caused the exception.

[Visual Basic]

```
Overrides Public ReadOnly Property Message As String
```

[C#]

```
public override string Message {get;}
```

Property Value

A string which describes the error that caused the exception.

Remarks

The **Message** property returns a string which describes the error that caused the exception.

See Also

WebStorageException Class | SocketTools Namespace

WebStorageException.Number Property

Gets a value which specifies the numeric value of the error that caused the exception.

[Visual Basic]

```
Public ReadOnly Property Number As Integer
```

[C#]

```
public int Number {get;}
```

Property Value

An integer value that specifies the error that caused the exception.

Remarks

The **Number** property returns an integer value which specifies the numeric value of the error that caused the exception. This value is the same as the values returned by the Windows Sockets API. For more information about socket error codes, see the Windows Socket Version 2 API error code documentation in MSDN.

WebStorageException Class | SocketTools Namespace

WebStorageException Methods

The methods of the **WebStorageException** class are listed below. For a complete list of **WebStorageException** class members, see the WebStorageException Members topic.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetBaseException (inherited from Exception)	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetObjectData (inherited from Exception)	When overridden in a derived class, sets the SerializationInfo with information about the exception.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString	Creates and returns a string representation of the current exception.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

WebStorageException Class | SocketTools Namespace

WebStorageException.ToString Method

Creates and returns a string representation of the current exception.

[Visual Basic]
```
Overrides Public Function ToString() As String
```

[C#]
```
public override string ToString();
```

Return Value

A string representation of the current exception.

Remarks

The **ToString** method returns a representation of the current exception that is intended to be understood by humans. Where the exception contains culture-sensitive data, the string representation returned by **ToString** is required to take into account the current system culture. Although there are no exact requirements for the format of the returned string, it should attempt to reflect the value of the object as perceived by the user.

This implementation of **ToString** obtains the numeric error code value and a description of the error that caused the current exception. If there is no error message or it is an empty string, then no error message is returned.

This method overrides **ApplicationException.ToString**.

WebStorageException Class | SocketTools Namespace

WhoisClient Class

Request registration information for an Internet domain name.

For a list of all members of this type, see WhoisClient Members.

System.Object
  SocketTools.WhoisClient

```
[Visual Basic]
Public Class WhoisClient
    Implements IDisposable
```

```
[C#]
public class WhoisClient : IDisposable
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

The WhoisClient class library provides an interface for requesting registration information for an Internet domain name. When a domain name is registered, the organization that registers the domain must provide certain contact information along with technical information such as the primary name servers for that domain.

This class provides an interface for requesting that information and returning it to the program so that it can be displayed or processed. This class would be most commonly used to query the Whois server at **whois.internic.net** to obtain information about a specific Internet domain name or an administrative contact at that domain.

Requirements

Namespace: SocketTools

Assembly: SocketTools.WhoisClient (in SocketTools.WhoisClient.dll)

See Also

WhoisClient Members | SocketTools Namespace

WhoisClient Members

WhoisClient overview

Public Static (Shared) Fields

whoisPortDefault	A constant value which specifies the default port number.
whoisTimeout	A constant value which specifies the default timeout period.

Public Instance Constructors

WhoisClient Constructor	Initializes a new instance of the WhoisClient class.

Public Instance Properties

AutoResolve	Gets and sets a value that determines if host names and addresses are automatically resolved.
Blocking	Gets and sets a value which indicates if the client is in blocking mode.
Handle	Gets a value that specifies the client handle allocated for the current session.
HostAddress	Gets and sets a value which specifies the Internet address used to establish a connection.
HostName	Gets and sets a value which specifies the host name used to establish a connection.
IsBlocked	Gets a value which indicates if the current thread is performing a blocking client operation.
IsConnected	Gets a value which indicates if a connection to the remote host has been established.
IsInitialized	Gets a value which indicates if the current instance of the class has been initialized successfully.
IsReadable	Gets a value which indicates if there is data available to be read from the socket connection to the server.
Keyword	Gets and sets the default search keyword.
LastError	Gets and sets a value which specifies the last error that has occurred.
LastErrorString	Gets a value which describes the last error that has occurred.
LocalAddress	Gets the local Internet address that the client is bound to.
LocalName	Gets a value which specifies the host name for the local system.
LocalPort	Gets the local port number the client is bound to.

Options	Gets and sets a value which specifies one or more client options.
RemotePort	Gets and sets a value which specifies the remote port number.
RemoteService	Gets and sets a value which specifies the remote service.
SearchType	Gets and sets the type of query to be performed by the remote server.
Status	Gets a value which specifies the current status of the client.
ThreadModel	Gets and sets a value which specifies the threading model for the class instance.
ThrowError	Gets and sets a value which specifies if method calls should throw exceptions when an error occurs.
Timeout	Gets and sets a value which specifies a timeout period in seconds.
Trace	Gets and sets a value which indicates if network function logging is enabled.
TraceFile	Gets and sets a value which specifies the name of the logfile.
TraceFlags	Gets and sets a value which specifies the client function tracing flags.
Version	Gets a value which returns the current version of the WhoisClient class library.

Public Instance Methods

AttachThread	Attach an instance of the class to the current thread
Cancel	Cancel the current blocking client operation.
Connect	Overloaded. Establish a connection with a remote host.
Disconnect	Terminate the connection with a remote host.
Dispose	Overloaded. Releases all resources used by WhoisClient.
Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from Object)	Gets the Type of the current instance.
Initialize	Overloaded. Initialize an instance of the

	WhoisClient class.
Read	Overloaded. Read data from the server and store it in a byte array.
Reset	Reset the internal state of the object, resetting all properties to their default values.
Search	Overloaded. Search for the specified record using the specified keyword and search type.
ToString (inherited from Object)	Returns a String that represents the current Object.
Uninitialize	Uninitialize the class library and release any resources allocated for the current thread.

Public Instance Events

OnCancel	Occurs when a blocking client operation is canceled.
OnConnect	Occurs when a connection is established with the remote host.
OnDisconnect	Occurs when the remote host disconnects from the local system.
OnError	Occurs when an client operation fails.
OnRead	Occurs when data is available to be read from the client.
OnTimeout	Occurs when a blocking operation fails to complete before the timeout period elapses.
OnWrite	Occurs when data can be written to the client.

Protected Instance Methods

Dispose	Overloaded. Releases the unmanaged resources allocated by the WhoisClient class and optionally releases the managed resources.
Finalize	Destroys an instance of the class, releasing the resources allocated for the session and unloading the networking library.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

WhoisClient Class | SocketTools Namespace

WhoisClient Constructor

Initializes a new instance of the WhoisClient class.

[Visual Basic]

```
Public Sub New()
```

[C#]

```
public WhoisClient();
```

See Also

WhoisClient Class | SocketTools Namespace

WhoisClient Properties

The properties of the **WhoisClient** class are listed below. For a complete list of **WhoisClient** class members, see the WhoisClient Members topic.

Public Instance Properties

AutoResolve	Gets and sets a value that determines if host names and addresses are automatically resolved.
Blocking	Gets and sets a value which indicates if the client is in blocking mode.
Handle	Gets a value that specifies the client handle allocated for the current session.
HostAddress	Gets and sets a value which specifies the Internet address used to establish a connection.
HostName	Gets and sets a value which specifies the host name used to establish a connection.
IsBlocked	Gets a value which indicates if the current thread is performing a blocking client operation.
IsConnected	Gets a value which indicates if a connection to the remote host has been established.
IsInitialized	Gets a value which indicates if the current instance of the class has been initialized successfully.
IsReadable	Gets a value which indicates if there is data available to be read from the socket connection to the server.
Keyword	Gets and sets the default search keyword.
LastError	Gets and sets a value which specifies the last error that has occurred.
LastErrorString	Gets a value which describes the last error that has occurred.
LocalAddress	Gets the local Internet address that the client is bound to.
LocalName	Gets a value which specifies the host name for the local system.
LocalPort	Gets the local port number the client is bound to.
Options	Gets and sets a value which specifies one or more client options.
RemotePort	Gets and sets a value which specifies the remote port number.
RemoteService	Gets and sets a value which specifies the remote service.
SearchType	Gets and sets the type of query to be performed

	by the remote server.
Status	Gets a value which specifies the current status of the client.
ThreadModel	Gets and sets a value which specifies the threading model for the class instance.
ThrowError	Gets and sets a value which specifies if method calls should throw exceptions when an error occurs.
Timeout	Gets and sets a value which specifies a timeout period in seconds.
Trace	Gets and sets a value which indicates if network function logging is enabled.
TraceFile	Gets and sets a value which specifies the name of the logfile.
TraceFlags	Gets and sets a value which specifies the client function tracing flags.
Version	Gets a value which returns the current version of the WhoisClient class library.

See Also

WhoisClient Class | SocketTools Namespace

WhoisClient.AutoResolve Property

Gets and sets a value that determines if host names and addresses are automatically resolved.

[Visual Basic]

```
Public Property AutoResolve As Boolean
```

[C#]

```
public bool AutoResolve {get; set;}
```

Property Value

Returns **true** if host names are automatically resolved to Internet addresses. The default value is **false**.

Remarks

Setting the **AutoResolve** property determines if the class automatically resolves host names and addresses specified by the **HostName** and **HostAddress** properties. If set to **true**, setting the **HostName** property will cause the class to automatically determine the corresponding IP address and update the **HostAddress** property accordingly. Likewise, setting the **HostAddress** property will cause the class to determine the host name and update the **HostName** property. Setting this property to **false** prevents the class from resolving host names until a connection attempt is made.

It is important to note that setting the **HostName** or **HostAddress** property may cause the current thread to block, sometimes for several seconds, until the name or address is resolved. To prevent this behavior, set this property value to **false**.

See Also

WhoisClient Class | SocketTools Namespace

WhoisClient.Blocking Property

Gets and sets a value which indicates if the client is in blocking mode.

[Visual Basic]

```
Public Property Blocking As Boolean
```

[C#]

```
public bool Blocking {get; set;}
```

Property Value

Returns **true** if the client is in blocking mode; otherwise it returns **false**. The default value is **true**.

Remarks

Setting the **Blocking** property determines if client operations complete synchronously or asynchronously. If set to **true**, then each client operation (such as sending or receiving data) will return when the operation has completed or timed-out. If set to **false**, client operations will return immediately. If the operation would result in the client blocking (such as attempting to read data when no data has been sent by the remote host), an error is generated.

It is important to note that certain events, such as **OnDisconnect, OnRead** and **OnWrite** are only fired if the client is in non-blocking mode.

See Also

WhoisClient Class | SocketTools Namespace

WhoisClient.Handle Property

Gets a value that specifies the client handle allocated for the current session.

[Visual Basic]

```
Public ReadOnly Property Handle As Integer
```

[C#]

```
public int Handle {get;}
```

Property Value

An integer which represents a client handle. If there is no active connection, a value of -1 is returned.

Remarks

The **Handle** property specifies the numeric descriptor of the current client session.

See Also

WhoisClient Class | SocketTools Namespace

WhoisClient.HostAddress Property

Gets and sets a value which specifies the Internet address used to establish a connection.

[Visual Basic]

```
Public Property HostAddress As String
```

[C#]

```
public string HostAddress {get; set;}
```

Property Value

A string which specifies an Internet address.

Remarks

The **HostAddress** property can be used to set the Internet address for a remote system that you wish to communicate with. If the **AutoResolve** property is set to **true** and the address is assigned to a valid host name, the **HostName** property will be updated with that value.

See Also

WhoisClient Class | SocketTools Namespace

WhoisClient.HostName Property

Gets and sets a value which specifies the host name used to establish a connection.

[Visual Basic]

```
Public Property HostName As String
```

[C#]

```
public string HostName {get; set;}
```

Property Value

A string which specifies a host name.

Remarks

The **HostName** property can be used to set the host name for a remote system that you wish to communicate with. If the **AutoResolve** property is set to **true** and the name can be resolved to a valid Internet address, the **HostAddress** property will be updated with that value.

See Also

WhoisClient Class | SocketTools Namespace

WhoisClient.IsBlocked Property

Gets a value which indicates if the current thread is performing a blocking client operation.

[Visual Basic]

```
Public ReadOnly Property IsBlocked As Boolean
```

[C#]

```
public bool IsBlocked {get;}
```

Property Value

Returns **true** if the current thread is blocking, otherwise returns **false**.

Remarks

The **IsBlocked** property returns **true** if the current thread is blocked performing an operation. Because the Windows Sockets API only permits one blocking operation per thread of execution, this property should be checked before starting any blocking operation in response to an event.

If the **IsBlocked** property returns **false**, this means there are no blocking operations on the current thread at that time. However, this does not guarantee that the next client operation will not fail. An application should always check the return value from a client operation and check the value of the **LastError** property if an error occurs.

Note that this property will return **true** if there is any blocking operation being performed by the current thread, regardless of whether this specific instance of the class is responsible for the blocking operation or not.

See Also

WhoisClient Class | SocketTools Namespace

WhoisClient.IsConnected Property

Gets a value which indicates if a connection to the remote host has been established.

[Visual Basic]

```
Public ReadOnly Property IsConnected As Boolean
```

[C#]

```
public bool IsConnected {get;}
```

Property Value

Returns **true** if the connection has been established; otherwise returns **false**.

Remarks

The **IsConnected** property can only be used to indicate if there is still a logical connection to the remote host. It cannot be used to detect abnormal conditions such as the remote host aborting the connection, the physical network connection being lost or other critical errors.

See Also

WhoisClient Class | SocketTools Namespace

WhoisClient.IsInitialized Property

Gets a value which indicates if the current instance of the class has been initialized successfully.

[Visual Basic]

```
Public ReadOnly Property IsInitialized As Boolean
```

[C#]

```
public bool IsInitialized {get;}
```

Property Value

Returns **true** if the class instance has been initialized; otherwise returns **false**.

Remarks

The **IsInitialized** property is used to determine if the current instance of the class has been initialized properly. Normally this is done automatically by the class constructor, however there are circumstances where the class may not be able to initialize itself.

The most common reasons that a class instance may not initialize correctly is that no runtime license key has been defined in the assembly or the license key provided is invalid. It may also indicate a problem with the system configuration or user access rights, such as not being able to load the required networking libraries or not being able to access the system registry.

See Also

WhoisClient Class | SocketTools Namespace

WhoisClient.IsReadable Property

Gets a value which indicates if there is data available to be read from the socket connection to the server.

[Visual Basic]

```
Public ReadOnly Property IsReadable As Boolean
```

[C#]

```
public bool IsReadable {get;}
```

Property Value

Returns **true** if there is data available to be read; otherwise returns **false**.

Remarks

The **IsReadable** property returns **true** if data can be read from the client without blocking. For non-blocking sessions, this property can be checked before the application attempts to read the client. Note that even if this property does return **true** indicating that there is data available to be read, applications should always check the return value from the **Read** method.

See Also

WhoisClient Class | SocketTools Namespace

WhoisClient.Keyword Property

Gets and sets the default search keyword.

```
[Visual Basic]
Public Property Keyword As String
```

```
[C#]
public string Keyword {get; set;}
```

Property Value

A string which specifies the default search keyword.

Remarks

The **Keyword** property specifies the value used when querying the remote server. The keyword may refer to a handle, a user name or a mailbox name. Setting this property provides the default keyword for the **Search** method.

Keywords may contain special characters that instruct the server how to match the value. These values are outlined in RFC 954, the standards document that describes the WHOIS/NICNAME protocol. These forms are typically recognized:

Example	Description
value	Search for value as either a user name or a handle.
value...	Search for value that matches anything up to that point.
!value	Search for a handle that matches the given value.
last, first	Search for the specified name.
user@	Search for mailboxes with the given user name.
@host	Search for mailboxes on the specified host.
user@host	Search for mailboxes for the user on the specified host.

If the keyword uses any of these special forms, the **SearchType** property must be set to **searchAny**, which tells the control not to modify the keyword value when submitting the query to the server. Note that all keyword forms may not be supported by a given server, and additional types of searches may be supported.

See Also

WhoisClient Class | SocketTools Namespace

WhoisClient.LastError Property

Gets and sets a value which specifies the last error that has occurred.

[Visual Basic]

```
Public Property LastError As ErrorCode
```

[C#]

```
public WhoisClient.ErrorCode LastError {get; set;}
```

Property Value

Returns an ErrorCode enumeration value which specifies the last error code.

Remarks

The **LastError** property returns the error code associated with the last error that occurred for the current instance of the class. It is important to note that this value only has meaning if the previous method indicates that an error has actually occurred.

It is possible to explicitly clear the last error code by assigning the property to the value **ErrorCode.errorNone**.

The error code value can be cast to an integer value for display purposes if required. For a description of the error that can be displayed using a message box or some other similar mechanism, get the value of the **LastErrorString** property.

See Also

WhoisClient Class | SocketTools Namespace

WhoisClient.LastErrorString Property

Gets a value which describes the last error that has occurred.

[Visual Basic]

```
Public ReadOnly Property LastErrorString As String
```

[C#]

```
public string LastErrorString {get;}
```

Property Value

A string which describes the last error that has occurred.

Remarks

The **LastErrorString** property can be used to obtain a description of the last error that occurred for the current instance of the class. It is important to note that this value only has meaning if the previous method indicates that an error has actually occurred.

See Also

WhoisClient Class | SocketTools Namespace

WhoisClient.LocalAddress Property

Gets the local Internet address that the client is bound to.

[Visual Basic]

```
Public ReadOnly Property LocalAddress As String
```

[C#]

```
public string LocalAddress {get;}
```

Property Value

A string which specifies an Internet address.

Remarks

The **LocalAddress** property returns the local Internet address that the client is bound to when a connection is established with a remote host. This property may return either an IPv4 or IPv6 formatted address, depending on the type of connection that was established.

See Also

WhoisClient Class | SocketTools Namespace

WhoisClient.LocalName Property

Gets a value which specifies the host name for the local system.

[Visual Basic]
```
Public ReadOnly Property LocalName As String
```

[C#]
```
public string LocalName {get;}
```

Property Value

A string which specifies the local host name.

Remarks

The **LocalName** property returns the fully-qualified host name assigned to the local system. If the system has not been configured with an Internet domain name, then this property will return the NetBIOS name assigned to the local system.

See Also

WhoisClient Class | SocketTools Namespace

WhoisClient.LocalPort Property

Gets the local port number the client is bound to.

[Visual Basic]

```
Public ReadOnly Property LocalPort As Integer
```

[C#]

```
public int LocalPort {get;}
```

Property Value

An integer value which specifies a port number. The default value is 0.

Remarks

The **LocalPort** property is used to identify the local port number that the client is bound to to when a connection is established with a remote host.

See Also

WhoisClient Class | SocketTools Namespace

WhoisClient.Options Property

Gets and sets a value which specifies one or more client options.

[Visual Basic]
```
Public Property Options As WhoisOptions
```

[C#]
```
public WhoisClient.WhoisOptions Options {get; set;}
```

Property Value

Returns one or more WhoisOptions enumeration flags which specify the options for the client. The default value for this property is **whoisOptionNone**.

Remarks

The **Options** property specifies one or more default options options which are used when establishing a connection using the **Connect** method.

See Also

WhoisClient Class | SocketTools Namespace

WhoisClient.RemotePort Property

Gets and sets a value which specifies the remote port number.

[Visual Basic]

```
Public Property RemotePort As Integer
```

[C#]

```
public int RemotePort {get; set;}
```

Property Value

An integer value which specifies a port number.

Remarks

The **RemotePort** property is used to set the port number that will be used to establish a connection with a remote host. If the port number specifies a well-known port, the **RemoteService** property will be updated with that name.

See Also

WhoisClient Class | SocketTools Namespace

WhoisClient.SearchType Property

Gets and sets the type of query to be performed by the remote server.

[Visual Basic]
```
Public Property SearchType As WhoisSearchType
```

[C#]
```
public WhoisClient.WhoisSearchType SearchType {get; set;}
```

Property Value

A WhoisSearchType enumeration value which specifies the default type of search to be performed.

Remarks

The **SearchType** property specifies the default type of query to be performed by the remote server using the **Search** method. If you wish to perform a more complex query using the syntax outlined in RFC 954, specify a search type of **searchAny** and then provide the search string value that you want to submit.

See Also

WhoisClient Class | SocketTools Namespace

WhoisClient.Status Property

Gets a value which specifies the current status of the client.

[Visual Basic]
```
Public ReadOnly Property Status As WhoisStatus
```

[C#]
```
public WhoisClient.WhoisStatus Status {get;}
```

Property Value

A WhoisStatus enumeration value which specifies the current client status.

Remarks

The **Status** property returns the current status of the client. This property can be used to check on blocking connections to determine if the client is interacting with the remote host before taking some action.

See Also

WhoisClient Class | SocketTools Namespace

WhoisClient.ThreadModel Property

Gets and sets a value which specifies the threading model for the class instance.

[Visual Basic]
```
Public Property ThreadModel As ThreadingModel
```

[C#]
```
public WhoisClient.ThreadingModel ThreadModel {get; set;}
```

Property Value

Returns one or more ThreadingModel enumeration value which specifies the threading model for the client. The default value for this property is **modelSingleThread**.

Remarks

The **ThreadModel** property specifies the threading model that is used by the class instance when a connection is established. The default value for this property is **modelSingleThread**, which specifies that only the thread that established the connection should be permitted to invoke methods. It is important to note that this threading model does not limit the application to a single thread of execution. When a session is established using the **Connect** method, that session is attached to the thread that created it. From that point on, until the session is terminated, only the owner may invoke methods in that instance of the class. The ownership of the class instance may be transferred from one thread to another using the **AttachThread** method.

Setting this property to **modelFreeThread** disables certain internal safety checks that are performed by the class and may result in unexpected behavior unless you ensure that access to the class instance is synchronized across multiple threads. The application must ensure that no two threads will attempt to invoke a blocking method at the same time. In other words, if one thread invokes a method, the application must ensure that another thread will not attempt to invoke any other method at the same time using the same instance of the class.

Changing the value of this property will not affect an active client session. The threading model must be specified prior to invoking the **Connect** method.

See Also

WhoisClient Class | SocketTools Namespace | AttachThread Method | ThreadingModel Enumeration | ThreadModel Attribute

WhoisClient.ThrowError Property

Gets and sets a value which specifies if method calls should throw exceptions when an error occurs.

[Visual Basic]

```
Public Property ThrowError As Boolean
```

[C#]

```
public bool ThrowError {get; set;}
```

Property Value

Returns **true** if method calls will generate exceptions when an error occurs; otherwise returns **false**. The default value is **false**.

Remarks

Error handling for when calling class methods can be done in either of two different styles, according to the value of this property.

If the **ThrowError** property is set to **false**, the application should check the return value of any method that is used, and report errors based upon the documented value of the return code. It is the responsibility of the application to interpret the error code, if it is desired to explain the error in addition to reporting it. This is the default behavior.

If the **ThrowError** property is set to **true**, then exceptions will be generated whenever a method call fails. The program must be written to catch these exceptions and take the appropriate action when an error occurs. Failure to handle an exception will cause the program to terminate abnormally.

Note that if an error occurs while a property is being read or modified, an exception will be raised regardless of the value of the **ThrowError** property.

WhoisClient Class | SocketTools Namespace

WhoisClient.Timeout Property

Gets and sets a value which specifies a timeout period in seconds.

[Visual Basic]

```
Public Property Timeout As Integer
```

[C#]

```
public int Timeout {get; set;}
```

Property Value

An integer value which specifies a timeout period in seconds.

Remarks

Setting the **Timeout** property specifies the number of seconds until a blocking operation fails and returns an error.

The timeout period is only used when the client is in blocking mode. Although this property can be changed when the client is in non-blocking mode, the value will be ignored until the client is returned to blocking mode.

For most applications it is recommended the timeout period be set between 10 and 20 seconds.

WhoisClient Class | SocketTools Namespace

WhoisClient.Trace Property

Gets and sets a value which indicates if network function logging is enabled.

[Visual Basic]

```
Public Property Trace As Boolean
```

[C#]

```
public bool Trace {get; set;}
```

Property Value

Returns **true** if network function tracing is enabled; otherwise returns **false**. The default value is **false**.

Remarks

The **Trace** property is used to enable (or disable) the tracing of network function calls. When enabled, each function call is logged to a file, including the function parameters, return value and error code if applicable. This facility can be enabled and disabled at run time, and the trace log file can be specified by setting the **TraceFile** property. All function calls that are being logged are appended to the trace file, if it exists. If no trace file exists when tracing is enabled, the trace file is created.

The tracing facility is available in all of the SocketTools networking classes and is enabled or disabled for an entire process. This means that once trace logging is enabled for a given component, all of the function calls made by the process using any of the SocketTools classes will be logged. For example, if you have an application using both the File Transfer Protocol and Post Office Protocol classes, and you set the **Trace** property to **true**, function calls made by both classes will be logged. Additionally, enabling a trace is cumulative, and tracing is not stopped until it is disabled for all classes used by the process.

If trace logging is not enabled, there is no negative impact on performance or throughput. Once enabled, application performance can degrade, especially in those situations in which multiple processes are being traced or the logfile is fairly large. Since logfiles can grow very quickly, even with modest applications, it is recommended that you delete the file when it is no longer needed.

When redistributing your application, make sure that you include the **SocketTools10.TraceLog.dll** module with your installation. If this library is not present, then no trace output will be generated and the value of the **Trace** property will be ignored. Only those function calls made by the SocketTools networking classes will be logged. Calls made directly to the Windows Sockets API, or calls made by other classes, will not be logged.

WhoisClient Class | SocketTools Namespace

WhoisClient.TraceFile Property

Gets and sets a value which specifies the name of the logfile.

[Visual Basic]

```
Public Property TraceFile As String
```

[C#]

```
public string TraceFile {get; set;}
```

Property Value

A string which specifies the name of the file.

Remarks

The **TraceFile** property is used to specify the name of the trace file that is created when network function tracing is enabled. If this property is set to an empty string (the default value), then a file named **SocketTools.log** is created in the system's temporary directory. If no temporary directory exists, then the file is created in the current working directory.

If the file exists, the trace output is appended to the file, otherwise the file is created. Since network function tracing is enabled per-process, the trace file is shared by all instances of the class being used. If multiple class instances have tracing enabled, the **TraceFile** property should be set to the same value for each instance. Since trace files can grow very quickly, even with modest applications, it is recommended that you delete the file when it is no longer needed.

The trace file has the following format:

```
 MyApp INF: WSAAsyncSelect(46, 0xcc4, 0x7e9, 0x27) returned 0 MyApp WRN:
connect(46, 192.0.0.1:1234, 16) returned -1 [10035] MyApp ERR: accept(46,
NULL, 0x0) returned -1 [10038]
```

The first column contains the name of the process that is being traced. The second column identifies if the trace record is reporting information, a warning, or an error. What follows is the name of the function being called, the arguments passed to the function and the function's return value. If a warning or error is reported, the error code is appended to the record (the value is placed inside brackets).

If parameters are passed as integer values, they are recorded in decimal. If the parameter or return value is a pointer (a memory address), it is recorded as a hexadecimal value preceded with "0x". A special type of pointer, called a null pointer, is recorded as NULL. Those functions which expect socket addresses are displayed in the following format:

```
aa.bb.cc.dd:nnnn
```

The first four numbers separated by periods represent the IP address, and the number following the colon represents the port number in host byte order. Note that in the second line of the above example, the control is attempting to connect to a system with the IP address 192.0.0.1 on port 1234.

Note that if the specified file cannot be created, or the user does not have permission to modify an existing file, the error is silently ignored and no trace output will be generated.

See Also

WhoisClient Class | SocketTools Namespace

WhoisClient.TraceFlags Property

Gets and sets a value which specifies the client function tracing flags.

[Visual Basic]
```
Public Property TraceFlags As TraceOptions
```

[C#]
```
public WhoisClient.TraceOptions TraceFlags {get; set;}
```

Property Value

A TraceOptions enumeration which specifies the amount of detail written to the trace logfile.

Remarks

The **TraceFlags** property is used to specify the type of information written to the trace file when network function tracing is enabled.

Because network function tracing is enabled per-process, the trace flags are shared by all instances of the class being used. If multiple class instances have tracing enabled, the **TraceFlags** property should be set to the same value for each instance. Changing the trace flags for any one instance of the class will affect the logging performed for all SocketTools classes used by the application.

Warnings are generated when a non-fatal error is returned by a network function. For example, if data is being written and the error **errorOperationWouldBlock** occurs, a warning is generated because the application simply needs to attempt to write the data at a later time.

See Also

WhoisClient Class | SocketTools Namespace

WhoisClient.Version Property

Gets a value which returns the current version of the WhoisClient class library.

[Visual Basic]
```
Public ReadOnly Property Version As String
```

[C#]
```
public string Version {get;}
```

Property Value

A string which specifies the version of the class library.

Remarks

The **Version** property returns a string which identifies the current version and build of the WhoisClient class library. This value can be used by an application for validation and debugging purposes.

WhoisClient Class | SocketTools Namespace

WhoisClient Methods

The methods of the **WhoisClient** class are listed below. For a complete list of **WhoisClient** class members, see the WhoisClient Members topic.

Public Instance Methods

AttachThread	Attach an instance of the class to the current thread
Cancel	Cancel the current blocking client operation.
Connect	Overloaded. Establish a connection with a remote host.
Disconnect	Terminate the connection with a remote host.
Dispose	Overloaded. Releases all resources used by WhoisClient.
Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from Object)	Gets the Type of the current instance.
Initialize	Overloaded. Initialize an instance of the WhoisClient class.
Read	Overloaded. Read data from the server and store it in a byte array.
Reset	Reset the internal state of the object, resetting all properties to their default values.
Search	Overloaded. Search for the specified record using the specified keyword and search type.
ToString (inherited from Object)	Returns a String that represents the current Object.
Uninitialize	Uninitialize the class library and release any resources allocated for the current thread.

Protected Instance Methods

Dispose	Overloaded. Releases the unmanaged resources allocated by the WhoisClient class and optionally releases the managed resources.
Finalize	Destroys an instance of the class, releasing the resources allocated for the session and unloading the networking library.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

WhoisClient Class | SocketTools Namespace

WhoisClient.AttachThread Method

Attach an instance of the class to the current thread

[Visual Basic]
```
Public Function AttachThread() As Boolean
```

[C#]
```
public bool AttachThread();
```

Return Value

A boolean value which specifies if the client could be attached to the current thread. If this method returns **false**, the client could not be attached to the thread and the application should check the value of the LastError property to determine the cause of the failure.

Remarks

When an instance of the class is created it is associated with the current thread that created it. Normally, if another thread attempts to perform an operation using that instance, an error is returned. This is used to ensure that other threads cannot interfere with an operation being performed by the owner thread. In some cases, it may be desirable for one thread in an application to create an instance of the class, establish a connection and then pass that instance to another worker thread. The **AttachThread** method can be used to change the ownership of the class instance to the new worker thread.

This method should be called by the new thread immediately after it has been created, and if the new thread does not release the handle itself, the ownership of the handle should be restored by the original thread. Under no circumstances should **AttachThread** be used to forcibly destroy an instance of a class allocated by another thread while a blocking operation is in progress. To cancel a blocking operation, use the **Cancel** method and then delete the class instance after the blocking function exits and control is returned to the current thread.

See Also

WhoisClient Class | SocketTools Namespace

WhoisClient.Cancel Method

Cancel the current blocking client operation.

[Visual Basic]

```
Public Sub Cancel()
```

[C#]

```
public void Cancel();
```

Remarks

When the **Cancel** method is called, the blocking client operation will not immediately fail. An internal flag is set which causes the blocking operation to exit with an error. This means that the application cannot cancel an operation and immediately perform some other blocking function. Instead it must allow the calling stack to unwind, returning back to the blocking operation before making any further function calls.

WhoisClient.Connect Method

Establish a connection with a remote host.

Overload List

Establish a connection with a remote host.

public bool Connect();

Establish a connection with a remote host.

public bool Connect(string);

Establish a connection with a remote host.

public bool Connect(string,int);

Establish a connection with a remote host.

public bool Connect(string,int,int);

Establish a connection with a remote host.

public bool Connect(string,int,int,WhoisOptions);

See Also

WhoisClient Class | SocketTools Namespace

WhoisClient.Connect Method ()

Establish a connection with a remote host.

[Visual Basic]

```
Overloads Public Function Connect() As Boolean
```

[C#]

```
public bool Connect();
```

Return Value

A boolean value which specifies if the connection has been established. If the client is in blocking mode, a return value of **true** indicates that the connection has completed and the application may send and receive data from the remote host. If the client is in non-blocking mode, a return value of **true** indicates that the client has successfully created a socket and the connection is in progress.

When a non-blocking connection has completed, the OnConnect event will be fired. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

Remarks

This method establishes a connection using assigned property values.

The value of the **HostName** or **HostAddress** property will be used to determine the host name or address to connect to.

The value of the **RemotePort** property will be used to determine the port number to connect to.

The value of the **Timeout** property will be used to specify the timeout period.

The value of the **Options** property will be used to specify the default options for the connection.

See Also

WhoisClient Class | SocketTools Namespace | WhoisClient.Connect Overload List

WhoisClient.Connect Method (String)

Establish a connection with a remote host.

[Visual Basic]

```
Overloads Public Function Connect( _
   ByVal hostName As String _
) As Boolean
```

[C#]

```
public bool Connect(
   string hostName
);
```

Parameters

hostName

A string which specifies the remote host to establish a connection with. This may specify a host name or an Internet address in dot-notation.

Return Value

A boolean value which specifies if the connection has been established. If the client is in blocking mode, a return value of **true** indicates that the connection has completed and the application may send and receive data from the remote host. If the client is in non-blocking mode, a return value of **true** indicates that the client has successfully created a socket and the connection is in progress.

When a non-blocking connection has completed, the OnConnect event will be fired. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

WhoisClient Class | SocketTools Namespace | WhoisClient.Connect Overload List

WhoisClient.Connect Method (String, Int32)

Establish a connection with a remote host.

[Visual Basic]

```
Overloads Public Function Connect( _
   ByVal hostName As String, _
   ByVal hostPort As Integer _
) As Boolean
```

[C#]

```
public bool Connect(
   string hostName,
   int hostPort
);
```

Parameters

hostName

A string which specifies the remote host to establish a connection with. This may specify a host name or an Internet address in dot-notation.

hostPort

An integer which specifies the port number for the connection. This value must be greater than zero and the maximum valid port number is 65535.

Return Value

A boolean value which specifies if the connection has been established. If the client is in blocking mode, a return value of **true** indicates that the connection has completed and the application may send and receive data from the remote host. If the client is in non-blocking mode, a return value of **true** indicates that the client has successfully created a socket and the connection is in progress.

When a non-blocking connection has completed, the OnConnect event will be fired. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

See Also

WhoisClient Class | SocketTools Namespace | WhoisClient.Connect Overload List

WhoisClient.Connect Method (String, Int32, Int32)

Establish a connection with a remote host.

[Visual Basic]

```
Overloads Public Function Connect( _
   ByVal hostName As String, _
   ByVal hostPort As Integer, _
   ByVal timeout As Integer _
) As Boolean
```

[C#]

```
public bool Connect(
   string hostName,
   int hostPort,
   int timeout
);
```

Parameters

hostName

A string which specifies the remote host to establish a connection with. This may specify a host name or an Internet address in dot-notation.

hostPort

An integer which specifies the port number for the connection. This value must be greater than zero and the maximum valid port number is 65535.

timeout

An integer value that specifies the number of seconds that the method will wait for the connection to complete before failing the operation and returning to the caller. This value is only meaningful for blocking connections.

Return Value

A boolean value which specifies if the connection has been established. If the client is in blocking mode, a return value of **true** indicates that the connection has completed and the application may send and receive data from the remote host. If the client is in non-blocking mode, a return value of **true** indicates that the client has successfully created a socket and the connection is in progress.

When a non-blocking connection has completed, the OnConnect event will be fired. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

See Also

WhoisClient Class | SocketTools Namespace | WhoisClient.Connect Overload List

WhoisClient.Connect Method (String, Int32, Int32, WhoisOptions)

Establish a connection with a remote host.

[Visual Basic]

```
Overloads Public Function Connect( _
   ByVal hostName As String, _
   ByVal hostPort As Integer, _
   ByVal timeout As Integer, _
   ByVal options As WhoisOptions _
) As Boolean
```

[C#]

```
public bool Connect(
   string hostName,
   int hostPort,
   int timeout,
   WhoisOptions options
);
```

Parameters

hostName
A string which specifies the remote host to establish a connection with. This may specify a host name or an Internet address in dot-notation.

hostPort
An integer which specifies the port number for the connection. This value must be greater than zero and the maximum valid port number is 65535.

timeout
An integer value that specifies the number of seconds that the method will wait for the connection to complete before failing the operation and returning to the caller. This value is only meaningful for blocking connections.

options
One or more of the WhoisOptions enumeration flags.

Return Value

A boolean value which specifies if the connection has been established. If the client is in blocking mode, a return value of **true** indicates that the connection has completed and the application may send and receive data from the remote host. If the client is in non-blocking mode, a return value of **true** indicates that the client has successfully created a socket and the connection is in progress.

When a non-blocking connection has completed, the OnConnect event will be fired. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

See Also

WhoisClient Class | SocketTools Namespace | WhoisClient.Connect Overload List

WhoisClient.Disconnect Method

Terminate the connection with a remote host.

[Visual Basic]

```
Public Sub Disconnect()
```

[C#]

```
public void Disconnect();
```

Remarks

The **Disconnect** method terminates the connection with the remote host and releases the client handle allocated by the class. Note that the socket is not immediately released when the connection is terminated and will enter a wait state for two minutes. After the time wait period has elapsed, the client will be released by the operating system. This is a normal safety mechanism to handle any packets that may arrive after the connection has been closed.

See Also

WhoisClient Class | SocketTools Namespace

WhoisClient.Dispose Method

Releases all resources used by WhoisClient.

Overload List

Releases all resources used by WhoisClient.

public void Dispose();

Releases the unmanaged resources allocated by the WhoisClient class and optionally releases the managed resources.

protected virtual void Dispose(bool);

See Also

WhoisClient Class | SocketTools Namespace

WhoisClient.Dispose Method ()

Releases all resources used by WhoisClient.

[Visual Basic]

```
NotOverridable Overloads Public Sub Dispose() _
    Implements IDisposable.Dispose
```

[C#]

```
public void Dispose();
```

Implements

IDisposable.Dispose

Remarks

The **Dispose** method terminates any active connection and explicitly releases the resources allocated for this instance of the class. In some cases, better performance can be achieved if the programmer explicitly releases resources when they are no longer being used. The **Dispose** method provides explicit control over these resources.

Unlike the **Uninitialize** method, once the **Dispose** method has been called, that instance of the class cannot be re-initialized and you should not attempt to access class properties or invoke any methods. Note that this method can be called even if other references to the object are active.

See Also

WhoisClient Class | SocketTools Namespace | WhoisClient.Dispose Overload List

WhoisClient.Dispose Method (Boolean)

Releases the unmanaged resources allocated by the WhoisClient class and optionally releases the managed resources.

[Visual Basic]

```
Overridable Overloads Protected Sub Dispose( _
   ByVal disposing As Boolean _
)
```

[C#]

```
protected virtual void Dispose(
   bool disposing
);
```

Parameters

disposing

A boolean value which should be specified as **true** to release both managed and unmanaged resources; **false** to release only unmanaged resources.

Remarks

The **Dispose** method terminates any active connection and explicitly releases the resources allocated for this instance of the class. In some cases, better performance can be achieved if the programmer explicitly releases resources when they are no longer being used. The **Dispose** method provides explicit control over these resources.

Unlike the **Uninitialize** method, once the **Dispose** method has been called, that instance of the class cannot be re-initialized and you should not attempt to access class properties or invoke any methods. Note that this method can be called even if other references to the object are active.

You should call **Dispose** in your derived class when you are finished using the derived class. The **Dispose** method leaves the derived class in an unusable state. After calling **Dispose**, you must release all references to the derived class and the **WhoisClient** class so the memory they were occupying can be reclaimed by garbage collection.

See Also

WhoisClient Class | SocketTools Namespace | WhoisClient.Dispose Overload List

WhoisClient.Finalize Method

Destroys an instance of the class, releasing the resources allocated for the session and unloading the networking library.

[Visual Basic]

```
Overrides Protected Sub Finalize()
```

[C#]

```
protected override void Finalize();
```

See Also

WhoisClient Class | SocketTools Namespace

WhoisClient.Initialize Method

Initialize an instance of the WhoisClient class.

Overload List

Initialize an instance of the WhoisClient class.

public bool Initialize();

Initialize an instance of the WhoisClient class.

public bool Initialize(string);

See Also

WhoisClient Class | SocketTools Namespace | Uninitialize Method

WhoisClient.Initialize Method ()

Initialize an instance of the WhoisClient class.

[Visual Basic]

```
Overloads Public Function Initialize() As Boolean
```

[C#]

```
public bool Initialize();
```

Return Value

A boolean value which specifies if the class was initialized successfully.

Remarks

The Initialize method can be used to explicitly initialize an instance of the WhoisClient class, loading the networking library and allocating resources for the current thread. Typically it is not necessary to explicitly call this method because the instance of the class is initialized by the class constructor. However, if the **Uninitialize** method is called, the class must be re-initialized before any other methods are called.

See Also

WhoisClient Class | SocketTools Namespace | WhoisClient.Initialize Overload List | Uninitialize Method

WhoisClient.Initialize Method (String)

Initialize an instance of the WhoisClient class.

[Visual Basic]

```
Overloads Public Function Initialize( _
   ByVal licenseKey As String _
) As Boolean
```

[C#]

```
public bool Initialize(
   string licenseKey
);
```

Return Value

A boolean value which specifies if the class was initialized successfully.

Remarks

The Initialize method can be used to explicitly initialize an instance of the WhoisClient class, loading the networking library and allocating resources for the current thread. Typically an application would define the license key as a custom attribute, however this method can be used to initialize the class directly.

The runtime license key for your copy of SocketTools can be generated using the License Manager utility that is included with the product. Note that if you have installed an evaluation license, you will not have a runtime license key and cannot redistribute any applications which use the WhoisClient class.

Example

The following example shows how to use the Initialize method to initialize an instance of the class. This example assumes that the license key string has been defined in code.

```
SocketTools.WhoisClient whoisClient = new SocketTools.WhoisClient();

if (whoisClient.Initialize(strLicenseKey) == false)
{
    MessageBox.Show(whoisClient.LastErrorString, "Error",
                    MessageBoxButtons.OK, MessageBoxIcon.Exclamation);
    return;
}
```

```
Dim whoisClient As New SocketTools.WhoisClient

If whoisClient.Initialize(strLicenseKey) = False Then
    MsgBox(whoisClient.LastErrorString, vbIconExclamation)
    Exit Sub
End If
```

WhoisClient.Read Method

Read data from the server and store it in a byte array.

Overload List

Read data from the server and store it in a byte array.

public int Read(byte[]);

Read data from the server and store it in a byte array.

public int Read(byte[],int);

Read data from the server and store it in a string.

public int Read(ref string);

Read data from the server and store it in a string.

public int Read(ref string,int);

See Also

WhoisClient Class | SocketTools Namespace

WhoisClient.Read Method (Byte[])

Read data from the server and store it in a byte array.

[Visual Basic]

```
Overloads Public Function Read( _
   ByVal buffer As Byte() _
) As Integer
```

[C#]

```
public int Read(
   byte[] buffer
);
```

Parameters

buffer

A byte array that the data will be stored in.

Return Value

An integer value which specifies the number of bytes actually read from the server. A return value of zero specifies that the remote host has closed the connection and there is no more data available to be read. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Read** method returns data that has been read from the server, up to the size of the byte array passed to the method. If no data is available to be read, an error will be generated if the client is in non-blocking mode. If the client is in blocking mode, the program will stop until data is received from the server or the connection is closed.

See Also

WhoisClient Class | SocketTools Namespace | WhoisClient.Read Overload List

WhoisClient.Read Method (Byte[], Int32)

Read data from the server and store it in a byte array.

```
[Visual Basic]
Overloads Public Function Read( _
   ByVal buffer As Byte(), _
   ByVal length As Integer _
) As Integer
```

```
[C#]
public int Read(
   byte[] buffer,
   int length
);
```

Parameters

buffer

A byte array that the data will be stored in.

length

An integer value which specifies the maximum number of bytes of data to read. This value cannot be larger than the size of the buffer specified by the caller.

Return Value

An integer value which specifies the number of bytes actually read from the server. A return value of zero specifies that the remote host has closed the connection and there is no more data available to be read. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Read** method returns data that has been read from the server, up to the number of bytes specified. If no data is available to be read, an error will be generated if the client is in non-blocking mode. If the client is in blocking mode, the program will stop until data is received from the server or the connection is closed.

See Also

WhoisClient Class | SocketTools Namespace | WhoisClient.Read Overload List

WhoisClient.Read Method (String)

Read data from the server and store it in a string.

[Visual Basic]

```
Overloads Public Function Read( _
   ByRef buffer As String _
) As Integer
```

[C#]

```
public int Read(
   ref string buffer
);
```

Parameters

buffer
A string that will contain the data read from the client.

Return Value

An integer value which specifies the number of bytes actually read from the server. A return value of zero specifies that the remote host has closed the connection and there is no more data available to be read. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Read** method returns data that has been read from the server, up to a maximum of 4096 bytes. If no data is available to be read, an error will be generated if the client is in non-blocking mode. If the client is in blocking mode, the program will stop until data is received from the server or the connection is closed.

This method should only be used if the remote host is sending data that consists of printable characters. Binary data should be read using the method that accepts a byte array as the buffer parameter.

See Also

WhoisClient Class | SocketTools Namespace | WhoisClient.Read Overload List

WhoisClient.Read Method (String, Int32)

Read data from the server and store it in a string.

```
[Visual Basic]
Overloads Public Function Read( _
   ByRef buffer As String, _
   ByVal length As Integer _
) As Integer
```

```
[C#]
public int Read(
   ref string buffer,
   int length
);
```

Parameters

buffer
A string that will contain the data read from the client.

length
An integer value which specifies the maximum number of bytes of data to read.

Return Value

An integer value which specifies the number of bytes actually read from the server. A return value of zero specifies that the remote host has closed the connection and there is no more data available to be read. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Read** method returns data that has been read from the server, up to the number of bytes specified. If no data is available to be read, an error will be generated if the client is in non-blocking mode. If the client is in blocking mode, the program will stop until data is received from the server or the connection is closed.

This method should only be used if the remote host is sending data that consists of printable characters. Binary data should be read using the method that accepts a byte array as the buffer parameter.

See Also

WhoisClient Class | SocketTools Namespace | WhoisClient.Read Overload List

WhoisClient.Reset Method

Reset the internal state of the object, resetting all properties to their default values.

[Visual Basic]

```
Public Sub Reset()
```

[C#]

```
public void Reset();
```

Remarks

The **Reset** method returns the object to its default state. If a socket has been allocated, it will be released and any active connections will be terminated. All properties will be reset to their default values.

See Also

WhoisClient Class | SocketTools Namespace

WhoisClient.Search Method

Search for the specified record using the default keyword and search type.

Overload List

Search for the specified record using the default keyword and search type.

public bool Search();

Search for the specified record using the default search type.

public bool Search(string);

Search for the specified record using the specified keyword and search type.

public bool Search(string,WhoisSearchType);

WhoisClient Class | SocketTools Namespace

WhoisClient.Search Method ()

Search for the specified record using the default keyword and search type.

[Visual Basic]

```
Overloads Public Function Search() As Boolean
```

[C#]

```
public bool Search();
```

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **Search** method submits the specified keyword and type of search to the server. The data returned by the server can be read using the **Read** method. Note that the text returned by a UNIX based server may only contain linefeeds at the end of each line of text, rather than the standard carriage return/linefeed used on Windows systems.

The value of the **Keyword** property will specify the search keyword. The value of the **SearchType** property is used to specify the type of search that is performed. By default, all record types will be searched.

WhoisClient Class | SocketTools Namespace | WhoisClient.Search Overload List

WhoisClient.Search Method (String)

Search for the specified record using the default search type.

[Visual Basic]

```
Overloads Public Function Search( _
   ByVal keyword As String _
) As Boolean
```

[C#]

```
public bool Search(
   string keyword
);
```

Parameters

keyword

A string which specifies the keyword to search for. Typically this is the name of a domain, user handle or an email address.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **Search** method submits the specified keyword and type of search to the server. The data returned by the server can be read using the **Read** method. Note that the text returned by a UNIX based server may only contain linefeeds at the end of each line of text, rather than the standard carriage return/linefeed used on Windows systems.

The value of the **SearchType** property is used to specify the type of search that is performed. By default, all record types will be searched.

WhoisClient Class | SocketTools Namespace | WhoisClient.Search Overload List

WhoisClient.Search Method (String, WhoisSearchType)

Search for the specified record using the specified keyword and search type.

[Visual Basic]

```
Overloads Public Function Search( _
   ByVal keyword As String, _
   ByVal search As WhoisSearchType _
) As Boolean
```

[C#]

```
public bool Search(
   string keyword,
   WhoisSearchType search
);
```

Parameters

keyword
: A string which specifies the keyword to search for. Typically this is the name of a domain, user handle or an email address.

search
: A WhoisSearchType enumeration which specifies the type of search to be performed.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **Search** method submits the specified keyword and type of search to the server. The data returned by the server can be read using the **Read** method. Note that the text returned by a UNIX based server may only contain linefeeds at the end of each line of text, rather than the standard carriage return/linefeed used on Windows systems.

WhoisClient Class | SocketTools Namespace | WhoisClient.Search Overload List

WhoisClient.Uninitialize Method

Uninitialize the class library and release any resources allocated for the current thread.

[Visual Basic]

```
Public Sub Uninitialize()
```

[C#]

```
public void Uninitialize();
```

Remarks

The **Uninitialize** method terminates any active connection, releases resources allocated for the current thread and unloads the networking library. After this method has been called, no further client operations may be performed until the class instance has been re-initialized.

If the **Initialize** method is explicitly called by the application, it should be matched by a call to the **Uninitialize** method when that instance of the class is no longer needed.

See Also

WhoisClient Class | SocketTools Namespace | Initialize Method

WhoisClient Events

The events of the **WhoisClient** class are listed below. For a complete list of **WhoisClient** class members, see the WhoisClient Members topic.

Public Instance Events

⚡ OnCancel	Occurs when a blocking client operation is canceled.
⚡ OnConnect	Occurs when a connection is established with the remote host.
⚡ OnDisconnect	Occurs when the remote host disconnects from the local system.
⚡ OnError	Occurs when an client operation fails.
⚡ OnRead	Occurs when data is available to be read from the client.
⚡ OnTimeout	Occurs when a blocking operation fails to complete before the timeout period elapses.
⚡ OnWrite	Occurs when data can be written to the client.

See Also

WhoisClient Class | SocketTools Namespace

WhoisClient.OnCancel Event

Occurs when a blocking client operation is canceled.

[Visual Basic]

```
Public Event OnCancel As EventHandler
```

[C#]

```
public event EventHandler OnCancel;
```

Remarks

The **OnCancel** event is generated when a blocking client operation, such as sending or receiving data, is canceled with the **Cancel** method. To assist in determining which operation was canceled, check the value of the **Status** property.

See Also

WhoisClient Class | SocketTools Namespace

WhoisClient.OnConnect Event

Occurs when a connection is established with the remote host.

[Visual Basic]

```
Public Event OnConnect As EventHandler
```

[C#]

```
public event EventHandler OnConnect;
```

Remarks

The **OnConnect** event occurs when a connection is made with a remote host as a result of a **Connect** method call. When the **Connect** method is called and the **Blocking** property is set to **false**, a socket is created but the connection is not actually established until after this event occurs. Between the time connection process is started and this event fires, no operation may be performed on the client other than calling the **Disconnect** method.

This event is only generated if the client is in non-blocking mode.

See Also

WhoisClient Class | SocketTools Namespace

WhoisClient.OnDisconnect Event

Occurs when the remote host disconnects from the local system.

[Visual Basic]

```
Public Event OnDisconnect As EventHandler
```

[C#]

```
public event EventHandler OnDisconnect;
```

Remarks

The **OnDisconnect** event occurs when the remote host closes its connection, terminating the client session with the application. Because there may still be data in the client receive buffers, you should continue to read data from the client until the **Read** method returns a value of 0. Once all of the data has been read, you should call the **Disconnect** method to close the local socket and release the resources allocated for the client.

This event is only generated if the client is in non-blocking mode.

See Also

WhoisClient Class | SocketTools Namespace

WhoisClient.OnError Event

Occurs when an client operation fails.

```
[Visual Basic]
Public Event OnError As OnErrorEventHandler
```

```
[C#]
public event OnErrorEventHandler OnError;
```

Event Data

The event handler receives an argument of type WhoisClient.ErrorEventArgs containing data related to this event. The following **WhoisClient.ErrorEventArgs** properties provide information specific to this event.

Property	Description
Description	Gets a value which describes the last error that has occurred.
Error	Gets a value which specifies the last error that has occurred.

Remarks

The **OnError** event occurs when a client operation fails.

See Also

WhoisClient Class | SocketTools Namespace

WhoisClient.ErrorEventArgs Class

Provides data for the OnError event.

For a list of all members of this type, see WhoisClient.ErrorEventArgs Members.

System.Object
  System.EventArgs
    SocketTools.WhoisClient.ErrorEventArgs

[Visual Basic]

```
Public Class WhoisClient.ErrorEventArgs
    Inherits EventArgs
```

[C#]

```
public class WhoisClient.ErrorEventArgs : EventArgs
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

ErrorEventArgs specifies the numeric error code and a description of the error that has occurred.

An OnError event occurs when a method fails.

Requirements

Namespace: SocketTools

Assembly: SocketTools.WhoisClient (in SocketTools.WhoisClient.dll)

WhoisClient.ErrorEventArgs Members | SocketTools Namespace

WhoisClient.ErrorEventArgs Members

WhoisClient.ErrorEventArgs overview

Public Instance Constructors

WhoisClient.ErrorEventArgs Constructor	Initializes a new instance of the WhoisClient.ErrorEventArgs class.

Public Instance Properties

Description	Gets a value which describes the last error that has occurred.
Error	Gets a value which specifies the last error that has occurred.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString (inherited from Object)	Returns a String that represents the current Object.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

WhoisClient.ErrorEventArgs Class | SocketTools Namespace

WhoisClient.ErrorEventArgs Constructor

Initializes a new instance of the WhoisClient.ErrorEventArgs class.

[Visual Basic]

```
Public Sub New()
```

[C#]

```
public WhoisClient.ErrorEventArgs();
```

See Also

WhoisClient.ErrorEventArgs Class | SocketTools Namespace

WhoisClient.ErrorEventArgs Properties

The properties of the **WhoisClient.ErrorEventArgs** class are listed below. For a complete list of **WhoisClient.ErrorEventArgs** class members, see the WhoisClient.ErrorEventArgs Members topic.

Public Instance Properties

Description	Gets a value which describes the last error that has occurred.
Error	Gets a value which specifies the last error that has occurred.

See Also

WhoisClient.ErrorEventArgs Class | SocketTools Namespace

WhoisClient.ErrorEventArgs.Description Property

Gets a value which describes the last error that has occurred.

[Visual Basic]

```
Public ReadOnly Property Description As String
```

[C#]

```
public string Description {get;}
```

Property Value

A string which describes the last error that has occurred.

See Also

WhoisClient.ErrorEventArgs Class | SocketTools Namespace | Error Property

WhoisClient.ErrorEventArgs.Error Property

Gets a value which specifies the last error that has occurred.

[Visual Basic]

```
Public ReadOnly Property Error As ErrorCode
```

[C#]

```
public WhoisClient.ErrorCode Error {get;}
```

Property Value

ErrorCode enumeration which specifies the error.

See Also

WhoisClient.ErrorEventArgs Class | SocketTools Namespace | Description Property

WhoisClient.OnRead Event

Occurs when data is available to be read from the client.

[Visual Basic]
```
Public Event OnRead As EventHandler
```

[C#]
```
public event EventHandler OnRead;
```

Remarks

The **OnRead** event occurs when data is available to be read from the client. This event is level-triggered, which means that once this event fires, it will not occur again until some data has been read from the client. This design prevents an application from being flooded with event notifications. It is recommended that your application read all of the available data from the server and store it in a local buffer for processing. See the example below.

This event is only generated if the client is in non-blocking mode.

Example

```
Private Sub Socket_OnRead(ByVal sender As Object, ByVal e As System.EventArgs)
Handles Socket.OnRead
    Dim strBuffer As String
    Dim nRead As Integer

    Do
        ' Read up to m_nBufferSize bytes of data from the server
        nRead = Socket.Read(strBuffer, m_nBufferSize)

        If nRead > 0 Then
            ' Append the data to an internal buffer for processing
            m_dataBuffer = m_dataBuffer + strBuffer
        End If
    Loop Until nRead < 1

    ProcessData()
End Sub
```

See Also

WhoisClient Class | SocketTools Namespace

WhoisClient.OnTimeout Event

Occurs when a blocking operation fails to complete before the timeout period elapses.

[Visual Basic]

```
Public Event OnTimeout As EventHandler
```

[C#]

```
public event EventHandler OnTimeout;
```

Remarks

The **OnTimeout** event occurs when a blocking operation, such as sending or receiving data on the client, fails to complete before the specified timeout period elapses. The timeout period for a blocking operation can be adjusted by setting the **Timeout** property.

This event is only generated if the client is in blocking mode.

See Also

WhoisClient Class | SocketTools Namespace

WhoisClient.OnWrite Event

Occurs when data can be written to the client.

[Visual Basic]
```
Public Event OnWrite As EventHandler
```

[C#]
```
public event EventHandler OnWrite;
```

Remarks

The **OnWrite** event occurs when the application can write data to the client. This event will typically occur when a connection is first established with the remote host, and after the **Write** method has failed because there was insufficient memory available in the client send buffers. In the second case, when some of the buffered data has been successfully sent to the remote host and there is space available in the send buffers, this event is used to signal the application that it may attempt to send more data.

This event is only generated if the client is in non-blocking mode.

See Also

WhoisClient Class | SocketTools Namespace

WhoisClient.ErrorCode Enumeration

Specifies the error codes returned by the WhoisClient class.

[Visual Basic]
```
Public Enum WhoisClient.ErrorCode
```

[C#]
```
public enum WhoisClient.ErrorCode
```

Remarks

The WhoisClient class uses the **ErrorCode** enumeration to specify what error has occurred when a method fails. The current error code may be determined by checking the value of the **LastError** property.

Note that the last error code is only meaningful if the previous operation has failed.

Members

Member Name	Description
errorNone	No error.
errorNotHandleOwner	Handle not owned by the current thread.
errorFileNotFound	The specified file or directory does not exist.
errorFileNotCreated	The specified file could not be created.
errorOperationCanceled	The blocking operation has been canceled.
errorInvalidFileType	The specified file is a block or character device, not a regular file.
errorInvalidDevice	The specified file type is invalid or not a regular file.
errorTooManyParameters	The maximum number of function parameters has been exceeded.
errorInvalidFileName	The specified file name contains invalid characters or is too long.
errorInvalidFileHandle	Invalid file handle passed to function.
errorFileReadFailed	Unable to read data from the specified file.
errorFileWriteFailed	Unable to write data to the specified file.
errorOutOfMemory	Out of memory.
errorAccessDenied	Access denied.
errorInvalidParameter	Invalid argument passed to function.
errorClipboardUnavailable	The system clipboard is currently unavailable.
errorClipboardEmpty	The system clipboard is empty or does not contain any text data.
errorFileEmpty	The specified file does not contain any data.
errorFileExists	The specified file already exists.

errorEndOfFile	End of file.
errorDeviceNotFound	The specified device could not be found.
errorDirectoryNotFound	The specified directory could not be found.
errorInvalidbuffer	Invalid memory address passed to function.
errorBufferTooSmall	The specified buffer is not large enough to contain the data.
errorNoHandles	No more handles are available to this process.
errorOperationWouldBlock	The specified operation would block the current thread.
errorOperationInProgress	A blocking operation is currently in progress.
errorAlreadyInProgress	The specified operation is already in progress.
errorInvalidHandle	Invalid handle passed to function.
errorInvalidAddress	Invalid network address specified.
errorInvalidSize	Datagram is too large to fit in specified buffer.
errorInvalidProtocol	Invalid network protocol specified.
errorProtocolNotAvailable	The specified network protocol is not available.
errorProtocolNotSupported	The specified protocol is not supported.
errorSocketNotSupported	The specified socket type is not supported.
errorInvalidOption	The specified option is invalid.
errorProtocolFamily	Specified protocol family is not supported.
errorProtocolAddress	The specified address is invalid for this protocol family.
errorAddressInUse	The specified address is in use by another process.
errorAddressUnavailable	The specified address cannot be assigned.
errorNetworkUnavailable	The networking subsystem is unavailable.
errorNetworkUnreachable	The specified network is unreachable.
errorNetworkReset	Network dropped connection on remote reset.
errorConnectionAborted	Connection was aborted due to timeout or other failure.
errorConnectionReset	Connection was reset by remote network.
errorOutOfBuffers	No buffer space is available.
errorAlreadyConnected	Connection already established with remote host.
errorNotConnected	No connection established with remote host.
errorConnectionShutdown	Unable to send or receive data after connection shutdown.
errorOperationTimeout	The specified operation has timed out.
errorConnectionRefused	The connection has been refused by the remote host.

errorHostUnavailable	The specified host is unavailable.
errorHostUnreachable	Remote host is unreachable.
errorTooManyProcesses	Too many processes are using the networking subsystem.
errorTooManyThreads	Too many threads have been created by the current process.
errorTooManySessions	Too many client sessions have been created by the current process.
errorInternalFailure	An unexpected internal error has occurred.
errorNetworkNotReady	Network subsystem is not ready for communication.
errorInvalidVersion	This version of the operating system is not supported.
errorNetworkNotInitialized	The networking subsystem has not been initialized.
errorRemoteShutdown	The remote host has initiated a graceful shutdown sequence.
errorInvalidHostName	The specified hostname is invalid or could not be resolved.
errorHostNameNotFound	The specified hostname could not be found.
errorHostNameRefused	Unable to resolve hostname, request refused.
errorHostNameNotResolved	Unable to resolve hostname, no address for specified host.
errorInvalidLicense	The license for this product is invalid.
errorProductNotLicensed	This product is not licensed to perform this operation.
errorNotImplemented	This function has not been implemented on this platform.
errorUnknownLocalhost	Unable to determine local host name.
errorInvalidHostAddress	Invalid host address specified.
errorInvalidServicePort	Invalid service port number specified.
errorInvalidServiceName	Invalid or unknown service name specified.
errorInvalidEventId	Invalid event identifier specified.
errorOperationNotBlocking	No blocking operation in progress on this socket.
errorSecurityNotInitialized	Unable to initialize security interface for this process.
errorSecurityContext	Unable to establish security context for this session.
errorSecurityCredentials	Unable to open certificate store or establish security credentials.
errorSecurityCertificate	Unable to validate the certificate chain for this

	session.
errorSecurityDecryption	Unable to decrypt data stream.
errorSecurityEncryption	Unable to encrypt data stream.
errorOperationNotSupported	The specified operation is not supported.
errorInvalidProtocolVersion	Invalid application protocol version specified.
errorNoServerResponse	No data returned from server.
errorInvalidServerResponse	Invalid data returned from server.
errorUnexpectedServerResponse	Unexpected response code returned from server.
errorServerTransactionFailed	Server transaction failed.
errorServiceUnavailable	The service is currently unavailable.
errorServiceNotReady	The service is not ready, try again later.
errorServerResyncFailed	Unable to resynchronize with server.
errorInvalidProxyType	Invalid proxy server type specified.
errorProxyRequired	Resource must be accessed through specified proxy.
errorInvalidProxyLogin	Unable to login to proxy server using specified credentials.
errorProxyResyncFailed	Unable to resynchronize with proxy server.
errorInvalidCommand	Invalid command specified.
errorInvalidCommandParameter	Invalid command parameter specified.
errorInvalidCommandSequence	Invalid command sequence specified.
errorCommandNotImplemented	Specified command not implemented on this server.
errorCommandNotAuthorized	Specified command not authorized for the current user.
errorCommandAborted	Specified command was aborted by the remote host.
errorOptionNotSupported	The specified option is not supported on this server.
errorRequestNotCompleted	The current client request has not been completed.
errorInvalidUserName	The specified username is invalid.
errorInvalidPassword	The specified password is invalid.
errorInvalidAccount	The specified account name is invalid.
errorAccountRequired	Account name has not been specified.
errorInvalidAuthenticationType	Invalid authentication protocol specified.
errorAuthenticationRequired	User authentication is required.
errorProxyAuthenticationRequired	Proxy authentication required.

errorAlreadyAuthenticated	User has already been authenticated.
errorAuthenticationFailed	Unable to authenticate the specified user.
errorNetworkAdapter	Unable to determine network adapter configuration.
errorInvalidRecordType	Invalid record type specified.
errorInvalidRecordName	Invalid record name specified.
errorInvalidRecordData	Invalid record data specified.
errorConnectionOpen	Data connection already established.
errorConnectionClosed	Server closed data connection.
errorConnectionPassive	Data connection is passive.
errorConnectionFailed	Unable to open data connection to server.
errorInvalidSecurityLevel	Data connection cannot be opened with this security setting.
errorCachedTLSRequired	Data connection requires cached TLS session.
errorDataReadOnly	Data connection is read-only.
errorDataWriteOnly	Data connection is write-only.
errorEndOfData	End of data.
errorRemoteFileUnavailable	Remote file is unavailable.
errorInsufficientStorage	Insufficient storage on server.
errorStorageallocation	File exceeded storage allocation on server.
errorDirectoryExists	The specified directory already exists.
errorDirectoryEmpty	No files returned by the server for the specified directory.
errorEndOfDirectory	End of directory listing.
errorUnknownDirectoryFormat	Unknown directory format.
errorInvalidResource	Invalid resource name specified.
errorResourceRedirected	The specified resource has been redirected.
errorResourceRestricted	Access to this resource has been restricted.
errorResourceNotModified	The specified resource has not been modified.
errorResourceNotFound	The specified resource cannot be found.
errorResourceConflict	Request could not be completed due to the current state of the resource.
errorResourceRemoved	The specified resource has been permanently removed from this server.
errorContentLengthRequired	Request must include the content length.
errorRequestPrecondition	Request could not be completed due to server precondition.
errorUnsupportedMediaType	Request specified an unsupported media type.

errorInvalidContentRange	Content range specified for this resource is invalid.
errorInvalidMessagePart	Message is not multipart or an invalid message part was specified.
errorInvalidMessageHeader	The specified message header is invalid or has not been defined.
errorInvalidMessageBoundary	The multipart message boundary has not been defined.
errorNoFileAttachment	The current message part does not contain a file attachment.
errorUnknownFileType	The specified file type could not be determined.
errorDataNotEncoded	The specified data block could not be encoded.
errorDataNotDecoded	The specified data block could not be decoded.
errorFileNotEncoded	The specified file could not be encoded.
errorFileNotDecoded	The specified file could not be decoded.
errorNoMessageText	No message text.
errorInvalidCharacterSet	Invalid character set specified.
errorInvalidEncodingType	Invalid encoding type specified.
errorInvalidMessageNumber	Invalid message number specified.
errorNoReturnAddress	No valid return address specified.
errorNoValidRecipients	No valid recipients specified.
errorInvalidRecipient	The specified recipient address is invalid.
errorRelayNotAuthorized	The specified domain is invalid or server will not relay messages.
errorMailboxUnavailable	Specified mailbox is currently unavailable.
errorMailboxReadOnly	The selected mailbox cannot be modified.
errorMailboxNotSelected	No mailbox has been selected.
errorInvalidMailbox	Specified mailbox is invalid.
errorInvalidDomain	The specified domain name is invalid or not recognized.
errorInvalidSender	The specified sender address is invalid or not recognized.
errorMessageNotDelivered	Message not delivered to any of the specified recipients.
errorEndOfMessageData	No more message data available to be read
errorInvalidmessageSize	The specified message size is invalid.
errorMessageNotCreated	The message could not be created in the specified mailbox.
errorNoMoreMailboxes	No more mailboxes exist on this server.

errorInvalidEmulationType	The specified terminal emulation type is invalid.
errorInvalidFontHandle	The specified font handle is invalid.
errorInvalidFontName	The specified font name is invalid or unavailable.
errorInvalidPacketSize	The specified packet size is invalid.
errorInvalidPacketData	The specified packet data is invalid.
errorInvalidPacketId	The unique packet identifier is invalid.
errorPacketTTLExpired	The specified packet time-to-live period has expired.
errorInvalidNewsGroup	Invalid newsgroup specified.
errorNoNewsgroupSelected	No newsgroup selected.
errorEmptyNewsgroup	No articles in specified newsgroup.
errorInvalidArticle	Invalid article number specified.
errorNoArticleSelected	No article selected in the current newsgroup.
errorFirstArticle	First article in current newsgroup.
errorLastArticle	Last article in current newsgroup.
errorArticleExists	Unable to transfer article, article already exists.
errorArticleRejected	Unable to transfer article, article rejected.
errorArticleTransferFailed	Article transfer failed.
errorArticlePostingDenied	Posting is not permitted on this server.
errorArticlePostingFailed	Unable to post article on this server.
errorInvalidDateFormat	The specified date format is not recognized.
errorFeatureNotSupported	The specified feature is not supported on this server.
errorInvalidFormHandle	The specified form handle is invalid or a form has not been created.
errorInvalidFormAction	The specified form action is invalid or has not been specified.
errorInvalidFormMethod	The specified form method is invalid or not supported.
errorInvalidFormType	The specified form type is invalid or not supported.
errorInvalidFormField	The specified form field name is invalid or does not exist.
errorEmptyForm	The specified form does not contain any field values.
errorMaximumConnections	The maximum number of client connections exceeded.
errorThreadCreationFailed	Unable to create a new thread for the current process.
errorInvalidThreadHandle	The specified thread handle is no longer valid.

errorThreadTerminated	The specified thread has been terminated.
errorThreadDeadlock	The operation would result in the current thread becoming deadlocked.
errorInvalidClientMoniker	The specified moniker is not associated with any client session.
errorClientMonikerExists	The specified moniker has been assigned to another client session.
errorServerInactive	The specified server is not listening for client connections.
errorServerSuspended	The specified server is suspended and not accepting client connections.
errorNoMessageStore	No message store has been specified.
errorMessageStoreChanged	The message store has changed since it was last accessed.
errorMessageNotFound	No message was found that matches the specified criteria.
errorMessageDeleted	The specified message has been deleted.
errorFileChecksumMismatch	The local and remote file checksums do not match.
errorFileSizeMismatch	The local and remote file sizes do not match.
errorInvalidFeedUrl	The news feed URL is invalid or specifies an unsupported protocol.
errorInvalidFeedFormat	The internal format of the news feed is invalid.
errorInvalidFeedVersion	This version of the news feed is not supported.
errorChannelEmpty	There are no valid items found in this news feed.
errorInvalidItemNumber	The specified channel item identifier is invalid.
errorItemNotFound	The specified channel item could not be found.
errorItemEmpty	The specified channel item does not contain any data.
errorInvalidItemProperty	The specified item property name is invalid.
errorItemPropertyNotFound	The specified item property has not been defined.
errorInvalidChannelTitle	The channel title is invalid or has not been defined.
errorInvalidChannelLink	The channel hyperlink is invalid or has not been defined.
errorInvalidChannelDescription	The channel description is invalid or has not been defined.
errorInvalidItemText	The description for an item is invalid or has not been defined.
errorInvalidItemLink	The hyperlink for an item is invalid or has not been defined.

errorInvalidServiceType	The specified service type is invalid.
errorServiceSuspended	Access to the specified service has been suspended.
errorServiceRestricted	Access to the specified service has been restricted.
errorInvalidProviderName	The specified provider name is invalid or unknown.
errorInvalidPhoneNumber	The specified phone number is invalid or not supported in this region.
errorGatewayNotFound	A message gateway cannot be found for the specified provider.
errorMessageTooLong	The message exceeds the maximum number of characters permitted.
errorInvalidProviderData	The request returned invalid or incomplete service provider data.
errorInvalidGatewayData	The request returned invalid or incomplete message gateway data.
errorMultipleProviders	The request has returned multiple service providers.
errorProviderNotFound	The specified service provider could not be found.
errorInvalidMessageService	The specified message is not supported with this service type.
errorInvalidMessageFormat	The specified message format is invalid.
errorInvalidConfiguration	The specified configuration options are invalid.
errorServerActive	The requested action is not permitted while the server is active.
errorServerPortBound	Unable to obtain exclusive use of the specified local port.
errorInvalidClientSession	The specified client identifier is invalid for this session.
errorClientNotIdentified	The specified client has not provided user credentials.
errorInvalidClientState	The requested action cannot be performed at this time.
errorInvalidResultCode	The specified result code is not valid for this protocol
errorCommandRequired	The specified command is required and cannot be disabled.
errorCommandDisabled	The specified command has been disabled.
errorCommandSequence	The command cannot be processed at this time.
errorCommandCompleted	The previous command has completed.
errorInvalidProgramName	The specified program name is invalid or unrecognized.

errorInvalidRequestHeader	The request header contains one or more invalid values.
errorInvalidVirtualHost	The specified virtual host name is invalid.
errorVirtualHostNotFound	The specified virtual host does not exist.
errorTooManyVirtualHosts	Too many virtual hosts created for this server.
errorInvalidVirtualPath	The specified virtual path name is invalid.
errorVirtualPathNotFound	The specified virtual path does not exist.
errorTooManyVirtualPaths	Too many virtual paths created for this server.
errorInvalidTask	The asynchronous task identifier is invalid.
errorTaskActive	The asynchronous task has not finished.
errorTaskQueued	The asynchronous task has been queued.
errorTaskSuspended	The asynchronous task has been suspended.
errorTaskFinished	The asynchronous task has finished.

WhoisClient.TraceOptions Enumeration

Specifies the logging options that the WhoisClient class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]
```
<Flags>
Public Enum WhoisClient.TraceOptions
```

[C#]
```
[Flags]
public enum WhoisClient.TraceOptions
```

Remarks

The WhoisClient class uses the **TraceOptions** enumeration to specify what kind of debugging information is written to the trace logfile. These options are only meaningful when trace logging is enabled by setting the **Trace** property to **true**.

Members

Member Name	Description	Value
traceDefault	The default trace logging option. This is the same as specifying the **traceInfo** option.	0
traceInfo	All network function calls are written to the trace file. This is the default value.	0
traceError	Only those network function calls which fail are recorded in the trace file.	1
traceWarning	Only those network function calls which fail, or return values which indicate a warning, are recorded in the trace file.	2
traceHexDump	All network function calls are written to the trace file, plus all the data that is sent or received is displayed, in both ASCII and hexadecimal format.	4
traceProcess	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for multithreaded applications that are using worker threads.	4096

WhoisClient.WhoisOptions Enumeration

Specifies the options that the WhoisClient class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]

```
<Flags>
Public Enum WhoisClient.WhoisOptions
```

[C#]

```
[Flags]
public enum WhoisClient.WhoisOptions
```

Remarks

The WhoisClient class uses the **WhoisOptions** enumeration to specify one or more options to be used when establishing a connection with a remote host. Multiple options may be specified if necessary.

There are currently no additional options for WhoisClient class. This enumeration is provided for future expansion.

Members

Member Name	Description	Value
optionNone	No option specified.	0
optionDefault	The default connection option. This is the same as specifying **optionNone**.	0
optionFreeThread	This option specifies that class methods may be called from any thread, and not only the thread that established the connection. Using this option disables certain internal safety checks that are made by the class and may result in unexpected behavior unless you ensure that access to the class instance is synchronized across multiple threads.	524288

Requirements

Namespace: SocketTools

Assembly: SocketTools.WhoisClient (in SocketTools.WhoisClient.dll)

See Also

SocketTools Namespace

WhoisClient.WhoisSearchType Enumeration

Specifies the search options supported by the WhoisClient class.

[Visual Basic]

```
Public Enum WhoisClient.WhoisSearchType
```

[C#]

```
public enum WhoisClient.WhoisSearchType
```

Remarks

The **WhoisSearchType** enumeration specifies the types of queries that can be performed using the **Search** method. If you wish to perform a more complex query using the syntax outlined in RFC 954, specify a search type of **searchAny** and then provide the search string value that you want to submit.

Members

Member Name	Description
searchAny	Search for any value that matches the given keyword value. This is the default search type.
searchHandle	Search for a handle that matches the given keyword value.
searchName	Search for a user name that matches the given keyword value.
searchMailbox	Search for a user mailbox that matches the given keyword value.

Requirements

Namespace: SocketTools

Assembly: SocketTools.WhoisClient (in SocketTools.WhoisClient.dll)

See Also

SocketTools Namespace

WhoisClient.WhoisStatus Enumeration

Specifies the status values that may be returned by the WhoisClient class.

[Visual Basic]

```
Public Enum WhoisClient.WhoisStatus
```

[C#]

```
public enum WhoisClient.WhoisStatus
```

Remarks

The WhoisClient class uses the **WhoisStatus** enumeration to identify the current status of the client.

Members

Member Name	Description
statusUnused	A client session has not been created. Attempts to perform any network operations, such as sending or receiving data, will generate an error.
statusIdle	A client session has been created, but is not currently in use. A blocking socket operation can be executed at this point.
statusConnect	The client is in the process of establishing a connection with a remote host.
statusRead	The client is in the process of receiving data from a remote host.
statusWrite	The client is in the process of sending data to a remote host.
statusDisconnect	The client session is being closed and subsequent attempts to access the client will result in an error.

Requirements

Namespace: SocketTools

Assembly: SocketTools.WhoisClient (in SocketTools.WhoisClient.dll)

See Also

SocketTools Namespace

WhoisClient.OnErrorEventHandler Delegate

Represents the method that will handle the OnError event.

[Visual Basic]

```
Public Delegate Sub WhoisClient.OnErrorEventHandler( _
   ByVal sender As Object, _
   ByVal e As ErrorEventArgs _
)
```

[C#]

```
public delegate void WhoisClient.OnErrorEventHandler(
      object sender,
      ErrorEventArgs e
   );
```

Parameters

sender

The source of the event.

e

An ErrorEventArgs that contains the event data.

Remarks

When you create an **OnErrorEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnErrorEventHandler** delegate declaration.

Requirements

Namespace: SocketTools

Assembly: SocketTools.WhoisClient (in SocketTools.WhoisClient.dll)

See Also

SocketTools Namespace

WhoisClient.RuntimeLicenseAttribute Class

Attribute that defines the runtime license key for the class.

For a list of all members of this type, see WhoisClient.RuntimeLicenseAttribute Members.

System.Object
  System.Attribute
    SocketTools.WhoisClient.RuntimeLicenseAttribute

[Visual Basic]

```
<AttributeUsage(ValidOn:=AttributeTargets.Assembly, AllowMultiple:=False,
   Inherited:=True)>
Public Class WhoisClient.RuntimeLicenseAttribute
    Inherits Attribute
```

[C#]

```
[AttributeUsage(ValidOn=AttributeTargets.Assembly, AllowMultiple=False,
   Inherited=True)]
public class WhoisClient.RuntimeLicenseAttribute : Attribute
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

The RuntimeLicense attribute is used to define the runtime license key that will be used when an instance of the class is created. This attribute is defined in the assembly information module for the language, such as AssemblyInfo.cs when programming C#. The runtime license key must be defined if you wish to redistribute your application.

The runtime license key for your copy of SocketTools can be generated using the License Manager utility that is included with the product. Note that if you have installed an evaluation license, you will not have a runtime license key and cannot redistribute any applications which use the WhoisClient class.

Example

```
<Assembly: SocketTools.WhoisClient.RuntimeLicense("abcdefghijklmnop")>
```

```
[assembly: SocketTools.WhoisClient.RuntimeLicense("abcdefghijklmnop")]
```

Requirements

Namespace: SocketTools

Assembly: SocketTools.WhoisClient (in SocketTools.WhoisClient.dll)

WhoisClient.RuntimeLicenseAttribute overview

Public Instance Constructors

WhoisClient.RuntimeLicenseAttribute Constructor	Constructor for the RuntimeLicense attribute which defines the runtime license key.

Public Instance Properties

LicenseKey	Returns the value of the runtime license key.
TypeId (inherited from Attribute)	When implemented in a derived class, gets a unique identifier for this Attribute.

Public Instance Methods

Equals (inherited from Attribute)	
GetHashCode (inherited from Attribute)	Returns the hash code for this instance.
GetType (inherited from Object)	Gets the Type of the current instance.
IsDefaultAttribute (inherited from Attribute)	When overridden in a derived class, returns an indication whether the value of this instance is the default value for the derived class.
Match (inherited from Attribute)	When overridden in a derived class, returns a value indicating whether this instance equals a specified object.
ToString (inherited from Object)	Returns a String that represents the current Object.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

WhoisClient.RuntimeLicenseAttribute Class | SocketTools Namespace

WhoisClient.RuntimeLicenseAttribute Constructor

Constructor for the RuntimeLicense attribute which defines the runtime license key.

[Visual Basic]

```
Public Sub New( _
   ByVal licenseKey As String _
)
```

[C#]

```
public WhoisClient.RuntimeLicenseAttribute(
   string licenseKey
);
```

Parameters

licenseKey

A string argument which specifies the runtime license key which will be used to initialize the class library.

Remarks

The runtime license key for your copy of SocketTools can be generated using the License Manager utility that is included with the product. Note that if you have installed an evaluation license, you will not have a runtime license key and cannot redistribute any applications which use the WhoisClient class.

WhoisClient.RuntimeLicenseAttribute Class | SocketTools Namespace

WhoisClient.RuntimeLicenseAttribute Properties

The properties of the **WhoisClient.RuntimeLicenseAttribute** class are listed below. For a complete list of **WhoisClient.RuntimeLicenseAttribute** class members, see the WhoisClient.RuntimeLicenseAttribute Members topic.

Public Instance Properties

LicenseKey	Returns the value of the runtime license key.
TypeId (inherited from Attribute)	When implemented in a derived class, gets a unique identifier for this Attribute.

See Also

WhoisClient.RuntimeLicenseAttribute Class | SocketTools Namespace

WhoisClient.RuntimeLicenseAttribute.LicenseKey Property

Returns the value of the runtime license key.

[Visual Basic]

```
Public Property LicenseKey As String
```

[C#]

```
public string LicenseKey {get; set;}
```

Property Value

A string which contains the runtime license key.

See Also

WhoisClient.RuntimeLicenseAttribute Class | SocketTools Namespace

WhoisClientException Class

The exception that is thrown when a client error occurs.

For a list of all members of this type, see WhoisClientException Members.

System.Object
  System.Exception
    System.ApplicationException
      SocketTools.WhoisClientException

[Visual Basic]

```
Public Class WhoisClientException
    Inherits ApplicationException
```

[C#]

```
public class WhoisClientException : ApplicationException
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

A WhoisClientException is thrown by the WhoisClient class when an error occurs.

The default constructor for the WhoisClientException class sets the **ErrorCode** property to the last client error that occurred.

Requirements

Namespace: SocketTools

Assembly: SocketTools.WhoisClient (in SocketTools.WhoisClient.dll)

See Also

WhoisClientException Members | SocketTools Namespace

WhoisClientException overview

Public Instance Constructors

WhoisClientException	Overloaded. Initializes a new instance of the WhoisClientException class.

Public Instance Properties

ErrorCode	Gets a value which specifies the error that caused the exception.
HelpLink (inherited from Exception)	Gets or sets a link to the help file associated with this exception.
InnerException (inherited from Exception)	Gets the Exception instance that caused the current exception.
Message	Gets a value which describes the error that caused the exception.
Number	Gets a value which specifies the numeric value of the error that caused the exception.
Source (inherited from Exception)	Gets or sets the name of the application or the object that causes the error.
StackTrace (inherited from Exception)	Gets a string representation of the frames on the call stack at the time the current exception was thrown.
TargetSite (inherited from Exception)	Gets the method that throws the current exception.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetBaseException (inherited from Exception)	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetObjectData (inherited from Exception)	When overridden in a derived class, sets the SerializationInfo with information about the exception.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString	Creates and returns a string representation of the current exception.

Protected Instance Properties

HResult (inherited from Exception)	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

WhoisClientException Class | SocketTools Namespace

WhoisClientException Constructor

Initializes a new instance of the WhoisClientException class with the last network error code.

Overload List

Initializes a new instance of the WhoisClientException class with the last network error code.

public WhoisClientException();

Initializes a new instance of the WhoisClientException class with a specified error number.

public WhoisClientException(int);

Initializes a new instance of the WhoisClientException class with a specified error message.

public WhoisClientException(string);

Initializes a new instance of the WhoisClientException class with a specified error message and a reference to the inner exception that is the cause of this exception.

public WhoisClientException(string,Exception);

See Also

WhoisClientException Class | SocketTools Namespace

WhoisClientException Constructor ()

Initializes a new instance of the WhoisClientException class with the last network error code.

[Visual Basic]

```
Overloads Public Sub New()
```

[C#]

```
public WhoisClientException();
```

Remarks

The ctor constructor sets the **ErrorCode** property to the last client error that occurred. For more information about the errors that may occur, refer to the WhoisClient.ErrorCode enumeration.

See Also

WhoisClientException Class | SocketTools Namespace | WhoisClientException Constructor Overload List

WhoisClientException Constructor (String)

Initializes a new instance of the WhoisClientException class with a specified error message.

[Visual Basic]

```
Overloads Public Sub New( _
   ByVal message As String _
)
```

[C#]

```
public WhoisClientException(
   string message
);
```

Parameters

message

The error message that explains the reason for the exception.

Remarks

The content of the ***message*** parameter is intended to be understood by humans. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

See Also

WhoisClientException Class | SocketTools Namespace | WhoisClientException Constructor Overload List

WhoisClientException Constructor (String, Exception)

Initializes a new instance of the WhoisClientException class with a specified error message and a reference to the inner exception that is the cause of this exception.

[Visual Basic]

```
Overloads Public Sub New( _
   ByVal message As String, _
   ByVal innerException As Exception _
)
```

[C#]

```
public WhoisClientException(
   string message,
   Exception innerException
);
```

Parameters

message

The error message that explains the reason for the exception.

innerException

The exception that is the cause of the current exception. If the ***innerException*** parameter is not a null reference, the current exception is raised in a **catch** block that handles the inner exception.

Remarks

The content of the message parameter is intended to be understood by humans. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

An exception that is thrown as a direct result of a previous exception should include a reference to the previous exception in the **InnerException** property. The **InnerException** property returns the same value that is passed into the constructor, or a null reference if the **InnerException** property does not supply the inner exception value to the constructor.

WhoisClientException Class | SocketTools Namespace | WhoisClientException Constructor Overload List

WhoisClientException Constructor (Int32)

Initializes a new instance of the WhoisClientException class with a specified error number.

[Visual Basic]

```
Overloads Public Sub New( _
   ByVal code As Integer _
)
```

[C#]

```
public WhoisClientException(
   int code
);
```

Parameters

code

An integer value which specifies an error code.

Remarks

This constructor sets the **ErrorCode** property to the specified error code. For more information about the errors that may occur, refer to the WhoisClient.ErrorCode enumeration.

See Also

WhoisClientException Class | SocketTools Namespace | WhoisClientException Constructor Overload List

WhoisClientException Properties

The properties of the **WhoisClientException** class are listed below. For a complete list of **WhoisClientException** class members, see the WhoisClientException Members topic.

Public Instance Properties

ErrorCode	Gets a value which specifies the error that caused the exception.
HelpLink (inherited from Exception)	Gets or sets a link to the help file associated with this exception.
InnerException (inherited from Exception)	Gets the Exception instance that caused the current exception.
Message	Gets a value which describes the error that caused the exception.
Number	Gets a value which specifies the numeric value of the error that caused the exception.
Source (inherited from Exception)	Gets or sets the name of the application or the object that causes the error.
StackTrace (inherited from Exception)	Gets a string representation of the frames on the call stack at the time the current exception was thrown.
TargetSite (inherited from Exception)	Gets the method that throws the current exception.

Protected Instance Properties

HResult (inherited from Exception)	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception.

See Also

WhoisClientException Class | SocketTools Namespace

WhoisClientException.ErrorCode Property

Gets a value which specifies the error that caused the exception.

[Visual Basic]
```
Public ReadOnly Property ErrorCode As ErrorCode
```

[C#]
```
public WhoisClient.ErrorCode ErrorCode {get;}
```

Property Value

Returns a WhoisClient.ErrorCode enumeration value which specifies the error code.

Remarks

The **ErrorCode** property returns the error code that specifies the cause of the exception.

The default constructor for the WhoisClientException class sets the error code to the last network error that occurred. For more information about the errors that may occur, refer to the WhoisClient.ErrorCode enumeration.

See Also

WhoisClientException Class | SocketTools Namespace

WhoisClientException.Message Property

Gets a value which describes the error that caused the exception.

[Visual Basic]

```
Overrides Public ReadOnly Property Message As String
```

[C#]

```
public override string Message {get;}
```

Property Value

A string which describes the error that caused the exception.

Remarks

The **Message** property returns a string which describes the error that caused the exception.

See Also

WhoisClientException Class | SocketTools Namespace

WhoisClientException.Number Property

Gets a value which specifies the numeric value of the error that caused the exception.

[Visual Basic]

```
Public ReadOnly Property Number As Integer
```

[C#]

```
public int Number {get;}
```

Property Value

An integer value that specifies the error that caused the exception.

Remarks

The **Number** property returns an integer value which specifies the numeric value of the error that caused the exception. This value is the same as the values returned by the Windows Sockets API. For more information about socket error codes, see the Windows Socket Version 2 API error code documentation in MSDN.

See Also

WhoisClientException Class | SocketTools Namespace

WhoisClientException Methods

The methods of the **WhoisClientException** class are listed below. For a complete list of **WhoisClientException** class members, see the WhoisClientException Members topic.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetBaseException (inherited from Exception)	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetObjectData (inherited from Exception)	When overridden in a derived class, sets the SerializationInfo with information about the exception.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString	Creates and returns a string representation of the current exception.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

WhoisClientException Class | SocketTools Namespace

WhoisClientException.ToString Method

Creates and returns a string representation of the current exception.

[Visual Basic]

```
Overrides Public Function ToString() As String
```

[C#]

```
public override string ToString();
```

Return Value

A string representation of the current exception.

Remarks

The **ToString** method returns a representation of the current exception that is intended to be understood by humans. Where the exception contains culture-sensitive data, the string representation returned by **ToString** is required to take into account the current system culture. Although there are no exact requirements for the format of the returned string, it should attempt to reflect the value of the object as perceived by the user.

This implementation of **ToString** obtains the numeric error code value and a description of the error that caused the current exception. If there is no error message or it is an empty string, then no error message is returned.

This method overrides **ApplicationException.ToString**.
